THE ENCYCLOPEDIA OF PSYCHOACTIVE PLANTS

ETHNOPHARMACOLOGY and Its APPLICATIONS

CHRISTIAN RÄTSCH

FOREWORD BY ALBERT HOFMANN

Translated by John R. Baker

with assistance from

Annabel Lee and Cornelia Ballent

Park Street Press
Rochester, Vermont

Acknowledgments for the English Edition

I am very gratified that my *Encyclopedia of Psycho-active Plants* has received so much international recognition that it is now being translated into English and published by Inner Traditions and the courageous Ehud Sperling.

I would like to give special thanks to Dr. John R. Baker for his outstanding translation of this *Encyclopedia* into English and for his meticulous efforts to eliminate typographical and printing errors and bibliographic inconsistencies! I would also like to thank Annabel Lee and Cornelia Ballent for their excellent translation work.

Translating a work of this size into another language is an enormous undertaking. For the translators, such a task poses many challenges; for the editorial staff, it requires a painstaking attention to detail and a continuous awareness of the big picture. And it is a risk for the publisher. For these reasons, I would also like to thank all of the readers of the English edition for their support of this project!

Foreword

“The real is just as magical as the magical is real.”

ERNST JÜNGER

SIZILISCHER BRIEF AN DE MOUD [SICILIAN LETTER TO THE MOON]

In this world, the point at which something happens is determined by the circumstances that call for it to happen. This *Encyclopedia of Psycho-active Plants* had to appear at just this time, for our contemporary society has need of such a work.

This need is connected with the spiritual and material dilemma of our times. It is not necessary to list all of the things that are no longer right in our world. But we can mention some: in the spiritual domain, materialism, egoism, isolation, and the absence of any religious foundation; on the material level, environmental destruction as a result of technological development and over-industrialization, the ongoing depletion of natural resources, and the accumulation of immense fortunes by a few people while the majority become increasingly destitute.

These ominous developments have their spiritual roots in a dualistic worldview, a consciousness that splits our experience of the world into subject and object.

This dualistic experience of the world first emerged in Europe. But it had already been at work in the Judeo-Christian worldview, with its god that sits enthroned above creation and humankind, and his admonition to “subdue . . . and have dominion . . . over every living thing that moveth upon the earth.”

This is now occurring at a terrifying rate.

A change for the better will come about only when a general shift in consciousness takes place. Our fractured consciousness, which Gottfried Benn characterized as a “fateful European neurosis,” must be replaced by a consciousness in which creator, creation, and created are experienced as a unity.

All means and all ways that will help lead to a new and universal spirituality are worthy of support. Chief among these is meditation, which can be enhanced and intensified through a variety of methods, including yogic practices, breathing exercises, and fasting, and through the appropriate use of certain drugs as pharmacological aids.

The drugs I am referring to belong to a special group of psychoactive substances that have been characterized as psychedelics and, more recently, as entheogens (psychedelic sacraments). These effect an enormous stimulation of sensory perceptions, a decrease or even neutralization of the I–Thou boundary, and alterations in consciousness in the form of both sensitization and expansion.

The use of such psychedelic drugs within a religio-ceremonial framework was discovered among Indian tribes in Mexico at the beginning and in the middle of the twentieth century.

This sensational discovery led to ethno-botanical investigations to remote areas around the world to search for psychoactive plants, the results of which were documented in numerous publications and pictures. The encyclopedic compilation of ancient knowledge and new discoveries about psychoactive plants that is in your hands was produced by a well-qualified author who has contributed important new insights on the basis of his own fieldwork. It is an undertaking of great value.

Disseminating knowledge about psychoactive plants, together with the proper ways to use them, represents a valuable contribution within the context of the many and growing attempts to bring about

a new, holistic consciousness. Transpersonal psychology, which is becoming ever more important in psychiatry, pursues the same goal within a therapeutic framework.

The holistic perspective is more easily practiced on living nature than on the inanimate objects created by humans. Let us look into a living mandala instead, such as that found in the calyx of a blue morning glory, which is a thousand times more perfect and beautiful than anything produced by human hand, for it is filled with life, that universal life in which both the observer and the observed find their own individual places as manifestations of the same creative spirit.

ALBERT HOFMANN, PH.D.

SUMMER 1997

Preface

“Thoughts are free, . . . for my thoughts tear the fences and walls asunder. . . .”

GERMAN FOLK SONG

My grandmother taught me many wise things that I have followed my entire life. In particular, her saying “An ounce of practice is worth a pound of theory” has had a considerable influence upon me and made it much easier to follow the path that has led me to the psychoactive plants.

It was during the 1967 “Summer of Love,” when I was ten years old, that I first heard of hashish. I was listening to the radio. A menacing voice spoke of the “horrible dangers” that were descending upon our imperiled youth with the “new wave of drugs” from the United States. The picture that continues to dominate our drug policies was sketched out in dramatic fashion: Hashish was a gateway drug that inevitably, even compellingly, led to death from a golden shot of heroin. This was terrible news! But by that time I had already learned that I should not trust my teachers or the conservative politicians. I instinctively felt that the voice on the radio was lying. As a result of that broadcast, I yearned for nothing more than finally to try hashish myself (my experiments with cigarettes were already behind me, and I had noticed that I could not find any use or enjoyment there). At that time, it was not as easy to obtain hashish as it is today. Two years went by before I had my first opportunity. Up until then, I had only smoked dried banana peels and inhaled chloroform that I had synthesized myself. One morning, on the school bus, an older student walked down the aisle and whispered, “Hash, hash, anyone want hash?” “I do!” I cried, barely able to contain my joy and excitement. Back then, one gram cost about 3.50 marks (roughly one U.S. dollar), my entire allowance. But what does money mean when we’re talking about the fulfillment of a two-year-old dream?

With the hashish in my pocket, I sat through my classes, bored to death as usual, waiting for the time when I would finally make it back home. After the ordeal of school, the time had finally come. I stood at home with my precious stash and pondered the best way to smoke it. Tobacco was not an option, for I genuinely disliked it. I went into the kitchen, saw a small bag of dried peppermint leaves, and immediately knew that I had found the appropriate admixture. I pedaled my bike into the nearby forest, stuffed a pipe full of mint and hashish, and lit it up. I immediately sensed that this mixture was easy to inhale, a wonderful contrast to those disgusting cigarettes. Although the effects were mild, they were enough to make me want to continue my experiments. The next time, I went into the forest with a friend and we smoked the pipe together. An incredible sense of mirth overwhelmed us, and we almost split our sides with laughter.

I now know that my quest to obtain hashish and my deliberations as to what it could best be combined with marked the beginnings of my ethnopharmacological research. Today, I still search for psychoactive plants in all corners of the world and experiment with them until I have had meaningful experiences with them and learned what I could from them. And I still feel that I am being lied to when the media and the politicians talk about “drugs” and “narcotics,” and I think to myself, “Oh, if only you too had smoked a nice pipe of hashish when you were twelve; so many problems could have been avoided!”

During my fieldwork in Nepal, I learned that the three fundamental evils of existence are hate, envy,

and ignorance. The tantric doctrine has developed a number of methods for becoming aware of these evils and overcoming them by means of altered states of consciousness. It is my hope that all people—especially the politicians and the psychiatrists of Western countries—will one day understand that ignorance is one of the main reasons behind the catastrophic condition of our Mother Earth!

During my extended journeys to the various continents, I have seen time and again how people in all cultures, and of all social strata, religions, and skin colors, consume psychoactive plants and psychoactive products. Why do people ingest psychoactive substances? Because a fundamental drive for inebriation, ecstasy, blissful sleep, knowledge, and enlightenment is written right into our genes.

While working on the manuscript of this book, I realized that it would be my first “life work.” The results of twenty years of research and experience are compiled in this work. I have collected information all over the world, assembled a large and specialized library, attended countless meetings and symposia, photographed my way through the plant world, and experimented with as many psychoactive plants as I could. The knowledge I have gained has now been distilled and organized into this encyclopedia.

Introduction

“The peculiar, mysterious longing and desire for stimulants that is common to almost all peoples has, to the extent that we are aware of historical traditions, always prevailed and been satisfied in the most varied of ways. Inducing a happy mood in which the emotions, sorrows, and everything else that may weigh upon the soul can be forgotten, shifting into a state of partial or completely absent consciousness in which the individual, detached from the present, surrounded by the glowing and shining images of an excessively amplified imagination, becomes free from the misery of his every day life or from bodily pains, artificially inducing peace and sleep for the fatigued body and mind in all cases where these necessary requirements for life cannot be brought about in the normal manner, and finally the wish to gain creative strength, both physically and mentally, by means of these stimulants—these are the primary reasons why these agents are used.”

LOUIS LEWIN

ÜBER PIPER METHYSTICUM (1885, 1)

Every day, most people in most cultures, whether Amazonian Indians or western Europeans, ingest the products of one or more psychoactive plants. Even the Mormons, who claim that they do not use “drugs,” have a psychoactive stimulant: Mormon tea (*Ephedra nevadensis*), which contains the very potent alkaloid ephedrine, the model substance for amphetamine.

The use of psychoactive substances is extraordinarily common in the countries of South America. After rising, a typical Amazonian Indian will drink guaraná, cacao, or maté (and sometimes all three together). After breakfast, he will place the first pinch of coca in his mouth, where, periodically renewed, it will remain until evening. In the afternoon, he will shift to a fermented beverage made of maize or manioc. In late afternoon, some powder that contains tryptamines may be snuffed into the nose. Ayahuasca is often used in the evening. It goes without saying that every free minute is filled with the smoking, chewing, sniffing, or licking of tobacco.

Among the Tukano Indians, the use of psychoactive plants is mythologically associated with the origins of the world. The Sun Father was a *payé*, a shaman, who gave the shamans of our time all of their knowledge and abilities. At the beginning of the world, he carried in his navel *vihó*, a snuff obtained from the bark of the parica tree (*Virola* spp.). The ayahuasca vine came into the world through his daughter. As she was lying in labor, one of her fingers broke off. The midwife at her side took the finger and guarded it in the *maloca*, the cosmic roundhouse. A young man who saw this stole the finger. He buried it, and the ayahuasca liana grew from that spot. Another daughter of the Sun Father was also heavy with child. As she writhed about in the pains of labor, one of her fingers broke off as well. This time, the midwife took the finger and buried it herself. This gave rise to the first coca plant. Because these plants are associated with the origins of the world, they are considered sacred.

In the modern Western world, the use of psychoactive plant products is very widespread, but their sacredness has been profaned. How many of us today, when we are sipping our morning coffee, are aware that the Sufis venerated the coffee bush as a plant of the gods and interpreted the stimulating effects of caffeine as a sign of God’s favor? Who of us, lying in bed and smoking the first cigarette of the day, knows that tobacco is regarded as a gift of the gods that aids shamans in journeying into other realities? How many recall the frenzied Bacchanalia in honor of Dionysos as they drink a glass of wine with their lunch? And the evening beer in front of the television is downed without any knowledge of the sacred origin of this barley drink. Our ancestors, however, the Germanic peoples and the Celts, knew this, and they venerated such drinks and immortalized them in their poetry:

It is certain that the Celts knew of alcohol. The Greek and Roman authors of antiquity regarded them as passionate lovers of inebriating beverages. Drunkenness is a common theme in the epics, especially in Ireland. Gods and heroes competed with one another in their sheer unquenchable thirst for alcohol, whether in the form of wine, beer, or hydromel, the Celtic mead we still remember today. No religious festival was celebrated without an uninhibited drinking bout, a tradition which survives in our time in the form of (supposedly) folk customs. The most important aspect of such rituals is the *lifting off*, the *unleashing*, by means of which one forgets that man is an earthbound being. (Markale 1989, 203)

Indeed, it is this lifting off, this fact of getting “high,” the unleashing, the ecstasy, that is at the heart of the use of psychoactive plants and psychoactive products. This encyclopedia is a testimony to the wealth of knowledge that humans have acquired about these substances. Through proper use and proper knowledge, we too—like our ancestors—may learn to once again recognize the sacred nature of inebriants and utilize these to have profound experiences of the sacredness of nature.

What Are Psychoactive Plants?

Psychoactive plants are plants that people ingest in the form of simple or complex preparations in order to affect the mind or alter the state of consciousness.

Consciousness is an energy field that can expand, shift amorphously like an amoeba through the hidden corners of the world, dissolve in the ocean of desire, or crystallize in geometric clarity. Through the use of psychoactive plants and products, consciousness can be paralyzed, subdued, and contained; it can also be animated, stimulated, and expanded. Because psychoactive plants affect the mind, they have been characterized as *mind-moving substances*. The renowned Berlin toxicologist Louis Lewin (1850–1929) referred to all those substances that produce some sort of psychoactive effects as *phantastica*. Carl Hartwich (1851–1917), a pharmacist, described them as “human means of pleasure.” Timothy Leary (1920–1996) preferred to speak of them as *neuro-botanical substances*. Today, the terms *psychotropic* (“influencing the psyche”) and *psychopharmacologic* (“affecting the mind”) are often used to refer to these substances.

“Only plants had consciousness. Animals got it from them.”

DALE PENDELL *PHARMAKO/POEIA* (1995)

In the pharmacological literature, which commonly refers to them as *mind-altering substances*, psychoactive substances are clearly and systematically classified by precise scientific definitions (cf. Inaba and Cohen 1994; Seymour and Smith 1987; Wagner 1985):

Stimulants (“uppers”)

This category comprises substances that wake one up, stimulate the mind, incite the initiative, and may even cause euphoria but that do not effect any changes in perception. Among the most important plants in this category are coffee, tea, cacao, guaraná, maté, ephedra, khat, and coca.

Sedatives, Hypnotics, Narcotics (“downers”)

This category includes all of the calmative, sleep-inducing, anxiety-reducing, anesthetizing substances, which sometimes induce perceptual changes, such as dream images, and also often evoke feelings of euphoria. The most important psychoactive plants and products in this category are poppy, opium, valerian, and hops.

Hallucinogens (“all-arounders”)

This category encompasses all those substances that produce distinct alterations in perception, sensations of space and time, and emotional states. Most of the plants discussed in this encyclopedia fall into this category. Over the course of time, these substances have been referred to under a variety of names:

- Psychotomimetics (“imitating psychoses”)
- Psychotica (“inducing psychoses”)
- Hallucinogens (Johnson; “causing hallucinations”)
- Psychedelics (Osmund; “mind manifesting”)
- Entheogens (Ruck et al.; “evoking the divine within”)
- Entactogens (Nichols; “promoting self-knowledge”)
- Empathogens (Metzner; “stimulating empathy”)
- Eidetics (“giving rise to ideas”)
- Psychogenics (“affecting the mind”)
- Psychodysleptics (“softening the mind”)

Today, the most commonly used term is still *hallucinogen*. By definition, a hallucinogen is a substance that evokes hallucinations (Siegel 1995b), which are now medically defined as “sensory delusions that may involve several (to all) senses (= complexes) and are not the result of corresponding external sensory stimuli but possess a reality for the affected person; also occur in schizophrenia, stimulated brain states (e.g., due to poisoning, epilepsy, brain injuries, the effects of hallucinogens)” (*Roche Lexikon Medizin* 1987, 725).

Because the term *hallucination* now has a psychopathological tinge to it, nonmedical circles and publications usually prefer the terms *psychedelic*, *entheogen*, or *visionary substance* and accordingly speak of psychedelic, entheogenic, or visionary experiences:

The awakening of the senses is the most basic aspect of the psychedelic experience. The open eye, the naked touch, the intensification and vivification of ear and nose and taste. This is the Zen moment of satori, the nature mystic’s high, the sudden centering of consciousness on the sense organ, the real-eye-zation that this is it! I am eye! I am hear! I knose! I am in contact! (Leary 1998, 34)

Shamans, of course, the traditional specialists in psychoactive substances, do not speak of psychoactive drugs, psychotropics, or hallucinogens—not to mention narcotics—but of plant teachers, magical plants,³ plants of the gods, sacred beverages, et cetera. They revere these mind-altering plants and make them offerings; they use them not as recreational drugs or as something to get “high” with in the evening but as sacraments in their rituals. The shamans regard these plants as sacred because they make it possible for them to contact the true reality and the gods, spirits, and demons. They are sacred because within them dwell plant spirits, plant gods, or devas that one can ally oneself with and that are esteemed as the teachers, mothers, ambassadors, and *doctores* (physicians) of other realities. In addition, these sacred plants have the power to heal. They can liberate the ill from their afflictions and drive out harmful, disease-causing spirits. They also can bring spiritual awakening to healthy people and make possible mystical experiences. With the aid of these plants, one does not lose control, for control is ultimately an illusion.⁴ And they are used not to escape from reality but to recognize true reality:

We can see that these plants do more than simply maintain our body. They also promote and nourish our souls and make possible the enlightenment of our mind. Their existence is offering, sacrifice, and selfless love. The earth on which they grow is itself a sacrificial altar—and we who receive their blessings are the sacrificial priests. Through plants, the outer light of the sun and the stars becomes the inner light which reflects back from the foundations of our soul. This is the reason why plants have always and everywhere been considered sacred, divine. (Storl 1997, 20)

“Every life’s heart and desire
Burns with greater rapture, flickers more colorfully,
I welcome every inebriation,
I stand open to all torments,
Praying to the currents, taken with them
Into the heart of the world.”

HERMANN HESSE *VERZÜCKUNG* [RAPTURE] (1919)

The Use of Psychoactive Plants

Humans have a natural drive to pursue ecstatic experiences (Weil 1976; Siegel 1995a). The experience of ecstasy is just as much a part of being human and leading a fulfilling and happy life as is the experience of orgasm. In fact, many cultures use the same words to refer to ecstasy and to orgasm.⁵ The possibility of having ecstatic experiences is one of the fundamental conditions of human consciousness. All archaic and ethnographic cultures developed methods for inducing such experiences (Bourguignon 1973; Dittrich 1996). Some of these methods are more efficacious than others. The most effective method of all is to ingest psychoactive plants or substances.

These methods, however, require certain skills, for there are many factors that play a role in shaping the effects and the contents of the experiences. The most important is proper use—that is, a responsible and goal-oriented use.

Fitz Hugh Ludlow (1836–1870), whose book *The Hasheesh Eater* (published in 1857) was the first American literary work on the effects of hashish, has given us an amazing description of the proper way to use hashish:

There is a fact which can be given as a justification for the craving for drugs without coming close to dubious secondary motives, namely, that drugs are able to bring humans into the neighborhood of divine experience and can thus carry us up from our personal fate and the everyday circumstances of our life into a higher form of reality. It is, however, necessary to understand precisely what is meant by the use of drugs.

We do not mean the purely physical craving. . . . That of which we speak is something much higher, namely the knowledge of the possibility of the soul to enter into a lighter being, and to catch a glimpse of deeper insights and more magnificent visions of the beauty, truth, and the divine than we are normally able to spy through the cracks in our prison cell. But there are not many drugs which have the power of stilling such craving. The entire catalog, at least to the extent that research has thus far written it, may include only opium, hashish, and in rarer cases alcohol, which has enlightening effects only upon very particular characters. (Ludlow 1981, 181)

There are many different ways to use psycho-active plants. The reasons they are consumed range from relaxation, recreation, and pleasure (hedonism) to medical and therapeutic treatments and to ritual and religious ceremonies and spiritual growth. It is the task of culture and society to provide the individual with patterns for using them that serve these purposes.

Drug Culture

Both experience and research have very clearly demonstrated that every culture in the world either has used or still does use psychoactive substances in traditional contexts:

Every society, every time has its drug culture. Corresponding to the complexity of society, its drug culture may also be more or less complex, oriented, for example, around just one central drug or encompassing a number of drugs. It can also be subdivided into internal cultures that can contradict one another. (Marzahn 1994, 82)

These “internal cultures” are often referred to as “subcultures” or “scenes.” Within these cultural structures, cultural patterns often form that seem to be archetypical for human existence. Marzahn analyzed traditional rituals that employ psycho-active substances—he uses the term *drug*, most likely as a provocation—and from these developed a model that suggests that, throughout the world, common drug cultures continually emerge and establish themselves:

Yet the deepest meaning of the common drug culture appears to lie in the fact that this *internal order* is required because of this exiting, this stepping over boundaries; it is precisely what a culture of border crossers needs. In the context of the common drug culture, the use of drugs is not banished out of time and space. Rather, it has a clear and circumscribed place within both. People gather at a special place and surround themselves with the proper space and with beautiful devices. The communal use of the drug has a beginning and an end. It takes place according to an internal order, which has been derived from experience, and does not simply allow whatever anyone might want. With time, it has become condensed into a ceremony, a rite. This internal order and its outer form, the ritual, are what make it possible for the drug to be used properly and protect people from harm and destruction. In all normal drug cultures, it is a duty of those who have already had the experience to introduce the inexperienced to this order. (Marzahn 1994, 45)

“I allow dew drops to fall from the flowers onto the fields, which inebriate my soul.”

SONG OF NEZAHUALCOYOTL IN *ANCIENT NAHUATL POETRY*
(BRINTON 1887)

“Most people never realize that the purpose of intoxication is to sharpen the mind.”

ROBERT E. SVOBODA *AGHORA*
(1993, 175)

“Religions are false means for satisfying genuine needs.”

KARLHEINZ DESCHNER *BISSIGE APHORISMEN* [BITING APHORISMS]

Ritual Uses of Psychoactive Substances

It is possible to classify many psychoactive plants and the products made from them into different types of rituals that reflect how they are used. These include:

Shamanic initiation
Fly agaric mushroom (*Amanita muscaria*)
Cigar tobacco (*Nicotiana rustica*)

- Shamanic healing rituals
- Ayahuasca
 - Snuffs
 - Cebil (*Anadenanthera colubrina*)
 - Mushrooms
 - San Pedro (*Trichocereus pachanoi*)

- Shamanic ritual circles
- Ayahuasca
 - Mushrooms (*Panaeolus* spp., *Psilocybe* spp.)
 - Hemps (*Cannabis* spp.)
 - San Pedro (*Trichocereus pachanoi*) and cimora

- Vision quests
- Kinnikinnick
 - Thorn apples (*Datura* spp.)
 - Tobaccos (*Nicotiana* spp.)

- Rites of passage
- Balche’
 - Iboga (*Tabernanthe iboga*)
 - Hemp (*Cannabis indica* in Jamaica, among the Rastafarians)

- Rituals of greeting
- Kava-kava (*Piper methysticum*)
 - Cola nuts (*Cola* spp.)
 - Pituri

- Burial rituals
- Cola nuts (*Cola* spp.)
 - Alcohol

- Divination
- Henbanes (*Hyoscyamus* spp.)
 - Angel’s trumpets (*Brugmansia* spp.)
 - Ololiuqui (*Turbina corymbosa*)
 - Salvia divinorum*
 - Thorn apples (*Datura* spp.)
 - Incense

- Rain magic and rain ceremonies
- Henbane (*Hyoscyamus niger*)
 - Saguaro (*Carnegia gigantea*) wine

- Healing rituals within a religious cult
- Nutmeg (*Myristica fragrans*)

- Harmful magic
- Yagé, ayahuasca
 - Datura*, *Brugmansia*, *Solandra*

- Purification rituals
- Cassine, yaupon, black drink (*Ilex cassine*, *Ilex vomitoria*)
 - Guayusa (*Ilex guayusa*)
 - Enemas
 - Incense

- Sexual magic rituals (Tantra, Taoism, cult of Aphrodite)
- Mandrakes (*Mandragora* spp.)
 - Damiana (*Turnera diffusa*)
 - Oriental joy pills
 - Yohimbé (*Pausinystalia yohimba*)

- Initiation into secret societies and cults or cultic communities
- Iboga (*Tabernanthe iboga*)

Madzoka medicine

Religious ceremonies led by priests

Incense
Wine (libations)
Spiced coffee

Mystery cults

Haoma
Kykeon
Wine

Socially integrative ritual circles

Plants: cocas (*Erythroxylum* spp.), hemsps (*Cannabis* spp.), khat (*Catha edulis*), cola nuts (*Cola* spp.)
Products: balche', beer, chicha, palm wine, wine

Perceptual training

Tea (*Camellia sinensis*) ceremony
Kodoh (incense)

Meditation

Hemp (*Cannabis indica*)
Coffee (*Coffea arabica*)
Khat (*Catha edulis*)
Tea (*Camellia sinensis*)
Soma

In many cultures, the experts are the shamans, or sometimes the priests, diviners, or medicine people. However, in our culture there is a deep chasm, a wound, for the people who preserved our own traditional knowledge have disappeared as a result of forced Christianization, imperialism, the Inquisition, the persecutions of witches, the Enlightenment, and positivism. And yet in spite of this, the psychoactive life continues to pulse in the inner cultures. And the archaic patterns continue to remain relevant, so appropriate uses of psycho-active substances continue to emerge. This has produced what may be called “underground experts” in the proper use of psychoactive substances:

Through rhythm, internal order, and ritual, the common drug culture provides an orientation and a foothold in dealing with drugs: for our aspiration, because it embeds drug use within an understanding about the proper way to live, about the goals and forms of life, and about the role that befits drugs within these; for our knowledge, because it provides information about the mechanisms of actions, benefits, and drawbacks of drugs that is based upon experience and traditional knowledge; for our feelings, because it provides us with security in the simultaneously affirming and shy respect for drugs, thereby protecting us from ill-conceived fear and fascination, from both a demonizing worship and a demonization; and finally for our actions, because it develops and passes down rules that are recognized and respected because experience and validation have shown them to be meaningful and because they tell us which drugs, in which dosage, when, where, and with whom are beneficial and which are not. (Marzahn 1994, 47)

The Most Important Considerations: The Theory of Dosage, Set, and Setting

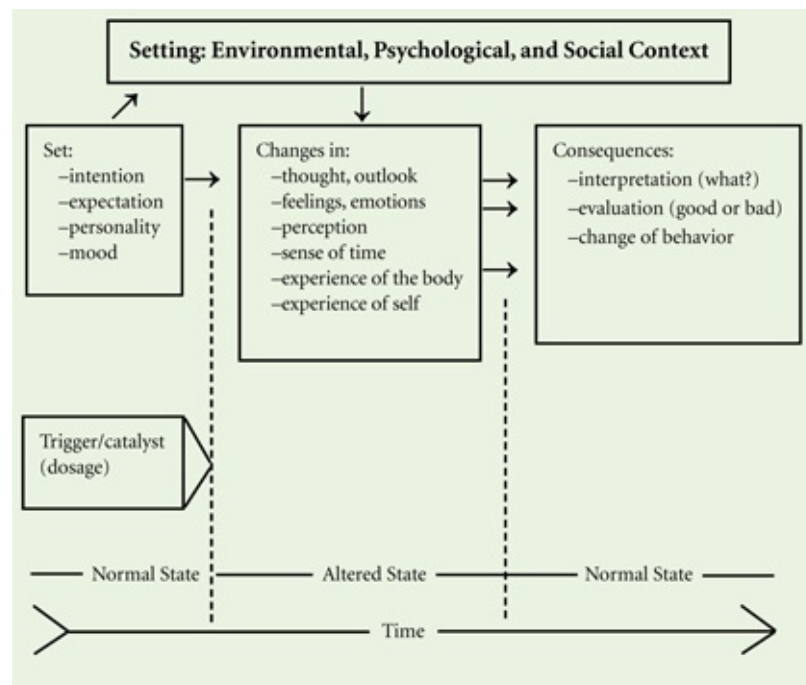

The theory of dosage, set, and setting provides a useful model for better understanding the effects of psychoactive plants. Dr. Timothy Leary (1920–1996), a Harvard professor, conducted scientific experiments with psychedelic substances (LSD and psilocybin) in the early 1960s. On the basis of his own experiences and his systematic observations, he and his colleagues Ralph Metzner and Richard

Alpert (Ram Dass) developed this theory (Leary et al. 1964), which states that there are three main factors responsible for the experiences induced by psychedelics. The first factor is the dosage—a truism since ancient times, or at least since Paracelsus. The set is the internal attitudes and constitution of the person, including his expectations, his wishes, his fears. The third aspect is the setting, which pertains to the surroundings, the place, and the time—in short, the space in which the experiences transpire. This theory clearly states that the effects are equally the result of chemical, pharmacological, psychological, and physical influences.

The model that Timothy Leary proposed for the psychedelics also applies to experiences with other psychoactive plants (including the stimulants and narcotics). All three factors must be carefully considered when one wishes to have experiences with and understand these plants. Even in the same person, the same plant can evoke very different effects if the dosage, set, and setting are changed.

The first factor, of course, pertains to the choice of plant. Then the proper dosage must be consumed. But what is a “proper” dosage? It is the amount that will produce the desired effects. But since the effects are not solely the result of the dosage, the proper dosage can be determined only by taking the other factors into consideration as well. As the saying goes, “An ounce of practice is worth a pound of theory.” This is especially true in the present context. When experimenting, one should always begin with low dosages. It is better to use too little than too much. You can always use more on the next occasion. If one rashly takes too much, the result may be unpleasant or even dangerous. When ingesting strychnine, for example, the dosage is extremely crucial. A small dosage can produce wonderful sensations and sexual vigor, whereas a large dosage can be lethal.

American Indians, for example, recognize three dosage levels for magic mushrooms: a medicinal, an aphrodisiac, and a shamanic. For the medicinal dosage, a quantity is administered that does not produce any psychoactive effects but that can heal certain ailments. The aphrodisiac dosage is higher: The mind is activated but not overpowered by visions or hallucinations; perception and sensitivity are heightened and the body is aroused and invigorated. The shamanic dosage catapults consciousness into an entirely different reality that is flooded with cosmic visions and enables a person to peer into worlds that are beyond the normal experience of space and time.

“In different cultures, drugs are often used in completely different manners. This demonstrates that the consumption of drugs is culturally shaped to a very large extent. Which substances are used, when, by whom, how, how often, and in which dosage, where, with whom, and

why, and also which conceptions are related to this are largely dependent upon the cultural membership of a user. Because of these influences, inebriation is experienced and lived out in very different ways, and a drug may be used for different purposes, may be assigned different functions.”

BLÄTTER

(1994, 123)

This beaded head of a jaguar bears witness to the great importance that psychoactive substances play in shamanism. The jaguar is a symbol of the shaman—for he can transform himself into this powerful animal—but he is also his power animal and ally. The shaman uses a psychoactive plant, the peyote cactus (*Lophophora williamsii*), to establish contact with this ally. The fantastic world he enters is echoed in the artistry of the beadwork. The visionary cactus itself is portrayed on the animal’s cheek. (By an unknown Huichol artist, ca. 1996)

Shamans throughout the world use psychoactive substances in order to penetrate into the other world, the other reality. Drumming helps ensure a safe journey during the visionary adventure. (Nepali shaman at Kalinchok, 1993)

During a dramatic visionary experience, the shaman obtains his special abilities and powers by dying as a person and being reborn as a shaman. Psychoactive substances often produce experiences of death and rebirth, as well as near-death experiences. (Huichol yarn painting, ca. 1995)

Set is perhaps the most important factor for becoming aware of the efficaciousness of a psychoactive plant, especially when a hallucinogenic substance is involved. These substances have the ability to activate, potentiate, and sometimes mercilessly expose everything that a person has in his or her consciousness or buried beneath it. People who were raised under the repressive conceptions of the Catholic religion, for example, may need to struggle with the original sin that was laid upon them in the cradle, whereas a nature-venerating pagan may perceive his or her partner as a temple of divine desire.

In traditional cultures, set is shaped primarily by the worldview that all individuals share and is especially expressed in a tribe's mythology. The mythology provides a kind of cartography of the visionary worlds and other realities. Using this cartography, an explorer of consciousness can reach the desired goal. And he can always count on the help of the shaman who accompanies him, for the shaman is the best cartographer of the other, visionary reality. Even when a person gets lost in that world, the shaman can bring him back. The contents of the visions, in other words, are shaped by culture.

Psychoactive Plants and Shamanic Consciousness

The shaman is not only a hunter, warrior, healer, diviner, and entertainer, but also a natural scientist and thinker. Anthropologist Elizabeth Reichel-Dolmatoff reports that among the Tanimuka, a Tukano Indian group, shamanism is consequently referred to as "thinking." The shaman, first and foremost, is a visionary who has genuine visions:

A shaman is one who has attained a vision of the beginnings and the endings of all things *and who can communicate that vision*. To the rational thinker, this is inconceivable, yet the techniques of shamanism are directed toward this end and this is the source of their power. Preeminent among the shaman's techniques is the use of the plant hallucinogens, repositories of living vegetable gnosis that lie, now nearly forgotten, in our ancient past. (McKenna 1992, 7)

“Shamanism is the door to the real world.” The ethnopsychologist Holger Kalweit spoke these words at a symposium in September 1996 entitled “The Shamanic Universe.” What he meant is that shamanic consciousness is the real world or, as the Indians say, the “true reality.”

For many Indians in the Central and South American rain forests, the everyday world is an illusion, a superficial necessity.⁶ “To those who know, this appears as the world of effects, whereas the world of myths is the world of causes” (Deltgen 1993, 125). Ayahuasca or yagé, the “drink of true reality,” helps people pierce through the illusion that is the everyday world and penetrate into the heart of reality. The reality that is experienced under the influence of ayahuasca is the reality of the myths, which appears to be more real and more meaningful. “The drug is a medium, a vehicle between this reality and that. It is the gateway to knowledge. The *kumú* [shaman], however, is the mediator between the two worlds, and may be more passive or more active, depending upon his power and his talents” (Deltgen 1993, 141). The effects of the “ingestion of these hallucinogens are not understood as an action produced by a special, that is, active chemical substance, but as a contact with spirit beings (owners, ‘mothers,’ species spirits), who control the corresponding plant and embody its ‘essence’” (Baer 1987, 1). The spirits of the plant are the same spirits who aid the shaman in the healing process: “The hallucinogenic plants, or the spirits that dwell within them, open the eyes of those who take them; they enable them to recognize the nonordinary reality, which is considered to be reality per se, and it is ultimately they, and not the shaman, who free the patient from his affliction” (Baer 1987, 79). Not everyone, however, can control the spirit helpers: “The *cají* [ayahuasca] thus does not make the shaman. To the contrary: he who is called to be a shaman, the spiritually gifted, is able to make something out of the drugs and their effects” (Deltgen 1993, 200).

Name	Active Substance	Dosage		Duration of Effects
		Alkaloid	Drugs (dried)	
Mushrooms	psilocybin psilocin	20 mg	3–5 g 2–8 mushrooms	4 hours
Peyote	mescaline phenethylamine	0.5–1.0 g	4–14 “buttons”	4–8 hours
Vines	lysergic acid amide	1–5 mg	5–40 seeds (up to 300!)	4–12 hours
Datura	tropanes (scopolamine/atropine)	5 mg	12–60 seeds 3–5 flowers	3–6 hours up to 24 hours

“Emissaries of the plant kingdom merge with human bodies and aid people in attaining other states of consciousness. Only the gods know which powers of nature are here at work. Possessed people give themselves in to sexual activities and join in the cosmic dance of joy. They celebrate festivals in the truest sense of the word. These festivities are an expression of that fundamental and timeless form of religious ceremony which is an invitation to the gods. Through this adoration, man makes a request, he offers the gods his body and soul, so that they will ‘take over’ these. Enlightenment.”

TIMOTHY LEARY

ON THE CRIMINALIZATION OF THE NATURAL
(NO DATE)

Like their shamans, most of the Indians of the Amazon base their lives upon the visions they receive through ayahuasca: “Our ancestors oriented the entire rhythm of their lives around the ayahuasca visions; whether it had to do with the making of weapons, drawings, art, colors, clothing, medicine, or something else, or it involved determining the most favorable time for a journey or to till the fields. They used the ayahuasca visions in their attempts to better organize themselves” (Rivas 1989, 182).

Shamans throughout the world consume psychoactive plants and products so that they may be able to enter the shamanic state of consciousness and travel to the visionary world, the other reality. The substances shamans use are very diverse both chemically and pharmacologically. The active substances they contain belong to different classes that are analogs of or related to different endogenous neurotransmitters (see the box above).⁷ Nevertheless, they are all pharmacological stimuli for achieving the selfsame purpose: to produce the shamanic state of consciousness.⁸

This fact was verified through the research of Adolf Dittrich, who demonstrated that experiences in altered states of consciousness—and compared to everyday reality, the shamanic state of consciousness is very altered—are identical at the core, no matter which pharmacological and/or psychological stimuli elicited them (Dittrich 1996).

On the basis of my own experiences with a variety of psychoactive plants, I can attest that different active substances can evoke the same state of consciousness, e.g., trance, but will not always do so, for the same drug can produce totally different effects in different people. In particular, the drugs found in *datura* exhibit striking differences (cf. Siegel 1981). Even in the same person, the same substance can induce very different effects depending upon the dosage, set, and setting. In order to produce the same state, i.e., the shamanic state of consciousness, more than just a psychoactive substance is needed. The user must also have the appropriate intention and the appropriate external conditions.⁹ The drug experience is heavily influenced by the mythological and cosmological matrix of the user and by the ritual that is taking place in the external world. Mythology and cosmology provide the topography or cartography of the shamanic world and show the ways into it and back out. The ritual provides the outer framework that facilitates the user's transition from everyday reality to shamanic reality and back.

The reasons why a plant is being used will strongly affect the content of the experiences. If it is being used to perform shamanic tasks, then it will tend to evoke shamanic realities. As with all human abilities, however, this talent is not the same in everyone. Only the most talented can become shamans. In the same way, humans all differ with regard to our boldness and courage. Only the most courageous of us can become shamans. Fearful people should not confront the gods and demons. It is for these reasons that in most societies that have institutionalized shamans, the use of plants with visionary effects is embedded within an exclusively ritual context. The visionary experiences take place against the familiar background of one's own culture.

"It can be said of very many inebriants that the same dose will enliven one individual and put another to sleep. Indeed, under different circumstances, they can produce almost opposite effects even in the same individual. Just as a person can be pepped up by morphine, he can become sleepy after coffee. Almost everyone knows that the same dose of alcohol can be something different in the morning and the evening, in the summer or the winter."

WOLFGANG HEUBNER

GENUß UND BETÄUBUNG DURCH CHEMISCHE MITTEL [ENJOYMENT AND STUPOR THROUGH CHEMICAL MEANS]

(1952, 36)

"Whoever the plant devas touch is no longer the same person [he was] before. The encounter shapes him. Like the Midewiwin healer with his herbal lore, he will be killed and reborn with new powers. He has truly become a citizen of both worlds."

WOLF-DIETER STORL *KRÄUTERKUNDE* [HERBAL LORE]

(1996b, 232)

The shamanic use of psychoactive plants follows a specific basic pattern, whereby it is relatively unimportant which substance is being used. First and foremost are the form, meaning, and purpose (function) of a ritual. The structure of the ritual follows a pattern that I have termed the "psychedelic

ritual of knowledge” (cf. Räscht 1991b):

Preparation

Collecting and preparing the drugs

Sexual abstinence, fasting

Practical purification (bathing, sweat house,¹⁰ enemas)

Symbolic purification

Utilization

Offerings to the gods (e.g., incense)

Prayers to the gods and/or plant spirits

Ingestion of the drug

Soul journey during trance

Communication with the plant spirits/gods/animal spirits

Integration

Diagnosis/prophecy

Instructions for how to behave

Offerings of thanks

The Fear of Psychoactive Plants

The fear of consciousness-expanding plants is at least as old as the Bible. In Genesis, this fear is thematically expressed as the Fall. The fruit of the tree of knowledge transforms a person into a god. But since we are allowed to worship only one god, no one else can stand on the same level as him (or her?).

In many hierarchical cultures with an imperialistic orientation (emphasizing power instead of knowledge), immediate mystical, ecstatic, or religious experience is heavily regulated and is usually even forbidden. The direct experience of the world has been replaced by an elaborate, theologically driven religion and is monopolized by the state. Paradise, that other reality, is administered by bureaucrats who have not personally experienced it and who sell it to the needy and those who crave ecstasy. Jonathan Ott has referred to this mechanism as the “pharmacratic inquisition” (1993). The Mexican inquisition provides the best historical example of the suppression of personal experience and its replacement by a state monopoly for administering the divine.

As the Europeans pushed into the New World, they encountered for the first time shamans, whom they contemptuously labeled “magicians” and “black artists.” The shamans’ gods and helping spirits were degraded as false gods, idols, and the devil’s work; their sacred drinks were defamed as witches’ brews. An Inquisition report from the colonial period written by D. Pedro Nabarre de Isla (issued on June 29, 1620) notes:

As for the introduction of the use of a plant or root named peyote . . . for the purpose of uncovering thievery, divinations about other occurrences, and prophesizing future events, this is a superstition which is to be condemned because it is directed against the purity and integrity of our sacred Catholic faith. This is certain, for neither this named plant nor any other possesses the power or intrinsic property of being able to bring about the alleged effects, nor can anything produce the mental images, fantasies, or hallucinations that are the basis of the mentioned divinations. In the latter, the influences and workings of the devil, the real cause of this vice, are clear, who first makes use of the innate gullibility of the Indians and their idolatrous tendencies and then strikes down many other people who do not sufficiently fear God and do not possess enough faith.

Even today, the sacred plants of the Indians and/or their active constituents are forbidden throughout the world. While the use of peyote, mescaline, psilocybin (the active principle of Mexican magic mushrooms), DMT, et cetera, is in principle exempt from punishment, the possession of or trafficking in these is nevertheless illegal (Körner 1994). The drug laws of our time, in other words, are rooted in the spirit of the Catholic Inquisition. As long as the sacred plants and substances of the Indians remain illegal, the war against the indigenous peoples of the Americas will not be over. Generally speaking, the U.S. “War on Drugs” is a continuation of European colonialism and an instrument for criminalizing the Indians and their spiritual kin.

This phobia about drugs is nothing new, for drugs have been viewed as wild and reprehensible since ancient times (think of the persecution of the mystical followers of Dionysos, as well as of the witches, alchemists, and hippies). The fear of drugs and the experiences associated with them is found even throughout the various camps of shamanism fans and in academic circles. Mircea Eliade, for example, discounted the use of drugs to produce trance and (archaic) ecstasy as “degenerate shamanism” (1975, 382). Many members of the New Age movement have claimed that they can attain “it” without drugs. There are also anthropologists who argue that just because “their” shaman apparently enters into trance without any pharmacological support, other shamans—about whom they know nothing—also should not need drugs. It appears, however, that almost all traditional shamans prefer pharmacological stimuli (Furst 1972a; Harner 1973; Ripinsky-Naxon 1993; Rosenbohm 1991; Vitebsky 1995). As one source puts it, “The Indians view the drugs as nourishment for the soul and venerate them because of their wondrous properties” (Diguët in Wagner, 1932, 67).

When the Christian Europeans encountered their first shamans, they saw them as black magicians, master witches who had allied themselves with the devil and who, with his help, were leading the other members of their tribe down the road to ruin. In the early ethnographic literature, they are referred to as magicians, witch doctors, medicine men, weather makers, mediums, and the like. A large portion of the literature on shamanism specialized in demonstrating that shamans are con artists who use sleight of hand to trick the other members of their tribes and that, in the best of cases, they are charlatans whose methods are irrational and superstitious.

In traditional psychiatry and psychoanalytical-oriented anthropology, shamans were regarded as schizophrenics, psychopaths, and sufferers of arctic hysteria, that is, as people who are ill. Strange indeed that these ill people are the very ones who concern themselves with the task of healing. In contrast, shamans have been glorified and proclaimed as saviors in antipsychiatric circles. This attitude gave rise to images of “psychiatric utopias in which the shaman was the leader” (Kakar 1984, 95). In the more recent ethnographic literature, especially that based upon the approach known as cognitive anthropology, shamans are looked at from the perspective of that which they represent for their communities: people who, because of their calling and their special gift of trance, are able to divine, diagnose, and heal. In doing so, they maintain harmony in the community, preserve the tribal myths and traditions, and ensure the survival of their people.^u

The interdiction of psychoactive plants and their effects is not bolstered solely by questionable politically based laws, but also receives support from the side of established science. Here, two concepts from psychiatry have played key roles: *psychotomimetic* and *model psychosis*. The first is a term for a substance that is said to mimic a psychosis; the second is a term used to characterize the experience. As a result, these plants and the effects they produce are viewed not as something sacred or mystical but as something pathological. This is reminiscent of such anthropologists and religious scholars as George Devereux and Mircea Eliade, who regarded shamans as psychopaths or people suffering from hysteria.

Since the end of the nineteenth century, Western psychiatry has known of and used drugs that alter consciousness (Grob 1995; Strassman 1995). The first such substance to be tested and used in

psychiatry was mescaline. Mescaline was first extracted, chemically identified, and synthesized from the Mexican peyote cactus at the end of the nineteenth century. At that time, the effects of mescaline upon healthy subjects were thought to be the same as those that were otherwise known only from psychiatric patients. This led to the idea of the pharmacologically induced “model psychosis” (cf. Leuner 1962; Hermle et al. 1988). During the twentieth century, other substances with similar effects were discovered in the plant world, synthesized in the laboratory, and tested on patients and even on prisoners (Hermle et al. 1993).

The concept of the model psychosis is simply another form of ethnocentrism. Whereas the Inquisition saw the workings of the devil in these psychoactive substances, psychiatrists interpreted the sacred visions as psychotic-like states, that is, as “artificially” induced mental illnesses. Today, however, the model psychosis concept has itself landed on the rubbish heap of modern high-technology science. Recent research into the brain activity of true psychotics and of healthy users of psychedelics, using PET scans, has demonstrated that very different regions of the brain are active in each (Hermle et al. 1992).

Another opinion prevalent in our world holds that “drugs” cannot be used intelligently but will automatically be “misused” (cf. Dobkin de Rios and Smith 1976). In our culture, it is commonly argued that narcotic drugs lead to “addiction” or “dependency.” Here, the views vary widely. In addition, the addictive potential of a substance is often used as the only definition of an inebriant (also frequently referred to as an “addictive drug”). Since addictive behaviors can arise with respect to almost every substance, many foods, luxury goods, and numerous medicines should also be seen as addictive substances. Many people, for example, are “addicted” to chocolate (cf. Ott 1985). Some have even argued that sugar is a drug, and an addictive one at that (McKenna and Pieper 1993). So, are chocolate and sugar invigorating foodstuffs, delicious luxury goods, or addictive drugs?

Since ancient times, psychoactive substances have been used by athletes as doping agents (cf. *Mammillaria* spp.). In the modern world of competitive sports, the plant substance **ephedrine** and its derivatives (amphetamines), camphor (cf. *Cinnamomum camphora*), **strychnine**, and **cocaine** have all been used. Of course, the use of doping agents is condemned, regarded as unsportsmanlike, forbidden, and strongly proscribed (Berendonk 1992). Many athletes, however, are like the “closet shamans” (see p. 20), constantly on the lookout for new ways to augment their performance. Recently, preparations of the ascomycete ***Cordyceps*** were successfully used for doping purposes. The athlete involved could not have her victory disallowed, however, for this was a dietary supplement, not a forbidden substance.

“The world is as one perceives it and what one perceives of it.”

ALBERT HOFMANN

LOB DES SCHAUENS [IN PRAISE OF LOOKING]
(1996)

The first botanical and chemical investigations of the peyote cactus (*Lophophora williamsii*) were conducted at the end of the nineteenth century. The extraordinary psychedelic effects of mescaline, an alkaloid isolated from this cactus, have influenced the history of European psychiatry.

Two psychoactive plants in an intimate embrace: an Amazonian ayahuasca vine (*Banisteriopsis caapi*) winding itself up the trunk of a coral tree (*Erythrina mexicana*).

The Study of Psychoactive Plants

Science begins by collecting data, facts, and objects and ends with systematic knowledge. This process characterized all of the early works of science, which condensed and concentrated the knowledge of their time and their world. There is also the human desire to experiment. We learn by trying things out, and we change our behavior as a result of our experiences. It is striking that all of the great plant researchers have been avid collectors of both information and materials and have also tested the effects of as many plants as possible on themselves, for how can one evaluate the effects of a plant if one has never seen or touched it, not to mention ingested it?

The study of psychoactive plants began with the beginnings of botany. Theophrastus (ca. 370–287 B.C.E.), the “father of botany,” has given us descriptions of numerous psychoactive plants and substances. Systematic science, which some trace back to the poet Homer (ninth–eighth centuries B.C.E.), was already being practiced in ancient times:

But Homer, who was the forefather of the sciences and of the history of ancient times and was a great admirer of Circe, attributed Egypt with the fame of its valuable herbs. . . . At least he described a great number of Egyptian herbs which were given to his Helen by the Pharaoh's wife, and spoke of that renowned *nepenthes*, which induced one to forget sorrow and forgive and which Helen should have had all the mortals drink. But the first of whom we still have knowledge was Orpheus, who reported some interesting things about herbs. We have already mentioned the admiration which Musaios and Hesiod, following his lead, had for *polium*. Orpheus and Hesiod recommended the burning of incense. . . . After him, Pythagoras, the first person known for his knowledge, wrote a book about the effects of plants in which he attributed their discovery and origin to Apollo, Asclepius, and all of the immortal Gods in general. Democritus also produced such a compilation; both visited the magicians in Persia, Arabia, Ethiopia, and Egypt. (Pliny, *Natural History* 25.12–3)

In late ancient times, other books of herbal lore joined Pliny's (23–79 C.E.) *Natural History*. The most important of these was Dioscorides's (ca. first century) *Teachings on Medicines*, which is still important in our time. This work provides information about numerous psychoactive plants, including their various names, preparations, and uses (cf. Rätsch 1995a).

In the Middle Ages, descriptions of psycho-active plants were found especially in the writings of Arabic and Indian authors, such as Avicenna (980–1037). In Germany, many plants (including hemp, henbane, and deadly nightshade) were described by the abbess Hildegard von Bingen (1098–1179) (Müller 1982).

The great period of the “fathers of botany” dawned at the beginning of the modern era. This period witnessed the publication of voluminous herbals full of information about psychoactive plants. Among their authors are Leonhart Fuchs (1501–1566), Jacobus Theodorus Tabernaemontanus (1522–1590), Hieronymus Bock (1498–1554), Otto Brunfels (ca. 1490–1534), and Pierandrea Matthioli (1500–1577).

During the colonization of the New World, the Spanish king sent physicians and botanists to Mexico and Peru. Their task was to investigate the indigenous flora to determine potential medicinal uses. The results were published in a number of compendia dedicated to American flora and its healing effects. All of these works contain numerous references to psychoactive plants and their medicinal and psychoactive uses (Pozo 1965, 1967).

The systematic study of psychoactive plants first began in the nineteenth century. Dr. Ernst von Bibra (1806–1878), a baron from Lower Franconia, was a private scholar typical of his time. He was wealthy by birth, achieved academic distinction, and dedicated his life to his studies, which he preferred to carry out within his own four walls. He studied medicine and philosophy in Würzburg and later lived in Nuremberg. When he was not traveling, he spent most of his time at his estate at Schwebheim. Bibra held liberal political views and was actively involved in the Revolution of 1848. Because of this, he was forced to leave the country for a time, during which he journeyed through South America (1849–50). While there, he became acquainted not only with many exotic cultures but also with a number of South American inebriants, especially coca and guaraná.

Just one year after Bibra published the remarkable journal of his travels,¹² his groundbreaking book *Die narkotischen Genußmittel und der Mensch* [The Narcotic Agents of Pleasure and Man] (Nuremberg 1855; published in English as *Plant Intoxicants* in 1995) appeared. A unique work, it became a true literary sensation, providing the first detailed descriptions of the psychoactive drugs that were known at the time and their effects. The author's own experiences, as well as his liberal disposition, were very discernible:

One could not name a single country in the whole wide world in which the inhabitants are not using some sort of narcotic. Indeed, almost all use several of them. Although perhaps only a few tribes use certain of these substances, millions of people employ the vast majority of them. (Bibra 1995, 218)

In his book, Bibra reported at great length about coffee, tea, maté, guaraná, cacao, fahan tea, fly agaric, thorn apple, coca, opium, lactucarium, hashish, tobacco, betel, and arsenic. The conclusions of his discussion have a very modern ring:

We have learned from experience that man can live without narcotics or without alcoholic drinks, which we wish to include here because of their similar effects. By taking these substances, however, man's life becomes brighter and therefore they ought to be approved. (221)

Clearly, the notion that we have a right to inebriation was already current at that time!

In German-speaking countries, Bibra's work launched a wave of interdisciplinary drug research that has continued into the present day. He was the chief source of inspiration for pharmacist Carl Hartwich (1851–1917), who compiled the most voluminous work on psychoactive plants to date (Hartwich 1911), as well as for toxicologist Louis Lewin (1850–1929). Even Albert Hofmann (b. 1906), a modern-day Swiss chemist specializing in the investigation of naturally occurring substances, feels a kinship with the baron, for Bibra called upon the chemists who would come after him to dedicate themselves to the study of psychoactive plants.

Arthur Heffter (1860–1925) took Bibra at his word. He was the first person to test an isolated plant component, in his case mescaline, by trying it out on himself. It is for this reason that we still refer to this method of conducting research through self-experimentation as the Heffter technique.

At about the same time as Bibra, the American Mordecai Cubitt Cooke (1825–1913) also was studying human inebriants, which he poetically described as the “Seven Sisters of Sleep” (Cooke 1860, reprinted in 1989). Paralleling Cooke's work, the Scotsman James F. Johnston was investigating the chemistry of everyday life and the substances that humans ingest for their pleasure. He published his work in 1855, the same year as Bibra.

In Italy, Paolo Mantegazza (1831–1910) is regarded as a pioneer of drug research (Samorini 1995b). In 1871, Mantegazza published in Milan his 1,200-page main work *Quadri della natura umana: Feste ed ebbrezze* [Pictures of Human Nature: Festivals and Inebriations].

Mantegazza was partial to coca, and in 1858 he published a sensational work entitled *Sulle virtù igieniche e medicinali della coca e sugli alimenti nervosi in generale* [On the Hygienic and Medicinal Virtues of Coca and Nerve Nourishment in General]. Like Bibra and Hartwich, Mantegazza was interested in all agents of inebriation and pleasure and was guided and inspired by these his entire life. Since most of his writings have appeared only in Italian, they have not attracted as much international attention as the publications of Bibra, Johnston, and Cooke.

Mantegazza's classification of inebriants is especially interesting. He divided the “nerve nourishment” into three families: 1. alcoholic nerve nourishment, with the two branches fermented and distilled beverages; 2. alkaloid nerve nourishment, with the branches caffeine and narcotics (among the narcotics, he included opium, hashish, kava-kava, betel, fly agaric, coca, ayahuasca, and tobacco); and 3. aromatic nerve nourishment (sage, oregano, rosemary, cinnamon, pepper, chili, etc.).

The psychiatrist Emil Kraepelin (1856–1926), who in 1882 published his medical and psychologically oriented book *Über die Beeinflussung einfacher psychologischer Vorgänge durch einige Arzneimittel* [On the Influencing of Simple Psychological Processes by Some Medicines],

followed a path different from Bibra's. That same year witnessed the publication of the revised second edition of *Die Schlaf- und Traumzustände der menschlichen Seele mit besonderer Berücksichtigung ihres Verhältnisses zu den psychischen Alienationen* [The Sleeping and Dreaming States of the Human Mind, with Special Emphasis Upon Their Relationship to the Psychic Alienations], by Heinrich Spitta, a dream researcher and professor of philosophy. Both books, each in its own way, dealt with the chemical agents that can be used to induce altered states. Shortly thereafter, the neurologist and "father of dream theory" Sigmund Freud (1856–1939) published his work *Ueber Coca* [On Coca], which helped make the use of cocaine fashionable. These pioneering works led to the development of psychopharmacology or pharmacopsychology, a field that has attracted psychiatrists, pharmacologists, pharmacognosists, and chemists. *Pharmacopsychology* has been defined as "the doctrine of influencing the mental life by means of chemically effective substances introduced into the body" (Lippert 1972, 10).

Dr. Ernst Freiherr von Bibra (1806–1878) was a pioneer in the ethnopharmacological study of psychoactive substances. His work *Die narkotischen Genußmittel und der Mensch* [The Narcotic Agents of Pleasure and Man] (1855) was the first comprehensive book on the topic and is still an important reference.

Shen-Nung, the legendary Red Emperor, is regarded as the founder of Chinese herbal medicine. He personally tried each herb, including the poisonous and inebriating ones, before recommending their use for healing purposes. Shen-Nung was thus the founder of the ethnopharmacological method of conducting bioassays, also known as the Heffter technique. (Ancient Chinese

The most important chemist in this history of research is the Swiss Albert Hofmann. Not only did he invent LSD while investigating the ergot alkaloids, but also he discovered the active principles in the magic mushrooms of Mexico as well as other American Indian magical drugs. Also of note is Alexander T. Shulgin, an American chemist of Russian descent who has played an especially significant role in the area of structure-effect relationships.

In anthropology or ethnology, investigations into the use of psychoactive plants did not begin until

the twentieth century.¹³ Among the pioneers of psychoactive ethnology are Pablo Blas Reko, Weston La Barre, Johannes Wilbert, Peter Furst, and Michael Harner. Today, the role played by Carlos Castaneda is a source of considerable controversy.

Toward the end of the nineteenth century, ethnobotany began to emerge as a specialized branch of science. The term was introduced in 1895 by John W. Harshberger (1869–1929). Both ethnologists and botanists have specialized in ethnobotany. A British scholar, Richard Spruce (1817–1893), was one of the pioneers of ethno-botany. Richard Evans Schultes (1915–2001), a former professor and former director of the Botanical Museum at Harvard University, is universally regarded as the “father of psychoactive ethnobotany.” His investigations in Mexico and South America have led to the discovery of numerous psychoactive plants (Davis 1996). Many of Schultes’s students have themselves become renowned ethnobotanists or ethnopharmacologists, including Timothy Plowman (1944–1989), Wade Davis, Mark J. Plotkin, and Tom Lockwood. The American botanist William Emboden is noted for making a creative leap to art history and has published many important works in this area.

Ethnomycology, the study of the cultural uses of fungi, was founded by the banker R. Gordon Wasson (1898–1986). In some ways, Jonathan Ott, a chemist who investigates natural substances, has become Wasson’s successor. Many other discoveries in ethnomycology have been made by Paul Stamets, Gastón Guzmán, and Jochen Gartz.

During the past thirty years, ethnopharmacology, the study of the cultural uses of pharmacologically active substances and their cognitive interpretations, has developed into a specialized field within the disciplines of ethno-botany and ethnomedicine. It is a young field that is very interdisciplinary in nature. This encyclopedia is a work of this nature.

Finally, we should also mention *closet shamans*. This term has come to be used for amateurs and hobbyists who experiment at home with psychoactive plants and preparations, occasionally making astonishing discoveries that are then eagerly taken up and pursued by scientists. Almost all of the research into ayahuasca analogs has been conducted by these closet shamans.

Most of the important discoveries in the field of psychoactive plants, including those having to do with their chemistry and pharmaceutical uses, have been made by German-speaking scientists. Is this an expression of some need of the German “soul”? Why this concentration on German soil? Is the Germanic god Wotan still at work? Wotan is both the god of knowledge and the restless shaman who will do whatever he can to satisfy his immeasurable thirst for knowledge. It was he who stole the Mead of Inspiration and brought it to us humans (Metzner 1994b).

Psychoactive Plants as Factors in the Development of Culture

The use of—and the need for—psychoactive plants is very ancient. Some authors have suggested that the roots lie somewhere in the Paleolithic period (Ripinsky-Naxon 1989; Westermeyer 1988). It appears that the connection to shamanism was already present at an early date (La Barre 1972). Although I personally do not believe that shamanism was one of the very first religions, I do think that the altered states of consciousness and visions induced by psychoactive plants have led to significant cultural innovations.

A person ingests a substance obtained from the environment and sinks into a flood of pictures, visions, and hallucinations. He is confronted by a previously unimagined quantity of images—images that seem somehow familiar, or archetypically known, we might say. Moreover, these images are complex and intricate, following one another in incredible sequences, and they have such detail that you cannot shake the feeling that you have somehow landed on the molecular level or are somewhere far away, in the depths of infinite space. Where do these pictures come from? Do they arise in the human brain as a result of the material interaction between molecules from without and the brain

stem? Can we, using these substances that come from outside of ourselves, look into realities that truly are outside and for which we normally have no perception? No matter the answer, the wonder or the mystery remains the same! Wherever the images come from, they are present, they can be perceived, they are a reality that can be experienced.

“Oh! Joy! Joy! I have seen the birth of life, the beginnings of movement. The blood pounds in my veins as if they would burst. I want to fly, swim, bark, bleat, roar, would that I had wings, a carapace, a rind, could fume smoke, would have a trunk, could coil my body, divide myself and enter into everything, could effuse myself into scents, unfurl myself like a plant, flow like water, vibrate like sound, shimmer like the light, assume every form, penetrate into every atom, sink down to the foundation of matter—be matter!”

GUSTAVE FLAUBERT

LA TENTATION DE SAINT ANTOINE [THE TEMPTATION OF ST. ANTHONY]

(1979, 189)

Many cultures and many researchers have concerned themselves with these questions. Although no one has been able to provide a definitive answer, the hypotheses and positions that have been put forth can be divided into two camps. One assumes that all reality is merely a projection of our own consciousness; the other holds that there are numerous or even infinitely many different realities in the external world.

We can take shamanism seriously only if we follow the second view, for if we assume that the shaman is only flying around within his own skull, then he would not be able to recover, liberate, and bring back stolen souls.

The internal images and visions induced by psychoactive plants appear to have influenced human art since the Stone Age (Biedermann 1984; Braem 1994). African rock art has been interpreted as an expression of altered states of consciousness, most likely induced by mushrooms or similar substances (Lewis-Williams and Dowson 1988, 1993). American Indian rock art has also been inspired by experiences with psychoactive plants (Wellmann 1978, 1981).

The images in the world of Hieronymus Bosch have been interpreted as the product of drug experiences as well. Nineteenth-century art would have been inconceivable without psychoactive plants (Kupfer 1996a, 1996b). To the observer, many of the pictures of the surrealists, especially those of Max Ernst, René Magritte, and Salvador Dalí, appear to be “drug pictures” or remind one of one’s own experiences in altered states. Hashish appears to have played a role in the development of surrealism, the philosophy of which was set forth in the *Surrealist Manifesto* of 1924: “Surrealism rests upon the belief in the greater reality of certain forms of associations that have been neglected until now, in the omnipotence of dreams, in the non-utilitarian play of thought” (Breton 1968, 26f.).

The founder of surrealism compared this art form with the effects of psychoactive substances:

Surrealism does not permit those who follow it to abandon it whenever they will. Everything points to the fact that it affects the mind in the same way as stimulants do; like these, it produces a certain condition of need and is able to drive a person to terrible revolts. Once again, if you will, we stand before a very artificial paradise, and our penchant to enter into it falls with the same rights under the same Baudelairean criticism as all the others. Thus, the analysis of the mysterious effects and special pleasures which it can impart—in some ways, Surrealism appears to be a *new vice*, which is not suitable for just a few; like hashish, it is able to satisfy all those who are particular—thus, such an analysis must be undertaken within this investigation.

Surrealistic images are like those pictures from opium inebriation, which a person is no longer evoking, but which are “spontaneously and tyrannically presented to him. He is incapable of fending them off; for the will has lost its power and no longer controls his abilities.” (Baudelaire) The question remains as to whether one ever “evoked” the images at all. (Breton

It appears that experimentation with psychoactive substances provided an important impetus to the art scene surrounding fantastic realism. Only a few artists, however, have publicly admitted as much. Ernst Fuchs even denied his drug experiences in one of his early biographies (Müller-Ebeling 1992). For most artists, it appears that the use of hashish and marijuana does not necessarily affect the creative process but functions instead as a way to focus concentration, in the way that some Indians use hashish in their meditation practice (e.g., Gustav Klimt). Albert Paris Gütersloh, an admitted cannabis user, provided a realistic assessment of the situation:

Every [artist] of my generation has made the acquaintance of hashish, and when I walk through the academy and sniff, I am certain: everyone in my class, at least, has as well. Does this mean that we are all hash artists? (cited in Behr 1995)

The discipline of anthropology provides us with many examples of cultural goods or artifacts that are the direct result of visionary experiences with psychoactive plants and products (Andritsky 1995). The yarn paintings of the Huichol are representations of their experiences with peyote, and the visions induced by ayahuasca have been the subject of numerous ayahuasca paintings.

The most important magical plants of Mexico were first described in the Aztec-language work of Fray Bernardino de Sahagun, the Florentine Codex: 515 Tlapatl (*Datura* spp.); 516 Nanacatl (*Psilocybe* spp.); 517 Peyotl (*Lophophora williamsii*); 518 Toloe (*Datura innoxia*). (Paso y Troncoso edition)

THE
PSYCHOACTIVE
PLANTS

“My heart wears flowers and fruits in the midst of the night . . .
I, Cinteotl [=Xochipilli], was born in paradise. I come from the land of flowers.
I am the new, the glorious, the unequalled flower.
Cinteotl was born of the water; as a mortal, as a young man he was born
from the heavenly blue House of the Fishes. A new, victorious god. He shines like the sun. His mother lived in the House of the Twilight,
as colorful as a Quetzal, a new, delightful flower.”

AZTEC HYMN

IN *MEXIKANISCHE MYTHOLOGIE* [MEXICAN MYTHOLOGY] (NICHOLSON 1967, 115f)

Which plants have been included in this encyclopedia? I considered all of those plants that my own research and experience have indicated to be psychoactive as well as those plants that other researchers or the literature have reported to be psychoactive. Here, we must keep in mind that there are plants for which a majority of subjects have reported no psychoactive effects. There also are plants that have a reputation of being hallucinogenic, but which no one has yet tried. To date, many of these plants have been the object of only cursory investigation. There also are a number of plants that have not yet been botanically determined or identified. The situation is complicated by the fact that the botanical data contained in the ethnographic literature are often incorrect, or at least very imprecise. Sometimes, it was difficult to decide whether a particular plant should be included in this work or not. One such case is St. John’s wort (*Hypericum perforatum* L.), which the ancient Germans used as a sedative and in modern phytotherapy is generally regarded as a natural tranquilizer (Becker 1994). St. John’s wort and the oil it yields do indeed exert a psychoactive effect, but only upon patients suffering from mental or emotional afflictions. As a rule, healthy individuals do not notice any psychotropic effects, even after ingesting large amounts.¹⁴ Such uncertain cases—to the extent that they are known—have not been included in these monographs.

Reflecting our current state of knowledge, I have treated the various psychoactive plants discussed in this book in several different ways. Well-known plants that have been investigated in some detail are examined in a very systematic fashion in the major monographs. Plants that have been little studied or about which very little is known are discussed in informal minor monographs. A number of very well-known and well-researched plants that are purported to produce psychoactive effects and are sometimes referred to as “legal highs” are considered in their own small section of informal monographs. This is followed by another section that focuses on a number of psychoactive plants whose botanical identity is unknown.

Because they are not plants in the strict sense, psychoactive fungi are presented in a section of their own. The section on psychoactive fungi is followed by another that focuses on psychoactive products that are obtained through often intricate procedures and/or from combinations of plants. Finally, there is a short section that examines the psychoactive constituents of plants. This section also serves as an aid in locating the plants discussed in the monographs.

Depicted here in a state of ecstasy, Xochipilli, the flower prince, was the Aztec god of psychoactive plants, eroticism, spring, inspiration, and music. This pre-Columbian statue clearly illustrates the great importance that people have placed upon visions as well as the manners in which such experiences have found expression in art.

On the Structure of the Major Monographs

The monographs are arranged alphabetically according to botanical names. Below the scientific name may be found the most common English name(s) or, when none is known, a common international name.

Some of the monographs treat not just one species but, rather, a number of species of the same genus. This is done either because the traditional users make no distinction between the different species or because the species all contain the same active constituents and/or are sources of the same products.

Family

Here, information is provided about the botanical family to which the plant belongs, along with additional details about taxonomy.

Forms and Subspecies

Any known forms, varieties, cultivars, or subspecies of the plant are listed here.

Synonyms

Most plants have been described in the botanical literature under more than one name. Under this heading may be found these nonvalid botanical names (including misspellings in the literature).

Folk Names

Folk and popular names are given here. Often, information is also furnished about the particular language a name is taken from, and translations of many of the terms are provided. Please note that the names of indigenous tribes and tribal languages referenced in these sections will be spelled in a variety of ways, rather than uniformly. The variant spellings reflect the spellings found in the

literature referenced for each plant.

History

Here may be found the most important information about the history of the plant, including its discovery, botanical description, and historical uses.

Distribution

Under this heading is provided information concerning the range as well as the natural occurrence of the plant in question.

Cultivation

Information about the more simple and successful methods of growing and cultivating a plant is provided under this heading. It should be noted, however, that more is required to successfully grow these plants than simply reading this information; it is also helpful to have a “green thumb,” experience, skill, and a deep love of the plant world.

Appearance

Here is provided a brief description of the plant. Other plants that might possibly be mistaken for it are mentioned, and the plant’s distinguishing features are emphasized. It should be noted that the information contained under this heading does not always conform to the standardized botanical descriptions (which may be found in the botanical literature).

Psychoactive Material

Under this heading, information is provided about the parts of the plant that are utilized, as well as products obtained from them (where appropriate, the pharmaceutical names of the raw drugs are also given).

Preparation and Dosage

Here may be found information for preparing and dosing the various raw drugs. While every attempt has been made to ensure that this information is as accurate as possible, it must be explicitly stated that this information should not be regarded as definitive. Identical dosages can produce very different responses in different individuals.

Ritual Use

Information concerning the traditional uses of the plant in shamanic rituals, priestly ceremonies, domestic festivals, and other experiences may be found here. As in the Folk Names sections, the spelling of indigenous tribal names will reflect the variant spellings found in the literature referenced.

Artifacts

Where possible, reference is made to three types of artifacts associated with the plant:

- Artifacts composed of the plant or manufactured from it
- Artistic representations of the plant (in paintings, architecture, etc.)
- Art works (paintings, poetry, music, theater pieces, etc.) whose inspiration has come from the use of the plant.

Medicinal Use

Many psychoactive plants are also of medicinal and therapeutic significance. Sometimes a plant's medicinal applications are much more important than its psychoactive uses. For these reasons, as much information as possible is provided about the medicinal uses of the plant under discussion. This includes ethnomedical, folk medical, biomedical, and homeopathic uses.

Constituents

Under this heading may be found a comprehensive listing of the known constituents of the plant.

Effects

Here, the effect or the pattern of effects of the plant is described. Once again, it should be kept in mind that different individuals can have very different experiences with the same plant.

Commercial Forms and Regulations

Many plants and/or the raw drugs obtained from them are available through commercial sources. Some plants are subject to particular regulations or laws. Pertinent information is included under this heading.

Literature

Here, references are provided to specialized literature on the plant under discussion.

Symbol Key

Those sources marked in the monographs with a* are listed in the general bibliography located at the end of this book (pages 878–907). Those marked with a ** may be found in the general literature on psychoactive fungi (pages 689–693), which follows the section devoted to them.

Terms in bold print within the running text refer to other entries in this book.

Where a question mark has been inserted in a table column, it indicates that the missing information poses an important question for further research.

Latua pubiflora, known as the tree of the magicians, is one of the world's rarest shamanic plants. The flower of this nightshade is 3 to 4 cm in length. (Photographed near Osorno, in southern Chile)

The Most Important Genera and Species from A to Z

Major Monographs

The following genera are discussed in the major monographs:

Acacia, Aconitum, Acorus, Agave, Alstonia, Anadenanthera, Areca, Argemone, Argyreia, Ariocarpus, Artemisia, Arundo, Atropa

Banisteriopsis, Boswellia, Brugmansia, Brunfelsia

Calea, Calliandra, Camellia, Cannabis, Carnegia, Catha, Cestrum, Cinnamomum, Coffea, Cola, Coleus, Convolvulus, Corynanthe, Coryphantha, Cytisus

Datura, Desfontainia, Diplopterys, Duboisia

Echinops, Ephedra, Erythrina, Erythroxylum, Escholzia

Heimia, Humulus, Hyoscyamus

Ilex, Iochroma, Ipomoea

Juniperus, Justicia

Lactuca, Latua, Ledum, Leonurus, Lolium, Lonchocarpus, Lophophora

Mammillaria, Mandragora, Mesembryanthemum, Mimosa, Mitragyna, Mucuna, Myristica

Nicotiana, Nuphar, Nymphaea

Pachycereus, Papaver, Passiflora, Paullinia, Pausinystalia, Peganum, Pelecyphora, Petroselinum, Phalaris, Phragmites, Phytolacca, Piper, Psidium, Psychotria

Rhynchosia

Salvia, Sassafras, Sceletium, Scopolia, Solandra, Solanum, Sophora, Strychnos

Tabernaemontana, Tabernanthe, Tagetes, Tanaecium, Theobroma, Trichocereus, Turbina, Turnera

Vaccinium, Veratrum, Virola, Vitis

Withania

Acacia Spp.

Acacia Species

Numerous acacias have played a role in ethnopharmacology and medical history. Some species (such as gum arabic) are used as sources for an excipient and incense, some are used as beer additives, and others provide DMT and other tryptamines. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Many Australian acacias contain high concentrations of *N,N*-DMT and are thus suitable for the production of psychedelic ayahuasca analogs. Although our studies of Australia's psychoactive flora have only just begun, they already have demonstrated great promise. (*Acacia* spp., photographed in southeastern Australia)

Catechu, the resin of the catechu tree (*Acacia catechu*), is one of the main ingredients in betel quids. (Photograph: Karl-Christian Lyncker)

Family

Leguminosae: Mimosaceae (Fabaceae) (Legume Family)

Synonyms

Many species of the genus *Acacia* were formerly assigned to the genera *Mimosa*, *Pithecolobium*, *Senegalia*, and *Racosperma*. In addition, some species previously described under the genus name *Acacia* have now been reclassified as *Anadenanthera* (see *Anadenanthera colubrina*) and *Mimosa* (see *Mimosa tenuiflora*, *Mimosa* spp.).

General

The genus *Acacia* encompasses 750 to 800 species (other sources list only approximately 130) found in tropical and subtropical regions throughout the world (Harnischfeger 1992). Most are medium-sized trees, the leaves of which are usually pinnate but sometimes edentate. The flowers appear in clusters and produce podlike fruits.

Some species are sold as cut flowers under the name “mimosa.” *Acacia farnesiana* (L.) Willd. yields an **essential oil** that is used as an aromatic substance in aromatherapy and in the manufacture of perfumes (Bärtels 1993, 89¹). Some acacias (such as gum arabic) have been used since ancient times as excipients for compound medicines and **incense**. Some species find use as additives in psychoactive products (**betel quid**, **beer**, **balche’**, **pituri**; for pulque, cf. *Agave* spp.). Many species are suitable for producing **ayahuasca analogs**. The bark and/or leaves of numerous Australian acacia species (*A. maidenii*, *A. phlebophylla*, *A. simplicifolia*) contain high concentrations of **N,N-DMT** (Fitzgerald and Sioumis 1965; Ott 1994, 85f.*; Rovelli and Vaughan 1967).

Acacia angustifolia (Mill.) Kuntze [syn. *Acacia angustissima* (Mill.) Kuntze, *Acacia filiciana* Willd.]—**pulque tree, timbre**

The root of this Mexican acacia provides an additive to pulque (a fermented beverage made from *Agave* spp.) that may have psychoactive effects. The Aztecs called this small tree *ocpatl*, “pulque drug”; in contemporary Mexican Spanish, it is known as *palo de pulque*, “tree of pulque.” *Acacia albicans* Kunth [syn. *Pithecolobium albicans* (Kunth) Benth.] was also used as a pulque additive.

Acacia baileyana F. von Muell.

This Australian acacia is found in New South Wales. It contains psychoactive **β-phenethylamines**, including tetrahydroharman, and may be suitable as an MAO-inhibiting additive in the preparation of **ayahuasca analogs**.

Acacia campylacantha Hochst. ex A. Rich [syn. *Acacia polyacantha* Willd. ssp. *campylacantha*] The leaves of this Old World species contain **N,NDMT** and other tryptamines (Wahba Khalil and Elkeir 1975). In West Africa, the bark is traditionally used as a psychoactive additive to a type of **beer** known as *dolo*¹⁵ that is brewed from certain cereal grains (*Sorghum* spp., *Pennisetum* spp.), sometimes with the addition of **honey**. The alcohol content normally ranges between 2 and 4%, and from 8 to 10% when honey has been added (Voltz 1981, 176). *Dolo* is consumed as a libation during offering ceremonies and other rites as well as in daily life. Its properties are held in high regard: “*Dolo* imparts strength and courage and brings a joy of living. It is customary to drink *dolo* when performing strenuous work. The farmer who is making a piece of wilderness cultivable, the smith who is working hard at the anvil, the warrior who is preparing himself for battle, the woman who is

in labor, the dancer who will be wearing the heavy, sacred mask . . . , all of them receive strength and courage from *dolo*, which is offered to them by their mother, wife, or sister” (Voltz 1981, 178).

***Acacia catechu* (L. f.) Willd.—catechu tree**

This acacia species, found in India, Indonesia, and Malaysia, can grow as tall as 20 meters. It is also known as cutch tree, khair, kath, katha, khadira, and ercha. Its heartwood is boiled in water for twelve hours to concentrate the extract, which is known as catechu, katechu, catechu nigrum, extractum catechu, succus catechu, terra catechu, terra japonica, pegu, black catechu, cutch, cachou, katha, khair, terra giapponica, khadira, and cato de pegú. Essentially four types are found in trade: Pegu catechu (= Bombay catechu), the most common type; Bengali catechu; Malaccan catechu; and Camou catechu (Harnischfeger 1992, 31). Catechu is an ancient Indian drug and is still officinal in Germany as well (*DAB6*).^{*} In Vedic times, the bark of *Acacia catechu* was known as *somatvak* and was associated with **soma**.

The *Acacia catechu* tree, indigenous to South Asia, produces a substance known as catechu, which is an important ingredient in betel quids. (Engraving from Pereira, *De Beginzelen der Materia Medica en der Therapie*, 1849)

Catechu is odorless and has a bitter, astringent taste that slowly turns sweet. It is largely water soluble and can be crystallized back out again. It is composed of flavonols and glycosides (fisetin, quercetin [cf. *Psidium guajava*, *Vaccinium uliginosum*], quercitrin), as well as flavonoids (catechine, catechin tanning agents) and red pigments (Harnischfeger 1992, 31). Catechu is thus responsible for the reddish coloration of the saliva that occurs when **betel quids** are chewed (Atkinson 1989, 775^{*}). In India and Nepal, catechu is used in dyeing and tanning. In the local ethnomedicine, it is employed as a tonic and for digestive ailments and skin diseases. However, the greatest economic significance of catechu is as a (coloring) additive to **betel quids** (Storrs 1990, 5^{*}). In Indian medicine, catechu is an ingredient in recipes for treating ulcers on the mucous membranes of the mouth, inflamed throats, and toothaches (Harnischfeger 1992, 32). Catechu is a definite tannin drug that is suitable for treating inflammations of the mucous membranes and diarrhea (Pahlow 1993, 453^{*}). Catechu has no psychoactive effects of its own but is simply an important component of a psychoactive product; however, it may have synergistic effects in this.

***Acacia confusa* Merr.**

This acacia species contains *N,N*-DMT and is usable as an additive in **ayahuasca analogs**.

***Acacia cornigera* (L.) Willd. [syn. *Acacia spadicigera* Cham. et Schlechtend.]—horned acacia**

The large binate thorns of this striking acacia are hollow and provide a home for ants. In Mayan, the small tree (also known as *akunte'*) is called *subin*, “dragon.” It plays an important role in the magical preparation of the ritual drink known as **balche'**. It is possible that parts of the tree were formerly added to the drink. The bark may contain *N,NDMT*. The Maya of San Antonio (Belize) use its roots and bark to treat snakebites. The root is made into a tea that is also consumed as an aphrodisiac and as a remedy for impotence. Other preparations are used to treat asthma and headaches (Arvigo and Balick 1994, 81*).

***Acacia maidenii* F. von Muell.—maiden's wattle**

All parts of this beautiful, upright, silvery tree contain tryptamines. The bark contains 0.36% *N,N*-DMT (Fitzgerald and Sioumis 1967). The leaves are usable in **ayahuasca analogs** as a source of DMT (Ott 1993, 246*). This acacia is easily cultivated in temperate zones (e.g., in California and southern Europe).

The horned acacia (*Acacia cornigera*) is an important magical plant for the Lacandon Maya. (Photographed in the Selva Lacandona, Chiapas, Mexico, 1996)

The bark of *Acacia maidenii*, collected in New South Wales, contains high concentrations of *N,N*-DMT.

Flowers and leaves of the Australian *Acacia maidenii*.

“In Canaan the prime oracular tree was the acacia—the ‘burning bush.’ . . . The acacia is still a sacred tree in Arabia Deserta and anyone who even breaks off a twig is expected to die within the year.”

ROBERT GRAVES

THE WHITE GODDESS (1948, 440, 441*)

***Acacia nubica* Benth—Nubian acacia**

The leaves of this African acacia contain *N,N*-DMT and other constituents (Wahba Khalil and Elkeir 1975). However, the concentrations do not appear to be sufficient for producing **ayahuasca analogs**.

***Acacia phlebophylla* F. von Muell.—buffalo sallow wattle**

This Australian species is rich in *N,N*-DMT. The leaves contain 0.3% *N,N*-DMT (Rovelli and Vaughan 1967), and are usable as a source of DMT for **ayahuasca analogs** (Ott 1993, 246*). This acacia may be the rarest species of the genus and is found only on Mount Buffalo.

The Australian *Acacia phlebophylla* is apparently the rarest species of acacia in the world. Its leaves contain large quantities of *N,N*-DMT.

Seedpods of *Acacia phlebophylla*.

***Acacia polyantha* Willd. [syn. *Acacia suma* (Roxb.) Buch.-Ham.]—white catechu tree**

The resin of this Indian acacia is sometimes used as catechu or as a catechu substitute in **betel quids** (see above). The leaves apparently contain *N,N*-DMT. Interestingly, the Sanskrit name of this plant is *somavalkah*, which associates it with the divine drink **soma**. This is also suggested by the Malayalam name *somarayattoli* (Warrier et al. 1993, 26*).

***Acacia retinodes* Schlechtend.—swamp wattle**

This Australian acacia is found primarily in swampy and humid areas. It contains **nicotine** (Bock 1994, 93*). No traditional use of this plant is known.

***Acacia senegal* (L.) Willd. [syn. *Acacia verec* Guill. et Perrott, *Senegalia senegal* (L.) Britt.]—gum arabic tree**

This African acacia is chiefly significant as the source of gum arabic, which is used as a binding agent in **incense** and for other purposes. The leaves contain *N,N*-DMT (Wahba Khalil and Elkeir 1975), although the concentration is very low. It is apparently not particularly suitable for producing **ayahuasca analogs**.

***Acacia simplicifolia* Druce**

The bark of the trunk of this acacia, which is found in Australia and New Caledonia, is said to contain up to 3.6% alkaloids; 40% of these are MMT, 22.5% *N,N*-DMT (= 0.81% DMT total concentration), and 12.7% 2-methyl-1,2,3,4-tetrahydro- β -carboline. The leaves contain up to 1% *N,N*-DMT, along with MMT, *N*-formyl-MMT, and 2-methyl-1,2,3,4-tetrahydro- β -carbo-line (Poupat et al. 1976). Both the bark and the leaves are suitable for the production of **ayahuasca analogs**.

***Acacia* spp.—wattle**

According to the reports of some closet shamans, the bark and leaves of many species of wattles (as acacias are known in Australia) clearly contain *N,N*-DMT. It is said that these can be used to make smokable extracts that produce definite tryptamine hallucinations. The Aborigines burned some species of *Acacia* to ashes, which they then added to **pituri**.

Commercial Forms and Regulations

Acacia seeds are occasionally sold in ethno-botanical specialty shops. Gum arabic is available without restriction and may be purchased in pharmacies in Germany. It is readily available in the United States as well.

Aconitum ferox Wallich ex Seringe

Blue Aconite

“The man who is struck by an arrow that has been smeared with the seeds of *shalmali* [*Bombax ceiba* L.] and *vidari* [*Ipomoea digitata* L.], together with *mula* [*Raphanus sativa* L.] and *vatsanabha* [*Aconitum ferox*] and the blood of the muskrat, will bite ten people, each of which will then bite ten other people in turn.”

KAUTILIYA ARTHASHASTRA (14, 1: SUTRA 29)

Family

Ranunculaceae (Buttercup Family); Helleboreae Tribe

Forms and Subspecies

Aconitum ferox may be a subspecies or variety of ***Aconitum napellus***. In Tibetan medicine, several forms of *Aconitum ferox* are distinguished from one another on the basis of their pharmacological properties (Aris 1992, 233*).

Synonyms

Aconitum ferox L.

Aconitum napellus var. *ferox*

Aconitum virorum Don

Delphinium ferox Baill.

Folk Names

Aconite, atis, ativish (Nepali, “very poisonous”), ativisha (Sanskrit, “poison”), bachnag (Persian), bachnâg (Hindi), bikh, bis, bis-h, bish (Arabic), black aconite, blue aconite, bong-nag, bong nga, gsang-dzim, Himalayan monkshood, Indian aconite, jádwár, kalakuta, mithavis (Hindi), monk’s hood, nang-dzim, nilo bikh, phyi-dzim, singya, sman-chen (Tibetan, “great medicine”), valsanabhi (Malay), vasanavi (Tamil), vatsamabhah (Sanskrit), vatsanabha, vatsanabhi (Malayalam), visha (Sanskrit, “poison”), wolfbane

History

Vedic and later Sanskrit texts indicate that the root of this *Aconitum* species was already being used as an arrow poison in ancient India in early times (cf. ***Aconitum spp.***). In contrast to their original use, these poison arrows were used not in the hunt but in warfare (Bisset and Mazars 1984, 19). In the *Shushrutasamhita*, the Ayurvedic writings of Shushruta (ca. 300 C.E.), *Aconitum ferox* is referred to as “vatsanabha.” Today, *Aconitum chasmanthum* is usually sold under the name “vatsanabha” (13). In the tenth century, the Persian physician Alheroo described the plant under the name *bish*. Europeans first became aware of *Aconitum ferox* in the nineteenth century during journeys to Nepal. During the nineteenth century, there was a thriving trade in the root tubers of *Aconitum ferox*, which were brought from Lhasa via Le (Mustang) to Ladakh (Laufer 1991, 57).

Distribution

Blue aconite is found in Nepal, Kashmir (northern India), Garhwal, Sikkim, and Bhutan at altitudes of

2,000 to 3,000 meters (Manandhar 1980, 7*). It is a typical Himalayan plant and has even been observed growing at 3,600 meters (Polunin and Stainton 1985, 5*). It is said to grow at altitudes as high as 4,500 meters (Pabst 1887, 7*).

Cultivation

Propagation occurs via seeds, which can be simply strewn about or grown in beds. Blue aconite prefers to grow over a stony or rocky substrate and also thrives in crevices and the hollow spaces between stones.

Appearance

This perennial plant produces tuberous roots and can grow up to 1 meter in height. The lower, long-stemmed leaves are pinnate and deeply retuse. Toward the top of the plant, the leaves become smaller and their stalks shorter. The helmet-shaped, blue-violet flowers are located in clusters at the end of the smooth, erect stem. The flower stalks grow directly out of the leaf axils. The fruit is a five-cusped, funnel-shaped capsule that opens at the top. In the Himalayas, blue aconite blooms during the monsoon season (from July to September, or until October in higher elevations). The root tubers, which have a dark brown cortex and are yellowish inside, regenerate annually.

Aconitum ferox is very similar to ***Aconitum napellus*** but is somewhat smaller and more stocky. It also bears fewer flowers, and these are spaced farther apart.

Aconitum ferox is easily confused with *Aconitum heterophyllum* Wall. ex Royle, known as *bachnak*, *atis*, or *prativisa* (Bisset and Mazars 1984, 15). However, *Aconitum heterophyllum* has cordate leaves with serrate edges, whereas *Aconitum ferox* has the same deeply retuse and pinnate leaves as ***Aconitum napellus***. Blue aconite can also be mistaken for another Himalayan species, *Aconitum spicatum* (Brühl) Stapf, which bears blue flowers as well (Polunin and Stainton 1985, 6*).

The flowers of the blue aconite (*Aconitum ferox*). Tantrists who follow the left-handed path smoke the herbage and roots of the plant as a potent inebriant.

Aconite is one of the most dangerous of all poisonous plants. However, like all poisons, it is also a valuable medicine. For this reason, aconite was formerly known as healing poison or poisonous remedy. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Psychoactive Material

- Root tuber (*tubera aconiti ferocis*, bish root)
- Herbage

Preparation and Dosage

When used in Ayurvedic medicine, the tubers are steeped in the milk or urine of sacred cows after harvesting to “purify” them. This removes the potent toxins from the root. Milk is said to more effectively detoxify the tubers (Warrier et al. 1993, 44*).¹⁶ The root tuber is ground into a paste for external application to treat neuralgia.

For tantric and psychoactive purposes, of course, the root is not detoxified. It is simply dried, minced, and consumed in **smoking mixtures**, normally with ganja (flowers of *Cannabis indica*). The leaves are dried and smoked.

Aconitum ferox is the most poisonous plant of the Himalayas and can very easily prove lethal! As little as 3 to 6 mg of aconitine, corresponding to only a few grams of dried or even fresh plant material, is sufficient to kill an adult.

Ritual Use

Among Indian Tantrists is an extreme sect known as the Aghoris. They follow the “left-handed” path, which regards sexuality and drugs as important methods for expanding consciousness. The Aghoris ingest plants associated with Shiva (hemp, *Datura metel*, opium from *Papaver somniferum*) and poisons (cobra venom, mercury, arsenic) so that they may experience the divine consciousness of their master. Aghoris produce mixtures of various plants for their large smoking tubes (*chilam*). One mixture for “advanced” individuals consists of ganja and *Aconitum ferox* roots (Svoboda 1993, 175).

Shiva is the Hindu god of inebriants and poisons. Myths relate how he personally tried all poisons at the beginning of the world. This caused him to turn blue, as blue as the flowers of blue aconite. Similarly, a Tantrist can assimilate himself with the god by ingesting every poison and surviving (according to the motto “That which does not kill me only makes me stronger”). In another version

of this story, the beating of the primeval ocean, or the churning of the milk ocean (*samudramathana*), not only brought forth the sacred cow but also caused the essences of all poisons to swirl up. Petrified with fear, the gods hurried to Kailash, where Shiva sat in meditation. They bade him help. Shiva took the poison in his hand and drank it. His wife Parvati became afraid for him and squeezed her husband's throat, which caused the poison to remain there and turned him completely blue. It is for this reason that Shiva is also known as Nilakanta, "blue throat." By performing this act, Shiva saved all creatures from death by poisoning. But a little of the poison slipped out of his hand and onto the Himalayas. Today, it still flows in the veins of blue aconite and other poisonous plants.

Artifacts

Hindu art contains numerous images of Shiva, many of which depict him with a blue skin color. Sometimes only his throat is blue. The *Saradatilaka Tantra* describes Shiva in his form as a "blue throat": He shines like a myriad of rising suns and has a glowing crescent moon in his long, matted hair. His four arms are adorned with snakes. He has five heads, each of which has three eyes, and is clad in only a tiger skin and is armed with his trident. It is possible that the plant spirit of *Aconitum ferox* has the same appearance.

Aconitum ferox, along with other species (including *Aconitum napellus*), is portrayed on Tibetan medical thangkas (paintings). One leaf of the Tibetan medical tree is dedicated to the plant, and this depicts how the "great medicine" can be used to make a medicinal butter (Aris 1992, 179, 233*).

Medicinal Use

In Ayurvedic medicine, the "purified" root tubers are used to treat neuralgia, painful inflammations, coughs, asthma, bronchitis, digestive problems, colic, weak hearts, leprosy, skin afflictions, paralysis, gout, diabetes, fever, and exhaustion (Warrier et al. 1993, 41ff.*).

These and other Himalayan species of aconite (*Aconitum heterophyllum*, *Aconitum balfourii* Stapf; cf. *Aconitum* spp.) find many uses in Tibetan medicine. The roots are regarded as a remedy for colds and "cold"; the herbage is used to treat ailments resulting from "heat." In Tibetan medicine, *Aconitum ferox* is also known as *smān-chen*, "great medicine"; the crushed roots, mixed with bezoar stones, are used as a universal antidote. The root is also used to treat malignant tumors (Laufer 1991, 57). The great medicine is also esteemed as a remedy for demonic possession (Aris 1992, 77*). In Nepalese folk medicine, blue aconite is used to treat leprosy, cholera, and rheumatism (Manandhar 1980, 7*).

Constituents

The entire plant contains the diterpenoid alkaloids aconitine and pseudoaconitine¹⁷ (Mehra and Puri 1970). The root tuber contains the greatest concentrations of these constituents and is thus the most dangerous part of the plant (cf. *Aconitum napellus*).

Effects

In Ayurvedic medicine, the root is attributed with sweet, narcotic, sedative, anti-inflammatory, diuretic, nervine, appetite-stimulating, digestion-promoting, stimulant, anaphrodisiac, calming, and antipyretic effects (Warrier et al. 1993, 41*).

The effects of a tantric smoking mixture containing aconite are said to be extreme. Even experienced Tantrists emphatically warn against its use (cf. *Aconitum napellus*).

Commercial Forms and Regulations

The seeds may sometimes be purchased in nurseries.

Aconitum napellus Linnaeus

Monkshood, Blue Rocket

Family

Ranunculaceae (Buttercup Family); Helleboreae Tribe

Forms and Subspecies

Monkshood is a polymorphous species with many subspecies and cultivated forms; it is regarded as taxonomically complex (Colombo and Tomè 1993):

Aconitum napellus ssp. *compactum* (Rchb.) Gayer *Aconitum napellus* ssp. *napellus*

Aconitum napellus ssp. *neomontanum* (Wulfen) Gayer

Aconitum napellus ssp. *pyramidale* (Mill.) Rouy et Fouc.

Aconitum napellus ssp. *tauricum*

Aconitum napellus ssp. *vulgare* Rouy et Fouc.

It is possible that ***Aconitum ferox*** may be a synonym or a subspecies or variety of *Aconitum napellus* (cf. Warrier et al. 1993, 41*).

Synonyms

Aconitum compactum (Rchb.) Gayer

Aconitum neomontanum Wulfen

Aconitum pyramidale Mill.

History

Theophrastus (ca. 370–287 B.C.E.) already provided a very precise description of the plant and its effects and origin. In ancient times, monks-hood, or aconite, was a feared poison associated with the legendary Colchian “witch” Medea (who was probably a Scythian shaman; cf. ***Cannabis ruderalis***)

and the gloomy underworld. Like hen-bane (*Hyoscyamus albus*), the plant was said to have sprung from the slaver of Cerberus, the hound of hell, and both plants were known as *apollinaris* (“Apollo’s plant”). Another legend states that monkshood rose from the blood of Prometheus, which dripped onto the rocks whenever the eagle came and ate his liver (Gallwitz 1992, 111).

Monkshood was an important “battle drug” in Roman politics. Emperor Claudius died in 54 C.E. from aconite poisoning (Schöpf 1986, 77*).¹⁹ The ancient Germans may have used the plant in their magical rituals, such as when the Berserkers were transformed into wolves. In the fourteenth century, Konrad von Megenberg described monks-hood and its poisonous effects in his *Buch der Natur* [Book of Nature]. Monkshood was and still is regarded as the most poisonous and most dangerous plant in Europe (Roth et al. 1994, 89*).

Monkshood (*Aconitum napellus*) was once a dreaded toxic and witches’ plant. Today, it is a popular garden ornamental. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Distribution

Monkshood occurs from Italy to Ireland and from Spain to the Himalayas. It is often found in subalpine zones. It belongs to the typical flora of the Alps and is (still) common in Switzerland.

Cultivation

Monkshood can be propagated by seeds or from separated tubers. Handling fresh root tubers can have dangerous toxic effects! The seeds are either sown in the spring by pressing them directly into the ground or raised in seedbeds. Monkshood prefers nutrient-rich soils and good, humus-rich earth. It also thrives in moist soils.

Appearance

This perennial herbaceous plant can grow as tall as 150 cm. The palmate leaves are deeply divided into five to seven lobes. The luxuriant, dark blue, helmet-shaped flowers form at the end of the stalk (terminal racemes). The sepal has the exact shape of a bumblebee, and this insect is also the plant’s most important (and perhaps even its only) pollinator. The follicular fruits contain multiple seeds. The blooming period is from June to August. The plant develops a new tuberous root each year, while the root from the previous year dies.

Aconitum napellus can be very easily confused with *Aconitum ferox* and many other *Aconitum* species (***Aconitum* spp.**). This does not present a problem from a pharmacological perspective, as most *Aconitum* species contain very similar active constituents. Some individuals have also confused

monkshood with larkspur (*Delphinium* spp.; cf. *Delphinium consolida*).

Psychoactive Material

—Root (tubera aconiti, radix aconiti, aconiti tuber)

—Herbage (herba aconiti, aconiti herba)

Corresponding to the plant's growth cycle, the drug should not be stored and used for periods in excess of one year (Roth et al. 1994, 88*).

Preparation and Dosage

The dried herbage can be smoked (see *Aconitum ferox*). However, no information is available concerning dosage. People must be cautioned against improper use of this plant. Even harvesting the leaves can cause the active constituents to enter the body and produce unintentional symptoms of poisoning (Roth et al. 1994, 89*). As little as 3 to 6 mg of aconitine, which often corresponds to only a few grams of dried or even fresh plant material, can be lethal for adults. Ingested orally, as little as 0.2 mg of aconitine can produce toxic symptoms. Tinctures were formerly used to treat migraine headaches and neuralgia. Up to five drops per day were ingested (Vonarburg 1997a, 65).

The roots were purportedly used in the manufacture of **witches' ointments**. They were also added to **wine** (cf. *Vitis vinifera*), which was drunk both for healing and for inebriating purposes (Pahlow 1993, 117*).

Although the plant is considered extremely toxic, children in Iceland have been reported to eat the flowers because of their honeylike sweetness (Olafsson and Ingolfssdottir 1994).

In ancient times, monkshood (*Aconitum napellus*) was feared as a poison; in the Middle Ages and the early modern period, it was purportedly used in the manufacture of witches' and flying ointments.

Ritual Use

In ancient times, monkshood was definitely used as a ritual poison:

Bent on his destruction, Medea mixed in a cup a poison, which she had brought long ago from the Scythian shores. This poison, they say, came from the mouth of the Echidnean dog. There is a cavern with a dark, yawning throat and a way down-sloping, along which Hercules, the hero of

Tiryns, dragged Cerberus with chains wrought of adamant, while the great dog fought and turned away his eyes from the bright light of day. He, goaded on to mad frenzy, filled all the air with his threefold howls, and sprinkled the green fields with white foam. Men think that these flecks of foam grew; and, drawing nourishment from the rich, rank soil, they gained power to hurt; and because they spring up and flourish on hard rocks, the country folk call them aconite. (Ovid, *Metamorphoses* 7.406ff.)

Monkshood was presumably also used in other Scythian preparations and in shamanic-magical rituals, e.g., to transform oneself into a wolf. It may already have been used in antiquity to prepare flying ointments. Since the early modern period, monkshood has been one of the chief ingredients in **witches' ointments**. Many of its folk names suggest that the plant was used for both ritual and psychoactive purposes: *hut des Jupiter* (hat of Jupiter), *venuswagen* (Venus's wagon), *wolfskraut* (wolf's plant), *hut des trolls* (hat of the troll), *Odins hut* (Odin's hat), *hex* (witch), et cetera.

Artifacts

In Christian art, the plant appears in paintings as a symbol of death (e.g., in *Maria Lactans* by the Master of Flémalle and in *The Lamentation of Christ*) (Gallwitz 1992, 113f.). In Europe, the plant was used as a symbol of the venomousness of nature. Monkshood is portrayed on Tibetan medicine thangkas alongside ***Aconitum ferox*** and ***Aconitum spp.*** (Aris 1992, 233*).

Gustav Meyrink (1868–1932), an author who was experienced in alchemy and the occult and who wrote about numerous psychoactive plants (cf. ***Cannabis indica***, ***Lophophora williamsii***, ***Veratrum album***, ***Amanita muscaria***), composed a very insightful story about monkshood, “Der Kardinal Napellus” [Cardinal Napellus]. In this story, he describes a sect “known as the ‘blue brothers,’ the followers of which have themselves buried alive when they sense that they are approaching their end.” The founder of the order, Cardinal Napellus, transformed himself into the first monkshood plant after his death. All of the plants were said to be derived from him. The sign of the order, of course, is the flower of *Aconitum napellus*, and a field of aconite grows in the cloister garden. The novitiates start the plants when they are accepted into the order, and they baptize these with blood and sprinkle them with blood shed from the wounds produced by flagellation. “The symbolic meaning of this strange ceremony of blood christening is that the person should magically plant his soul in the garden of paradise and nourish its growth with the blood of his desires.” The brothers in the order use the plant in a psychoactive manner: “When the flowers withered in the fall, we collected their poisonous seeds, which resemble small human hearts. In the secret tradition of the blue brothers, these represent the ‘mustard seed’ of faith, of which it is written that he who has it can move mountains, and we ate of these. Just as their terrible poison changes the heart and brings a person into a condition between life and death, so shall the essence of faith transform our blood—into miraculous power in the hours between the gnawing pain of death and ecstatic rapture” (Meyrink 1984). The story is reminiscent of the tantric use of ***Aconitum ferox***.

Medicinal Use

Because it has long been feared as a potent poison, monkshood never attained any great significance in folk medicine. In Western phytotherapy, tinctures of monkshood are used externally to ease the pains of gout, sciatica, and neuralgia and to treat feverish colds in their onset. They are less frequently used internally (Pahlow 1993, 116*).

In homeopathy, *Aconitum napellus* hom. is used in dilutions of D3 and greater in accordance with the medical descriptions to treat nervous and psychic ailments, e.g., as a result of anger, fright, agitation, or neuralgia (Pahlow 1993, 116*; Roth et al. 1994, 89*). Hahnemann had high praise for the

agent, for “its powers to help are miraculous” (Buchmann 1983, 29*). It is still used for numerous purposes today (Vonarburg 1997a, 1997b).

Constituents

The entire plant contains the alkaloid aconitine (= acetylbenzoylaconine) and aconitine acid. The highest concentrations are in the root, which is thus the most dangerous part of the plant. The root tubers contain large amounts of diterpenoid alkaloids of the so-called aconitine type (0.3–2.0%). The structures of some of these have not yet been determined (Bugatti et al. 1992). Aconitine is the primary alkaloid; mesaconitine, hypaconitine, napelline, and *N*-diethylaconitine are also present. In some subspecies, the primary alkaloid is mesaconitine (Olafsson and Ingolfsson, 1994). Aconitine is also present in all the other parts of the plant, although typically in only low concentrations. Aconitine has even been detected in the nectaries. As a result, it may be possible to produce a psychoactive **honey** from the plant.

“So is the man who has given aconite to three uncles to ride by on swaying feathers and to look down on us from there? Keep quiet when he comes by; if you so much as say ‘That’s the man who . . .’ you’ll be treated as if you’d accused him in court.”

JUVENAL *SATIRES*

(1.158–61)

“Monkshood is associated with the Nordic god Odin and the goddess Hel. Earlier tales referred to it as ‘Odin’s helm,’ [and] it was supposedly used as an ingredient in ‘lycoanthropic transformation ointments.’”

MAGISTER BOTANICUS

MAGISCHES KREUTHERKOMPENDIUM [COMPENDIUM OF MAGICAL HERBS]

(1995, 194*)

“It is established that of all poisons the quickest to act is aconite, and that death occurs on the same day if the genitals of a female creature are but touched by it. . . . Fable has it that aconite sprang out of the foam of the dog Cerberus when Hercules dragged him from the underworld, and that this is why it grows around Heraclea in Pontus, where is pointed out the entrance to the underworld used by Hercules. Yet even aconite the ancients have turned to the benefit of human health, by finding out by experience that administered in warm wine it neutralizes the sting of scorpions. It is its nature to kill a human being unless in that being it finds something else to destroy. Against this alone it struggles, regarding it as more pressing than the find. What a marvel! Although by themselves both are deadly, yet the two poisons in a human being perish together so that the human survives.”

PLINY

NATURAL HISTORY

(27.4f.)

Aconitine

Effects

When applied to the skin, monkshood is said to provoke sensations of tingling and hallucinations. Because of this, monkshood was purported to have been an important ingredient in **witches' ointments**. It is said to produce the sensation of wearing a garment made of fur or feathers. In the Rhineland, it is said that “[s]imply smelling the plant will make the nose swell up” (Gallwitz 1992, 113). Monkshood has a strong stimulating or inebriating effect upon horses. They become “foamy,” that is, fiery; for this reason, horse dealers at one time fed their animals monkshood before offering them for sale.

The description of the course of effects of monkshood poisoning is not exactly enticing: “The longer the time that the alkaloid and the drug are in contact with the mouth, the more pronounced will the local, sensory nerve effects in the mouth and throat be observable following acute aconitine or aconite poisoning. The tingling and burning may be followed by a loss of speech and a sensation of paralysis in the tongue and in the area around the mouth, so that speaking becomes difficult. When absorbed, feelings of tingling and formication [the sensation of being crawled upon by insects] in the fingers, hands, and feet very characteristically soon appear, sometimes with twitching of the face, followed by paralysis of the facial muscles. The person who has been poisoned is also disturbed by an unbearable sensation of coldness (the feeling of ‘ice water in the veins’) with hypothermia, caused by stimulation of the cold centers. This is followed by numbness, symptoms of paralysis in the arms and legs, and difficulties in breathing. Seeing green, dizziness, buzzing in the ears, and trigeminal pain have also been observed. Nausea and vomiting can occur, but can also be absent, as can diarrhea and increased urination. Respiratory difficulties and especially peculiar heart disturbances . . . can result in loss of consciousness and death due to heart or breathing problems. But consciousness may also be retained until death, which under these circumstances can occur within in the first hour” (Fühner 1943, 217f.*).

Commercial Forms and Regulations

In Europe, the wild plant—like all *Aconitum* species—is protected (Roth et al. 1994, 89*). The seeds of various subspecies, varieties, and cultivars are available in nurseries.

Aconitum spp.

Aconite Species

Family

Ranunculaceae (Buttercup Family); Helleboreae Tribe

Many *Aconite* species have worldwide ethno-botanical significance as medicines, psychoactive products, and arrow poisons.

Uses as Medicine

The following species of aconites (*chuan wu tou*) are used in traditional Chinese medicine and in Japanese kampo medicine (as cited in Wee and Keng 1992, 16f.*; Schneebeli-Graf 1992, 55*):

Aconitum carmichaelii Debeaux (*chuan wu tou* or *bushi*); also: var. *wilsonii* (Stapf ex Moltet) Munz
(*tsao wu tou*) *Aconitum chinense* Sieb. et Zucc.

Aconitum hemsleyanum E. Pritz

Aconitum transsectum Diels

Aconitum vulparia Rchb. ex Spreng. [syn. *Aconitum lycoctonum* auct. non. L.]

Only the dried rhizomes are used; they lose their potent toxicity during the drying process. In traditional Chinese medicine, aconite roots are characterized as stimulating, cardiotonic, anal-gesic, narcotic, and locally anesthetic. They stimulate the *yang* energy and are used for all *yang* ailments. The dosage lies between 3 and 8 g (Reid 1988, 115*).

The species *Aconitum carmichaelii* is common throughout southern China. The folk medicine of the region uses its roots for headaches, paralysis of one side of the body (hemiplegia), overheating of the body, rheumatism, arthritis, contusions, bruises, and broken bones. Pharmacological studies in China have demonstrated that this drug stimulates the body's own immune system. However, it has not yet been possible to isolate from the root a substance that might be responsible for these effects. It is possible that there may be a synergistic effect of several or even all of the active constituents (Chang et al. 1994). The Chinese medicinal drug (*fu tzu*) has the highest concentration of alkaloids (Bisset 1981).

In Japanese kampo medicine, which is based on Chinese herbalism, the roots of the species *Aconitum carmichaelii* are known as *bushi* and are used for weak digestion (cf. Murayama and Hikino 1984). Pharmacological investigations have determined that the so-called aconitans A, B, C, and D have hypoglycemic effects, i.e., they lower blood sugar levels (Hikino et al. 1989, 1983).

Psychoactive Products

Aconite (*Aconitum napellus*) is said to have been an important ingredient in **witches' ointments**. *Aconitum ferox*, a species found throughout the Himalayas, is a component of tantric **smoking mixtures** with drastic effects. Some Chinese species, the identity of which are unfortunately uncertain, but whose root drugs are known by the name "fu tzu" (including *Aconitum carmichaelii*), provided one of the main ingredients in **han-shih powder**.

The Asian species *Aconitum carmichaelii* is used in traditional Chinese medicine. Its roots were once used to produce elixirs for prolonging life.

Many Taoist elixirs of immortality contain large quantities of aconite, along with ominous fungi (*Psilocybe* spp.), arsenic, mercury, hemp (*Cannabis sativa*), and *Digitalis* spp. (cf. *Digitalis purpurea*) (Cooper 1984, 54*).

Use as Arrow Poison

Aconitum was used as an arrow poison in ancient Europe and in Asia and North America (Alaska) (Bisset 1989). In ancient China, the most important source of arrow poison was the root of *Aconitum carmichaelii* (wu tou, fu tzu, tsao wu) (Bisset 1979, 1981). Many northern Asian hunting peoples used the toxic root tubers of the following species of aconite to make their arrow poisons:

Aconitum delphinifolium DC.ssp. *chamissonianum* (Reichb.) ssp. *paradoxum* (Reichb.) Hult.

Aconitum fischeri Reichb.

Aconitum japonicum Thunb.

Aconitum kamtschaticum Reichb.

Aconitum maximum Pall. ex DC.

Aconitum napellus Thunb. non L.

Aconitum sachalinense Fr. Schmidt

Aconitum subcuneatum Nakai

Aconitum yezoense Nakai

Herb Paris (*Paris quadrifolia* L.; Liliaceae), once regarded as a poisonous plant but apparently only slightly toxic, was formerly known as *dollwurz* (crazy plant). It was included among the aconite plants under the name *Aconitum pardalianches*. Because the folk name *dollwurz* was primarily used to refer to the root of the deadly nightshade (*Atropa belladonna*) and obviously refers to its hallucinogenic effects, it is possible that herb Paris may be a psychoactive plant that has been forgotten. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

White monkshood (*Aconitum septentrionale*).

The harvesting of the roots is often accompanied by magical rites. The arrow poisons are usually produced using other substances as well. The Ainu, the original inhabitants of Japan, combined the principal ingredient with the leaves of *Artemisia vulgaris*, the toxin of the Japanese puffer fish (*Dasyatis akajei* Müller et Henle), and even *Nicotiana tabacum* (Bisset 1976). The notorious fugu fish provided an additional ingredient for an especially powerful arrow poison (Bisset 1976, 91; cf. **zombie poison**). The manner in which the Ainu tested whether the poison was usable and potent enough provides an interesting fact for explaining the effects of *Aconitum* in **witches' ointments**. They made a small cut in the thenar below the thumb and held a freshly cut root tuber against this. The poison caused the thumb to become numb and (temporarily) paralyzed. An experienced poison maker could evaluate the effectiveness of the root by the duration of its effects (Bisset 1976, 91).

Constituents

Most aconite species contain the very toxic aconitine alkaloids as well as the slightly toxic alkamines. Those species that are used for medicinal purposes have higher amounts of alkamines, whereas the species used to produce arrow poisons contain higher amounts of aconitines (Bisset 1976).

In China, the roots of *feng-feng*, or the plant *Siler divaricatum* (Turcz.) Benth. et Hook. f. (Umbelliferae), were once used as an antidote for aconite poisoning. But it has been said that the root of this plant “produces madness” (Schultes and Hofmann 1992, 56*). Although it has sometimes been claimed that *Siler divaricatum* is psychoactive, there is no evidence supporting this assertion.

This ancient Chinese representation of various aconite species is from the *Ch'ung-hsiu cheng-ho pen-ts'ao*.

Acorus calamus Linnaeus

Calamus, Sweet Flag

Family

Araceae (Arum Family)²⁰

Forms and Subspecies

Several varieties have been described, reflecting differences in the genomes and geographical distribution (Motley 1994, 397):

Acorus calamus var. *americanus* (Raf.) Wulff (North America, Siberia)

Acorus calamus var. *angustatus* Bess. (southeast Asia, Japan, Taiwan)

Acorus calamus var. *calamus* L. (Eurasia)

Acorus calamus var. *verus* L. (tetraploid form)

Acorus calamus var. *vulgaris* L. (Europe, India, Himalayas)

Synonyms

Acorus aromaticus Gilb.

Acorus odoratus Lam.

Acorus vulgaris L.

Acorus vulgaris (Willd.) Kerner

Folk Names

Ackermagen, ackerwurtz, ackerwurz, acore, acore aromatique, acore odorant, acore vrai, acori, acoro, acoro verdadero, acrois, ajîl-i-turkî (Persian), akoron (Greek), aksir-i-turki, a-notion aotitara, bach, bacha, bajegida (Kannada), beewort, belle angélique, bhadra (Sanskrit), bhuta-nashini (Sanskrit), boja, bojho (Nepali), bueng, calamo aromatico, calamus, canna cheirosa, chalmis, ch'ang (Chinese), ch'ang-jung, ch'ang-p'u, cinnamon sedge, dálau, dârau, déngau, deutscher ingwer, deutscher zittwer, erba cannella, erba di Venere (Italian, “plant of Venus”), flagroot, galanga des marais, ganghilovaj (Gujarati), gewürzkalmus, ghorabach, gladdon, gora vatch (Hindi), iggur, ighir jammu, jerangau, kahtsha itu (Pawnee, “medicine that lies in the water”), kalmoes, kalmuß, karmes, karmsen, kaumeles, ki we swask, kni (Egyptian), kolmas, kolmes, lubigan (Tagalog), magenwurz, Mongolian poison, moskwas'wask, muskrat root, muskwe s uwes, musquash, myrtle flag, myrtle grass, myrtle sedge, nabuguck (Chippewa), nagenwurz, pai-ch'ang, peze boao ka (Osage, “flat plant”), pine root, pow-e-men-artic (“fire root”), rat root, reed acorus, roseau aromatique, roseau odorant, safed-bach (Hindi), schiemen, schiemenwurz, schwertenwurz, sete, shui-ch'ang-p'u, shyobu (Japanese), sih kpetawote, sinkpe tawote (Lakota, “food of the muskrat”), sunkae (Lakota, “dog penis”), sweet calomel, sweet cane, sweet cinnamon, sweet flag, sweet flagroot, sweet grass, sweet myrtle, sweet rush, sweet segg, tatar, themeprü (Assamese), ugragandha (northern India), vaambu, vacha, vaj, vasa (Telugu), vasambu (Tamil), vash (Arabic), vashampe (Malayalam), vekhand (Marathi), venerea (Roman), venuspfanze, Venus plant, wada-kaha, warch, watchuske mitsu in, water flag, wechel, weekas, wee-kees, wehkes (“muskrat root”), wekas, wika, wike, wiken, wye (Kashmiri), yellow flag, zehrwurzhizome, zwanenbrood (Dutch, “swan bread”)

History

The history of calamus is still largely unknown. It is more than questionable whether the *akoron* of Dioscorides was actually calamus (Schneider 1974, 1:42*). In ancient times, it was believed that *akoron* was indigenous to the legendary gardens of Colchis (on the Balkan Peninsula on the Black Sea). Whether calamus was used as an aphrodisiac in ancient times, as it is in modern Egypt, cannot be determined with certainty. But if the ancient names do in fact refer to calamus, then it is likely that it was used for this purpose (cf. Pliny, *Natural History* 25.157).²¹ In Italy, it is still regarded as a “plant of Venus” (Samorini and Festi 1995, 33). The “calamus” of the Bible is now interpreted as *Andropogon aromaticus* L. or *Cymbopogon* spp. (cf. ***Cymbopogon densiflorum***). Remnants of *Acorus calamus* were reportedly found in the tomb of Tutankhamun (Motley 1994, 400; cf. also Germer 1985, 238f.*). It has also been suggested that calamus was an ingredient in some **witches’ ointments**.

Chinese sources contain what may be the oldest reference to sweet flag. The related but smaller species *Acorus gramineus* Soland. (*p’u*) was mentioned in the ancient Chinese *Shih Ching*, or the Book of Songs (ca. 1000–500 B.C.E.) (Keng 1974, 403*).

In Europe, sweet flag was well known during the late Middle Ages and has been esteemed as a medicinal plant since that time. It is not known whether it was present in pre-Columbian America. In any case, North American Indians became aware of its hallucinogenic effects as a result of ethnobotanical research (Motley 1994). The notion that calamus can have hallucinogenic effects was first published by Hoffer and Osmond (1967, 55f.*).

Distribution

Sweet flag is apparently indigenous to Central Asia or India (Motley 1994) and is common on Sri Lanka and in the Himalayas. It has spread throughout the world as a result of cultivation (Hooper 1937, 80*). The plant was not introduced into central Europe until the sixteenth century; since then, it has established itself along creeks and slow-moving bodies of water and in lakes.

The botany of *Acorus calamus* was not clarified until quite recently. Its most characteristic feature is the almost phalluslike inflorescence. (Engraving from Pereira, *De Beginselen der Materia Medica en der Therapie*, 1849)

“A Penobscot Indian had the following dream: A muskrat told him that it was a root and where it could be found. When the man awoke, he went in search of the muskrat root and made it into a medicine. In this way, he healed his people of the plague.”

FRANK G. SPECK

MEDICINE PRACTICES OF THE NORTHEASTERN ALGONQUIANS (1917)

Cultivation

Calamus is propagated vegetatively by planting divided pieces of the rhizomes or scions with shoots. Calamus requires a marshy or very moist location. It can also survive in still water and does particularly well along the moist margins of ponds.

In North America, the muskrat (*Ondatra zibethica*) appears to have played a substantial role in increasing the range and occurrence of the plant. The animal is “magically” attracted to the rhizome and not only eats the rhizomes of the fresh plant but also collects parts of these and stores them for future use. Under the proper conditions, these pieces may then produce new roots. It is possible that the muskrat’s characteristic scent may be due in no small part to its consumption of calamus (Morgan 1980, 237).

Appearance

Calamus is a perennial plant that may grow as tall as 120 cm. The rootstock (rhizome) spreads by creeping. The light to lushly green leaves are gladiate (like a sword blade) and distichous (in two rows). Rubbing them releases the typical calamus scent. The tiny, inconspicuous yellow-green flowers are attached to a spadix 5 to 8 cm in length. In its area of origin (India), sweet flag blossoms from April to June; in central Europe, from June to July.

The very similar but considerably smaller species *Acorus gramineus* Soland. is found throughout Asia. It is easily recognized by its very small leaves (10 to 20 cm in length), which also exude the typical calamus aroma when rubbed.

In North America, calamus is often confused with *Iris pseudacorus* L., commonly known as yellow flag, and *Iris versicolor* L., known as blue flag (Motley 1994, 400).

Psychoactive Material

—Rhizome (rhizoma calami, calami rhizoma, calamus root)

—Calamus oil (calami aetheroleum, oleum calami)

Preparation and Dosage

Calamus oil is used as an aromatic additive to **snuff powders** and snuffing tobacco (see *Nicotiana tabacum*) (Hooper 1937, 80*) and in alcoholic beverages (spirits, **alcohol**, **beer**) (Motley 1994, 398).

A tea (infusion or decoction) from chopped rootstock (1 teaspoon per cup) can be drunk to treat feelings of weakness, nervousness, and stomach and intestinal cramps and as a nervine or aphrodisiac (Frohne 1989). A strong decoction can also be used as a bath additive. Calamus is an ingredient in many bitter cordials (cf. **theriac**).

According to some North American Indians, an amount of calamus equivalent in size to a finger is sufficient to produce psychoactive effects. However, very high dosages (200 to 300 g of dried roots) have also been tested.

Ritual Use

In ancient China, calamus was clearly used in shamanism. However, this may have been the smaller species (*Acorus gramineus* Soland. or *Acorus gramineus* Soland. var. *pusillus* (Sieb.) Engl.) known as *ch’ang-p’u* (also *shi chang pu*). Mêng Shen wrote:

Those who wish to see spirits use the raw ma fruits [***Cannabis sativa***], *ch’ang-p’u* [*Acorus gramineus*], and *k’uei-chiu* [*Podophyllum pleianthum* Hance, syn. *Dysosma pleiantha* (Hance) Woods.; cf. ***Podophyllum peltatum***], ground in equal amounts, and make these into pills the size of a marble and take these every day when they look into the sun. After a hundred days, they will

be able to see spirits. (Li 1978, 23*)

In China, calamus is one of the oldest auspicious plants. It is said that the Taoist An-ch'isheng used wild calamus as an elixir, which caused him to become not only immortal, but invisible as well. Unfortunately, the methods of preparing and ingesting calamus for this purpose have not been passed down to us. Bundles of calamus leaves, together with *Artemisia vulgaris* (cf. ***Artemisia* spp.**), are still used as talismans during the dragon boat festival, and they are hung over the house door to protect against evil spirits (Motley 1994, 402).

The small Chinese relative of calamus (*Acorus gramineus*).

The characteristic inflorescence of calamus (*Acorus calamus*).

In Kashmir, the root is regarded as auspicious and should be the first thing a person looks upon on the morning of the traditional new year's festival (*navroj*) (Shah 1982, 299*). Indian snake charmers use pieces of calamus root to charm cobras (Motley 1994, 403).

Many North American Indians regard calamus as a panacea and tonic. The Iroquois used the root to detect witches and evil magic. Many Indians of the Northeast woodlands believe that the root has apotropaic effects and consequently hang it in the house or sew it into their children's clothing. The "spirits of the night" (nightmares) then stay away. The Winnebago, Ponca, Pawnee, Omaha, and Dakota make garlands of calamus grass that are used in secret rites (*wakan wacipi*, "sacred dance") and as hunting talsimans (Howard 1953; Morgan 1980, 235). The Chippewa combine calamus with *Aralia nudicaulis* L. and then boil a decoction in which they soak their fishing nets to ensure a good catch or to chase away rattlesnakes (Motley 1994, 404).

The Cheyenne use calamus roots as **incense** in their sweat lodge ceremonies. They simply toss pieces of the root onto the glowing stones in the sweat lodge. The smoke is said to be cleansing and beneficial to health. Pieces of calamus root as well as calamus leaves are also occasionally added to **smoking mixtures** or mixed with tobacco (*Nicotiana spp.*) (cf. **kinnikinnick**).

The Cree reputedly used calamus roots as a hallucinogen. It is said that they chewed a piece of root as long as a finger. The accuracy of this information, which has been repeated often in the psychedelic literature, is somewhat in doubt (cf. Morgan 1980; Ott 1993*; Schultes and Hofmann 1995*), as all experiments with American calamus—even those involving very high dosages (up to 300 g of rhizomes!)—have been completely unsuccessful. If the Cree did indeed possess a hallucinogen, it probably was not *Acorus calamus*. One Cree name for calamus—or, as the source notes, a very *similar* plant—is *pow-e-men-artic*, "fiery pepper root." The Cree frequently placed pieces of calamus root, which they called *wee-kees* (muskrat root), in their medicine bundles (Johnston 1970, 308*).

Amazingly, several evangelical churches in Lutheran parishes burned calamus in the 1950s as an incense during Easter (Motley 1994, 402).

Artifacts

A section of naturalist North American poet Walt Whitman's (1819–1892) renowned collection of poems *Leaves of Grass* bears the heading "Calamus." It is possible that the poems contained within this section were inspired by calamus or its effects (Morgan 1980, 235f.).

Medicinal Use

In the Ayurvedic system of medicine, calamus is used to treat sleeplessness, melancholy, neuroses, epilepsy, hysteria, memory loss, and fever (Vohora et al. 1990, 53). Calamus is used together with saffron (see ***Crocus sativus***) and milk to induce labor (Motley 1994, 403). Nepali Sherpas use a paste made from fresh rootstock as an antiseptic agent to treat wounds in animals (Bhattarai 1989, 47*). The Nepalis use the root for colds and coughs (Manandhar 1980, 9*) and as a tonic for the nerves (Singh et al. 1979, 188*). In Ayurvedic and Tibetan medicine, calamus is an important psychoactive plant: "*Vacha* literally means 'speak' and describes the power of the word, the intelligence, or the self-expression that is stimulated by this medicinal plant" (Lad and Frawley 1987, 175*).

Calamus is an exotic plant that is also commonly referred to as sweet flag. For centuries, it was known in the West only in the form of its rhizome. Herbals listed it under the name “Acorus of the apothecaries.” The illustrations in these books were based primarily upon the artists’ imaginations. (Woodcut from Lonicerus, *Kreuterbuch*, 1679)

It is for this reason that calamus root, when used as **incense**, has the effect of illuminating and strengthening the mind. It is often found in Tibetan incense mixtures that are burned to strengthen the nerves and to increase meditative concentration. It is also regarded as a rejuvenation tonic and as “nourishment for the Kundalini serpent” (Lad and Frawley 1987, 176*).

In the forest regions and neighboring plains of North America, calamus is a medicine that the Indians use for a great number of purposes. Decoctions of the root are used to treat stomach and intestinal ailments, digestive difficulties, and cramps. Fresh pieces of the root are chewed for headaches, colds, sore throats, and bronchitis. Dried, the root is also used to prepare a medicinal and ritual **snuff** (Morgan 1980).

Calamus is smoked or burned as incense to treat headaches, coughs, and colds (Motley 1994, 404). The Blackfeet, who obtained calamus roots via long trade routes, used it as an abortifacient. The root was chewed as a cure-all. To treat headaches, the Blackfeet would burn a mixture of ground root and tobacco (*Nicotiana spp.*) and inhale the smoke (Johnston 1970, 307f.*). The Chippewa manufactured a medicine from calamus root, the bark of *Xanthoxylum americanum* Mill., the root cortex of *Sassafras albidum*, and the root of *Asarum canadense* L.²² to treat colds and bronchitis (Morgan 1980, 240).

In traditional Chinese medicine, the rootstock of *Acorus gramineus* is used to treat forgetfulness, lack of concentration, hearing difficulties, buzzing in the ears, epilepsy, mental illnesses, sensations of being full in the stomach, and gastritis (Paulus and Ding 1987, 128*).

Constituents

Calamus root contains high levels of **essential oil** with decadienal, caryophyllene, humulene, curcumene, and β -asarone as well as the bitter principles acorone, neoacorone, and acorine, tanning agents, and mucilage (Chinese calamus contains α -asarone and β -asarone as well as eugenol, safrole, α -humulene, sekishone, etc.). The essential oil of *Acorus calamus* var. *americanus* is devoid of β -asarone (Motley 1994, 407). Plants from India contain especially high concentrations of asarone (Baxter et al. 1960; Vohora et al. 1990). Indian plants have also been reported to produce psychotropic

effects (Motley 1994, 405).

Calamus

“In paths untrodden,
In the growth by margins of pond-waters,
Escaped from the life that exhibits itself,
From all the standards hitherto publish’d, from the pleasures, profits, conformities,
Which too long I was offering to feed my soul,
Clear to me now standards not yet publish’d, clear to me that my soul,
That the soul of the man I speak for rejoices in comrades,
Here by myself away from the clank of the world,
Tallying and talk’d to here by tongues aromatic. . . .”

WALT WHITMAN

LEAVES OF GRASS

(1900)

The yellow gladiolus was once known as *Acorus vulgaris*, or common calamus. This was intended to distinguish it from the “calamus of the apothecaries,” the true calamus. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

The rhizomes of *Acorus gramineus* contain high amounts of essential oil, consisting of α asarone, β -asarone, eugenol, safrole, α -humulene, sekishone, and other constituents (Paulus and Ding 1987, 128*).

Effects

Asarone is regarded as the inebriating principle in the raw drug²³ (Baxter et al. 1960; Motley 1994, 399). Laboratory experiments have verified its effects upon the central nervous system (Vohora et al. 1990). It also has inebriating effects, which are presumably due to a metabolite, TMA or trimethylmethamphetamine (cf. *Myristica fragrans*). The essential oil has tonic effects, strengthens the stomach, and relieves cramps. It also has antibacterial effects. β -asarone is also reputed to have toxic and carcinogenic effects. Pharmacologically, asarone is said to act in a manner similar to papaverine (Motley 1994, 405).

Asarone

Eugenol

The assertion that calamus is hallucinogenic appears to be due more to wishful thinking than to actual experiences with the plant. Even with very high dosages (up to 100 g of decocted, dried rhizomes), I have been unable to detect any type of hallucinogenic, psychedelic, entheogenic, or other visionary effect. Instead, the effects of asarone appear to be more sedative in nature. I also am unaware of any experimentally inclined psycho-nauts who have been able to report successful experiments with calamus. In my opinion, calamus can be stricken from the list of so-called legal highs, at least until new evidence of its psychoactivity appears.

Commercial Forms and Regulations

Calamus root (*rhizoma calami*) can be obtained in herb shops and pharmacies. Calamus oil has been taken off the market because of its (doubtful) carcinogenic effects (Motley 1994, 407). In Germany, calamus is allowed to be used as an aromatic agent for schnapps and similar items as long as the amount of asarone per liter of the beverage it is added to does not exceed 1 mg (Roth et al. 1994, 92*).

Agave spp.

Agaves, Mezcal Plants

Family

Agavaceae (Century Plant Family; Zander 1994, 95*), previously Liliaceae (Lily Family)

Forms and Subspecies

There are approximately 136 species in the genus *Agave* in Mexico and neighboring regions (Gentry 1982). Many of the larger species are ethnobotanically and ethnopharmacologically significant.

Species used in the manufacture of fermented beverages (pulque, suguí, tesgüino, tizwin, mesagoli) and distilled spirits (tequila, mescal, pisto):

Agave americana L. (century plant, teometl, mescale)

Agave americana L. var. *expansa* (Jacobi) Gentry (mescal maguey)

Agave asperimma Jacobi

Agave atrovirens Karw. ex Salm. (maguey, metl, tlacametl)

Agave bocicornuta Gentry (mescal luchuguilla, sa'pulí)

Agave cerulata Trel. ssp. *dentiens* (Trel.) Gentry

Agave durangensis Gentry

Agave ferox Koch (maguey)

Agave hookeri Jacobi

Agave latissima Jacobi [syn. *Agave macroculmis* Tod., *A. coccinea* hort. non Roezl ex Jacobi]

Agave mapisaga Trel. (maguey manso, maguey mapisaga)

Agave mescal Koch (mescal agave)

Agave multifilifera Gentry (chahuí)

Agave pacifica Trel. (mescal del monte, mescal casero, gusime)

Agave palmeri Engelm.

Agave parryi Engelm.

Agave polianthiflora Gentry (ri'yéchili)

Agave potatorum Zucc. [syn. *Agave scolymus* Karw.] (tlacametl)

Agave potatorum Zucc. var. *verschaffeltii* (Lem.) Berger [syn. *Agave verschaffeltii* Lem.] (tlacametl)

Agave rhodacantha Trel.

Agave salmiana Otto ex Salm-Dyck [syn. *Agave atrovirens* Karw. var. *salmiana* (Otto ex SD.) Trel.,

Agave atrovirens Trel. and “of authors” (Gentry 1982, 13)] (maguey de pulque, tlacametl)

Agave shrevei Gentry (mescal blanco, o'tosá)

Agave tequilana Weber (tequila agave, maguey, blue agave)

Agave tequilana Weber cv. Azul (“blue variety”)

Agave vivipara L. [syn. *Agave angustifolia* Haw.] (babki, mescal de maguey)

Agave weberi Cels

Agave wocomahi Gentry (mescal verde, ojcome, pine maguey)

Agave zebra Gentry

For fibers, medicines, and sacrificial thorns (*pencas*):

Agave americana L.

Agave sisalana Perrine (henequen, sisal agave, kih)

Agave fourcroydes Lem. [syn. *Agave ixtlioides* Lem.] (henequen agave)

Folk Names

Agave, century plant, chupalla, henequen, maguei, maguey, mescal plant, meskalpflanze, metl, mezcal plant, pita

For the fermented juice:

Agave wine, iztac octli, mesagoli, mescal beer, metl, octli, pulque, suguí, tesgüino, tizwin, vino mescal, wine

For the distilled liquor:

Agave schnapps, mescal, mezcal, pisto, tequila, tuché (Huichol), vino mescal

History

Roasted remains of agaves, dated to approximately 8,000 years ago, have been recovered from the caves of Tehuacán (Mexico) (Wolters 1996, 28*). In prehistoric times, agave was already playing an important role as a source of food, inebriants, and materials in Mexico and the American Southwest. Some agaves were even used as poisons to stun fish in isolated bodies of water (Bye et al. 1975). The Mexican agaves were first described around 1577 by Francisco Hernández. The Conquistadors also remarked about the use of the fermented juice (pulque) (Gentry 1982).

The Mexican *Agave salmiana* is the most important species used to produce pulque and tequila.

In Yucatán (Mexico), great quantities of fibers obtained from the leaves of the sisal agave (*Agave sisalana*) are used to produce a variety of fiber products. This species can also be used to produce inebriating beverages. (Plantation at San Antonio Tehuiz,

The inflorescence of the century plant (*Agave americana*) develops when the plant is about fourteen years old. Afterward, the plant dies.

What Is Mescal?

The name *mescal* has created a great deal of terminological confusion about both psycho-active plants and their products.

The term is used to refer to a type of agave (the mescal agave), while the alcoholic spirits that are distilled from this species are also known as mescal or mezcal.

In southern California, *Yucca whipplei* Torr. is known as maguey, but also as mescal (Tim-brook 1990, 247*).

Even the peyote cactus (*Lophophora williamsii*) is called mescal or mescalito, while the buttons that are sliced from this cactus are called mescal buttons or mescal heads. In addition, the seeds of *Sophora secundiflora* are known as mescal beans.

In the “drug scene,” mescaline trips are often known as mescalitos.

In North America, the species *Agave felgeri* Gentry is known as *mescalito*.

With so many associations with the word *mescal*, it is not surprising that some people are firmly convinced that mescal spirits contain mescaline and are able to induce psychedelic effects.

In addition, it is rumored that the worm (actually a larva) that is contained in *mescal con gusano* contains special constituents and will induce hallucinogenic effects when eaten. Some people maintain that several worms must be eaten to obtain a sufficient dosage.

The blue agave (*Agave tequilana*) is regarded as the best plant for the production of tequila.

Mayahuel, the goddess of agave, the source of the inebriating pulque drink. (Codex Laud, 9r.)

Eating the *gusano de mescal*, an insect larva that lives in the mescal agave, will allegedly produce psychoactive effects.

Because the mescal worm is purportedly psychoactive and is, moreover, (still) legal, a California manufacturer had the idea of putting this unappetizing little creature into a lollipop.

According to Aztec historical records, pulque was “invented” in Central America between 1172 and 1291, after the Aztecs had migrated from the north (Gentry 1982, 8). Pulque has probably been used for a considerably longer period of time and was known to many peoples and tribes. Pulque and similar alcoholic beverages also played a role among the tribes of northern Mexico and in the American Southwest (cf. **beer**, **chicha**). The Apaches, for example, used agave to make fermented drinks (*tizwin*) that were ritually consumed during tribal festivals (Barrows 1967, 75*).

Today, the Mexican agaves are important primarily because they are used in the production of tequila, and they are popular throughout the world as ornamental plants.

Distribution

The genus *Agave* is indigenous to Mexico and the American Southwest. Numerous species of the genus are from Mexico and have been cultivated for various purposes since prehistoric times (Dressler 1953, 120f.*).

Cultivation

Agaves are propagated using bulblets (offshoots), which are planted in growing fields shortly before the beginning of the rainy season. After twelve to eighteen months, the plants are transplanted to production fields. When this occurs, all of the roots are cut away from the rootstock (Rehm and Espig 1996, 328*). Agaves are succulents (photo-synthesis occurs according to the crassulacean pattern) and can easily survive long periods without water. Some species thrive in the desert, others in tropical rain forests. Although the quality of the soil is not important, it should be well drained.

Appearance

Most agaves, and especially those species that are used in the production of pulque and spirits, are quite similar and rather uniform in appearance. They are hardy plants with thick, fleshy roots from which the fleshy leaf rosette grows. The lanceolate, cultrate, or hastate leaves are sharply pointed at the ends, and most have serrated edges and a very sharp, hard, woody tip. At the end of their lifetimes, the plants produce a paniced inflorescence on a straight, smooth stalk. The bulblets form in the axils of the flower bracts. From 1,000 to 4,000 bulblets may grow on one inflorescence (Rehm and Espig 1996, 327*).

Psychoactive Material

—Aguamiel (Spanish, “honey water”), the sugary juice that collects in the interior (the shaft) of the plant.

Shortly before the plant is ready to develop its inflorescence, a sap (*aguamiel*, *metl*) that is

very high in sugar accumulates in the shaft of the plant underneath the leaf crown. This sap apparently ferments as a result of microbial (*Pseudomonas lindneri*), wild yeast, or fungal activity (Gonçalves 1956). The plant produces the fermented drink known as pulque (also *mezcal* or *vino mezcal*) on its own. This process can be artificially controlled by removing a portion of the leaf crown. When this is done, the plant will produce a much greater quantity of the inebriating juice (around 2 liters per day). The plant will produce new pulque daily for up to one month (Bye 1979a, 152f.*).

—Mescal worm (*gusano de mescal*)

Preparation and Dosage

The plant juice can either be tapped while it is fermenting or fermented in a covered, but not tightly closed, vat.²⁴ Pulque contains 3% to 4% alcohol (Havard 1896, 34*). Various plants have been and still are added to the pulque to improve it and to modify its psychoactive effects (see table).

The Serí Indians of northern Mexico boil the narrow leaves of *Agave cerulata* Trel. ssp. *dentiens* (Trel.) Gentry, a plant they call *heme*, chop them into small pieces, and place them into the carapace of a sea turtle. They then press them with a stone, so that the juice collects within the carapace. The juice, which ferments within just a few days, is diluted with water prior to consumption (Felger and Moser 1991, 223*).

The Tarahumara manufacture *suguí* or *tesgüino* from a number of agaves. They boil the leaves in water, press the agave hearts (mescal hearts), or make an extract from the chopped leaves. Fermentation occurs on its own (Bye et al. 1975, 88).

The Indians of Arizona prepared their mescal beer from the inflorescences of *Agave parryi* and *Agave palmeri* (Havard 1896, 34*).

Alcoholic spirits (tequila, mescal) are distilled either from the plant juice (aguamiel) or from boiled and mashed leaves. The Yaqui Indians fortify their mescal liquor with the leaves of *Datura innoxia*. In Mexico, it is also common to use marijuana flowers (cf. *Cannabis sativa*), sugar, and chili pods (see *Capsicum spp.*) as additives to mescal (Reko 1936, 64*). Damiana (*Turnera diffusa*) is also a good tequila additive. In fact, there are a great number of recipes for tequila (Walker and Walker 1994).

It is said that the mescal worm (a larva approximately 5 cm in length) that is added to some mescal spirits should be eaten whole if a psychoactive effect is desired. Two or three worms is considered an effective dosage. Recently, a California manufacturer began producing sugar-free lollipops, each containing a mescal worm.

Pulque Additives

(Adapted with modifications from Bye 1979a, 153*; Bye 1979b, 38*; Bye et al. 1975; Furst 1974, 71*; Havard 1896, 39*; Marino Ambrosio 1966; Kuehne Heyder 1995.)

In the Yucatán, the roots of one maguey agave (perhaps *Agave americana* var. *expansa*) were used as an additive to **balche’**.

Ritual Use

Among the Aztecs, pulque was a drink sacred to the gods that could be drunk only on ritual occasions. The dosage was limited to four bowls. Men over the age of seventy, however, were allowed to drink until they were inebriated. Sacrificial celebrations were followed by ritual drinking bouts:

And on the following day, wine [= pulque] was drunk and the after-celebration of the festival took place. The wine that was drunk is called blue wine. Everyone drank wine, the old men, the old women, and the chiefs of the nobility, the married, the adults, and the princes of blood and

the leaders of the adults. And the first among the ranks of the young who were already strong, they too drank wine, but they drank in secret, they did not show themselves, they used the night as protection, they hid themselves under the grass so that they would not be seen. But if someone discovered them and it became known that they had drunk wine, then they would hit them with a jaw club so that their flesh would swell up, and they would shave their heads as slaves, drag them, kick them, throw them to the ground, and do everything evil to them until it sometimes occurred that they killed them. And after they had quieted their lust, they would throw them down, throw them out of the house. (Sahagun, Florentine Codex 2:34*)

The Brazilian pepper tree (*Schinus terebinthifolius*), known as a toxic plant, is used to fortify pulque obtained from agaves.

The seedpods of the mesquite tree (*Prosopis juliflora* DC.) contain 25 to 30% sugar and are thus ideal for use as a fermentation agent. Boiled and crushed in water, they yield a fresh, sweet beverage known in northern Mexico as *atole*. If allowed to stand, it quickly ferments. After one to two days, a beerlike drink results (**chicha**). The plant is also added to Mexican pulque.

An early European illustration of the American agave, which was interpreted as a relative of the aloe. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

The mescal agave (*Agave horrida* Lem.); its name is derived from the Aztec word *mexcalmetl*. (From Hernández, 1942/46 [Orig. pub. 1615]*)

The inebriating beverage was used as a ritual offering and libation for the gods and also was needed for human sacrifices. Before the ceremony, those whom the Aztecs were to sacrifice were required to drink four bowls of pulque, to which *Datura innoxia* or a decoction of the bark of the incense tree *Bursera bipinnata* had apparently been added. Once inebriated in this manner, they were allowed to have the priests rip the hearts out of their still-living bodies on the sacrificial altar.

In his 1541 work, *Historia de los indios de la Nueva España*, Motolinia had already alluded to the addition of *ocpatli*, apparently *Acacia angustifolia* (cf. *Acacia* spp.), and this addition was forbidden in the colonial period. The additive as well as the resulting drink were both known as *teoctli*, “divine pulque,” or *xochioctli*, “flower pulque” (Ott 1996d, 428*).

The Huastec, who live on the Gulf of Mexico, used pulque in all their rituals and glorified the state of inebriation it produced. Pulque was also used during the sexual magical rites held to honor the erotic images of their gods. Men and women would copulate before the statues as the priests administered pulque **enemas** to them (even today, pulque is still regarded as an aphrodisiac). Following this, the men and women would perform ritual anal coitus. It appears that the pulque that was used for these purposes was fortified with thorn apple roots (*Datura innoxia*) (Kuehne Heyder 1995).

Large quantities of spirits distilled from agaves were also consumed in shamanic rituals, especially during the peyote festivals of the Huichols (cf. *Lophophora williamsii*):

The shaman took a few swigs from a bottle of a potent liquor made from the agave plant, then passed it to me. I matched him swig for swig. Then he picked up the bowl of peyote gruel and took a long drink. I counted the gulps and took the same amount. This continued throughout the night. (Siegel 1992, 28*)

It should be noted that the **mescaline** contained in the peyote cactus strongly suppresses the effects of **alcohol**.

Pieces of agave are also used in ritual healing and fertility ceremonies, usually as amulets (Bye et al. 1975, 91). In Aztec sacrificial ceremonies, the tips of the leaves (*pencas*) were driven as thorns into the skin of the victims. They were also used in raising boys to be noblemen. Anyone who behaved inappropriately was punished using agave thorns (Gentry 1982, 10).

Artifacts

Aztec manuscripts contain numerous depictions of the pulque goddess Mayahuel and the foaming drink itself, as well as of drinking rituals, drinking sacrifices, and libations (Gonçalves 1956). Pulque also appears in Aztec songs and poems (Guerrero 1985).

In Cholula (Puebla), pre-Columbian wall paintings have been discovered that depict the ritual drinking of pulque. Peter Furst has identified the blossoms portrayed in one of the paintings as those of ***Turbina corymbosa***. He has suggested that the seeds of this plant, which produce psychedelic effects, were used as an additive to the pulque (Furst 1974, 71*).

Agaves, tequila bottles, and states of drunkenness resulting from tequila are common elements in the paintings of such Mexican artists as Eugenia Marcos, Elena Climent, Joel Renón, and Ricardo Martínez. Tequila is praised in many Mexican poems and songs (Artes de México 1994).

Medicinal Use

Different agaves find numerous uses in folk medicine. They are used to treat wounds, snake-bites, skin diseases, foot fungus, venereal diseases, toothaches, rheumatism, diarrhea, et cetera (Wolters 1996, 31f.*).

In Mexico, it is widely believed that *mezcal con gusano* has aphrodisiac effects, as the worm is thought to contain active constituents. And in general, tequila and mescal are popularly associated with sex and eroticism.

Preparations of *Agave americana* are also used in homeopathy (Wolters 1996, 35*).

Constituents

Agaves contain saponins, steroid saponins, hecogenin glycosides, large amounts of sugar (up to 8%), vitamin C, polysaccharides, and minerals (Wolters 1996, 34*). *Agave americana* contains saponine, a pungent **essential oil**, from 0.4 to 3% hecogenin, and oxalic acid (Roth et al. 1994, 103*). Agave juice contains 8% sugar (agavose), essential oil, and some papain. Pulque contains 2 to 4% alcohol as well as large amounts of vitamin C and has 204 calories per liter.

Effects

The effects of pure pulque are similar to those of **balche'**, **chicha**, and **palm wine**. However, there is also a noticeably refreshing component. In a pulque inebriation, one remains clearer than in a beer inebriation. Pulque that has been fortified with ***Psilocybe spp.*** is not merely inebriating, but also visionary. Visions of snakes are said to appear with some regularity (Havard 1896, 39*).

Commercial Forms and Regulations

A number of agave species are available in nurseries throughout the world as ornamentals. Pulque is found only in Mexico. The corresponding distilled spirits (tequila, mescal) are sold around the world and are subject to local regulations regarding alcoholic beverages. The best-quality tequila, manufactured using the blue agave (*Agave tequilana* cv. Azul), is only infrequently found outside of Mexico. Similarly, tequilas that have been stored and aged for longer periods are not easily obtained outside of Mexico.

“All inebriating beverages, including the hallucinogenic ones, stood under the protection of the goddess Mayahuel, who was originally only a simple farmer’s wife. The myth reports how she wanted to kill a mouse in the fields one day. But the animal escaped, danced fearlessly around her, and laughed at her. Dumbfounded, Mayahuel ultimately noticed that the mouse had nipped on a maguey plant, from which a milky juice was dripping. She collected this juice and took it with her to her house so that her husband could try it. After drinking it, the two of them became cheerful and completely relaxed, and life appeared to them to be pure joy. Because they consecrated the drink to the gods, these thanked Mayahuel by naming her the goddess of pulque, while her husband became Xochipilli (‘flower prince’), the lord of flowers and games.”

AZTEC MYTH

IN *MEXIKANISCHE MYTHOLOGIE* [MEXICAN MYTHOLOGY]

(NICHOLSON 1967, 69f.*)

The pulque agave, or maguey (*Agave atrovirens* Karw.), is known in Aztec as *metl*. (From Hernández, 1942/46 [Orig. pub. 1615]*)

Alstonia scholaris (Linnaeus) R. Brown

Dita Tree

Family

Apocynaceae (Dogbane Family)

Forms and Subspecies

None

Synonyms

Echites malabarica Lam.

Echites scholaris L.

Folk Names

Chatian (Hindi), chatiun, chattiyan, chhatim (Bengali), chhation, daivappala, devil tree, devil's tree, dirita, dita (Tagalog), dita tree, ditta, elilampala, elilappalai, maddale (Kannada), milky pine (in Australia), nandani, pala (Malayalam, Tamil), palai, palimara, pulai, saittan ka jat, saptachadah, saptaparna (Sanskrit, "seven-leaved"), saptaparnah, saptaparni, satvin (Marathi, "seven-leaved"), schulholzbaum, shaitan (Arabic, "devil"), shaitan wood, tanitan, weißquirlbaum, yaksippala

History

The dita tree has been used in South Asia to manufacture writing parchment since ancient times (Miller 1988, 20*). The wood was formerly used to make writing tablets for schoolchildren (Gandhi and Singh 1991, 89*). The related species *Alstonia venenata* R. Br. [syn. *Echites venenata* Roxb.] was used for similar purposes.

Although the seeds were used in the tantric cult, no traditional use of this plant as a hallucinogen is known (Scholz and Eigner 1983, 77*).

The tree is named after a professor from Edinburgh, Scotland, C. Alston (1685–1760). In Europe, the bark was once sold as a febrifuge and tonic (Schneider 1974, 1:77*).

Distribution

Although the dita tree is from India, it is now found throughout all of Southeast Asia (and Myanmar, the Philippines, and Thailand) (Padua et al. 1987, 14). It also occurs in the tropical rain forests of the east coast of Australia and on the Solomon Islands.

Cultivation

It may be possible to propagate the plant using seeds. The most successful method is to transplant young trees.

Appearance

This evergreen tree can grow to a height of 30 meters. Its bark is rough and gray. The branches are arranged circumambiently around the trunk, so that the crown looks like a parasol. The large lanceolate leaves, which can grow as long as 25 cm, are arranged in clusters of seven. The greenish

yellow flowers are small and inconspicuous; the fruits hang in pairs and form thin, slightly undulating or curved pods that can grow to 20 to 45 cm in length. A sticky and bitter sap flows through the bark.

The genus *Alstonia* encompasses some forty-three species that are found in all tropical zones. Some of these are difficult to distinguish from *Alstonia scholaris*, and they are presumably often confused with one another.

Psychoactive Material

- Bark, root cortex
- Leaves
- Latex

Preparation and Dosage

In India, when the intended use is medicinal, the bark (which possesses no aphrodisiac properties) is boiled together with rice.

The seeds are preferred when the proposed use is aphrodisiac or psychoactive in nature. Two grams of the seeds are crushed and allowed to steep in water overnight. The next day, the liquid is filtered and drunk. The dosage for aphrodisiac purposes can vary considerably among individuals. It is best to begin with 3 g per person and then slowly increase the dosage (Gottlieb 1974, 33*; Miller 1985, 11*).

Leaves and pseudoflowers of the dita tree (*Alstonia scholaris*).

The bark of the dita tree (*Alstonia scholaris*) is rich in alkaloids.

The dita tree (*Alstonia scholaris*) is both revered and feared in India and Nepal.

The leaves of the related species *Alstonia theaeformis* (Bogotá tea) are brewed to make a tea that is consumed for its stimulating effects (Lewin 1980 [orig. pub. 1929], 352*).

Ritual Use

The tree is considered “evil” in India. Some tribal peoples do not merely fear the tree but avoid it altogether. They believe that an evil spirit dwells within the tree that can possess any person who walks underneath the tree or sleeps in its shadow. Some also believe that the guardian of the tree can

bring death to those who sleep under its branches. These conceptions may be based upon the fact that the tree can induce visions. Because of this negative folklore, however, the tree has also been spared from the destruction being visited upon other tropical trees (Gandhi and Singh 1991, 89*).

The seeds of the tree play a significant role in the sexual magical practices of the Indian tantric cult. Unfortunately, little is known about this use (Miller 1988, 21f.*).

The Australian Aborigines used the latex as an adhesive for attaching ceremonial decorations (such as feathers) to their skins for rituals (Pearson 1992, 25*). It is possible that they also knew of and utilized the psychoactive properties of the dita tree. Apart from this, we know of no traditional usages for psychoactive purposes.

Artifacts

In tantric magic, mantras (magical formulae) were written on pieces of bark parchment that were then used as amulets.

Medicinal Use

The bark is generally regarded as a tonic (Wright et al. 1993, 41). In Ayurvedic medicine, it is also used to treat fever, malaria, lower abdominal ailments, diarrhea, dysentery, digestive problems, leprosy, skin diseases, pruritus, tumors, chronic ulcers, asthma, bronchitis, and frailty. Both the latex and the tender leaves are applied externally to tumors (Sala 1993, 1:97*). In India, the bark and root cortex are boiled with rice and ingested by girls daily for one to two weeks to treat leukorrhea (Bhandary et al. 1995, 152*). In the regions of Ganjam and Godawari, it is used to treat insanity and epilepsy (Scholz and Eigner 1983, 77*), while in Nepal it is used as a febrifuge and to treat malaria (Manandhar 1980, 15*). In Assam, a cold-water extract is drunk to treat malaria (Boissya et al. 1981, 221*). In the Philippines, the bark is used as a tonic and to treat diarrhea disorders of all types. A decoction of the young leaves is drunk for beri-beri (Padua et al. 1987, 14).

The bark of the Southeast Asian species *Alstonia angustifolia* Wall., *Alstonia macrophylla* Wall. ex G. Don, and *Alstonia spathulata* Bl. is also used as a traditional treatment for malaria and as a tonic (Padua et al. 1987, 13). In Africa, the species *Alstonia congensis* Engl. and *Alstonia boonei* De Wild. are also made into medicines for treating malaria (Wright et al. 1993, 41f.).

“Once upon a time, in the Western Ghats or hills of India lived a shepherd called Ramu who played the flute beautifully. Every day while his goats grazed in the mountains, Ramu sat under the Chatian tree and played his flute.

Now, in this Chatian tree lived a fierce spirit. When Ramu first came to sit under the tree he was just about to strike him dead when he heard the boy’s flute and was charmed by the melody.

The spirit danced among the leaves and branches. Soon, when he was used to Ramu coming every day, he ventured down from the tree and introduced himself. From then on Ramu would play and the spirit would dance in great happiness. The two became good friends.”

MANEKA GANDHI AND YASMIN SINGH A FOLKTALE FROM MADHYA PRADESH
(1989, 89–90*)

Constituents

The seeds contain hallucinogenic **indole alkaloids** (alstovenine, venenatine, chlorogenine, reserpine) as well as chlorogenic acid (Miller 1985, 10*). The bark through which the latex flows contains the alkaloids ditamine, echitamine (= ditaine), and echitenines (Miller 1985, 10*; Rätsch 1992, 73*). Ditamine, echitamine, alstovenine, and venenatine occur in all parts of the plant (Scholz and Eigner 1983, 77*).

Most *Alstonia* species contain **indole alkaloids** (Majumder and Dinda 1974; Mamatas-Kalamaras et al. 1975). The New Caledonian *Alstonia coriacea* Pancher ex S. Moore even contains a yohimbine

derivative (Cherif et al. 1989). The Malaysian species *Alstonia angustifolia* Wall. contains thirty-one alkaloids, **yohimbine** being the primary one (Ghedira et al. 1988). The Australian species *Alstonia muelleriana* Domin contains a complex mixture of indole alkaloids (Burke et al. 1973).

Effects

The bark is alleged to have aphrodisiac and, as a result of MAO inhibition (see **ayahuasca**), psychoactive effects. The primary constituent “alstovenine demonstrates MAO-inhibiting effects in low doses and in higher doses CNS-stimulating effects, stereotypy, and spasms. In contrast, the effects of venenatine are reserpine-like [cf. ***Rauvolfia* spp.**]” (Scholz and Eigner 1983, 77*). *Alstonia* “helps retain erection and delays orgasm during intercourse” (Miller 1985, 9*).

The alkaloid echitamine is said to kill the malaria pathogen; however, it is some ten times less effective than quinine. The effects upon malaria have not yet been clearly demonstrated pharmacologically (Wright et al. 1993).

“It was in *Tantric* India that the seed of the dita tree was first used as an aphrodisiac. Use of the drug was accompanied by an exercise that prolonged erection and delayed orgasm by control of specific genital muscles.”

Anadenanthera colubrina (Vellozo) Brennan

Cebil, Villca

Family

Leguminosae (Legume Family); Mimosoideae Section: Eumimoseae

Forms and Subspecies

There are two geographically isolated varieties or subspecies (von Reis Altschul 1964):

Anadenanthera colubrina var. *colubrina* Altschul: only in eastern Brazil²⁸

Anadenanthera colubrina var. *cebil* (Grisebach) Altschul: in the southern Andes region and neighboring areas (Argentina, Bolivia, Paraguay, Peru, southeastern Brazil)

Synonyms

Acacia cebil Grisebach

Anadenanthera excelsa Grisebach²⁹

Anadenanthera macrocarpa (Benth.) Spegazzini

Piptadenia cebil Grisebach

Piptadenia colubrina Benth.

Piptadenia grata (Willd.) Macbr.

Piptadenia macrocarpa Bentham = *A. colubrina* var. *cébil*

Folk Names

Aimpä, aimpä-kid, algarobo, angico, angico do cerrado, cabuim, cebil, cébil, cebíl, cebil blanco, cebil colorado, cebilo, cevil, cevil blanco, cevil colorado, cibil, curubu'y, curupai, curupai-curú, curupaí, curupaù blanca, curupaú barcino, curupay,³⁰ curupáy, curupaytí, guayacán,³¹ hataj (Wichi name for the **snuff**), hatax, huilca, huillca, jataj, kurupá, kurupaî, kurupaîraî, kurupayara, quebracho,³² sebil, sébil, sevil, tara huillca, tèék, tek (Wichi), uataj, uillca, uña de gato (Spanish, “cat claw”),³³ vilca, vilcas, villca, wilka, wil'ka, willca,³⁴ willka, xatax

The names used for the tree are usually the same as the names given to the **snuff** that is prepared from it.

History

The seeds of the variety known as *cebíl* were being smoked in pipes over 4,500 years ago in the Puna region of northwestern Argentina (Fernández Distel 1980).³⁵ Its use appears to have had a particularly profound effect upon the culture of Tiahuanaco (literally, “dwelling of the god”).

Cebíl's usage as a snuff in the southern Andes is first mentioned in the *Relación* of Cristobal de Albornoz. Use as an additive to maize beer (**chicha**) was first described by Polo de Ondegardo in 1571. The Mataco Indians are said to have brewed a *vino de cebil* (cebíl **wine**) even during the twentieth century.

It is uncertain whether the reports about the use of villca seeds that have come to us from the colonial period actually do refer to the seeds of *Anadenanthera colubrina*. Even today, other trees are also referred to as *vilca* (*Acacia visco* Lorentz ex Griseb., *Aspidosperma quebracho-blanco*).

Distribution

See “Forms and Subspecies” (above). In the region of Salta (northwestern Argentina), entire forests of cebíl trees stretch across the mountains and slopes.

Cultivation

The dried seeds can be germinated and then planted. The tree is relatively fast growing and can be cultivated in both tropical and subtropical climate zones.

Appearance

The tree, which grows to a height of only 3 to 18 meters, has a bark that is almost black and often features conical thorns or knotty constrictions. The leaves are finely pinnate and up to 30 cm in length. The whitish yellow flowers are globose. The leathery, dark brown seedpods can grow as long as 35 cm; they contain reddish brown seeds that are 1 to 2 cm wide, very flat, and roundish to rectangular. The tree is very difficult to distinguish from the closely related *Anadenanthera peregrina* (von Reis Altschul 1964).

In the twilight of evening, the tree “goes to sleep,” i.e., the pinnate leaves fold together, opening again the following morning. The stems of the leaves contain small glands that exude a sweet liquid. Certain types of ants are attracted to this and consume the nectar. At the same time, the ants destroy other pests that might pose a threat to the tree.

The tree is often confused with other species from the same family. For example, according to an oral communication from C. M. Torres, even professional botanists have incorrectly identified one tree found in the San Pedro de Atacama (northern Chile) that is also known as *vilca*, *Acacia visco* Lorentz ex Griseb. [syn. *Acacia visite* Griseb., *A. platensis* A. Manganaro, *Manganaroa platensis* (Mang.) Speg.], as *A. colubrina*.

The botanical identification is not always easy, as the species can exhibit considerable variation. The variety *colubrina*, for example, can form seedpods that are exactly like those of the genus *Prosopis* (von Reis Altschul 1964, 11).

Psychoactive Material

—Seeds (semen anadenanthera colubrina)

Preparation and Dosage

The ripe seeds are dried and may be lightly roasted, after which they are ground as fine as possible. As little as 150 mg to 0.5 g of this powder is effective when ingested nasally. One gram (which roughly corresponds to the weight of a large seed) represents a potent visionary dosage.

For smoking, the ripe, dried seeds are lightly roasted and then coarsely crushed. Some five to eight seeds are mixed with cut tobacco (*Nicotiana tabacum*) and occasionally with the leaves of aramo (*Amaranthus* spp., *Acacia caven* (Mol.) Molina, or *Acacia farnesiana*; cf. ***Acacia* spp.**) and rolled into a cigarette. An effective dosage is said to be half a cigarette per person.

When intended for oral ingestion, the seeds or the juice that is pressed from them is mixed with **chicha** and drunk. Two or three seeds can be boiled in water with the root of *Polypodium* spp. and drunk. Boiled, the seeds can also be mixed with **honey** and eaten. Another recipe calls for ingesting six ground seeds with some liquid (von Reis Altschul 1972, 38).

Ritual Use

Before the arrival of the Spanish, villca seeds must have had great ritual and religious importance in Peru, as high-ranking Andean priests and certain soothsayers (*umu*) were also known as *villca* or

vilca camayo (Cobo 1990, 267*; Salomon and Urioste 1991, 256*; *villac* [sic] in Arriaga 1992, 31*; von Reis Altschul 1967). One Indian shrine (*huaca*) was also referred to as *villca*, *vilcacona*, or *vilcabamba*, “place of the villca trees” or “villca forest,” and an especially sacred mountain is known as Villca Coto. The primeval survivors of a great flood retreated to the peak of this mountain (Ibid., 51*). There are numerous other examples of this kind (cf. von Reis Altschul 1972). Moreover, *villca* also appears to have been a name for **enemas**.

Villca seeds had great ritual significance as a **beer** additive in **chicha** intended for ceremonial consumption. Here, the “juice” of villca was trickled into the fermented beverage and consumed by soothsayers (*umu*) or “magicians” (= shamans) so that they could peer into the future (Cobo 1990*).

The ritual or shamanic use of snuffs made from this species of *Anadenanthera* has been documented for the following tribes: Quechua, Piro, Chiriguano, Yabuti, Atacama (Kunza), Comechingón, Diaguita, Allentiac, Millcayac, Humahuaca (Omoguaca), Ocloya, Mataco (Mataguay, Nocten), Vilela, and Guaraní (von Reis Altschul 1972).

The oldest archaeological evidence for a ritual or shamanic use of cebíl seeds comes from the Puna region of northwestern Argentina (Fernandez Distel 1980).

The shamans of the Wichi (= Mataco), who live in northwestern Argentina, still use a snuff they call *hataj* (Califano 1975). The Mataco shamans prefer smoking the dried and roasted seeds in pipes or cigarettes over sniffing the powder. They believe that it is only through *hataj* that they can penetrate into the other reality and have an effect upon it (Arenas 1992; Califano 1975; Domínguez and Pardal 1938). In recent years, some of the Mataco have become converts to Christianity. When this occurred, they immediately equated the biblical tree of knowledge with cebíl (Arenas 1992). The Mataco, however, regard this not as a “forbidden fruit” but as the fruit of a sacred tree that the shamans use to perform healings. The shaman Fortunato Ruíz has described cebíl seeds as a “door into the other world.” He smokes the seeds with tobacco and aramo—just as his ancestors did five thousand years before. Northwestern Argentina is thus the site of the longest uninterrupted tradition of ritual/shamanic use of a psychoactive or psychedelic substance on the planet.

The cebíl tree (*Anadenanthera colubrina* var. *cebil*) develops long seedpods that open in August and cover the ground with cebíl seeds. (Photographed in the cebíl forests of Salta, northwestern Argentina)

An opened seedpod of *Anadenanthera colubrina* var. *cebil*, showing the bufotenine-rich seeds.

The seeds of the southern Brazilian *Anadenanthera colubrina* var. *colubrina*.

Artifacts

Numerous pre-Columbian objects associated with snuff use (snuff trays, snuff tubes) have been found in northwestern Argentina (Puna) and northern Chile (Atacama Desert). The icon-ography of these objects was influenced by the visions produced by the cebíl seeds (see **snuffs**). A number of pipes made of clay have also been recovered from the region; the heads of some still contained cebíl seeds.

The petroglyphs and geoglyphs in the Atacama Desert as well as the images depicted on the ceramics of the Argentinian Puna region are clearly reminiscent of cebíl visions.

The hallucinations cebíl can induce appear to have exerted a considerable influence upon the iconography of the so-called Tiahuanaco style. The iconography of Chavín de Huantar is interwoven with similar motifs. The intertwined and entangled snakes that come out of the head of the oracle god can, for example, be interpreted as cebíl-induced hallucinations.

A two-thousand-year-old shamanic textile from the Chavín culture features depictions of seedpods that can easily be interpreted as those of *Anadenanthera colubrina* (Cordy-Collins 1982*).³⁶ In fact, a variety of iconographic elements in the Chavín culture have been interpreted as representations of *Anadenanthera* spp. (Mulvany de Peñaloza 1984*).

Several paintings on ceramics from the pre-Columbian Moche or Chimú include depictions of trees. The iconographic contexts and the botanical representations of these trees indicate that they may very well be construed as *Anadenanthera colubrina* (archaeologists typically interpret these as “algarrobo trees”³⁷ [Kutschner 1977, 14*; Lieske 1992, 155]).

In 1996, the German artist Nana Nauwald produced a painting about an experience with cebíl seeds. Entitled *Nothing Is Separate from Me*, the painting depicts the typical “wormlike” visions.

The novel *The Inca* includes a number of descriptions of psychoactive villca use (Peters 1991*).

The Mataco make bags, nets, et cetera, from agave fibers, some of which are dyed using extracts of cebíl bark. The seeds were also formerly used to make armbands.

Medicinal Use

A tea made from cebíl seeds and the root of *Polypodium* spp. is consumed for digestive problems. The seeds are drunk in **chicha** as a remedy for fever, melancholy, and other mysterious afflictions. In **honey**, they are used as a diuretic or to promote female fertility (von Reis Altschul 1972, 38). At the same time, cebíl is also regarded as an abortifacient (78). The resin of the variety *colubrina* is used like gum arabic (see *Acacia* spp.) and is said to be effective in the treatment of coughs. Sundried seeds of the variety *colubrina* are ingested in **snuff** form to treat constipation, chronic influenza, and headaches (78).

The Mataco use a decoction of the fresh (i.e., still green) cebíl pods as a wash for the head to treat headaches.

Constituents

The seeds contain tryptamines, primarily **bufotenine**. Some varieties contain only bufotenine (Pachter et al. 1959*). One species described for Argentina, so-called *Piptadenia macrocarpa* (= cebíl), contains bufotenine (Fish and Horning 1956). Other analyses found that samples of seeds from *Piptadenia macrocarpa* contained 5-MeOMMT, DMT, DMT-*N*-oxide, bufotenine, and 5-OH-DMT-*N*-oxide; seeds from “*Piptadenia excelsa*” contained DMT, bufotenine, and bufotenine-*N*-oxide, while seeds from “*Piptadenia colubrina*” contained only bufotenine (Farnsworth 1968, 1088*). Old samples of seeds were found to contain only 15 mg/g of bufotenine (de Smet and Rivier 1987).

According to an as yet unpublished analysis by Dave Repke, freshly harvested and quickly dried seeds from trees in northeastern Argentina (Salta) contain primarily bufotenine (over 4%) and an additional alkaloid (perhaps serotonin), but no other tryptamines or alkaloids. The same chemist found 12% bufotenine (!) in one of the samples (per oral communication from C. M. Torres).

Whether the seedpods or root cortex contains tryptamines has not yet been investigated. The ripe seedpods do contain some bufotenine.

Effects

The effects of cebíl snuff last for some twenty minutes and consist of profound hallucinations that are often in black and white, less frequently in color. These are not, or are only rarely, geometrical but are, rather, very flowing and decentralized. They are clearly reminiscent of the depictions of the Tiahuanaco culture.

When smoked, cebíl seeds also produce hallucinogenic effects that are very pronounced for approximately thirty minutes and that disappear completely within two hours. Because of the short duration of these effects, cebíl is an ideal drug for shamanic diagnoses. The effects begin with a sensation of bodily heaviness. After some five to ten minutes, visual hallucinations begin to appear when the eyes are closed. These either appear as phosphenes (entoptic or endogenous images of light that the “inner eye” sees in the form of characteristic patterns) or flow together in worm- and snakelike manners. Symmetrical and crystallographic hallucinations are less common. In rare cases, there may be strong visions having the character of reality (experiences of flying, journeys into other worlds, transformations into animals).

The false villca tree, often mistaken for *Anadenanthera colubrina*, is actually an acacia (*Acacia visco*). (Photographed in San Pedro de Atacama, northern Chile)

Representation of a shamanic or ritual hunt on a Mochican ceramic vessel (ca. 500 C.E.). The stag is “hanging” in a villca tree (*Anadenanthera colubrina*), which can be clearly recognized by its seedpods and pinnate leaves.

Bufotenine

Experience has shown that before smoking or sniffing cebíl, it is useful to chew coca (*Erythroxylum coca*) (or sniff some **cocaine**). This helps the visions become clearer and also obviates possible side effects.

Commercial Forms and Regulations

None

An experience with cebíl: “We darkened the room of our bungalow in the rainforest. The powder was relatively simple and unproblematic to sniff into the nose. It does not burn like others (e.g., *Anadenanthera peregrina*). The slight prickling in the nose is tolerable.

“At first I noticed how my body, especially the arms and legs, became heavy like lead; but the body sensation was warm and very pleasant (it was somewhat reminiscent of the initial effects of ketamine). I closed my eyes and waited for the coming effects with anticipation. After about five minutes, dancing phosphenes swirled before my eyes. The hopping and jumping points of light joined together into flowing forms and structures. It was as if the floodgates of the universe had been opened: Flowing patterns crashed into my field of view. From every point flowed streams and rivers of threads of light that quickly intertwined in and throughout one another, always in and throughout one another. And all this with incredible speed.

“Flowing patterns, yes, exactly the patterns that shoot out of the head of the god of Tiahuanaco! I then knew that it must have been this exact same snuff that had provided the inspiration for the artists of Tiahuanaco.

“The quickly changing patterns turned into a chaotic river of spermatozoa. They twisted and darted and shot in every direction, as if they—almost aggressively—wanted to fertilize the entire universe. After this appeared geometric figures that came forth from the depths of space and fell tunnel-like into my field of view.

“Up until now, I had not seen any colors. But now I had visions in pale color. The speed of the visions decreased, and suddenly they were over.

“As I opened my eyes in the darkened room, the brightness around me suddenly changed. For a moment I felt a trace of nausea. I had to burp, and then everything was wonderful. It was a truly new visionary experience. The effects lasted for a total of about 25 minutes.”

Anadenanthera peregrina (Linnaeus) Spegazzini

Cohoba, Yopo

Family

Leguminosae (Legume Family); Mimosoideae Section: Eumimoseae

Forms and Subspecies

There are two geographically isolated varieties: *Anadenanthera peregrina* var. *peregrina* Altschul: northern Brazil to the Antilles

Anadenanthera peregrina var. *falcata* (Benth.) Altschul: South America (in Brazil, only in the east)

History

Archaeological remains of seeds that were definitely used in ritual contexts have been found in Brazil, Chile, Colombia, Peru, Haiti, the Dominican Republic, and Puerto Rico (Ott 1996).

The **snuff** known as *cohoba*, which is made from *Anadenanthera peregrina*, was mentioned several times in early colonial sources, e.g., by Fra Bartolomé de las Casas (Safford 1916). In the early sixteenth century, Gonzalo Fernández de Oviedo y Valdés was the first to note that the powder was obtained from the seeds of a tree belonging to the legume family (Torres 1988). The island of Cuba

was apparently named after *cohoba*.

The first botanical description of the tree was provided by Linnaeus in 1753.

Distribution

The tree thrives only in the tropics, where it prefers drier locations such as savanna-like regions (grasslands), open plains, and fallow lands. It grows best in sandy and/or clay soils. In South America, it occurs naturally in Brazil, Guyana, Colombia, and Venezuela. The tree had already been planted on some Caribbean islands prior to the arrival of the Spanish, and it now grows wild in these areas. The relatively rare variety *falcata* occurs only in southern Brazil and Paraguay.

It is possible that these *Anadenanthera* grow even in Belize, in Central America (per oral communication from Rob Montgomery).

Cultivation

The ripe, dried seeds are easy to germinate and plant. The tree requires poor and relatively dry soil. It can be started in the moist tropics but quickly dies.

Appearance

This tree grows only to a height of 3 to 18 meters. It has a gray to black bark that is often covered with conical thorns. The leaves are finely pinnate and up to 30 cm long. The flowers are small and globose. The leathery, dark brown seedpods, which can grow as long as 35 cm, contain very flat and roundish seeds that are reddish brown in color and 1 to 2 cm across.

The tree is easily confused with *Anadenanthera colubrina*.

A device for sniffing niopo powder from *Anadenanthera peregrina*, used by the Guajibo Indians of the Upper Orinoco, Venezuela. (From Hartwich, *Die menschlichen Genußmittel*, 1911)

The bark of *Anadenanthera peregrina* is often warty in nature. This provides an easy way to distinguish it from the closely related and very similar *Anadenanthera colubrina*.

The typical finely pinnate leaves of *Anadenanthera peregrina*.

Pods and seeds of *Anadenanthera peregrina*, collected in Guyana.

Psychoactive Material

- Seeds
- Seedpods (with seeds)
- Bark (used by the Yecuana; von Reis 1991)

Preparation and Dosage

The ripe, dry seeds are usually lightly roasted and then ground into a fine, grayish green powder that is often mixed with an alkaline plant ash or ground snail shells and other additives (e.g., tobacco). The addition of the alkaline substances liberates the alkaloids (Brenneisen n.d.).

The Otomac collect the seedpods, which they then break, moisten, and allow to ferment. These are then mixed with manioc flour (*Manihot esculenta* Crantz) and slaked lime from various species of land snails, kneaded to a paste, and heated over a fire. The dried product is ground into a fine powder before being used as a snuff.

The Maué produce their snuff, which they call *paricá*, from the seeds of the variety *peregrina*, the ashes of an unidentified vine, and the leaves of an *Abuta* (*Abuta* is an **ayahuasca** additive) or *Cocculus* species.

The dosage is usually determined by the sniffing instrument that is used.

The indigenous peoples of the Amazon region knew of the technique of caoutchouc production [from the latex of *Hevea* spp.] long before the arrival of the Conquistadors. The Omogua, for example, used vessels of caoutchouc that they would fill with an inebriating agent [*Anadenanthera peregrina* powder]. A hole was drilled in the bottom, through which they introduced a tube for removing the inebriant and blowing it in one another's nostrils. (Pavia 1995, 137*)

The minimum dosage is approximately 1 g of seeds (when applied nasally). The snuff can be ingested in a series of dosages. The ground seeds are also administered in the form of an **enema**.

Ritual Use

Many tribes use the roasted seeds to manufacture **snuffs** that are used for shamanic purposes and that hunters also ingest to locate their prey. The Taino made great use of this powder during their healing rituals and tribal celebrations (Rouse 1992; Torres 1988). The shamanic use of both varieties of this species has been documented for the following tribes: Arawak, Guajibo, Cuiva-Guajibo, Maipure, Otomaco, Taino, Tukano, Yanomamö/Waika, Yecuana, Ciguayo, Igneri, Chibcha, Muisca, Guane, Lache, Morcote, Tecua, Tunebo (= Tama), Achagua, Caberre (Cabre), Cocaima, Piapoco, Arekana, Avane, Bainwa, Bare, Carutana, Catapolitani, Caua, Huhuteni, Ipeca, Maipure, Siusi, Tariana, Airico, Betoí, Jirara (Girara), Lucalia, Situfa (Citufa), Otomac, Pao, Saruro, Sáliva, Yaruro, Chiricoa, Puinave, Guaipunavo, Macú, Guaharibo, Shirianá, Yecuana, Omagua, Mura, Maué, Mundurucú, and various tribes in Paraguay.

“‘Piptadenia peregrina,’ he said in a monotone voice, ‘that is the key.’ . . .”

REINMAR CUNIS *ZEITSTURM* [TIME STORM]
(1979, 205)

Artifacts

The Caribbean Taino carved figures of gods from the hard and durable wood of *Anadenanthera* (von Reis 1991). Numerous objects of snuff paraphernalia have been discovered in the Dominican Republic (Alcina Franch 1982). One of these is a sniffing tube in the form of a naked woman who is spreading her legs and wearing a death's-head. In order to use this tube, you must place the skull against your nose. The other end, the opening of the vagina, is used to take in the snuff (Rouse 1992).

A recording of a snuff ritual with *epená* was published under the name *Hekura—Yanomamö*

Shamanism from Southern Venezuela (London: Quartz Publications, !QUARTZ004, 1980).

Donna Torres has produced a painting of *Anadenanthera peregrina* (published on the book cover of Ott 1995*).

A science-fiction story by Reinmar Cunis (1979) entitled *Zeitsturm* [Time Storm] involves journeying between realities, made possible by tryptamine derivatives from “*Piptadenia peregrina*.”

Medicinal Use

Both varieties produce a resin that resembles gum arabic (see *Acacia* spp.) in appearance and is used in the same manner. A decoction of the bark of the variety *peregrina* is used to treat dysentery and gonorrhea. The variety *falcata* is used to treat pneumonia.

Constituents

The seeds of both varieties contain the tryptamines *N,N*-DMT, 5-MeO-DMT, and 5-OHDMT (= **bufotenine**) as well as their *N*-oxides. Traces of **β-carbolines** have also been detected (Ott 1996).

The presence of appreciable quantities of bufotenine is characteristic of this species (Stromberg 1954). Only bufotenine could be detected in old seed material (from Spruce’s collection) (Schultes et al. 1977). It is possible that bufotenine may accumulate through the hydrolysis of *N,N*-DMT and 5-MeO-DMT when the seeds are stored.

5-MeO-DMT

β-carboline

The cover of a German science-fiction novel, in which a drug obtained from *Anadenanthera peregrina* plays a central role.

The bark also contains *N*-methyltryptamine, 5-methoxy-*N*-methyltryptamine, and 5-methoxy-*N,N*-dimethyltryptamine (Legler and Tschesche 1963). Another analysis found that the bark contains MMT, 5-MeO-MMT, DMT, and 5-MeODMT (Farnsworth 1968, 1088*). The seedpods also contain DMT.

Effects

When ingested nasally, the snuff induces psychedelic effects and produces multidimensional visions. Experiences of ego dissolution, death and rebirth, transformations into animals, and flying are common. The effects of the snuff last for some ten to fifteen minutes, although aftereffects may be noticeable for up to an hour.

During medicinal and pharmacological experiments, it was difficult to recognize the psychoactive effects (Turner and Merlis 1959).

Commercial Forms and Regulations

None

Areca catechu Linnaeus

Betel Palm

Family

Areceaceae, Palmae (Palm Family); Subfamily Ceroxylinae-Arecineae, Areceae Tribe

Forms and Subspecies

Numerous forms and varieties have been described, although these may represent only local races (cf. Raghavan and Baruah 1958):

Areca catechu f. *communis* (Philippines)

Areca catechu var. *alba* (Sri Lanka)

Areca catechu var. *batanensis* (Philippines)

Areca catechu var. *deliciosa* (India)

Areca catechu var. *longicarpa* (Philippines)

Areca catechu var. *nigra* (Java)

Areca catechu var. *silvatica* (may be the wild form)

Often, the local people give their own names to the “varieties.” These are usually based upon the appearance and size of the seeds and appear to have no botanical relevance. The cultivated palm is likely derived from *Areca catechu* var. *silvatica*.

The people of Sri Lanka make a distinction between the varieties *hamban-puwak*, which has long oval nuts, and *rata-puwak* or *Batavia-puwak*, which produces large round nuts (Macmillan 1991, 427*).

Synonyms

Areca guavaia nom. nud.

Folk Names

Adike, arbor areka, areca, areca nut palm, arecanut tree, arecapalme, arecca, arekapalme, arekpalme, arequero (Portuguese), aréquier, aréquir, arreck, ataykkamaram, avellana d’India, betelnußpalme, betelnut tree, betel palm, buoga, bynaubaum, catechupalme, fobal, fufal (Arabic), fûfal, ghowa, gooroaka, goorrecanut palm, gouvaka (Sanskrit), gurvaca, kamuku, kamunnu, kavunnu (Malayalam), mak, noix d’arec, paan supari, pakku, pakkumaram (Tamil), pan of India, papal (Persian), pinang (Malay), pinangpalme, ping-lang, pinlang, puga, pugah (Sanskrit), puwak, pynan, pynanbaum, sopari (Hindi), supari, surattu supary, tambul, tuuffel (Arabic)

The palm *Chrysalidocarpus lutescens* H. Wendl. [syn. *Areca lutescens* hort. non Bory] is often sold as an ornamental under the name “areca palm” (Bärtels 1993, 39*).

History

The name *areca*, which means “cavalier,” may be derived from the Kanarese word *adeke* or the Malayalam *adakka*. In early Sanskrit works, the palm is referred to as *gouvaka*. It was already mentioned in Jataka and Pali writings. The first description of the palm, however, is purportedly that of Herodotus (ca. 340 B.C.E.). Later, both the palm and the chewing of betel were more or less precisely discussed by many Arabic and European travelers (e.g., Abd Allah Ibn Ahmad, Marco Polo,

Vasco da Gama, Garcia da Orta, Abul Fazal, Jacobus Bontius) in their travel reports. The British traveler R. Knox, in his *Historical Relation of the Island of Ceylon* (London, 1681), was obviously impressed, and he described both the use of the betel nut and its economic significance. The first European pictorial representation of the betel nut is a copperplate engraving by Carolus Clusius in *Aromatum et simplicium aliquot medicamentorum . . . historia* (Antwerp, 1605).

Distribution

Almost all betel palms have been planted by humans. The origin of the assumed wild form has not been fully ascertained, although it may have come from the Sunda Isles or the Philippines (cf. Raghavan and Baruah, 1958). Since it can thrive only in regions with tropical rain forests, it is limited to such areas in Hindustan, Indochina, Pakistan, Sri Lanka (Ceylon), the Maldives, Madagascar, Egypt, East Africa, Arabia, southern China, Taiwan, Indonesia, Malaysia, Fiji, and Melanesia (Stewart 1994, 39*). Betel palms grow wild in Malabar (India).

Cultivation

The betel palm is grown primarily for its seeds (betel nuts), although it is also planted as an ornamental. Avenues lined with betel palms are typical features of most palaces and parks in India.

The betel palm can be grown in a variety of soil types. Cultivation is performed using pregerminated seeds. The saplings need to grow in the shade, as they may otherwise fall victim to the intense tropical sun. It is for this reason that trees that grow quickly and provide shade (e.g., *Erythrina indica* Lam.; see ***Erythrina spp.***) are first planted in betel palm plantations.

The palms bear fruit when they are ten to fifteen years of age. Typically, only the ripe fruits are harvested. One palm can bear fruit for forty-five to seventy years (Raghavan and Baruah 1958, 328). Cultivated betel palms are often infected by fungi, especially *Ganoderma lucidum* (Leys.) Karst. (see “**Polyporus mysticus**”) (Raghavan and Baruah 1958, 330f.).

Appearance

This fan palm can grow as tall as 25 meters and develop a trunk between 30 and 50 cm in diameter. The loculate fronds grow to some 2 meters in length. The male and female flowers are found in spadices located below the leaves. The palm can produce up to three such spadices, each of which yields 150 to 200 fruits. The ovoid fruits, which can be as long as 7 cm in length, contain one brown, reticulate seed (the endosperm, or actual betel nut) that can weigh from 3 to 10 g.

In Europe, the betel plant was once regarded as a species of date palm that is able to make a person “drunk.” Although this botanical illustration is inaccurate, the betel nut itself is depicted as it occurs in nature. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

Betel palms (*Areca catechu*) can attain a stately height.

The tuftlike inflorescence of the betel palm (*Areca catechu*).

Betel “nuts” are actually the seeds of the areca fruit (*Areca catechu*).

Fermented and colored betel nuts from Varanasi (India).

Slicing betel nuts reveals the astonishing, fractal-like structure of their natural inner world.

A typical leaf of *Areca triandra*, the nuts of which can be used as a betel substitute.

The betel palm is easily confused with the Caribbean king palm (*Roystonea regia*; cf. Anzeneder et al. 1993, 33*) and with some species of the genus *Veitchia*, found in the Philippines and Oceania (Stewart 1994, 196*). It is difficult to distinguish from the closely related species *Areca triandra* Roxb. (India) and *Areca vestiaria*.

Psychoactive Material

—Areca nuts (arecae semen, formerly semen arecae, nuces arecae); also known as betel nut, areca nut, noix d'arec, puwag

In Sri Lanka (Ceylon), the seeds of the closely related species *Areca concinna* Thwaites are sometimes chewed as a substitute for the true betel nut (Raghavan and Baruah 1958, 318). In the Philippines, the seeds of another related species, *Areca ipot* (known as *bungang-ipot*), are used as a substitute (Stewart 1994, 40*). The seeds of the palm *Areca laxa* Ham. serve as a substitute on the Andaman Islands, while *Areca nagensis* Griff is used in Bengal and *Areca glandiformis* Lam. and *Calyptrocalyx spicatus* Blume are used on the Moluccas for the same purpose (Hartwich 1911, 529*). In Assam, the seeds of *Gnetum montanum* Mark. [syn. *G. scandens* Roxb. (Gnetaceae)], known locally as *jagingriube*, are chewed as a substitute for areca nuts (Jain and Dam 1979, 54*). In India, the bark of *Loranthus falcatus* L. (Loranthaceae) is used as a substitute for areca nuts and has narcotic effects. The fruits of *Pinanga dicksonii* Blume are also used as an areca substitute in India, while the fruits of *Pinanga kuhlii* Blume are used in the Malay Archipelago for the same purpose (Hartwich 1911, 529*).³⁸

In many areas of India, freshly harvested betel nuts are preferred. In order to maintain their freshness, these may be stored for several months in a vessel full of water. When the nuts dry, they become very hard and can then be chewed only with difficulty. Sometimes, however, even dried betel nuts can be found in the market. These are dried in the sun for six to seven weeks before sale (as so-called *chali* nuts). In Malaysia, cracked betel nuts are smoked with gum benzoin, which imparts to them a pleasant aroma; these are sold in the markets as *pinang ukup* (see **incense**). In addition, whole, ripe, dried nuts (*pinang kossi*); halved, dried nuts (*pinang blah*); smoked nuts (*pinang salai*); and semi-ripened, salted nuts (*pinang asin*) are also sold in the markets.

Sometimes, nearly ripe betel nuts are harvested and boiled in a decoction of betel leaves (*Piper betle* L.); pieces of bark from *Syzygium jambolanum* DC., *Pterocarpus santalinus* L., *Adenanthera pavonia* L., and *Ficus religiosa* L.; and some slaked lime and oils. This lends them a reddish color (from the red sandalwood) and a beautiful luster. Such nuts have a more aromatic taste and remain soft for a longer period of time (Raghavan and Baruah 1958, 332f.).

Occasionally, freshly harvested, tender, unripe nuts are boiled in a solution of lime, dried, and exported. Cut into slices, these nuts are sold under the name *kali* (Macmillan 1991, 427*).

Preparation and Dosage

Betel nuts have their greatest ethnopharmacological significance as the primary ingredient in **betel quids**.

Fermenting the fruits can even produce an areca **wine** (Raghavan and Baruah 1958, 316). Leaves that have been inoculated with beer yeast (*Saccharomyces cerevisiae*) are employed for alcoholic fermentation.

One betel quid contains approximately one-quarter to one-half nut. According to Roth et al. (1994, 141*), the maximal individual dosage is 4 g. Eight to 10 g of powdered seed can be sufficient to produce lethal effects.

A dosage of 2 mg of the isolated main alkaloid, arecoline, produces strong stimulating effects. The individual dosage should not exceed 5 mg.

Ritual Use

The most important ritual use of the betel nut occurs in ceremonies involving **betel quids** (cf. also *Piper betle*).

In Melanesia, betel nuts are considered magical once a magician has uttered an appropriate formula

over them. They then carry the magical power of the words in themselves and can transfer this to a goal (a person, an action, an object). They are often used as carriers of love magic.

In India, the flowers of the betel palm are one of the flowers used as ceremonial offerings. The tree itself is symbolically venerated as Ganesha (Gupta 1991, 79*).

The leaves of the betel palm also have ritual significance. They are used in Buddhist ceremonies and during initiations. On Sri Lanka, watertight bowls are woven from the leaves, and newborn boys are ritually bathed in these.

In Southeast Asia (Indonesia), betel palm leaves are placed before the door of a newlywed couple and attached to their house as a sign of honor (Meister 1677, 57*).

Artifacts

In India, the hard areca nuts are carved into small bottles or containers for storing **incense**.

The palm is occasionally found depicted in Indian and Thai art.

Medicinal Use

In India, betel nuts are administered primarily to dispel tapeworms (Raghavan and Baruah 1958, 338). Betel nuts were also once a popular anthelmintic in Europe, especially in veterinary medicine (Macmillan 1991, 426*; Pahlow 1993, 430*). They also found use in folk medicine for diarrhea and similar ailments.

Betel nuts are used for a variety of purposes in Ayurveda and Unani, the two traditional medical systems of India and its neighboring regions. They are administered to treat digestive problems and nervous disorders. A decoction of them is also esteemed as a tonic and aphrodisiac (especially in combination with other substances) (Raghavan and Baruah 1958, 338). Similar uses of betel nuts can be found in traditional Chinese medicine and in Cambodia. Malay magicians and poisoners use a mixture of betel nuts and opium (see *Papaver somniferum*) to poison and rob their victims.

In Iran, areca nuts are mixed with sugar and coriander and administered to induce labor (Hooper 1937, 86*).

Constituents

The seeds contain various alkaloids (0.3 to 0.6%) of a relatively simple chemical structure: 0.1 to 0.5% arecoline (primary alkaloid), as well as arecaine, arecaine, arecolidine, guvacoline, isoguvacine, and guvacine. Tanning agents (tannins: galotannic acid, gallic acid, D-catechol, phlobatannin), mucilage, resin, carbohydrates (saccharose, galactan, mannan), proteins, saponines, carotene, minerals (calcium, phosphorus, iron), and fat (sitosterol) are also present (Raghavan and Baruah 1958, 335 ff.). When betel nuts are chewed in combination with slaked lime, the alkaloid arecoline is transformed into arecaine.

Recently, *Areca* seeds were discovered to contain four new polyphenolic substances (NPF-86IA, NPF-86IB, NPF-86IIA, NPF-86IIB) that may be able to inhibit a membrane-bound enzyme (5'-nucleotidase) (Uchino et al. 1988).

Effects

Arecoline, the primary alkaloid, is a parasympathomimetic. It has stimulating effects, strongly promotes salivation, and has anthelmintic (worm-killing) properties; it can also induce brachycardia (deceleration of the heartbeat) and tremors. Eight to 10 g of the seed can be lethal, death resulting from cardiac or respiratory paralysis (Roth et al. 1994, 140*). The polyphenolic substances (NPF-86IA, NPF-86IB, NPF-86IIA, NPF-86IIB) have tumor-inhibiting and immune-strengthening effects (Uchino et al. 1988). The oil of areca nuts has antifertility properties (Roth et al. 1994, 140*). An

aqueous extract strengthens the body's own immune system (Raghavan and Baruah 1958, 339). As for the psychoactivity of the pure areca nut:

An inebriating beverage can be produced by allowing the fresh fruits of the betel palm to ferment.

“Its fruits are like nutmegs, when this fruit areca is broken out of its red-yellow mold. It is universally esteemed by the inhabitants of India, from kings to the lowest beggar, because they chew this fruit, both green and dry, smeared with betel flowers and a little lime from shells, more because it is a custom passed down from their ancestors than from necessity.

“And it is true that it imparts a well-scented breath and purple-red lips. It is for this reason that the Portuguese ladies do not wish to kiss any European man, regardless of how disgusting they might not otherwise be, before they have chewed this fruit, or one generally known as betel, claiming that the Dutch or the Germans stink from their throats when they do not chew this fruit.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]

(1677, CH. 8, 1*)

Areca vestiaria is easily mistaken for the betel palm. Its fruits and seed may also contain the stimulating substance arecoline.

The effects of the common areca nut are only slight, resulting at most in a sense of dizziness that is short in duration. However, there are some forms that can have strong toxic effects. The seed of *Areca catechu* L. var. *nigra* from Java (*akar pining hitam*) produces narcolepsy and sedation and can cause death. Other forms have inebriating effects: such as one from Burma known as

“*toung-noo*,” one from the Moluccas known as “*pining-mabok*,” and another from Ceylon. (Hartwich 1911, 528f.*)

Commercial Forms and Regulations

“Since betel is nonaddictive, it does not appear on any of the international lists of addictive drugs” (Roth et al. 1994, 141*). Betel nuts are freely sold and easily available in all the countries of Asia. In Europe, they are occasionally available in pharmacies.

Arecoline

“After a few days, a great festival was to take place. The people came to the festival from near and far. Mongumér-anim [a primeval being, a culture hero] was supposed to kill the pig, but during the night before the festival Mana seduced Monguméranim’s wife. For this reason, he was afraid of Mongumér-anim and would not let his club leave his hands. During the night . . . , when the singing was well

under way, Mana used the opportunity to kill Mongumér-anim. He gave him a blow to the head with a club and then fled. . . . The people mourned Monguméranim. His Nakari [the unmarried girls of his totemic group] wrapped him in eucalyptus bark and placed him in his grave. The next morning, an areca palm had grown from the grave, a beautiful, slender tree that already bore ripe fruit and that had previously been unknown. All of the people came by and admired the tree and tried its nuts. . . . From that time on, it has been customary to chew betel nuts.”

Argemone mexicana Linnaeus

Mexican Prickly Poppy

Family

Papaveraceae (Poppy Family)

Forms and Subspecies

In addition to the common yellow-blooming *Argemone mexicana* L. var. *typica* Prain, there is a white-blooming form that is known as *chicalote* in Mexico and is usually referred to as *Argemone mexicana* L. var. *ochroleuca* Sweet (Martínez 1987, 1050*). Another form that is almost thornless has been described under the name *Argemone mexicana* L. f. *leiocarpa* (Greene) G.B. Ownb. (Lucas 1962, 3; Grey-Wilson 1995, 74*).

There is only one named cultivar, notable for its very large and beautiful flowers (Grey-Wilson 1995, 74*): *Argemone mexicana* L. cv. Yellow Lustre.

Three previously described varieties are now recognized as species in their own rights (Grey-Wilson 1995, 75, 78*):

Argemone mexicana var. *hispida* Wats. = *Argemone munita* Dur. et Hilg.

Argemone mexicana var. *rosea* (Hook.) Reiche = *Argemone rosea* Hook.

Argemone mexicana var. *rosea* Coulter ex Greene = *Argemone sanguinea* Greene

Folk Names

Amapolas del campo (Spanish, “field poppy”), Bermuda thistle, bhatbhamt (Hindi), bird-in-the-bush, brahmadanti (Sanskrit), carbincho, cardo, cardo lechero, cardo santo (Spanish, “sacred thistle”), cardosanto, cardui flava, carhuinchu, carhuinchunca, carquincho, caruancho, chadron béni, chadron mabré, chicallotl, chicalote,⁴⁰ chichicallotl, chichilotl (Aztec), chillazotl, donkey thistle, fischgemüse, fischkraut, flowering thistle, gailshe, gamboge thistle, gold thistle of Peru, guechinichi (Zapotec), h-am (Maya), hierba loca⁴¹ (Spanish, “crazy herb”), infernal fig, ixkanlol (Maya, “yellow flower”), Jamaican thistle, kantankattiri (Malayalam), kawinchu (Quechua), k’í’ix k’an lòl (modern Maya, “prickly yellow flower”), k’í’ix sák lòl (modern Maya, “prickly white flower”), kutiyotti (Tamil),

Mexican poppy, Mexican prickly poppy, Mexican thistle, Mexican thorn poppy, mexikanischer stachelmohn, mihca:da:c (Mixe), mizquitl, pavero messicano (Italian), pavot du mexique, pavot espineux (French), pharamgi dhattura (Hindi), pili katili (Hindi), ponnummattai (Tamil), ponnummattu (Malayalam), prickly pepper, prickly poppy, queen thistle, satayanasi, shate (Zapotec), stachelmohn, stinking thistle, svarnasiri (Sanskrit), teufelsfeige, thistle, thistley-bush, tlamexaltzin (Nahuatl), tsolich (Huastec, “lost”), XaSáokS (Serí), xaté (Tarascan), xicólotl, yellow thistle, zèbe dragon (Creole, “dragon herb”)

History

During the time of the Aztecs, the prickly poppy was known as the nourishment of the dead; souls would refresh themselves on it in the realm of the dead and in the rain-rich paradise (Rätsch 1985). Prickly poppy is mentioned in numerous documents from the colonial period (Sahagun, Hernández, *Yerbas y hechizarias*, etc.) and in Europe was already well known by 1597, when it was described by John Gerard. At the beginning of the twentieth century, Chinese residents of Mexico were said to produce a kind of opium from the prickly poppy that they used as a legal substitute for *Papaver somniferum* (Reko 1938, 94f.*). Today, the dried plant is smoked as a marijuana substitute (see *Cannabis indica*) and aphrodisiac. In India, the plant is called *pharamgi dhattura* because of its psychoactive properties, and it is regarded as a sister of *Datura metel* (Warrier et al. 1993, 169*).

Distribution

The plant is from the American tropics but is now found throughout the world (Franquemont et al. 1990, 89*). It is common in tropical Africa (Lucas 1962) as well as India and Nepal.

Cultivation

Prickly poppy is very easily grown from seed. The seeds may be either simply dispersed in spring or planted in seedbeds. The plant prefers light, sandy soils, but with sufficient sunlight it can adapt to any type of soil (Grubber 1991, 23*). It can tolerate climates that are tropically moist, hot and dry, subtropical, or moderate. Under cultivation, it can thrive for two or more years.

Appearance

This annual plant, which can grow up to 1 meter in height, has several branches and produces a yellowish latex. The bluish leaves are compound and have thorny ends; some are deeply retuse. The flowers, which appear singly, can grow 4 to 6 cm across and have six yellow petals. The four- or six-chambered fruits are heavily thorned capsules that stand erect and are filled with small black seeds. The plants often bear flowers and fruits at the same time. In the tropics, prickly poppy can flower throughout the year.

The Aztec name for the Mexican prickly poppy (*Argemone mexicana* L.) is *chicallotl*, “thorn.” (From Hernández, 1942/46 [Orig. pub. 1615]*)

“And all poisonous herbs are eaten in the Underworld.
And all who go to the Underworld eat prickly poppy [*Argemone mexicana*].
And all that is not eaten here on the Earth is eaten in the Underworld.
And it is said that nothing else is eaten.”

BERNARDINO DE SAHAGUN

IN *EINIGE AUSGEWÄHLTE KAPITEL AUS DEM GESCHICHTSWERKE DES FRAY BERNARDINO DE SAHAGUN* [SEVERAL SELECTED CHAPTERS FROM THE HISTORICAL WORKS OF FRA BERNARDINO DE SAHAGUN] (SELER 1927, 302f.*)

The plant is easily confused with the closely related *Argemone platyceras* Link et Otto (also found in Mexico) and with the North American species *Argemone albiflora* Hornemann and *Argemone polyanthemos* (Fedde) G. Ownb. [syn. *Argemone alba* James]. It is also very similar to the South American (Argentinean) species *Argemone subfusiformis* Ownb. ssp. *subfusiformis*, which in the local Spanish is also known *cardo santo* or *cardo amarillo* (Bandoni et al. 1972). The blue prickly poppy of Hawaii, *Argemone glauca* (Prain) Pope, is also very similar and is practically indistinguishable from the white-flowered *Argemone mexicana* var. *ochroleuca*. The former, however, has leaves that are somewhat bluer in color.

Occasionally, the prickly poppy may be confused with Mary’s thistle, *Silybum marianum* (L.) Gaertn. (Grey-Wilson 1995, 74*).

Psychoactive Material

- Leaves
- Flowers
- Capsules
- Latex, dried

Preparation and Dosage

The dried herbage can be smoked alone or in **smoking blends**. The latex that is tapped from the capsule can be dried and smoked. No information is available about dosages (Gottlieb 1973, 9*). In Urubamba (Peru), *gringos* smoke the dried flowers as a marijuana substitute (Franquemont et al.

1990, 89*). Further research is needed to determine the appropriate dosages.

Mexican Opium?

Chicalote, *el opio mexicano*, or chicalote opium, allegedly results when *Argemone mexicana* is pollinated by *Papaver somniferum*. This “produces capsules which, in an unripe state, do indeed allow one to obtain a product which, like opium, induces self-forgetfulness and total contentment” (Reko 1938, 94*). Botanical experiments have demonstrated that this is not possible and that the idea appears to have sprung from the author’s imagination (Emboden 1972, 63f.*; Tyler 1966, 278*).

Ritual Use

It is not entirely clear whether the Aztecs or any other Mesoamerican peoples used the prickly poppy for psychoactive purposes. Since it was regarded as a nourishment of the dead, it is possible that its consumption or use may have been controlled or prevented; in any case, its use was limited to the priests. It may have been utilized for shamanic journeys into the worlds beyond (Rätsch 1985).

The prickly poppy was a sacred plant of the Aztec rain god Tláloc, who reigned in Tlálocan, the “kingdom of dreams” (Knab 1995, 67*):

The rain was attributed to the rain god, the rain priest. He created, allowed to fall, scattered the rain and the hail, enabled the trees, the grass, the maize to blossom, sprout up, become green, burst open, grow. Moreover, he was also said to be responsible when people drowned in water or were killed by lightning.

And he was adorned in the following manner: a thick mask of soot over his face, his face painted with liquid cautschuk, he is smeared with soot; his face is spotted with a paste from the seeds of the prickly poppy, he wears the raiment of the dew, he wears the garb of the fog, he bears a crown of heron feathers, a neckband of green gems, he wears sandals of foam, and bells, he has white rushes for hair. (Sahagun, Florentine Codex 1: 4*)

Tláloc was also associated with two other psychoactive plants: *iztauhiatl* (*Artemisia mexicana*) and *yauhtli* (*Tagetes lucida*; see *Tagetes* spp.) (Ortiz de Montellano 1980).

The Mexican prickly poppy (*Argemone mexicana*) was one of the sacred plants of the Aztec rain god, Tláloc. (Codex Vaticanus 3773, fol. 23)

The white-blossomed variety of the Mexican prickly poppy (*Argemone mexicana* var. *ochroleuca*).

The typical yellow flower of the Mexican prickly poppy (*Argemone mexicana*) reveals its affinity with the opium poppy.

The North American prickly poppy (*Argemone albiflora*) produces narcotic effects similar to those of its Mexican relative.
(Photographed in the Badlands, South Dakota)

Sacrificial foods that included prickly poppy seeds were prepared for a variety of ceremonies (Sahagun, Florentine Codex 2:21*). The Aztecs used prickly poppy seeds to make a dough that was ground so fine that it became a kind of tar. They used this tar to form an image of their (highest) god Huitzilopochtli. During celebrations in honor of the god, the priest would “kill” this image with a

spear. Its “flesh,” which was called “god food,” was distributed among the worshippers (Sahagun, Florentine Codex 3:1, 2*).

Artifacts

Numerous pre-Columbian sculptures, wall paintings, frescoes, ceramics, and illuminated manuscripts depict the rain god Tláloc (García Ramos 1994). The prickly poppy, however, does not appear to have been portrayed in any of these contexts (cf. *Turbina corymbosa*).

The flower painter Hans Simon Holtzbecker (from Hamburg) painted a botanically correct portrait of the plant for the Gottorfer Codex (ca. 1650) (de Cuveland 1989, table 52*).

Medicinal Use

The medicinal use of prickly poppy juice to treat eye ailments is common and is found, for example, among the Mixe and the Maya (Lipp 1991, 187*; Roys 1976, 94*). The Serí Indians of northern Mexico prepare a tea from leaves wrapped in linen that they drink for kidney pains. The tea is also said to dispel the “bad” blood that accumulates during birth (Felger and Moser 1974, 427*). The Pima Indians of northern Mexico also use the leaves to treat kidney ailments (Pennington 1973, 221*); a decoction is drunk for difficulties with urination (Eldridge 1975, 316*). The Yucatec Maya utilize the plant for gallbladder disorders (Pulido and Serralta 1993, 47*).

In Peru, a plaster made of prickly poppy is used to treat muscle pains (Chavez 1977, 192*). The inhabitants of many Caribbean islands apply the latex to remove warts and use a decoction for sleeplessness and other sleep disorders. A tea from the leaves is used for asthma (Seaworth 1991, 128*).

In Ladakh, an aqueous extract of crushed leaves is used externally to treat eye diseases and eczema (Navchoo and Buth 1989, 141*). In Uttar Pradesh (India), the latex is combined with oil and cumin powder (*Cuminum cyminum* L.) to make a paste that is applied externally as a treatment for skin diseases, eczema, and flesh worms (Siddiqui et al. 1989, 484*). In Nigeria and Senegal, the prickly poppy is esteemed for its sedative effects. Use of the leaves as a sedative was known even in Europe (Schneider 1974, 1:123*; Watt 1967).

In Hawaii, the yellowish latex of *Argemone glauca* is used to treat toothaches, neuralgia, and ulcers (Krauss 1981, 44*).

Constituents

Although it has often been claimed that **morphine** is present in the prickly poppy, this information is strongly contested (Blohm 1962, 25*). Nevertheless, the entire plant is rich in alkaloids, with a concentration of 0.125% in the roots and stalk (Roth et al. 1994, 142*). The leaves, stalks, and seeds contain the alkaloids berberine and proto-pine (fumarine, macleyine) (Oliver-Bever 1982, 30). The roots also contain coptisine, up to 0.099% α -allocryptopine (= α -fagarine), chelerythrine, and dihydrochelerythrine. The rather toxic sanguinarine and dihydrosanguinarine are also present in the seeds (Bose et al. 1963). Argemonine was isolated from the leaves and capsules and identified as *N*-methylpavine (Martell et al. 1963). The entire plant contains the isoquinoline alkaloids (–)-canadanine, queilantifoline, queleritrine, allocryptatopine, (–)-tetrahydropalmatine, reticuline, sanguinarine, esculerine, and meta-hydroxy(–)-estilopine (Lara Ochoa and Marquez Alonso 1996, 37*).

Effects

Little is known about the plant’s psychoactive effects: “The seeds have a cannabis-like effect and the herb, juice and flowers are reputed to be narcotic in many countries” (Oliver-Bever 1982, 30). There

are increasing reports from Mexico of aphrodisiac and euphoriant effects after smoking the dried herbage. The thickened latex has induced potent narcotic effects and delirium.

Commercial Forms and Regulations

The seeds are occasionally available in nurseries or ethnobotanical specialty shops. The plant is not subject to any regulations or legal restrictions.

“The prickly poppy is so full of sharp and poisonous thorns that a person who has one of these stick in his throat will doubtlessly go directly to Heaven or to Hell.”

JOHN GERARD *THE HERBALL*
(1597)

“The four of us smoked [the prickly poppy] and did more than just good to ourselves. As the stick was making its second round, an agreeable state of inebriation began in me. My head was blown free, my body was pleasurably warm, and I could feel how my blood whipped through its canals. The circle of friends gave me additional comfort, in particular as they appeared in a special glow in the evening sun. I found myself among beloved people. This feeling did not search long for an expression, but found one with gentle and yet rapid speed. My eyes lost their focus, and all of my other senses were stimulated in the most delicious manner. Even after the time of the bodies, the senses long remained in that fantastic state in which they are forbidden to perceive all those obscenities, to name all those realities, that we normally do. I found it difficult to steer my steps through the streets, to use fork and knife appropriately at the table, to enjoy the wine from a glass. The shortly measured sleep of this night—not much more than four hours—allowed us to experience the morning in complete and rested freshness.”

Argyreia nervosa (Burman f.) Bojer

Baby Hawaiian Wood Rose, Silver Morning Glory

Family

Convolvulaceae (Morning Glory Family)

Forms and Subspecies

There may be an African variety.

Synonyms

Argyreia speciosa (L. f.) Sweet *Convolvulus speciosus* L. f.

Folk Names

Baby Hawaiian woodrose, bastantri (Sanskrit), chamang-pins-dansaw, elefantenwinde, elephant creeper, Hawaiian baby woodrose, hawaiianische holzrose, Hawaiian woodrose, holzrose, jamangpi-danok, jatapmasi, marikkunni, marututari, mile-a-minute, miniature wood-rose, monkey rose, samandar-ka-pat (Hindi), samudrappacca, samudrasos, samuttirappaccai (Tamil), samuttirappalai, silberkraut, silver morning glory, soh-ring-kang, vrddhadarukah (Sanskrit), woodrose, woolly morning glory

Argyreia nervosa is often confused with *Ipomoea, tuberosa* L.⁴² [= *Merremia tuberosa* (L.) Rendle; syn. *Operculina tuberosa* (L.) Meissn.], which is also known and sold under the name “Hawaiian wood rose.” Its Hawaiian name is *pili-kai*.

History

The plant is originally from India, where it has been used medicinally since ancient times. It must have been introduced into Hawaii at a very early date, for its “home” now lies in the Pacific Islands. We know of no traditional use as an entheogen. The discovery that the wood rose is a potent psychedelic is a result of phytochemical research (Shawcross 1983).

Distribution

The baby Hawaiian wood rose is found throughout India and on Sri Lanka at altitudes of up to 900 meters. It is common in Uttar Pradesh (India), both in the wild and in cultivation. The plant is part of the indigenous flora of Australia and also occurs in Africa. It is now planted in all tropical regions as an ornamental or an inebriant (Bärtels 1993, 214*).

Cultivation

The plant is easily grown from seed. These are either planted after having been germinated or placed in germinating pots. The baby wood rose requires a great deal of water and a warm, preferably tropical climate. Unfortunately, when grown as an indoor plant, it almost never develops flowers (and therewith no seeds). It can also be propagated through cuttings (Grubber 1991, 33*).

Appearance

This vigorous perennial vine, which can climb as high as 10 meters, produces a latexlike sap in its

cells. The opposite petiolate leaves are cordate and can grow up to 27 cm in length. Their undersides are covered with hairs and have a silvery appearance (hence the name silver morning glory). The violet- or lavender-colored flowers are funnel shaped and attached to cymes. The sepals are also covered with hairs. The roundish fruits are berry shaped and contain smooth brown seeds. Each seed capsule contains from one to four seeds (one dosage).

The genus *Argyreia* consists of some ninety species (Bärtels 1993, 214*), many of which are easily confused with *Argyreia nervosa*. It is also easily mistaken for the vine *Calystegia sepium* (L.) Brown. It is sometimes even confused with the Hawaiian wood rose *Merremia tuberosa*.

“It struck me that I had remained in the real world during the wood rose session [14 seeds], whereby I understood it much better. As a result, while many of the interesting aspects of a regular trip had remained out of reach (strange worlds, adventures . . .), the thing had not been nearly as strenuous. If you do not leave the real world, then you will not have any difficulties integrating yourself back into it.”

KRIK, DESCRIBING AN *ARGYREIA NERVOSA* EXPERIENCE

IN *PSYCHOAKTIVE PFLANZEN* [PSYCHOACTIVE PLANTS] (SCHULDES 1995, 98*)

Psychoactive Material

—Seeds

—Roots

Preparation and Dosage

Four to 5 g represent a good starting dosage (Ott 1993, 140*). Generally, four to eight seeds (corresponding to approximately 2 g) are considered sufficient to produce an LSD-like experience (Gottlieb 1973, 17*). Thirteen or fourteen seeds are given as a maximum dose. The seeds should be ground before use (Ott 1979, 58*) and can be washed down with water. The seeds can also be chewed thoroughly (Jackes 1992, 13*). The highest dosage that has been reported in the literature is fifteen seeds (Smith 1985).

The seeds are also used in a preparation known as Utopian bliss balls. These consist of five *Argyreia* seeds, damiana herbage (*Turnera diffusa*), ginseng root (*Panax ginseng*), fo-ti-tieng (*Centella asiatica*; cf. **herbal ecstasy**), and bee pollen.

The dosage for *Merremia tuberosa* is also given as four to eight seeds (Gottlieb 1973, 18*); the psychoactivity of this plant, however, is uncertain (Schuldes 1995; cf. Grierson 1996, 88).

Ritual Use

To date, we know of no traditional use of this psychoactive plant (Brown and Malone 1978, 14*). The baby Hawaiian wood rose is a possible candidate for the **soma** plant, which was described as a vine.

It is unknown whether the shamanic Huna religion used the seeds as entheogenic, magical, or medicinal agents, although this is possible. In Hawaii, poor individuals who were unwilling or unable to pay the exaggerated black market prices for Hawaiian marijuana (*Cannabis indica*) used and still use the seeds as an inebriant (Brown and Malone 1978, 15*; Emboden 1972*). In contrast, the plant does not appear in the traditional ethnobotany of Hawaii (cf. Krauss 1993).

Today, the seeds are used in the white Australian drug scene as psychedelic agents. It is not known whether the Aborigines ever used them. In the Californian subculture, the seeds as well as preparations made with them are used in sexual magical rituals à la Crowley.

Artifacts

None

Medicinal Use

The plant has been used in Ayurvedic medicine since ancient times. The root is regarded as a tonic for the nerves and brain and is ingested as a rejuvenation tonic and aphrodisiac and to increase intelligence. It is also prescribed for bronchitis, cough, “seminal weakness,” nervousness, syphilis, diabetes, tuberculosis, arthritis, and general debility (Warrier et al. 1993, 1:173*). The baby Hawaiian wood rose is also used in the folk medicine of Assam (Jain and Dam 1979, 53*). Many *Argyreia* species, e.g., *Argyreia pilosa* Arn., also find use in Indian folk medicine as febrifuges (Bhandary et al. 1995, 153*).

The tropical climber *Calystegia sepium* is often mistaken for the wood rose (*Argyreia*); the seeds of *Calystegia* also appear to contain psychoactive substances. (Photographed in Palenque, Mexico)

The inflorescence of the baby Hawaiian wood rose (*Argyreia nervosa*). (Photographed on Oahu, Hawaii)

The effects of the Hawaiian wood rose (*Meremmia tuberosa*) are said to be similar to those of *Argyreia nervosa*. (Photographed on Oahu, Hawaii)

The seeds of *Argyreia nervosa* are rich in psychoactive ergot alkaloids. (Photograph: Karl-Christian Lyncker)

Constituents

The seeds contain 0.3% **ergot alkaloids** and are thus the most potent of all vine drugs (Hylin and Watson 1965). The ergot alkaloids agroclavine, ergine, isoergine (= isolysergic acid amide), chanoclavine-I and -II, racemic chanoclavine-II, elymoclavine, festuclavine, lysergene, lysergol, isolysergol, molliclavine, penniclavine, stetoclavine, isosetoclavine, ergometrinine, lysergic acid- α -hydroxyethylamide, isolysergic acid- α -hydroxyethylamide, and ergonovine (ergometrine) have been demonstrated to be present (Brown and Malone 1978, 15*; Chao and Der Marderosian 1973b, 2436f.). Chanoclavine-I is one of the principal constituents not just in *Argyreia nervosa* but also in most species of *Argyreia* as well as in other representatives of the Family Convolvulaceae. The overall alkaloid composition is reminiscent of that of *Turbina corymbosa*. The related vine *Stictocardia tiliifolia* (Desr.) Hallier f. from Panama also contains large quantities of ergot alkaloids (ergine, chanoclavine-I, chanoclavine-II, festuclavine, lysergol, ergometrinine, lysergic acid- α -hydroxy-ethylamide, and ergonovine [ergometrine]) (Chao and Der Marderosian 1973b, 2437).

Effects

Most psychonauts characterize the effects of four to eight seeds as very similar to those of LSD (Smith 1985), that is, entailing typical psychedelic patterns and sensations. Reports describe colorful visions of a mystical nature. The effects typically last for six to eight hours or even longer (Ott 1979, 58*). *Argyreia* is also regarded as an aphrodisiac: "Following ingestion, the user attains a euphoric state which is soon followed by a pleasant tingling throughout the body that can last for several hours" (Stark 1984, 28*). There may also be mild side effects, including nausea, exhaustion, and

subsequent constipation (Jackes 1992, 13*). When taken in high doses, the trip will sometimes begin with intense nausea (Smith 1985).

Commercial Forms and Regulations

The seeds are available in nurseries and are not subject to any additional regulations.

Ariocarpus fissuratus (Engelm.) K. Schum.

False Peyote, Living Rock

Family

Cactaceae (Cactus Family)

Forms and Subspecies

This variable species is divided into two varieties:

Ariocarpus fissuratus var. *fissuratus* (Engelm.) K. Schum.

Ariocarpus fissuratus var. *lloydii* (Rose) Anderson

Synonyms

Anhalonium engelmanni Lem.

Anhalonium fissuratum (Engelm.) Engelm.

Ariocarpus intermedius

Ariocarpus lloydii Rose

Mammillaria fissurata Engelm.

Roseocactus fissuratus (Engelm.) Berger

Roseocactus intermedius

Roseocactus lloydii (Rose) Berger

Folk Names

Chaute, chautle, dry whiskey, falscher peyote, false peyote, falso peyote, hikuli sunamí (Tarahumara, “false peyote”), lebender stein, living rock, living star, pata de venoda (Spanish, “deer paw”), peyote, peyote cimarrón (Spanish, “wild peyote”), pezuña de venado, star cactus, star rock, sternenkaktus, sunami, tsuwíri (Huichol), wollfruchtkaktus

History

This cactus, which is usually referred to as false peyote or dangerous peyote (see *Lophophora williamsii*), was certainly already well known in pre-Spanish times. Colonial sources, however, make no mention of it. Today, it is a sought-after species for many cactus enthusiasts and breeders.

Distribution

This species is found only in southwestern Texas, New Mexico, and northern Mexico.

Cultivation

The plant can be grown from seed; it requires well-draining cactus soil (otherwise, like *Lophophora williamsii*).

Appearance

Ariocarpus fissuratus is a small tuberous cactus that grows only a few centimeters tall. Its nodes end in pointed triangles, which give the plant a starlike appearance. The flower is pink-violet. The furrows of the variety *lloydii* are considerably smaller, so it does not have such a jagged appearance

(Preston-Mafham 1995, 15*).

Ariocarpus fissuratus is easily confused with the closely related *Ariocarpus retusus* Scheidw. The Huichol Indians also refer to the latter species as *tsuwíri*, “bad peyote”; it is known in Spanish as *falso peyote*, “false peyote,” and may have been used as a peyote substitute. Also very similar, with violet or white flowers, is *Ariocarpus kotschoubeyanus* (Lem.) K. Schum., which is found in the Mexican states of Durango, Nuevo León, and San Luis Potosí (Preston Mafham 1995, 16*). This species is also known as false peyote or deer paw (Bravo Hollis and Scheinvar 1995, 63*).

Psychoactive Material

—Buttons (aboveground cactus flesh)

Preparation and Dosage

Unknown; it is apparently eaten while fresh or dried until its effects become noticeable.

It is said that the cactus was formerly used by the inhabitants along the Texas-Mexico border to fortify the maize beer (**chicha**) they called *tizwin*; it purportedly made them “temporarily crazy and uncontrollable” (Havard 1896, 38*).

Ritual Use

If this cactus has any ritual use at all, it is only as a peyote substitute (see *Lophophora williamsii*). The Huichol Indians strongly warn against eating this cactus, for it has the reputation of being associated with sorcery (Furst 1971).

Artifacts

A related species of *Ariocarpus* is depicted on a Laotian stamp.

Medicinal Use

Unknown

Constituents

Both varieties have been found to contain the **βphenethylamines** hordenine and *N*-methyltyramine. The var. *fissuratus* also yielded *N*-methyl-3, 4-dimethoxy-phenethylamine (McLaughlin 1969; Mata and McLaughlin 1982, 95*). *Ariocarpus retusus* contains hordenine, *N*-methyltyramine, *N*-methyl-3,4-dimethoxy-β-phenethylamine, and *N*-methyl-4-methoxy-β-phenethylamine (Braga and McLaughlin 1969; Neal and McLaughlin 1970). Other species of *Ariocarpus* have also yielded hordenine and methyltyramine (Bruhn 1975; Mata and McLaughlin 1982, 95*; Speir et al. 1970).

The blossoming *Ariocarpus trigonus* of Mexico, on a stamp from the Southeast Asian country of Laos.

Hordenine

N-methyltyramine

An *Ariocarpus* button, used as a peyote substitute.

The relatively rare northern Mexican *Ariocarpus fissuratus* is known as false peyote or dangerous peyote.

Effects

The renowned Huichol shaman Ramón Media Silva described the effects as contrasting with the pleasant effects of peyote: “When you eat it, you become crazy; you fall into the canyons, you see scorpions, snakes, dangerous animals, you are unable to walk, you fall, you often fall to your death by falling from the cliffs.”

The effects of *Ariocarpus* are said to be very dangerous, particularly for those who do not possess a strong “Huichol heart” (Furst 1971, 183).

Commercial Forms and Regulations

The cactus (as well as other species of the genus) is available in cactus nurseries. Often, however, it is sold for astronomical prices.

Artemisia absinthium Linnaeus

Absinthe, Wormwood

Family

Compositae: Asteraceae (Aster Family); Antemideae Tribe

Forms and Subspecies

The wild form occasionally differs from the cultivated form. There also are several chemotypes (see “Constituents”).

Synonyms

Absinthium majus Geoffr.

Absinthium officinale Lam.

Absinthium vulgare Lam.

Folk Names

Absint-alsem (Dutch), absinth, absinthe, absinthium vulgare, absinthkraut, agenco, ajenjo, ajenjo común, ambrosia (ancient Greek), apsinthos, arteneil, assenzio vero (Italian), bitterer beifuß, botrys, common wormwood, eberreis, echter wermut, gengibre verde (Spanish, “green ginger”), grande absinthe, green muse, grüne fee (German, “green fairy”), heilbitter, hierba santa (Spanish, “sacred herb”), la fée verte, magenkraut, ölde, rîhân (Arabic), sage of the glaciers, schweizertee, wermôd (Saxon), wermut, wermutkraut, wermutpflanze, wor-mod (Old English), wormod, worm-wood, wurmkraut

History

Wormwood and its qualities were already well known in ancient times. This and other species of *Artemisia* were sacred to the Greek goddess Artemis—hence their name (Vernant 1988). However, it is uncertain whether the early sources used the Greek name *absinthion* as a catch-all term for a number of ***Artemisia* spp.** or even other plants (asters) (Schneider 1974, 1:136ff.*).

In medieval times, the powers of wormwood were praised in Latin hexameter in the *Hortulus* of Walahfried Strabo (ninth century) (Stoffler 1978). Hildegard von Bingen euphorically praised it as “the most important master against all exhaustions” (*Physica* 1.109).

In the sixteenth century, Spanish Jesuits brought the Old World plant, which was known as *hierba santa*, “sacred herb,” to the entire world, particularly Central and South America (Hoffmann et al. 1992, 37*).

In central Europe, the **essential oil** (also known as absinthe oil) was distilled from the plant and mixed with **alcohol**. This drink, known as absinthe, became a fashionable drug, especially in nineteenth-century artistic circles. Chronic use, however, had terrible side effects (brain damage; so-called absinthism) (Schmidt 1915). It is still unclear whether absinthism was due to the thujone or to other ingredients (e.g., heavy metal salts) (Proksch and Wissinger-Gräfenhahn 1992, 363). Because wormwood was an inebriating drug, and because it was also used as an illegal abortifacient (by quack physicians), it was soon banned as a result of “increasing misuse” (Vogt 1981) in France in 1922 (Arnold 1988, 3043) and in Germany in 1923. At about the same time, the “green fairy” (as the

psychedelic drink was called) was also made illegal in Switzerland under threat of severe fines and imprisonment (Rätsch 1996). Today, absinthe cannot be (officially) obtained anywhere.

Since the early 1990s, many Swiss “scene” bars have been selling beverages known as *die grüne fee* (“the green fairy”). These drinks do not contain any genuine and illegal absinthe but consist of other commercial alcoholic beverages. The true green fairy is available only through private channels. No one has been able to explain to me why absinthe became known as the green fairy. One woman conjectured that it might have something to do with the effects, for absinthe is said to carry people away as if they had been enchanted by a fairy. Others suggested that it refers to the often greenish color of the absinthe. One Swiss man informed me that absinthe is the “most psychedelic alcohol there is.”

Distribution

Wormwood is found throughout Europe, North Africa, Asia, and North and South America. Large numbers of the plant grow wild in Valais (Switzerland).

Cultivation

Wormwood is quite easy to grow from its very small seeds. The best method is to sow the seeds in a bed sheltered from the rain and press them a little into the ground. The seeds should be watered with care so that they are not constantly shifted around and their germination disturbed (Grubber 1991, 67*). Wormwood prefers dry soils; it also thrives well on rocky subsoil. Most of the areas in which wormwood is grown for pharmaceutical use are in eastern Europe (Proksch and Wissinger-Gräfenhahn 1992, 360).

Appearance

The perennial, upright, somewhat branched shrubby herb grows to a height of 50 to 100 cm. The finely pinnate, whitish gray leaves are covered on both sides with fine hairs and have a feltlike, silky surface. When crushed, they immediately exude the characteristic aromatic-bitter scent of the essential oil. The spherical, clustery yellow flowers are attached paniculate to the ends of the branches. The flowering lasts from July to September. The stalks wilt in the fall. The root-stock produces new shoots in the spring.

Wormwood (*Artemisia absinthium*) can differ in appearance from one location to another. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“The drinking of absinthe resembles the smoking of cannabis together with the drinking of wine. The secret of the drink lies in the proper proportion of alcohol to thujonene. This leads to a synergistic effect. Absinthe is cannabis in a bottle. I drink it in the traditional manner, with sugar and ice water. But be careful! Strange things happen after the third draft.”

RT/*ABSINTH* (*ENTHEOGENE* 5, 1995, 49)

Artemisia absinthium is easily confused with other members of the genus, including mugwort (*Artemisia vulgaris*) (see ***Artemisia* spp.**). Worm-wood is almost indistinguishable from ***Artemisia mexicana***.

Psychoactive Material

—Aboveground herbage (absinthii herba, herba absinthii, absinthii cacumina florentia, summitates absinthii, wermutkraut)

The percentages of constituents in the plant are highest when it is harvested during the flowering season. The dried herbage should be stored away from light.

Preparation and Dosage

The fresh or dried herbage (it is best to use leaves only from the ends of the twigs) are added to boiling water and allowed to steep for five minutes. One g of dried leaves in 1 cup of hot water represents a single medicinal dosage (Roth et al. 1994, 146*).

Wormwood herbage can also be smoked alone or as an ingredient in **smoking mixtures**; it is also used as an **incense**, e.g., in smudge bundles (cf. ***Artemisia* spp.**).

In ancient times, the plant was already being used to produce medicinal wines:

A wine, the so-called wormwood wine, is also made from it, especially in Propontis and in Thrace, where it . . . is used when fever is lacking. They also drink it in the summer before, for they believe that is wholesome to the health. . . . But the juice of absinthe appears to exert the same effects, except that we do not consider it good to drink, for it is contrary to the stomach and causes headaches. (Dioscorides 3.23)

In ancient China, wormwood was used as an additive to rice wine (cf. **sake**).

In 1797, M. Pernod, a Frenchman who was living in Switzerland at the time, developed the emerald green drink known as absinthe by distilling a preparation of an herb mash of worm-wood, anise (*Pimpinella anisum* L. [syn. *Anisum vulgare* Gaertn.]), fennel, lemon balm (*Melissa officinalis* L.), hyssop, and other herbs (Arnold 1988, 3043). Absinthe definitely has a much more pleasant taste when only the distilled oil of *Artemisia absinthum* is used. Herbal extracts can impart an unpleasantly bitter taste to the liquor.

Absinthe was also produced by macerating the following herbs in a high-proof **alcohol** (brandy or similar spirits, with up to 85% ethanol content) (Albert-Puleo 1978, 69):

Wormwood leaves	<i>Artemisia absinthium</i>
Angelica root	<i>Angelica archangelica</i> L. (cf. theriac) [syn. <i>Archangelica officinalis</i> Hoffm.]
Calamus root	<i>Acorus calamus</i>
Dictamnus leaves	<i>Origanum dictamnus</i> L. [syn. <i>Amaracus dictamnus</i> (L.) Benth.]
Star anise fruits	<i>Illicium verum</i> Hook. f.
Cinnamon bark	<i>Cinnamomum verum</i> Presl.
Peppermint	<i>Mentha piperita</i> L., <i>Mentha</i> spp. (cf. <i>Mentha pulegium</i>)
Hyssop herbage	<i>Hyssopus officinalis</i> L.
Fennel seeds	<i>Foeniculum vulgare</i>

To prepare absinthe, coriander (*Coriandrum sativum* L.), sweet marjoram (*Majorana hortensis* Moench [syn. *Origanum majorana* Boiss.]), nutmeg (***Myristica fragrans***), marjoram (*Origanum vulgare* L., *Origanum* spp.), chamomile (*Chamomilla recutita* (L.) Rauschert [syn. *Matricaria chamomilla* L.]), parsley (***Petroselinum crispum***), juniper (*Juniperus communis* L.; cf. ***Juniperus recurva***), and spinach (*Spinacia oleracea* L.) have also been used (Pendell 1995, 103*).

Dale Pendell, one of the last of the Beat poets, developed a recipe of his own that induces profound psychoactive effects:

30 g Wormwood leaves (*Artemisia absinthium*)
8.5 g Hyssop herbage (*Hyssopus officinalis*)
1.8 g Calamus root (***Acorus calamus***)
6.0 g Lemon balm leaves (*Melissa officinalis*) 30 g Anise seed (*Pimpinella anisum*)
25 g Fennel seed (***Foeniculum vulgare***)
10 g Star anise fruits (*Illicium verum*)
3.2 g Coriander seeds (*Coriandrum sativum*)

Found seldom in the wild, wormwood (*Artemisia absinthium*) is an ancient European medicinal and inebriating plant. (Photographed in Valais, Switzerland)

Lightly crush the herbs and place them in a vessel that can be sealed. Add 800 ml of 85 to 95% **alcohol**. Allow the vessel to stand closed for a week, shaking it slightly from time to time. Then add 600 ml of water and allow the entire contents to macerate for an additional day. Pour off the liquid and squeeze the remaining fluid out of the herbs and into the extract. The herbs can then be added to vodka or another type of spirits and squeezed once more (Pendell 1995, 112*).

Contemporary (Swiss) absinthe recipes are kept secret. The wormwood is distilled together with other herbs. The color may be clear, greenish, or yellowish. The taste is strongly reminiscent of anisette or Pernod. Absinthe is diluted with water prior to consumption (approximately 1:1). The resulting mixture is milky-cloudy.

An absinthelike drink named *yolixpa* (Nahuatl, “in the view of the heart”) is distilled in Puebla (Mexico) and drunk ritually (Knab 1995, 219*). It is produced from *aguardiente* (sugarcane spirits; cf. **alcohol**) to which such herbs as *Artemisia mexicana* have been added. Absinthelike love drinks made of alcoholic spirits and the appropriate herbs were once produced in Switzerland as well (Lussi 1997).

German wormwood wine⁴⁵ contains only trace amounts of the essential oil (Fühner 1943, 239*).

Ritual Use

In ancient times, the name *artemisia* (which was derived from that of the goddess Artemis, the sister of Apollo and the god of healing) was primarily used to refer to wormwood, mugwort, and related species (cf. *Artemisia spp.*).⁴⁶ Unfortunately, very few ancient texts have come down to us that are able to cast light upon the connection between these plants and the virgin goddess. The Greek word *artemisia* means “intactness,” a clear reference to the chasteness of the goddess, who, as the mistress of wild animals, functions as a mixture of Amazon, witch, and shamaness. In ancient Greece, Artemis was revered as the patron goddess of virgins. In the ancient Orient, she was regarded as the ruler of the Amazons. During the Italian Renaissance, she became Diana, the witch goddess. In spring, during the time of the full moon, ecstatic and orgiastic Artemis festivals were held to honor the goddess. As

part of these festivities, the goddess was symbolically consumed in the form of wormwood and mugwort. In Laconia, boisterous Artemis festivals were held that featured obscene activities, wild dances, travesties, and masks. The men would wear women's masks and the women would strap on phalluses (Giani 1994, 89*). It appears that these festivals were actually mystery rites and fertility rituals.

Artifacts

Absinthe was a legendary drug among artists and Bohemians at the end of the nineteenth century (Conrad 1988). It was popularized primarily through the absinthe pictures of the Parisian painters Henri de Toulouse-Lautrec (1864–1901) and Édouard Manet (1832–1883). The manic-depressive painter Vincent van Gogh (1853–1890) appears to have been addicted to absinthe. His paintings, especially those in which brilliant yellow tones predominate (the renowned “Van Gogh yellow”), are good representations of the perceptual changes caused by thujone (Arnold 1988). Pablo Picasso also helped immortalize absinthe (Adams 1980). Paul Gauguin even took an ample supply of absinthe with him when he traveled to Tahiti. Alfred Jarry referred to absinthe as “holy water” (Pendell 1995, 110*).

Absinthe was also a source of literary inspiration for such writers as Arthur Rimbaud, Ernest Dowson, Charles Cros, H. P. Lovecraft, Charles Baudelaire, Oscar Wilde, Jack London, Ernest Hemingway, Gustave Kahn, Victor Hugo, Alfred de Musset, and Paul Verlaine (Conrad 1988; Pendell 1995: 103ff.*). These authors have left us with a number of poems praising absinthe.

Medicinal Use

In ancient Egypt, wormwood was commonly used as a remedy, an aromatic substance, and an additive to **wine** (cf. *Vitis vinifera*) and **beer** and to dispel worms and to treat pains in the anal region. Today, wormwood is still used in Yemen to alleviate the pains associated with parturition (Fleurentin and Pelt 1982, 102f.*).

In European folk medicine, wormwood is one of the most important gynecological agents for abortion and to induce menstruation and labor. In tea form, it is consumed primarily for stomach pains, lack of appetite, feelings of fullness, gallbladder problems, vomiting, and diarrhea (Pahlow 1993, 339*).

In homeopathy, absinthium is used in accordance with the medical descriptions to treat such ailments as epilepsy and nervous and hysterical spasms (Pahlow 1993, 340*).

Constituents

Wormwood contains large quantities of bitter substances (absinthine) and an **essential oil** that is rich in thujone. The four primary components of the essential oil are (+)-thujone (= α -thujone), cis-epoxyocimene, trans-sabinylacetate, and chrysanthenylacetate. Wormwood develops a variety of chemotypes; for this reason, the composition of the essential oil can vary considerably. Any one of the four primary components can dominate, depending upon the location where the herb originated. For example, (+)-thujone dominates in altitudes of up to 1,000 meters (Proksch and Wissinger-Gräfenhahn 1992, 360). Thujone has a molecular symmetry not unlike that of **THC** (Castillo et al. 1975).

“Use it to help yourself,
and boil the bitter green of the woody wormwood;
then pour the juice from spacious bowls
And wash the highest part of the head with it.
When you have washed the fine hairs with this brew,
then remember to lay thereon,
bundles of leaves tied together,

and wrap a snug bandage around the hair after the bath. Before too many hours have passed in the course of time, you will be amazed by this agent and by all of its other powers.”

WALAHFRIED STRABO

HORTULUS 9

“[T]he use of psychedelic *Artemisia* preparations combined synergistically with the lunar effect would have facilitated the ecstatic and orgiastic rites of *Artemisia*.”

MICHAEL ALBERT-PULEO

“MYTHOBOTANY, PHARMACOLOGY, AND CHEMISTRY OF THUJONE-CONTAINING PLANTS AND DERIVATIVES” (1978, 68)

In addition to the essential oil, the herbage also contains sesquiterpene lactones, glycosides of camphor oil, tanning agents, and quercetin (cf. *Acacia* spp., *Psidium guajava*, *Vaccinium uliginosum*, *kinnikinnick*) (Proksch and Wissinger-Gräfenhahn 1992, 361).

Effects

The extremely bitter wormwood tea has been demonstrated to soothe the stomach (Hoffmann et al. 1992, 37*). The pharmacological effects of thujone, which is chemically related to camphor (see *Cinnamomum camphora*) and pinene, are very similar to those of **THC** (Castillo et al. 1975). The literature contains frequent reports of hallucinations as well as of spasms and epileptic-like seizures following consumption of absinthe (Arnold 1988, 3043; Schmidt 1915; Walker 1906).

Because of the presence of thujone, a potent psychoactive substance, absinthe liquor is much stronger than other types of alcoholic beverages and produces different effects (cf. **alcohol**):

The absinthe did indeed have inebriating effects upon me, but these were quite different than with “normal” schnapps. The stimulant effects of absinthe were quite strong, it woke me up and also kept me awake for a long time. I was partially bathed in aphrodisiac sensations, and I partially flowed in that direction. As the effects increased, I had the sensation that I was floating away. It was like the kiss of the green fairy. —Unfortunately, the next day the head was in as much pain as the inebriation had been delightful during the previous evening. I had never before experienced such a brutal hangover. (Rätsch 1996, 286)

A line of **cocaine** is said to be a very effective treatment for the torments of an absinthe headache.

In comparison to absinthe, the effects of the herbage when smoked are quite mild, producing only a slight euphoria.

Commercial Forms and Regulations

In central Europe, wormwood herbage is officinal (*DAB10*, *Helv. VII*, *ÖAB90*, *BHP83*); the minimum

amount of essential oil must be 0.2% (Proksch and Wissinger-Gräfenhahn 1992, 362). The herbage is sold without restriction; only absinthe is illegal. However, we find the same thing occurring here as with other instances of legal proscriptions, for the illegal substance continues to be distilled in underground circles. Today, absinthe is banned around the world, but it is still being illegally produced in some of the German-speaking regions of Switzerland according to old, traditional recipes. Absinthe connoisseurs pay precious little attention to the fact that the substance is severely restricted. In Switzerland, absinthe was made illegal primarily because it was being used (or abused) to terminate pregnancies. Today, anyone caught distilling absinthe illegally faces a fine of 100,000 Swiss francs (Rätsch 1996).

Artemisia mexicana Willdenow et Spreng.

Mexican Wormwood

Family

Compositae: Asteraceae (Aster Family); Antemideae Tribe; Abrotanum Section

Forms and Subspecies

Today, *Artemisia mexicana* is usually regarded as a subspecies of the North American western mugwort (Argueta et al. 1994, 628*; Lee and Geissman 1970; Ohno et al. 1980, 104; Pulido Salas and Serralta Peraza 1993, 16*): *Artemisia ludoviciana* Nutt. ssp. *mexicana* (Willd.) Keck (cf. ***Artemisia* spp.**). The plant also has one variety: *Artemisia mexicana* var. *angustifolia* (Mata et al. 1984).

Synonyms

Artemisia ludoviciana ssp. *mexicana* (Willd.) Keck

Artemisia vulgaris ssp. *mexicana* (Hall.) Clem.

Folk Names

Agenjo del país, ajenjo, ajenjo del país, altamisa, altamiza, altaniza, ambfe (Otomí), artemisia, azumate de puebla, cola de zorillo, (“little tail of the fox”), ensencio de mata verde (“incense of the green bush”), epazote de castilla, estafiate,⁴⁷ estaphiate, estomiate, green wormwood, guietee, guitee (Zapotec), haway, hierba de San Juan (Spanish, “Saint John’s herb”), hierba maestra (Spanish, “master herb”), hierba maistra, incienso verde (Spanish, “green incense”), istafiate, istafiatl, ixtauhyatl (Aztec), iztauhiatl, iztauhyatl (Nahuatl), kamaistra (Popoluca), kaway si’isim, Mexican wormwood, mexikanischer beifuß, mexmitzi (Otomí), osomiate, quije-tes (Zapotec), ros’sabl’i (Rarámuri), si’isim (Maya), te ts’ojol (Huastec), tlalpoyomatli (Aztec), tsakam ten huitz (Huastec), tsi’tsim (Yucatec), xun, zizim

History

The Aztecs and other Indians of Mesoamerica were already using Mexican wormwood for ritual and medicinal purposes in pre-Columbian times. Today, the prime significance of the plant is in folk medicine. In Mexico, the herbage is often smoked as a marijuana substitute (cf. ***Cannabis indica***).

The first European to describe Mexican worm-wood and compare it to its European counterpart was the Franciscan priest and book burner Diego de Landa (1524–1579).

Distribution

The plant occurs in both the dry and warm regions of Mexico (the Valley of Mexico, San Luis Potosí, Veracruz, Chihuahua) and the Yucatán Peninsula (Martínez 1994, 134*). It is also said to occur in Arizona and New Mexico (Ohno et al. 1980, 104).

Cultivation

See *Artemisia absinthium*.

Appearance

Mexican wormwood, which can grow as tall as 1 meter in height, is so similar to the European species that even experts can have difficulty distinguishing the two. Some botanists and ethnobotanists believe that it is a variety or subspecies of *Artemisia absinthium*.

Psychoactive Material

—Herbage without the roots

—Roots

Preparation and Dosage

The fresh herbage can be added to aguardiente, mescal, tequila (cf. *Agave spp.*), or any other distilled spirits (cf. **alcohol**) for optimal extraction (Martínez 1994, 134*). Mexican wormwood is one of the herbs used to manufacture the absinthelike herbal liquors of Central Mexico known as *yolixpa*.

The dried herbage can be smoked. One to 3 g produces mild psychoactive effects. Three to 4 g of the dried herbage, taken internally, has strong anthelmintic effects (Martínez 1994, 135*). Higher dosages can induce abortions.

Ritual Use

The Aztecs were already using *Artemisia mexicana* as a ritual **incense** in pre-Columbian times:

Tlalpoyomatli, its leaves are smoky, gray, soft; it has many flowers. Incense is made from this plant: it produces an agreeable scent; it produces a perfume. This incense spreads, it is distributed over the entire country. (Sahagun, Florentine Codex 11:6*)

Mexican wormwood (*Artemisia mexicana*) is almost indistinguishable from European wormwood. The Mexican plant, however, is more potently psychoactive. (Photographed in Veracruz, Mexico)

“[In the Yucatán], There is wormwood, much leafier and more aromatic than what we have here, and with longer and narrower leaves; the Indians grow it for the scent and for pleasure, and I have noticed that the plants grow better when the Indian women put ashes at the foot.”

FRAY DIEGO DE LANDA

AN ACCOUNT OF THE THINGS OF YUCATÁN, XLIX

(2000:158*)

The aromatic plant was sacred to Uixtociuatl, the Aztec goddess of salt and salt makers. The Aztec name for Mexican wormwood, *itztauhyatl*, is sometimes translated as “water of the goddess of salt” (Argueta et al. 1994, 628*). During her festival, which occurred in the seventh month

(Tecuilhuitonli), the goddess was portrayed by apries-tess who carried a staff that was used in a dance:

While dancing, she swings her shield around in a circle, makes movements with it. And she carries a rush staff, decorated with papers and sprinkled with caoutchouc, and furnished on three sides with shells. And where the staff bears the chalice-shaped enlargements, there too is wormwood herbage. Crossed feathers are on it, it bears crossed feathers. When dancing, she supports herself on this, places it firmly into the ground and circles around it, making movements towards the four directions. And ten days long they sang and danced for her in the manner of women; everyone was occupied with this, the salt people, the salt makers, the old women and the women in middle age and the maidens and the girls who had just grown to be maidens. While the sun is still there, still shines, they begin to dance. They are arranged in rows, they arrange themselves in rows. Using a rope, which they call “flower rope,” they take hold of one another, forming a long row. They wear a wormwood flower on their heads. And they sing, they scream loudly, sing with a very high voice, their song is just as the centzontle sings somewhere in the forest, like a clear little bell are their voices. (Sahagun, Florentine Codex 2:26*)

Mexican wormwood is one of the plants sacred to Tláloc, the rain god, who was also associated with *Argemone mexicana* and *Tagetes lucida* (see *Tagetes spp.*).

Documents from the colonial period make no mention of any use of this plant as a psychoactive plant. However, Jacinto de la Serna did refer to Mexican wormwood in the same breath as peyote (*Lophophora williamsii*) and ololiuqui (*Turbina corymbosa*) (Garza 1990; Ott 1993, 393*). In modern Mexico, the leaves are smoked as a marijuana substitute. It is possible that ritual forms for using the plant have developed in conjunction with this use.

Artifacts

The plant was sometimes depicted in connection with the Aztec goddess Uixtociuatl (= Huixtocihuatl) and her festival.

Medicinal Use

The herbage is used as an antispasmodic in Mexican folk medicine (Cerna 1932, 303*). An extract obtained with a mixture of alcohol and water is medicinally drunk for stomach ailments and digestive problems (Martínez 1994, 134*). The plant is listed in the Mexican pharmacopoeia as an anthelmintic and a stomachic (Dibble 1966, 66*; Lara Ochoa and Marquez Alonso 1996, 55*). In modern folk medicine (which was influenced by the Aztecs), the roots and herbage are used to treat epilepsy and rheumatism and to induce menstruation and abortion, and are also drunk as a tonic (Reza D. 1994). Teas made from the plant are drunk to treat lack of appetite. Alcoholic extracts with *albahaca* (see *Ocimum micranthum*) are said to heal diseases caused by “bad winds” (Argeuta et al. 1994, 628f.*). The Yucatec Maya use the herbage as a fumigant for treating headaches (Pulido Salas and Serralta Peraza 1993, 16*). Decoctions are drunk for coughs, asthma, and diarrhea (Roys 1976, 310*). Both the Yucatec Maya and other Indians also use the plant for birth control (to induce menstruation and abortion).

Constituents

In addition to the **essential oil**, which is composed in part of the terpenes borneol, alcafor, limonene, α -phellandrene, and β -phellandrene, the primary active component is santonin. An alkaloid of

unknown structure is also said to be present (Martínez 1994, 134*). The herbage contains azulene, butenolide, **coumarins**, flavones, polyacetylenes, lactones, and sesquiterpenes (armefolin, 8- α -acetoxymexifolin, artemexifolin) (Argueta et al. 1994, 628*; Dibble 1966, 66*; Lara Ochoa and Marquez Alonso 1996, 55*). Although it is likely present, thujone has not yet been detected.

A sample from Arizona was found to contain the eudesmanolides (sesquiterpene lactones) douglanin, ludovicin-A, ludovicin-B, and ludovicin-C. Mexican plants contain the sesquiterpene lactones arglanin, douglanin, armexin, estafiatin, chrysartemin-A,⁴⁸ and artemolin (Lee and Geissman 1970; Ohno et al. 1980, 104; Romo et al. 1970).

Effects

Smoking the dried herbage initially produces a mild, pleasant stimulation that can—depending upon dosage and sensitivity—increase to a euphoric state, very much like the effects of marijuana.

Taken internally, the herbage and the oil it yields have anthelmintic and abortative effects. Overall, the plant is said to be less toxic than *Artemisia absinthium* and therefore more easily tolerated (Martínez 1994, 134*).

Commercial Forms and Regulations

In Mexico, the dried herbage is available in markets and herbal shops.

Coumarin

Artemisia spp.

Artemisia Species

Family

Compositae: Asteraceae (Aster Family); Antemideae Tribe

To date, a number of species of this genus have been described that display interesting pharmacological properties that can be characterized as stimulating, tonic, and antispasmodic (Morán et al. 1989a). In all of the places where species of *Artemisia* are found—and they are found almost worldwide—they are used for ethnomedicinal purposes. For example, *Artemisia herba alba* L. is used in Arabic folk medicine to treat diabetes. Its abilities to lower blood sugar levels have been experimentally verified (Twaij and Al-Badr 1988). The Nepalese Sherpas use the juice of freshly pressed leaves of *Artemisia dubia* Wall. ex Besser (*titepati*, *kemba girbu*) as an antiseptic and a decoction for fevers (Bhattarai 1989, 47*). The malarial agent artemisinin (= quinghaosu) was discovered in the Asian *Artemisia annua* L. (El-Feraly et al. 1986).

Many *Artemisia* species are used ritually as **incense**, in the peyote cult (see *Lophophora williamsii*), and as medicines. Even mugwort (*Artemisia vulgaris*), which was introduced from Europe, is used as “sage” (*tägyi*). Some species that have gynecological effects are sacred to the Greek goddess Artemis (Brøndegaard 1972).

Artemisia frigida contains camphor (the plant is even regarded as a source of camphor; cf. *Cinnamomum camphora*). Some species of *Artemisia* contain the psychoactive substance thujone (see **essential oils**). Methoxylated flavonoids are common in the genus (Rodríguez et al. 1972). Many species of *Artemisia* have muscle-relaxing and antiasthmatic effects (Morán et al. 1989c) and are thus suitable for use in **smoking blends**. They include:

Artemisia scoparia Waldst. et Kit.

Artemisia sieversiana (Ehrh.) Willd.

Artemisia argyi Leveille et Vaniot

Artemisia caerulescens ssp. *gallica* (Willd.) K. Pers.

The West European *Artemisia caerulescens* ssp. *gallica* is rich in an essential oil with a high thujone content (Morán et al. 1989b).

***Artemisia copa* Phil.—copa-copa, copa tola** This species is found in northern Chile. The inhabitants of the Toconse oasis (Atacama Desert) claim that this plant has the power to induce dreams (Aldunate et al. 1981, 205*). It apparently even has hallucinogenic properties (Aldunate et al. 1983*).

***Artemisia ludoviciana* Nutt.—prairie sagebrush, western mugwort, white sage, präiriebeifuß** This variable species is divided into the following varieties and subspecies (Ohno et al. 1980, 104):

Artemisia ludoviciana Nutt. [syn. *Artemisia gnaphalodes*, *Artemisia purshiana* Bess.]

Artemisia ludoviciana var. *ludoviciana* Nutt.

Artemisia ludoviciana ssp. *albula* (Woot.) Keck.

Artemisia ludoviciana ssp. *mexicana* (Willd.) Keck. [syn. ***Artemisia mexicana*** Willd.]

The subspecies differ with regard to the composition of the sesquiterpene lactones that are present (Ohno et al. 1980).

Ethnobotanical research now suggests that Paleo-Indians brought the use of mugwort as incense with them into the New World from Asia some 30,000 years ago (Storl 1995).

Pontic wormwood (*Artemisia pontica* L.) contains thujone. In former times, it was used together with wormwood to manufacture absinthe. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

There is almost no ritual among the Plains Indians that does not include smudging with *Artemisia ludoviciana*. The ascending aromatic smoke is a prayer. It links together Maká, the Mother Earth, with Wakan Tanka, the Great Spirit, who is active in all creatures. The Plains Indians use western mugwort primarily for spiritual purification, to dispel disease spirits and negative powers, to treat possession, and to protect the home. The herbage is also used as an **incense** in peyote ceremonies, as pillows (support) for “Father Peyote” (cf. *Lophophora williamsii*), and as an altar covering. The herbage as well as the leaves are suitable for use as a tobacco (*Nicotiana tabacum*) substitute and are a component of ritual and medicinal **smoking blends** and **kinnikinnick**.

The aboveground portion of the plant contains an **essential oil** with thujone as well as the lactone glycosides santonin and artemisin, which are responsible for the anthelmintic effects. The sesquiterpene lactone anthemidin has been found in *Artemisia ludoviciana* (Epstein et al. 1979). Four santanolides (ludovicin-A, -B, -C, and luboldin) as well as camphor have also been detected (Domínguez and Cárdenas 1975). The essential oil has antibacterial properties (Overfield et al. 1980, 99). A variety of guaianolides have been discovered in *Artemisia ludoviciana* var. *ludoviciana* (Ohno et al. 1980). Occasionally, mild psychoactive effects (euphoria, sensations of being “high”) have been reported following deep inhalation.

The species *Artemisia tridentata* Nutt. is used in the Great Plains as an alternative to *Artemisia ludoviciana*. *Artemisia tridentata* also contains sesquiterpene lactones (Asplund et al. 1972). Sagebrush (*Artemisia arbuscula arbuscula*) is used as an incense as well. It contains an essential oil with cineole, camphor (cf. *Cinnamomum camphora*), camphene, *p*-cymene, and other compounds (Epstein and Gaudioso 1984). A number of Plains Indians also use *Artemisia cana* Pursh and the

subspecies *cana* as a ritual **incense**. This plant is also rich in sesquiterpene lactones (Bhadane and Shafizadeh 1975; Lee et al. 1969).

The North American prairie sagebrush (*Artemisia ludoviciana*) is the most important ritual incense of the Plains Indians. It also contains an essential oil with stimulating effects.

Pati, a Himalayan species of mugwort (*Artemisia* spp.), is used as an incense to support meditation and as a psychoactive beer additive. (Photographed in Langtang, Nepal)

“Artemis—
Queen, hear me,
Much beckoned daughter of Zeus,
Thundering, highly praised Titaness,
Exalted archeress!
All-illuminating, torch bearing,
Goddess Diktynna, who smiles upon the childbed;
Helper in labor,
But who herself knows the childbed not.
She who unties the girdle, Friend of madness,
Dispeller of Troubles,
Huntress, Runner, Hurler of arrows,

***Artemisia nilagirica* (Clarke) Pamp.**

The Lodha, a tribe from West Bengal (India), call this species *ote-paladu*. Tribe members inhale the smoke of the burning herbage as a sedative. This effect is also widely known in Southeast Asia. The Santal use an oil pressed from the leaves as a local anesthetic. The Oraon smoke the dried leaves to induce hallucinations (Pal and Jain 1989, 466).

***Artemisia tilesii* Ledeb.**

The Yupik Eskimos live in southwest Alaska. Because of the paucity of flora in the tundra, they know of only a very few medicinal plants. The fresh or dried herbage of this small *Artemisia* is used to treat skin diseases, painful joints, and chest colds. A decoction is made from the herbage that is said to be strong enough once it has turned green. It is administered externally and internally. The ample **essential oil** consists almost entirely of thujone and isothujone, whereby thujone predominates. Thujone has potent psychoactive powers, while the effects of isothujone are similar to those of **codeine** (Overfield et al. 1980).

***Artemisia tournefortiana* Reichenb.—burnak**

This species is indigenous to the Himalayas. In Ladakh, it is used as a psychoactive additive to **beer** (Navchoo and Buth 1990, 319*).

Arundo donax Linnaeus

Giant Reed

Family

Gramineae: Poaceae (Grass Family); Festuceae Tribe

Forms and Subspecies

There is a small form that has striped leaves and is frequently cultivated as an ornamental: *Arundo donax* L. cv. Variegata.

Synonyms

Arundo bambusifolia Hkr.

Arundo bengalensis Retz.

Arundo glauca Bub.

Arundo sativa nom. nud.

Folk Names

Arundo cypria, *arundo tibialis*, *auleticon*, *barinari* (Hindi), *calamia*, *calamus*, *calamus cyprius*, *cana*, cane of Spayne, cane sticks, *canna*, *canna hispanica*, *caña brava*, *carizzo*, *carizzo de castilla*, *casab* (Arabic), *donax*, *flötenrohr*, giant reed, great reed, *guna pipi* (Siona, “rock reed”), *harundo*, *hasab* (Arabic), *hispanischried*, *italienisches rohr*, *juco*, *juinanashu(p)jua* (Kamsá), *kalamos* (Greek), *kinapipi* (Secoya, “rock reed”), *kyprisches rohr*, *nalaka* (Sanskrit), *navadna trstenika* (Slovenic), *nbt* (ancient Egyptian), *pfahlrohr*, *pfeilrohr*, *pilco*, *rede*, *rede of Spayne*, *ried*, *riesenschilf*, *riet*, *rohr*, *rohr aus syrien*, *roseau*, *shaq* (Chumash), *spanisches rohr*, *Spanish cane*, *Spanish reed*, *tubito*, *uenyinanashuf*, *xapij*, *xapij-aacöl* (Serí, “great reed grass”), *yuntu* (Mapuche), *zahn rohr*

History

Archaeological finds, e.g., of flutes made from the stalks, demonstrate that *Arundo donax* was used widely in ancient Egypt since at least the time of the New Kingdom (Germer 1985, 204*). The stems have been used around the world to make shafts for arrows (Timbrook 1990, 246*). The plant has long been associated with the pastoral god Pan, in part because its shafts were used to make pipes of Pan. *Arundo donax* may have been the wondrous “twelve gods’ plant” of late antiquity (see **dodecatheon**). Because it appears in the legend of the Buddha, the reed is also sacred to Buddhists (Gupta 1991, 18f.*). It is only recently that the psychoactive properties of the reed have become known (Ott 1993, 245*).

The reed (*Arundo donax*) is the largest species of true grass known in Europe. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

The phalluslike shoots on the roots of *Arundo donax* may explain why the grass is sacred to the lusty god Pan.

The giant reed (*Arundo donax*), with its typical spikes. (Photographed on Naxos, Greece)

One of the many cultivated forms of *Arundo donax* (cv. Variegata) bred for ornamental purposes.

Distribution

The giant reed is originally from the Mediterranean region, but it spread quickly throughout the world. It has been present in the New World since the sixteenth century.

Cultivation

The simplest method is to plant root segments that have been dug up and separated from the main root or to take scions with young shoots. The scion, with its small piece of root, can be placed in water before transplanting. Young, phalluslike roots (which may help to explain the association with the phallic god Pan) will form almost overnight.

Appearance

The stalks, which grow in bundles from the nodular rhizomes, can grow 4 to 6 meters tall. The lanceolate leaves are 3 to 5 cm wide and over 50 cm in length. The symmetrical panicles can grow as long as 70 cm. In the tropics, the grass can grow over 10 meters tall. The striped form that is grown as an ornamental reaches a height of only about 3 meters.

Arundo donax is easily confused with ***Phragmites australis***.

Psychoactive Material

—Rhizome (rhizoma arundinis donacis)

Preparation and Dosage

The fresh rhizome is cleaned, cut into small pieces, and macerated in an alcohol-water mixture (1:1). The maceration can be concentrated by evaporation. The residue, which is rich in alkaloids, can then be prepared in a manner appropriate for **ayahuasca analogs**.

The Shipibo shamans from Caimito use the giant reed as an **ayahuasca** additive. Northern Peruvian folk healers (*curanderos*) sometimes set up crosses of reeds when making the San Pedro drink (see ***Trichocereus pachanoi***) so that the brew will not boil over. Otherwise, it will not bring good fortune (Giese 1989, 229*).

Little is known about dosages. Fifty mg of the extract (in combination with 3 g of ***Peganum harmala*** seeds) does not appear to produce any psychedelic effects. Unfortunately, little is also known about toxic dosages. Great care should be exercised when experimenting with *Arundo donax* (cf. ***Phragmites australis***).

Ritual Use

In ancient times, the reed not only was consecrated to the nature god Pan but also was sacred to Silvanus and Priapus. It is not known whether the reed was used as a psychoactive agent in the cult of Pan. On the other hand, the syrinx, the pipes of Pan, are made from reeds, and these not only produce beautiful melodies but also can spread a “Panic terror” (Borgeaud 1988). This story may be a metaphor for the great psychoactive power of the root (for most people, DMT experiences are profoundly terrifying).

It was once thought that the Greco-Roman columns of ancient times had been inspired by the stalks of the reed (*Arundo donax*). (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Apart from this, there are only a few rumors of a ritual use as a psychoactive plant that can be taken seriously:

There are statements about a secret Sufi tradition in which *Arundo donax* and *Peganum harmala* have been linked with mystical initiation. If this is in fact true, then this would be evidence for the use of a reliable ayahuasca analog in the ancient Near East—the celebrated **soma** of the Arians. (DeKorne 1995, 28)

Artifacts

Several ancient Egyptian paintings depict grasses and thickets of grasses that can be interpreted as either *Arundo donax* or ***Phragmites australis*** (Germer 1985, 204*). The stems were made into panpipes. They also appear to have been used as a model for the design of certain columns.

In the New World, the shafts of *Arundo donax* were used not only in the manufacture of arrows but also as ritual objects. The poles for the prayer flags of the Huichols (cf. ***Lophophora williamsii***) are made from *Arundo donax* stems (per oral communication from Stacy Schaeffer). Today, Ecuadoran Indians still make panpipes from the stalks (Vickers and Plowman 1984, 13*). In Colombia, shamans wear the fronds as ear ornaments (Bristol 1965, 103*).

Medicinal Use

The rootstock was used in folk medicine primarily as a diuretic, i.e., an agent that promotes urination (Wassel and Ammar 1984).

In homeopathy, an essence of fresh root shoots called “*Arundo mauritanica*—water reed” was an important remedy around 1863 (Schneider 1974, 1:144f.*).

Constituents

The rhizome contains at least five tryptamines: ***N,N*-DMT**, **5-MeO-DMT**, **bufotenine**, dehydrobufotenine, and bufotenidine (DeKorne 1995, 27; Ghosal et al. 1969; Wassel and Ammar 1984). Little is known about other constituents.

Effects

According to Dioscorides, the flower tufts of *Arundo donax*—just like those of *Phragmites australis*—induce deafness if they get into the ear (1:114).

The reports about the effects of an **ayahuasca analog** made with *Arundo donax* are not very promising and do not encourage others to experiment:

For example, I once ingested one gram of *Peganum harmala* extract with 50 mg of an *Arundo donax* extraction. There was no psychoactivity at all, but I did suffer a modest allergic reaction. Within an hour I noticed that my vision was impaired—there was some difficulty in focusing on the print in a magazine. Later, my eyes felt watery and slightly swollen. The next day, I had a medium conjunctivitis with occasional hives appearing on my body. It took three days for these symptoms to subside. Obviously, one should take extreme care when experimenting with any new plant species, especially those which have no known history of shamanic usage. (DeKorne 1994, 97*)

Commercial Forms and Regulations

None

“Pan, the Mighty, I call to you
the god of the shepherds, the totality of the universe—
Heaven, Ocean, Earth, the queen of all,
and the immortal fire,
for all are the limbs of Pan.
Come, blessed one, Jumper, running in a circle,
He who rules with the Horae, Goat-footed god:
Friend of souls ardent for god, Ecstatic, cave-dweller—
You play the world’s harmony
with merry flute tones,
.....
Off then, Blessed one, Ecstatic one,
to the libations of sacred virtue!
A blessed end shall join life;
To the marrow of the earth Enthrall the Panic terrors
Power!”

ORPHIC HYMN

“There is a real world, but it lies behind this luster and this illusion, behind all of the ‘hunting for Gobelin tapestries, dreams at full speed’! Behind it, as if behind a veil. . . . The old ones knew what it meant to lift the veil. They called it: beholding the god Pan.”

ARTHUR MACHEN

DER GROÖE PAN [THE GREAT PAN] (1994, 10)

Atropa belladonna Linnaeus

Belladonna, Deadly Nightshade

Family

Solanaceae (Nightshade Family); Atropoideae (= Solanoideae), Atropeae (= Solaneae) Tribe

Forms and Subspecies

Two varieties are distinguished on the basis of the color of their flowers and ripe fruits (Lindequist 1992, 423):

Atropa belladonna var. *belladonna*: violet flowers, black fruits

Atropa belladonna var. *lutea* Döll.[syn. *Atropa lutescens* Jacq. ex C.B. Clarke, *Atropa pallida* Bornm.,
Atropa belladonna L. var. *flava*, perhaps *Atropa acuminata* Royle ex Lindl.]: pure yellow flowers,
yellow fruits

Synonyms

Atropa belladonna L. ssp. *gallica* Pascher

Atropa belladonna L. ssp. *grandiflora* Pascher

Atropa belladonna L. ssp. *minor* Pascher

Atropa lethalis Salisb.

Atropa lutescens Jacq. ex C.B. Clarke

Atropa pallida Bornm.

Belladonna baccifera Lam.

Belladonna trichotoma Scop.

Folk Names

Banewort, beilwurz, belladonna, belladonne, belledame, bennedonne, bockwurz, bollwurz, bouton noir, bullkraut, cerabella, chrottebeeri, chrotteblueme “toad flower”), deadly nightshade, deiweilskersche, dol, dollkraut, dolo, dolone, dolwurtz, dulcruyt, dwale, dway berry, English belladonna, great morel, groote nachtschaed, große graswurzel, hexenbeere, hexenkraut, höllenkraut, irrbeere, jijibe laidour (Moroccan), judenkernlein, judenkirsche, lickwetssn, mandragora theophrasti, mörderbeere, morel, morelle furieuse, poison black cherry, pollwurz, rasewurz, rattenbeere, satanskraut, saukraut, schlafapfel, schlafbeere, schlafkirsche, schlafkraut, schwarzber, schwindelbeere, sleeping nightshade, solanum bacca nigra, solanum lethale, solatrum mortale, strignus, teufelsauge, teufelsbeere, teufelsbeeri, teufelsgäggele, teufelsgückle, teufelskirsche, tintenbeere, todeskraut, tollbeere, tolle tüfus-beeri, tollkraut, tollkirsche, tüfus-beeri, waldnachtschaden, waldnachtschatt, waldnachtschatten, uva lupina “wolf’s berry”), uva versa, walkerbaum, walkerbeere, wolfsauge, wolfsbeere, wolfskirsche, wutbeere, wuth-beer, yerva mora

History

Since ancient times, belladonna has been feared as a poisonous plant and demonized as a plant of witches. It has even been suggested that the plant was responsible for the extinction of the dinosaurs. These mighty lizards may have poisoned themselves on the plant or caused their own demise through hallucinations.

It is possible that Dioscorides described the deadly nightshade under the name *stychnos manikos* (Schneider 1974, 1:160*). However, this name has caused great confusion and continues to pose an ethnobotanical puzzle (cf. *Datura stramonium*, *Solanum* spp., *Strychnos nux-vomica*).

Belladonna may be identical to the *morion*, the “other, growing near caves,” “male” mandrake (*Mandragora officinarum*). *Morion* literally means “male member” and refers to the plant’s use as a *tollkraut* (in Middle High German, *toll* = mad, as in “crazy,” and *kraut* = plant). The deadly nightshade has been used as an aphrodisiac since antiquity.

The genus name is derived from that of Atropos (= “the terrible, merciless”), one of the Three Fates or Goddesses of Destiny, who determine life and death. It is Atropos who cuts the thread of life.

In the ancient Orient, belladonna was used as an additive to **beer** and **palm wine**. The Sumerians appear to have used it to treat numerous ailments caused by demons.

Little is known about the history of the deadly nightshade during the early Middle Ages. In the eleventh century, the plant was used as a “chemical weapon” in the war between the Scots and the invading Danes. The Scots added juice from the berries to their dark beer and gave this to the thirsty Danes, who were subsequently overpowered as they lay in a delirious stupor (Schleiffer 1979, 143ff.*; Vonarburg 1996, 62).

The demonization and denouncement of the plant, which was utilized in pagan rituals, had already begun by the time of Hildegard von Bingen:

The deadly nightshade has coldness in it, and yet holds disgust and paralysis in this coldness, and in the earth, and at the place where it grows, the devilish prompting has a certain part and a role in its arts. And it is dangerous for a man to eat and to drink, for it destroys his spirit, as if he were dead. (*Physica* 1:52)

This demonization continued into later times (*teufelsbeere* = “devil’s berry,” *teufelsgägele* = “little devil’s berry,” *teufelskirsche* = “Devil’s cherry”), as the plant was linked to the **witches’ ointments** and regarded as a dangerous and demonic plant. Because belladonna can easily produce toxic states that can prove lethal, its role as a magical plant has never been significant.

The deadly nightshade (*Atropa belladonna*) is one of the most significant medicinal plants in the history of pharmacy. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

“When we encounter the deadly nightshade during our excursion through the columned halls of the forest, a strange feeling comes over us, as if a secretive being with fixed, staring eyes were standing behind the mysterious plant. Its sparkling, shiny black fruits reflect back to us in the dark light of the forest. The deadly nightshade has an aura of danger about it, and we can feel as we look at it that caution is advised.”

BRUNO VONARBURG

*DIE TOLLKIRSCH*E [THE DEADLY NIGHTSHADE]

(1996, 61)

The Italian herbalist Matthioli was the first to mention the name *belladonna*, “beautiful woman,” explaining that Italian women would drip juice pressed from the plant into their eyes in order to make themselves more beautiful. The juice contains **atropine**, which effects a temporary dilation of the pupils (mydriasis). At the time, large black pupils were the epitome of beauty. Because of this dilatory effect, belladonna juice also gained great significance in eye medicine. Ophthalmologists still use **atropine**, named after *Atropa*, to achieve the same effect. Atropine, the active principle of the plant, was first isolated from the deadly nightshade in 1833 by the German apothecary Mein (Vonarburg 1996, 62).

Distribution

Belladonna is indigenous to central and southern Europe and Asia Minor. From there, it spread throughout Western Europe, as far as Iran, and all across North Africa. It is rare in Greece, where it is found only in mountainous regions. In the Alps, it grows at altitudes of up to 1,700 meters (Krueider et al. 1993, 128*). It prefers shady locations and requires chalky soils (Vonarburg 1996, 61).

Cultivation

The simplest and most successful method of cultivating belladonna is to take cuttings from newly formed shoots or layers of the rootstock. This must be done in the spring. Cultivation from seed is rather difficult, as less than 60% of the seeds are viable. This notwithstanding, the use of seeds is important in commercial production (Morton 1977, 284*). Belladonna is cultivated on a large scale in southern and eastern Europe, Pakistan, North America, and Brazil.

Appearance

This herbaceous perennial, which can grow as tall as 1.5 meters, develops straight, ramified stalks, oblong leaves, and bell-shaped, brownish violet flowers that are enclosed in a five-cusped green calyx. The fruit, which is initially green but then turns shiny black, is roughly the size of a cherry and sits upon the five-pointed calyx. Belladonna blooms between June and August and often already bears fruits at this time. The variety *lutea* has yellow flowers, yellow fruits, and a green stem.

The deadly nightshade produces an attractive nectar that bees and bumblebees enthusiastically collect and transform into psychoactive **honey** (Hazlinsky 1956). The plant is also pollinated by these insects (Vonarburg 1996, 62).

Although belladonna can be mistaken only for other *Atropa* species (see page 85), the *Scopolia* species (see *Scopolia carniolica*) are an occasional source of confusion.

Historical sources often confused the deadly nightshade with the bittersweet nightshade (*Solanum dulcamara*) and the black nightshade (*Solanum nigrum*; cf. ***Solanum* spp.**) (Schneider 1974, 1:160*) and occasionally with the sleeping berry (***Withania somnifera***). The herb Paris (*Paris quadrifolia* L.; cf. ***Aconitum* spp.**) has also been regarded as a form of belladonna (Schwamm 1988, 133).

Psychoactive Material

—Leaves (belladonnae folium, belladonnae herba, folia belladonnae, herba belladonnae, solani

furiosi, belladonnablätter). The pharmaceutical raw drug is sometimes falsified with leaves of tree-of-heaven (*Ailanthus altissima* L.), poke-berry (*Phytolacca americana* L., ***Phytolacca acinosa***), *Hyoscyamus muticus*, *Physalis alkekengi* L. (cf. ***Physalis* spp.**), and *Scopolia carniolica*.

—Roots (belladonnae radix, radix belladonnae, belladonnawurzel). The pharmaceutical raw drug is sometimes falsified with the roots of pokeberry (*Phytolacca americana* L., ***Phytolacca acinosa***) or ***Scopolia carniolica***.

—Fresh or dried fruits (belladonnae fructus, fructus belladonnae).

The typical violet-tinged flower of the deadly nightshade (*Atropa belladonna*).

The rare yellow-blooming variety of the deadly nightshade (*Atropa belladonna* var. *lutea*).

The shiny black fruit of the deadly nightshade has a seductively sweet taste.

The ripe fruit of the yellow-blooming *Atropa belladonna* var. *lutea* is also yellow and is easily mistaken for the fruits of the mandrake (*Mandragora*).

Preparation and Dosage

The leaves of the wild form should be harvested in May or June, as their alkaloid content is greatest at this time. They are dried in the shade and must then be stored away from light in an airtight container. It is best to harvest the fruits when they are almost ripe. These must be dried in a dry, ventilated location. Both the leaves and the fruits are suitable for use in **smoking blends** and can be combined with dried fly agaric mushrooms (*Amanita muscaria*) and hemp (*Cannabis indica*). Pharmaceutical cigarettes made of belladonna leaves soaked in a tincture of opium (cf. *Papaver somniferum*) were still being prescribed as recently as 1930 (Schneider 1974, 1:162*).

Ingestion of one or two fresh berries produces mild perceptual changes approximately one to two hours after consumption. Three or four fresh berries is regarded as a psychoactive aphrodisiac; three to a maximum of ten berries represents a hallucinogenic dosage. Ten to twenty berries is said to be lethal; among children, as few as two or three berries can cause death (Vonarburg 1996, 62). Extreme care should be exercised with *Atropa belladonna*! With some individuals, even the smallest amounts can have devastating results (delirious states). Using the plant as a fumigant or as an ingredient in **smoking blends** is the least dangerous method of consumption.

When used (internally) for medicinal purposes, 0.05 to 0.1 g of dried and powdered leaves is regarded as an average individual dosage (Lindequist 1992, 429). The therapeutic dosage of **atropine** is listed as 0.5 to 2 mg. A pleasant psycho-active dosage is 30 to 200 mg of dried leaves or 30 to 120 mg of dried roots, either smoked or ingested internally (Gottlieb 1973, 5*).

Belladonna is reputed to have been an ingredient in **witches' ointments** and was used as a magical fumigant. One traditional "oracular incense" had the deadly nightshade as its chief component and

active ingredient (cf. **incense**). It contained:

leaves of fool's parsley [*Aethusa* spp., *Apium* spp., or *Sium* spp.], harvested during the new moon,
acorns [*Quercus* spp.], plucked during the full moon while naked,
leaves and flowers of the deadly nightshade, harvested at midday,
leaves of vervain [*Verbena officinalis*], plucked by hand in the afternoon,
leaves of wild peppermint [*Mentha* spp.], picked in the morning,
leaves of the thistle [*Viscum album*], from the previous year, cut at midnight.
(Magister Botanicus 1995, 185*)

Unfortunately, no precise details about the amounts to use have come down to us.

Belladonna berries can also be mashed, fermented, and distilled into **alcohol** and were formerly used as a psychoactive additive to **beer**, **mead**, **palm wine**, and **wine**. They are also an ingredient in the Moroccan spice mixture known as *ras el hanout* (Norman 1993, 96f.*).

Ritual Use

Since ancient times, deadly nightshade has probably been used in the same or a very similar manner as mandrake (see ***Mandragora officinarum***). It is possible that its root was also used as a substitute or an alternative to that of the mandrake. Folktales have preserved the remnants of a belladonna cult that suggest that this may have been the case. In Hungary, for example, the root “is dug up on the night of St. George while naked, and a bread offering is made as if to an elfish monster” (Höfler 1990, 90*). In Romania, the deadly nightshade is also known as the wolf cherry, the flower of the forest, the lady of the forest, and the empress of herbs.

Belladonna is common in some regions of southern Germany. It is uncertain whether the plant is part of the indigenous flora or was introduced during the early Middle Ages. The German names for the plant are suggestive of its psychoactive effects (*schlafbeere* = “sleeping berry,” *rasewurz* = “mad root,” *tollkirsche* = “crazy cherry”) and contain pagan references (*wolfsauge* = “wolf’s eye,” *wutbeere* = “rage berry”); the wolf is the animal of Wotan and *wut* (= fury, ecstasy) is his characteristic (*wuotan*, “the furious”). The deadly nightshade is also associated with the daughters of Wotan: “On the Lower Rhine, its fruits are known as *Walkerbeeren* [“Valkyrie berries”], and the plant itself is known as the *Walkerbaum* [“Valkyrie tree”], and anyone who ate of the berries would fall victim to the Valkyries” (Perger 1864, 182 f.*). The Valkyries are the daughters of Heaven and Earth (Wotan and Erda) who accompany the souls of heroes who have fallen in battle to Valhalla, where they are entertained with inebriating **mead** while they await the Götterdämmerung, the Twilight of the Gods (i.e., the rebirth of the world). Since Wotan is the lord of the Wild Chase as well as of the hunt and the forest, he was also closely associated with hunters. Consequently, as late as the nineteenth century, southern German hunters would still often consume three or four belladonna berries before going out hunting, a practice that was said to sharpen their perception and make them better hunters.⁴⁹

Belladonna, the goddess of the deadly nightshade, is depicted with a wreath made from the leaves and fruits of *Atropa belladonna*. She appears to be deep in a nightshade dream. (*Belladonna*; engraving after a painting by Gabriel Max, printed in the *Jugendstil* journal *Gartenlaube*, 1902)

Atropos, the goddess of destiny who severs the thread of life, provided the inspiration for the botanical name of the deadly nightshade. (Floor mosaic, Roman period, Cyprus)

Although the deadly nightshade is regarded as a classic witches' plant, only a very few details have come down to us concerning its magical use in witches' rituals. In his work *Magiae naturalis* [Natural Magic], Giovanni Battista della Porta (ca. 1535–1615) wrote that a person could use an arcanum (secret means) to transform himself into a bird, fish, or goose—the sacred animal that was sacrificed to Wotan/Odin at the time of the winter solstice—and thereby have much amusement. He listed belladonna first among the agents that could be used for these purposes (Schleiffer 1979, 139f.*).

In Celtic rituals and in the neo-pagan rituals of certain modern “witches cults” (Wicca) that are

based upon these, following a fasting period of fourteen days⁵⁰ (one fortnight), the oracular fumigation noted above was and is still carried out during the night of the full moon preceding the festival of Samhain (November 1). A tea made of *Amanita muscaria* was also consumed on that day:

The members of a band of people knowledgeable about herbs would then gather in the “sacred” night and select one of their own, who would then sit before the incense vessel as the oracular priest/ess and inhale the toxic fumes.

The resulting toxic effects of the smoke would place the priest/ess into a trance state in which he or she would then serve as oracle and answer the questions of the others or establish contact to the spirits or gods. It is also interesting that a priest or priestess was never allowed to function as the oracle on two consecutive occasions. (Magister Botanicus 1995, 185f.*)

Artifacts

In the nineteenth century and in the 1920s, both the berry of the deadly nightshade and belladonna in its anthropomorphic form were frequently portrayed in printed material (e.g., by Erich Brukal, Paul Wending; cf. Rätsch 1995, 138*). It is not known whether these pictures were the result of the artists’ personal experiences with bella-donna preparations. It is possible that the legends concerning the witches’ plant and the spirit that lives within it provided all the inspiration they needed.

The short film *Belladonna*, by herman de vries and others, depicts a magical ritual in which witches use the deadly nightshade. It shows a young woman walking through the forest in search of the plant; when she finds it, she disrobes and rubs its fruits all over her body. The film then attempts to portray the resulting psychoactive effects. An experimental film entitled *Atropa belladonna—Die Farbe der Zeit* [*Atropa bella-donna—The Color of Time*] was also inspired by the myth of the beautiful woman and the spirit of the plant (Friel and Bohn 1995).

Belladonna has also left its marks on both psychedelic and heavy metal music (e.g., Ian Carr, *Belladonna*, as well as the band Belladonna) and in the music of Andreas Vollenweider.

The book *Right Where You Are Sitting Now: Further Tales of the Illuminati*, by Robert Anton Wilson, provides a turbulent literary version of belladonna inebriation (1982, 13–26).

Medicinal Use

The deadly nightshade has been used for medicinal purposes since ancient times, e.g., as an analgesic (cf. **soporific sponge**). It was often administered to “dispel demons” (in other words, it was likely used in therapies to treat depressions, psychoses, and other mental illnesses). Rudiments of such psychiatric usage have been preserved in northern Africa.

In Morocco, the dried berries, together with a small amount of water and some sugar, are made into a tea that can “help produce a good mental condition.” This tea is also an aphrodisiac for men. It is also said “that a small dose of belladonna clears the mind and enables one to do intellectual tasks” (Venzlaff 1977, 82*). A couple of fresh berries are also said to increase the ability to remember.

In the nineteenth century, extracts of the root and herbage were used to treat jaundice, dropsy, whooping cough, convulsive cough, nervous ailments, scarlet fever, epilepsy, neuroses, renal colic, various skin diseases, eye inflammations, and diseases of the urinary and respiratory tracts, the throat, and the esophagus (Schneider 1974, 1:161*).

A mother tincture obtained from the fresh plant together with the rootstock at the end of the flowering season (*Atropa belladonna* hom. *PFX* and *RhHAB1*, *Belladonna* hom. *HAB1*) as well as various dilutions (normally D4 and above) are used in homeopathy for numerous purposes, depending upon the medical description (Vonarburg 1996, 63).

Constituents

The entire plant contains between 0.272 and 0.511% **tropane alkaloids**; the variety *lutea* contains only 0.295% (Lindequist 1992, 424). The stalk can contain up to 0.9% alkaloids, the unripe fruits up to 0.8%, the ripe fruits from 0.1 to 9.6%, and the seeds approximately 0.4%. In the living plant, (–)-hyoscyamine predominates; following harvest, during the drying and storage process, this is converted to **atropine**. The dried leaves contain 0.2 to 2% alkaloids, the dried root 0.3 to 1.2%. Hyoscyamine is the primary component (68.7%), apoatropine is the secondary alkaloid (17.9%), and many other tropane alkaloids are also present (433).

The psychedelic wave of the late 1960s also swept over many jazz musicians in the early 1970s. In 1972, the trumpeter Ian Carr dedicated an entire album (*Belladonna*) to the hallucinogenic deadly nightshade. In this cover photograph, however, the musician is actually shown standing among field poppies (*Papaver rhoeas*). (CD cover 1990, Linam Records.)

The alkaloids in the plant apparently pass into the tissues of animals that have eaten the foliage, the fruits, or the roots. In one eighteenth-century case, an entire family experienced hallucinations after eating a rabbit. Rabbits appear to be fond of the plant and do not display any toxic reactions (Ruspini 1995).

Effects

The clinical picture of the effects of belladonna is rather homogeneous (and reminiscent of the effects of *Datura* and *Brugmansia*):

Within a quarter of an hour, the following toxic symptoms appear: psychomotor disquiet and general arousal, not infrequently of an erotic nature, urge to speak, great euphoria (cheerfulness, urge to laugh), but also fits of crying, strong desire for movement, which may be manifested as an urge to dance, disturbances of intention, manneristic and stereotypic movements, choreatic states, ataxia, disturbances of thought, sensations of befuddlement, confused speech, screaming, hallucinations of a diverse nature; increasing states of excitation culminating in frenzy, rage, madness, with complete lack of ability to recognize the surroundings. (Roth et al. 1994, 158*)

Death can result from respiratory paralysis. The (main) effects last for three to four hours; the effects on vision may continue for three to four days.

Belladonna-induced hallucinations are typically described as threatening, dark, demonic, devilish, hellish, very frightening, and profoundly terrifying. Many users have compared the effects to those of a “Hieronymus Bosch trip” and have indicated that they have no intention of repeating the experiment (Gabel 1968; Illmaier 1996; Pestolozzi and Caduff 1986).

The alkaloids also cause the mucous membranes to become very dry and the face to turn red, while

the pulse rate accelerates and the pupils dilate.

Commercial Forms and Regulations

In Germany, belladonna leaves and roots are available in pharmacies and require a physician’s prescription (Lindequist 1992, 431).

“For the Moirai alone in life . . .
Observe what occurs to us.
The Moirai know everything, everything,
and the seeing mind of Zeus,
Their aerial, their gentle,
friendly hearts come by:
Atropos, Lachesis, Clotho;
Come, daughters of the noble father,
Inescapable, invisible
nocturnal, immortal,
givers of all, taking the mortal
The compulsion of necessity . . .”
ORPHIC HYMN TO THE MOIRAI

“The world is much more absurd and threatening than most people comprehend. Just ask any of the people that have partaken of the belladonna, and they will attest to this.”

ROBERT ANTON WILSON

RIGHT WHERE YOU ARE SITTING NOW: FURTHER TALES OF THE ILLUMINATI

(1982, 26)

Other Species of Belladonna

The genus *Atropa* is composed of four to six species, all of which occur only in Eurasia (D’Arcy 1991, 79*; Symon 1991, 147*). The genus is treated inconsistently in the taxonomic literature. The only species that has attained any ethnopharmacological significance as a psycho-active plant is *Atropa belladonna*. Only the Indian belladonna has acquired a certain ethnomedicinal usage. All species contain

tropane alkaloids, primarily hyoscyamine and **atropine**, along with apoatropine, belladonnine, and cuscohygrine (in the roots). The leaves also contain quercetin and camphor oil derivatives and **coumarins (scopoletin)** (Lindequist 1992, 423*).

***Atropa aborescens* [nom. nud.?]**

This species, collected in Martinique, “contains narcotic poisonous substances” (von Reis and Lipp 1982, 266*).

***Atropa acaulis* L.**

Synonym for *Mandragora officinarum*

***Atropa acuminata* Royle ex Lindl. [syn. *Atropa belladonna* var. *acuminata*, *Atropa belladonna* C.B. Clarke non. L.]—Indian belladonna, sagangur**

This species occurs only in the Indian districts of Barmula, Kinnaur, Simla, and Nainital. It is very similar to *Atropa belladonna*, in particular the yellow-flowered subspecies. But this species produces yellow flowers and black fruits (Morgan 1977, 289*). For this reason, it has recently been regarded more as a synonym, although it may represent a local variety or subspecies. Indian belladonna has almost the same alkaloid content as the European species, but it has a higher concentration of scopolamine (approximately 30% of the total alkaloids). It is cultivated in Afghanistan and Kashmir for pharmaceutical purposes. The Indian raw drug is very often falsified with the roots of *Phytolacca acinosa* (Morton 1977, 290*). *Atropa acuminata* is also regarded as a synonym for *Atropa baetica*.

***Atropa baetica* Willk.—Iberian belladonna**

This species is found in Spain and possesses a higher alkaloid content (with only a little **scopolamine**) than *Atropa belladonna*.

***Atropa caucasica* Kreyer—Caucasian belladonna**

The only other Asian species besides *Atropa acuminata*.

***Atropa cordata*—heart-leaved belladonna**

This species is apparently a broad-leaved European form of *Atropa belladonna*.

***Atropa digitaloides*—finger-leaved belladonna**

This species is apparently a small-leaved European form of *Atropa belladonna*.

***Atropa komarovii* Blin. et Shal—Turkmenic belladonna**

Found only in Turkmenistan, this species is being tested for commercial cultivation as a source of alkaloids.

***Atropa mandragora* (L.) Woodville**

Synonym for *Mandragora officinarum*.

***Atropa* x *martiana* Font Quer**

Hybrid from *Atropa baetica* and *Atropa bella-donna*.

***Atropa pallidiflora* Schönb.-Tem.**

Has an alkaloid concentration that is approximately as high as that of *Atropa belladonna*, although the mixture contains approximately 30% scopolamine.

***Atropa rhomboidea* Gill. et Hook**

Now known as *Salpichroa organifolia* (Lam.) Baill., this plant occurs in the southern portion of South America as far as Tierra del Fuego (Zander 1994, 496*).

The fruit of the deadly nightshade (*Atropa belladonna*), whole and in cross section.

Banisteriopsis caapi (Spruce ex Grisebach) Morton

Ayahuasca Vine

Family

Malpighiaceae (Barbados Cherry Family); Pyramidotroae, Banisteriae Tribe

Forms and Subspecies

Two varieties have been distinguished (D. McKenna 1996):

Banisteriopsis caapi var. *caupari*

Banisteriopsis caapi var. *tukonaka*

The first form has a knotty stem and is considered to be more potent; the second has a completely smooth stem.

The Andoques Indians distinguish among three forms of the vine, depending upon the types of effects each has upon the shamans: *iñotaino'* (transformation into a jaguar), *hapataino'* (transformation into an anaconda), and *kadanytaino'* (transformation into a goshawk) (Schultes 1985, 62). The Siona make a distinction among the following cultivated forms: *wa'í yahé* ("flesh yahé," with green leaves), *ya'wi yahé* ("pekari yahé," with yellow-striped leaves), *naso ãnya yahé* ("monkey snake yahé"), *naso yahé* ("monkey yahé," with striped leaves), *yahé repa* ("proper yahé"), *tara yahé* ("bone yahé," with knotty stems), *'aíro yahé* ("forest yahé"), *bi'ã yahé* ("bird yahé," with small leaves), *sia sewi yahé* ("egg sewi yahé," with yellowish leaves), *sêsé yahé* ("white-lipped peccary yahé"), *wêki yahé* ("tapir yahé," of large size), *yaí yahé* ("jaguar yahé"), *nea yahé* ("black yahé," with dark stems), *horo yahé* ("flower yahé"), and *sisé yahé* (Vickers and Plowman 1984, 18f.*).

Synonyms

Banisteria caapi Spruce ex Griseb.

Banisteria quitensis Niedenzu

Banisteriopsis inebrians Morton

Banisteriopsis quitensis (Niedenzu) Morton

Folk Names

Amarón wáska, "boa vine"), ambi-huasca (Inga, "medicine vine"), ambiwáska, ayahuasca amarilla, ayahuascaliane, ayahuasca negra, ayahuasca vine, ayawasca, ayawáska, bejuco de oro ("gold vine"), bejuco de yagé, biaj (Kamsá, "vine"), biáxa, biaxíi, bichémia, caapi,⁵¹ caapí, camárambi (Piro), cauupuri mariri, cielo ayahuasca, cuchiyahuasca, cushi rao (Shipibo, "strong medicinal plant"), doctor, hi(d)-yati (d)yahe, iáhi', kaapi, kaapistrauch, kaheé, kahi, kalí, kamarampi (Matsigenka), máo de onça, maridi, natem, natema, nepe, nepi, nishi (Shipibo, "vine"), oo'-na-oo (Witoto), purga-huasca, purga-huasca de los perros, rao (Shipibo, "medicinal plant"), reéma (Makuna), sacawáska, sacha-huasca (Inga, "wild vine"), seelenliane, seelenranke, shurifisopa, tiwaco-mariri, totenliane, vine of the dead, vine of the soul, yagé, yagé cultivado, yagé del monte, yagé sembrado, yahe, yaje, yáje, yajé, yajén, yaji, yaxé (Tukano, "sorcerer's plant")

History

The word *ayahuasca* is Quechuan and means “vine of the soul” or “vine of the spirits” (Bennett 1992, 492*). The plant has apparently been used in South America for centuries or even millennia to manufacture psychoactive drinks (**ayahuasca**, *natema*, *yahé*, etc.). Richard Spruce (1817–1893) collected the first botanical samples of the vine between 1851 and 1854 (Schultes 1957, 1983c*). The original voucher specimens have even been tested for alkaloids (Schultes et al. 1969).

The German ethnographer Theodor Koch-Grünberg (1872–1924) was one of the first to observe and describe the manufacture of the caapi drink from *Banisteriopsis caapi* (1921, 190ff.). The pharmacology was first elucidated in the mid-twentieth century (see **ayahuasca**).

Distribution

It is not certain where the plant originated, as it is now cultivated in Peru, Ecuador, Colombia, and Brazil, that is, throughout the entire Amazon basin. Wild plants appear to be chiefly stands that have become wild (Gates 1982, 113).

Cultivation

The plant is cultivated almost exclusively through cuttings, as most cultivated plants are infertile (Bristol 1965, 207*). A young shoot or the tip of a branch is allowed to stand in water until it forms roots, after which it is transplanted or simply placed into humus-rich, moist soil and watered profusely. The fast-growing plant thrives only in moist tropical climates and does not typically tolerate any frost.

Appearance

This giant vine forms very long and very woody stems that branch repeatedly. The large, green leaves are round-ovate in shape, pointed at the end (8 to 18 cm long, 3.5 to 8 cm in width), and opposite. The inflorescences grow from axillary panicles and have four umbels. The flowers are 12 to 14 mm in size and have five white or pale pink sepals. The plant flowers only rarely (Schultes 1957, 32); in the tropics, the flowering period is in January (although it can also occur between December and August). The winged fruits appear between March and August (Ott 1996) and resemble the fruits of the maple (*Acer* spp.). The plant is quite variable, which is why it has been described under several different names (see “Synonyms”).

Inflorescence and fruit of the ayahuasca vine (*Banisteriopsis caapi*). Under cultivation, the vine rarely develops flowers.
(Drawing by Sebastian Rätsch)

The Tukanos and other Indians of the Amazon regard the ayahuasca vine as a snake that can bear humans into the world of the spirits. (Traditional representation, from Koch-Grünberg, *Zwei Jahre bei den Indianern Nordwest-Brasiliens*, 1921*)

The vine is closely related to *Banisteriopsis membranifolia* and *Banisteriopsis muricata* (see *Banisteriopsis* spp.) and can easily be confused with these (Gates 1982, 113). It is also quite similar to *Diplopterys cabrerana*.

Psychoactive Material

- Stems, fresh or dried (banisteriae lignum)
- Bark, fresh or dried, of the trunk (banisteriae cortex)
- Leaves, dried

Preparation and Dosage

In Amazonia, dried pieces of the bark and the leaves are smoked. The Witotos powder dried leaves so that they can smoke them as a hallucinogen (Schultes 1985).

The vine is rarely used alone to produce **ayahuasca** or yagé:

The Tukano prepare the yagé by dissolving it in cold water, not, as is done by other tribes to the south, by boiling. Short pieces of the liana are macerated in a wooden mortar, unmixed with the leaves or with other ingredients. Cold water is added, and the liquid is passed through a sieve and placed in a special ceramic vessel. This solution is prepared two or three hours before its proposed ceremonial use, and it is later drunk by the group from small cups. These drinking vessels hold 70 cubic cm and between drinks, six or seven in number, intervals of about an hour elapse. (Reichel-Dolmatoff 1970, 32).

In between they drink **chicha**, a slightly fermented **beer**, and smoke copious amounts of tobacco (*Nicotiana rustica*, *Nicotiana tabacum*).

The vine is usually prepared together with one or more additives so that it develops either psychedelic (using plants that contain DMT, primarily *Psychotria viridis*) or healing (e.g., with *Ilex guayusa*) powers (see list at **ayahuasca**).

Small baskets made of strips of ayahuasca bark 4 to 6 mm in thickness (total dry weight = 13 to 14 g) are now being produced in Ecuador; each basket corresponds to the dosage for one person. These little baskets are stuffed with leaves of *Psychotria viridis* (approximately 20 g) and boiled to prepare

a psychedelic drink.

Ritual Use

The Desana, a Colombian Tukano tribe, drink pure **ayahuasca** only on ritual occasions, although these do not have to be associated with any particular purpose, such as healing or divination. Only men may consume the drink, although the women are involved as dancers (i.e., as entertainment). The ritual begins with the recitation of creation myths and is accompanied by songs. It lasts for eight to ten hours. Very large amounts of **chicha** are also consumed while the ritual is in progress (Reichel-Dolmatoff 1970, 32).

For more on ritual use, see **ayahuasca**.

Artifacts

See **ayahuasca**.

Medicinal Use

In some areas of the Amazon, and among the followers of the Brazilian Umbanda cult, a tea made from the ayahuasca vine is drunk as a remedy for a wide variety of diseases and may also be used externally for massaging into the skin (Luis Eduardo Luna, pers. comm.).

Constituents

The entire plant contains alkaloids of the β **carboline** type. The principal alkaloids are **harmine**, **harmaline**, and tetrahydroharmine. Also present are the related alkaloids harmine-*N*-oxide, harmic acid methylester (= methyl-7-methoxy- β carboline-1-carboxylate), harmalinic acid (= 7-methoxy-3,4-dihydro- β -carboline-1-carboxyl acid), harmic amide (= 1-carbamoyl-7-methoxy- β carboline), acetylnorharmine (= 1-acetyl-7-methoxy- β -carboline), and ketotetrahydronorharmine (= 7-methoxy-1,2,3,4-tetrahydro-1-oxo- β -carboline) (Hashimoto and Kawanishi 1975, 1976). Also present are shihuninine and dihydroshihunine (Kawanishi et al. 1982).

The stems contain 0.11 to 0.83% alkaloids, the branches 0.28 to 0.37%, the leaves 0.28 to 0.7%, and the roots between 0.64 and 1.95%. Of these, 40 to 96% is harmine. Harmaline is completely absent in some samples, while in others it can comprise as much as 15% of the total alkaloid content (Brenneisen 1992, 458). The stems and bark also contain large quantities of tanning agents.

It has also been reported that the vine contains **caffeine**. This information is probably due to confusion with *Paullinia yoco* (cf. **Paulinia spp.**) (Brenneisen 1992, 458).

Effects

The vine functions as a potent MAO inhibitor, whereby only the endogenous enzyme MAO-A is inhibited (see **ayahuasca**). As a result, both endogenous and externally introduced tryptamines, such as **N,N-DMT**, are not broken down and are thus able to pass across the blood-brain barrier.

The ayahuasca vine (*Banisteriopsis caapi*) blooms in January. The plant only flowers in the tropics.

Harmine

Harmaline

“Caapi is a decoction of a Malpighiaceae shrub (*Banisteria*) and is prepared in the following way by the men only, for the women do not drink any Caapi. The roots, stems, and leaves are pounded in a wide, trough-shaped mortar into a greenish brown mass that is washed in a pot with a little water, squeezed thoroughly, and then pounded in the mortar and washed again. The resulting mush, which bears something of a resemblance to cow dung, is strained through two fine sieves placed on one another into the Caapi vessel, whereby this is aided by hitting against the edge of the sieve. The pot with the unappetizing drink is covered carefully with leaves and placed in front of the house for a time. The Caapi vessel always has the same bulging urn shape and is always painted with the same yellow pattern against a dark red background. Remarkably, these are very similar to the patterns that are painted on the round exterior of the signal drums. At the upper edge, the vessel has two leaf-shaped handles that protrude out horizontally and are used to carry it, and two holes, in which a string for hanging it is attached. It is never washed but is newly painted from time to time.

“The effects of Caapi resemble hashish inebriation. One can see how the Indians say that everything is much larger and more beautiful than it really is. The house is enormously large and magnificent. They see many, many people, especially many women.—The erotic appears to play a central role in this inebriation.—Large, colorful snakes wind their way up and down the house posts. All of the colors are garishly colorful. Some who drink Caapi suddenly fall into a deep unconsciousness state and then have the most beautiful dreams, and admittedly also the most beautiful headache when they awake—hangover.”

THEODOR KOCH-GRÜNBERG

When the vine is used alone, it produces mood-enhancing and sedative properties. In higher dosages, the **harmine** present in the plant (above 150 to 200 mg) can induce nausea, vomiting, and shivering (Brenneisen 1992, 460).

In the 1960s, Reichel-Dolmatoff was able to take part in numerous ayahuasca rituals among the Desana. He wrote the following about his experience with a repeated administration of a drink that was said to have been made only from *Banisteriopsis caapi*:

My own experience was as follows: first draft, pulse 100, a sense of euphoria, followed by a passing drowsiness; second draft, pulse 84; fourth drink, pulse 82 and strong vomiting; sixth draft, pulse 82, severe diarrhea. Almost immediately there appeared to me spectacular visions in color of a multitude of intricate designs of marked bilateral symmetry, which passed slowly in oblique bands before my range of vision, my eyes being half closed. The visions continued, becoming modified, for more than twenty minutes, during which time I was entirely conscious and able to describe my experience very clearly on the tape recorder. There were no acoustical phenomena and no figures represented. (Reichel-Dolmatoff 1970, 33)

Commercial Forms and Regulations

Pieces of the vine are only rarely offered in ethnobotanical specialty stores. There are no regulations concerning the plant.

Banisteriopsis spp.

Banisteriopsis Species

Family

Malpighiaceae (Barbados Cherry Family); Banisteriae Tribe

Today, some ninety-two species of the genus *Banisteriopsis* are recognized. Most species occur in the tropical lowlands of Central and South America. A few species are also found in Asia.

Banisteriopsis argentea (Spreng. ex A. Juss.) Morton

A native of India, this species contains tetrahydroharman, 5-methoxytetrahydroharman, **har-mine**, **harmaline**, and the β -**carboline** leptaflorin (Ghosal et al., 1971). The leaves contain only 0.02% alkaloids [(+)-*N*₆-methyltetrahydroharmane, ***N,N*-DMT**, *N,N*-DMT-*N*₆-oxide, (+)-tetrahydroharmane, harmaline, choline, betaine, (+)-5-methoxytetrahydroharmane] (Ghosal and Mazumder 1971). We know, however, of no traditional use as a psychoactive plant (Schultes and Farnsworth 1982, 147*). *Banisteriopsis argentea* may be synonymous with *Banisteriopsis muricata* (see below).

Banisteriopsis inebrians Morton

In the Amazonian lowlands of Ecuador, *Banisteriopsis inebrians* is known as *barbasco*. In South America, the word *barbasco* is used primarily to refer to fishing trees (*Piscidia* spp.) and other plants that can be used to poison fish (e.g., *Clibadium* spp.). The Indians pound the fresh roots of *Banisteriopsis inebrians*, place the result into a coarse-meshed basket, and put this in the water. The fish poison then spreads as a milky exudation (Patzelt 1996, 261*).

In southern Colombia (in the Vaupés and Río Piraparaná region), this ayahuasca species is used ritually to prepare yagé or kahi primarily by the Barasana (see **ayahuasca**). In the language of the Barasana, this species is known as *kahi-ukó*, “yagé catalyst,” *yaiya-sûava-kahi-ma*, “red jaguar yagé,” and *kumua-basere-kahi-ma*, “yagé for shamanizing.” Under the influence of this vine, it is said that one sees things in shades of red, dances, and is able to see people who are normally invisible. According to the mythology of the Barasana, this vine was brought to people in the yuruparí trumpet; for this reason, it is also known as *hêkahi-ma*, “yuruparí yagé” (Hugh-Jones 1977, 1979; Schultes 1972, 142f.*). Today, it is regarded as a synonym for ***Banisteriopsis caapi***. It contains the same alkaloids (O’Connell and Lynn 1953).

Banisteriopsis maritini (Juss.) Cuatrecasas var. *laevis* Cuatrecasas

This species is found in the Amazon region of Colombia. The Makuna Indians purportedly use it to manufacture yagé (Schultes 1975, 123).

Banisteriopsis muricata (Cavanilles) Cuatrecasas [syn. *Banisteria acanthocarpa* Juss., *Banisteria muricata* Cav., *Banisteriopsis argentea* (H.B.K.) Robinson in Small, *Heterpterys argentea* H.B.K., and others]

In Ecuador, where this species is known as *mii*, the Waorani use it as the basis for **ayahuasca**. The shaman (*ido*) prepares the drink from bark scrapings that are slowly boiled. He can use the drink to heal a person as well as to send him a disease or even death. A disease can be healed only when the

person who has caused the illness also brews the healing drink (Davis and Yost 1983, 190f.*).

The Witoto from Puca Urquillo on the Río Ampiyacu (Peru) call this vine *sacha ayahuasca*, “wild vine of the soul,” and say that it can be used in place of *Banisteriopsis caapi* (Davis and Yost 1983, 190f.*). In Peru, this plant is also known as *ayahuasca de los brujos* (“ayahuasca of the sorcerers”); in Bolivia it is called *bejuco hoja de plata* (“silver leaf vine”); in Argentina, *sombra de tora* (“shadow of the steer”); and in El Salvador, *bejuco de casa* (“vine of the house”), *pastora* (“shepherdess”; cf. *Salvia divinorum*, *Turnera diffusa*), and *ala de zompopo*. Of all the species of *Banisteriopsis*, this plant is the most widely distributed.

The vine is also found in the lowlands of southern Mexico (Selva Lacandona) and in Petén (Guatemala) (per oral communication from Rob Montgomery). It is possible that the ancient Maya may have used it to produce a kind of “maya-huasca” (see **ayahuasca analogs**).

The plant contains both β -**carboline**s (**har-mine**, etc.) and **N,N-DMT**. DMT is present not in the vine itself (i.e., the stems) but in the leaves. This American species may be identical to the Indian *Banisteriopsis argentea* (see above).

Intertwining stems of *Banisteriopsis muricata*, found in Petén (Guatemala) and Chiapas (Mexico), recall numerous illustrations of cosmic umbilical cords from the Classic and post-Classic Mayan period. Some people believe that the Maya used this vine to brew a type of “mayahuasca.” (Photographed in Tikal)

This yellow-blossomed vine was published under the name *Banisteria tomentosa*. (Copperplate engraving, colorized, nineteenth century)

***Banisteriopsis quitensis* (Niedenzu) Morton**

This species is purported to have hallucinogenic effects (Schultes and Farnsworth 1982, 188*). Today, it is regarded as a synonym for *Banisteriopsis caapi*.

***Banisteriopsis rusbyana* (Niedenzu) Morton**

This name is now regarded as a synonym for *Diplopterys cabrerana*.

An Indian plays on the yuruparí trumpet; according to mythical tradition, the trumpet came from the heavens filled with *Banisteriopsis* spp. (From Koch-Grünberg, *Zwei Jahre bei den Indianern Nordwest-Brasiliens*, 1921*)

“Ayahuasca [from *Banisteriopsis* spp.] is drunk among the Cashinahua to obtain information which would otherwise remain concealed. The hallucinations are regarded as the experiences of one’s own dream spirit; they are clues about the future and memories of the past, and with them the drinker can learn about things, people, and events that are far removed.”

ARA H. DER MARDEROSIAN, ET AL. “THE USE AND HALLUCINATORY PRINCIPLE OF A PSYCHOACTIVE BEVERAGE OF THE CASHINAHUA TRIBE (AMAZON BASIN)” (1970, 7)

Early illustration of the frankincense tree, which was long unknown in Europe. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

Boswellia sacra Flückiger

Frankincense Tree

Family

Burseraceae (Bursera Family)

Forms and Subspecies

The true frankincense tree can exhibit considerable variation, depending upon its place of origin. For this reason, it has been described under numerous names that refer solely to local varieties, forms, or races. The taxonomy of the genus *Boswellia* is represented very irregularly in the literature, particularly the nonbotanical literature. An additional difficulty lies in the fact that many species of the genus produce resins that are sold under the name frankincense (Watt and Sellar 1996, 22f.).

Synonyms

Boswellia bhau-dajiana Birdwood

Boswellia carteri Birdwood

Boswellia thurifera sensu Carter

Folk Names

Ana, bayu, beyo, djau der, echter weihrauchbaum, encens, frankincense, frankincense tree, incense tree, kundara (Persian), kundur (Persian), lebona (Hebrew), libanotis (Greek), lubân, luban-tree, maghrayt d'scheehaz (Arabic), mohr (Somali), mohr madow, mohr meddu, neter sonter (Egyptian), oliban, olibanum (Roman), olibanumbaum, seta kundura (Hindi), weihrauchbaum, weihrauchstrauch, weyrauch, wicbaum, wichboun

History

Frankincense, the true incense, is the golden yellow, pleasantly aromatic resin of the bushlike frankincense tree, great forests (“balsam gardens”) of which thrive near the Red Sea, especially in Arabia (the ancient land of incense known as Sa’kalan) and Somalia (the legendary land of Punt) (Wissman 1977). For at least four thousand years, frankincense has been obtained in these regions from incisions made in the bark of the tree (Howes 1950). In ancient times, this was the most coveted of all resins used for incense, and it was transported along the famed Incense Road—probably the most important trade route of antiquity—between Egypt and India (Groom 1981; Kaster 1986).

Since ancient times, frankincense resin has been used to manufacture **incense**, cosmetics, and perfumes. Arabian women still burn frankincense to perfume their bodies, in particular the vulva (Martinetz et al. 1989). This not only lends them a more pleasant scent but also is said to make them more erotic.

The true frankincense tree (*Boswellia sacra*) in its natural habitat. (Photograph: Walter Hess)

Two qualities of olibanum, the resin of the frankincense tree (*Boswellia sacra*). Left, high-quality ware from Eritrea; right, the coarser, impure product from Ogaden.

Frankincense has been attributed with psycho-active powers since the early modern period (Lonicerus 1679, 738*; Menon and Kar 1971; Farnsworth 1972, 68*). As a result, frankincense was swallowed, burned, or smoked in the Ottoman Empire, in Arabia, and even in Europe (often in combination with opium; cf. *Papaver somniferum*). Other incense plants have also been claimed to induce hallucinogenic effects (cf. *Bursera bipinnata*).

The history of frankincense and the tree it is obtained from is simultaneously a history of mistaken identities and confusion, as all drop-shaped aromatic resins were once referred to as “frankincense” (Schneider 1974, 1:185f.*). Since all species of *Boswellia*—and their resins—display considerable variation, the botanical classification is often a question of chance (cf. Hepper 1969). The botanical identity of the stock plant was not determined until the middle of the nineteenth century (Carter 1848; Hepper 1969).

Distribution

The frankincense tree occurs in Somalia and southern Arabia. In Somalia, it is primarily found in areas between 100 and 1,800 meters above sea level (Pabst 1887, 1:54*).

Cultivation

Cultivation methods (assuming any are actually known) are a well-protected secret of the peoples who live from the collection of frankincense. The ancient Egyptians attempted to plant frankincense trees in Egypt but were unsuccessful in spite of their great knowledge of gardening (Dixon 1969). They excavated small trees together with soil that they then shipped back to Egypt in tubs. The trees died shortly thereafter.

Appearance

This small, rather graceful tree grows from 4 to 5 meters in height, and in rare cases to 6 meters. It has a robust trunk and a dark brown, papery bark that sheds repeatedly and immediately regrows. Each year, new shoots form that are thickly adorned with short yellow trichomes. The pinnate leaves grow in clusters on the ends of the branches. The small, petiolate flowers grow from the leaf axils and are arranged in panicle racemes. The whitish flowers have five petals and ten red stamens. The small fruits form light brown capsules that have three lobes, in which the angular stones sit individually with the small seeds. Flowering occurs in April.

The true frankincense tree is very easily confused with *Boswellia serrata* Roxb., the Indian incense tree, especially because this species is also a source of incense (Indian frankincense) (Schneider 1974, 1:187*). The very similar *Boswellia papyrifera* (Del.) Hochst. is easily distinguished on the basis of its height; it grows much taller and is more ramified than the other species.

Psychoactive Material

—Resin (olibanum, Somalian olibanum, Aden olibanum, Bible incense, Arabian olibanum)
In Persia (Iran), a distinction is made between two types of olibanum: *kundara zakara*, “male incense,” is dark yellow to reddish in color and comes in the form of round drops; *kundara unsa*, “female incense,” is yellowish-whitish, pale, and transparent and usually comes in the form of oblong drops (Hooper 1937, 92*).

Resins used to counterfeit frankincense are false incense (spruce resin; *Picea* spp.), gum arabic (cf. *Acacia* spp.), fir resin (*Abies* spp.), mastic (*Pistacia lentiscus* L.), sandarac (the resin of *Tetraclinis articulata* (Vahl) Mast or *Callitris quadrivalvis* Vent.), and calcite crystals (Pabst 1887, 1:56*).

Preparation and Dosage

The resin is obtained by making long (4 to 8 cm), deep incisions into the bark. A special scalpel-like instrument known as a *mengaff* is used for this purpose. According to Theophrastus, the resin should be collected during the dog days, i.e., the hottest time of the year. Pliny also noted that the first incision into the bark of the stock plant should be made around the time of the rising of the Dog Star (Sirius).

Frankincense is an important component in many recipes for psychoactive **incense**. It is also an ingredient in the **Oriental joy pills** and was formerly used as a spice in wine (cf. *Vitis vinifera*).

“[Amun] transformed herself into the form of the majesty of her spouse, the king of Upper and Lower Egypt; they [Amun and Thoth] found her as she rested in the splendor of her palace.—She awakened from the scents of the god; she laughed at his majesty. . . . She was filled with joy to see his beauty, his body went into her body, [the palace] was flooded with the scents of the god, all of his scents were [scents] from Punt [the land of incense].”

TEMPLE INSCRIPTION AT DER EL-BAHARI (CA. 1550 B.C.E.) CITED IN *WEIHRAUCH UND MYRRHE* [FRANKINCENSE AND MYRRH] (MARTINETZ ET AL. 1989, 103)

“God does not permit himself to be held, nor heard, nor seen, but in the scent of the divine flower or the taste of the sacred juice, it is most likely that the conception of him will be awakened. Using incense, balsam, and sacred oils, through tonic and heart-strengthening

plant extracts, the Egyptians speak directly to the gods, they begin to breathe, to speak, to open their mouths and live.”

PAUL FAURE

MAGIE DER DÜFTE [MAGIC OF SCENTS]

(1990, 23)

Other Types of Olibanum

The following species of *Boswellia*, which occur in East Africa and India, also yield resins that are referred to and marketed as olibanum:

<i>Boswellia frereana</i> Birdw. gekar, elemi olibanum,	African elemi, yegaar
<i>Boswellia papyrifera</i> (Del.) Hochst. [syn. <i>Amyris</i> <i>papyrifera</i> Gaill. ex Del.] olibanum	Ethiopian olibanum, Eritrean
<i>Boswellia serrata</i> Roxb. ⁵⁰ [syn. <i>Boswellia thurifera</i> Colebr., <i>Boswellia glabra</i> Roxb., <i>Canarium</i> <i>balsamiferum</i> Willd.]	Indian incense, salakhi, lobhan, thus indica

An ancient Egyptian illustration of the frankincense tree as a potted plant, in the grave of Hatshepsut (1504–1483 B.C.E.). The inscription reads: “Greening incense tree, 31 pieces; brought here among the delicacies for the majesty of the god Amun, the lord of the earthly throne. Never has its like been seen since the creation of the universe.” (From Engel)

Ritual Use

For both cultic and economic reasons, frank-incense was the most important **incense** of the ancient Assyrians, Hebrews, Arabs, Egyptians, and Greeks. The resin was used as a fumigant and offered to the gods at every ceremony. The Assyrians burned it especially for Ishtar, the queen of the heavens, for Adonis, the god of resurrecting nature, and for Bel, the Assyrian high god. The Assyrian kings, who were also high priests, offered frankincense to the tree of life, which was sprinkled with wine (cf. *Vitis vinifera*) as it was bathed in smoke. The pagan, pre-Islamic Arabs consecrated frankincense to Sabis, their sun god, and the entire supply was required to be stored in the temple of the sun. Among the Hebrews, frankincense was one of the ingredients of the sacred incense and a symbol of divinity. The Bible refers to it as a sacred incense and an article of tribute and trade. It later became the most important incense of the Catholic Church. In central Europe, the resin of the frankincense tree became known primarily through the Catholic Church. At the time of Charlemagne, it was burned not only during masses but also during the “trials by ordeal” that were common at the time.

Egyptian and Greek magicians of the late ancient period used the smoke to conjure demons, the intermediary beings that they wished to put to use. In Egypt, the frankincense tree was consecrated to Amun of Thebes. Incense was also sacred to Hathor, the goddess of drunkenness (cf. *Mandragora officinarum*). For the Romans as well, there was no ceremony, no triumphal procession, no public or private celebration that did not include the use of this aromatic resin. It was said that frankincense “enabled one to recognize god.” Frankincense manna was sacred to the sun and the oracular god Apollo (cf. *Hyoscyamus albus*). Frankincense was also important in the cult of Aphrodite. Offering the goddess incense was a way to ensure that the hetaerae, or temple servant girls, would be provided with sufficient clientele. In Ethiopia, frankincense is still burned to “control evil spirits” (Wilson and Mariam 1979, 30*). Similar practices have been preserved in certain Swiss folk customs (Vonarburg 1993).

Artifacts

Both frankincense and the tree from which it comes are frequent subjects in ancient Egyptian works of art (wall paintings, poetry). There are a great many incense vessels and other devices for burning incense (cf. Martinetz et al. 1989).

Medicinal Use

Frankincense was used for numerous medicinal purposes in ancient times and was praised by Hippocrates, Celsus, Dioscorides, Galen, Marcellus, and Serenus Sammonicus. It was used to produce oils to treat colds, **enemas** to treat constipation, agents for cleaning wounds, bandages to treat the “sacred fire” (cf. *Claviceps purpurea*), and ointments against frostbite, burns, skin nodules, rashes, scabies, warts, psoriasis, inflammations, excrescence, watery eyes, scars, ear inflammations, boils, rheumatism, and gout. More recently, an extract of *Boswellia serrata* (H 15)⁵³ has been used with success in Western medicine and phyto-therapy to treat rheumatoid arthritis (Etzel 1996). **Essential oils** distilled from a number of different types of frankincense are also becoming increasingly important in aromatherapy (Watt and Sellar 1996).

In traditional Chinese medicine, frankincense is generally regarded as a stimulant, and it is used to treat leprosy, skin diseases, menstrual cramps, coughs, and lower abdominal pains. The smoke or the

essential oil is inhaled for coughs.

In the early modern period, frankincense was even used for “psychiatric” purposes as a mood-enhancer:

The smoke of Olibani is good for heavy eyes / when taken in there. It removes sorrow / increases reason / strengthens the heart / and makes one of cheerful blood. (Lonicerus 1679, 738*)

In Ethiopia, frankincense is burned as a fumigant to treat fever and as a tranquilizer (Wilson and Mariam 1979, 30*).

Constituents

All types of frankincense are composed of 53% resin ($C_{30}H_{32}O_4$), gum, essential oil, boswellic acids, bitter principles, and mucilage. Frankincense contains 5 to 10% **essential oil**, consisting of pinene, limonene, cadinene, camphene, Π -cymene, borneol, verbenone, verbenol, dipentene, phellandrene, olibanol, and other substances. The composition of the essential oils of the different species varies somewhat (Tucker 1986). The essential oil from bejo (olibanum from Somalia) contains 19% α -thujene and 75% α -pinene, as well as sabinene, α -cymene, limonene, β -caryophyllene, α -muurolene, caryophyllene oxide, and other, unknown substances. The oil of olibanum Eritrea consists of approximately 52% octyl acetate; the oil of olibanum Aden contains approximately 43% α -pinene (Watt and Sellar 1996, 28).

For years, both the literature and the media have reported claims that pyrochemical modifications and reactions produce **THC** when frankincense is burned (Martinetz et al. 1989, 138; Faure 1990, 30).⁵⁴ To date, however, THC has not been detected in any genus other than **Cannabis**. The results of recent studies at the Pharmaceutical Institute of the University of Bern have demonstrated that no THC is produced when frankincense resin is burned; not even one nanogram was detected (Kessler 1991). But since there are numerous types of olibanum, it may be that some of these do contain THC or produce it when burned while others do not. However, the smoke was not “investigated with respect to other psychotropic substances, so that its last secrets are still preserved” (Hess 1993, 11).

Effects

Both olibanum and the incense of the church have long been attributed with inebriating, euphoriant, and mood-improving effects (Menon and Kar 1971). The *Universallexikon* of 1733 to 1754 states:

It strengthens the head, reason, and sense, but when it is used needlessly, it awakens painful days in the head and is damaging to the reason, otherwise it cleanses the blood, strengthens the heart, takes away sorrow, and makes the blood cheerful.

Cases of “olibanum addiction” are still observed and noted in the toxicological literature (Martinetz et al. 1989, 138). It is not unlikely that many people attended church services in the past because of the inebriating effects of olibanum.

Commercial Forms and Regulations

The olibanum that is now found in trade comes primarily from *Boswellia sacra*, the true frankincense tree, which is indigenous to Somalia, Iran, and Iraq. Olibanum is traded in different qualities and is named after its place of origin (Aden, Eritrea, Beyo). The unrefined drops (olibanum electum) are the best. Olibanum is available without restriction and can be obtained from sources specializing in

devotional articles and incenses.

Brugmansia arborea (Linnaeus) Lagerheim

Angel's Trumpet Tree

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

There are presumably different cultivars.

Because of their variability and the many hybrids, angel's trumpets are often very difficult to classify (Preissel and Preissel 1997). The botanical literature is also quite chaotic concerning the taxonomy of these plants (Bristol 1966 and 1969; Lockwood 1973).

Synonyms

Datura arborea L.

Datura arborea Ruíz et Pav.

Datura cornigera Hook.

Brugmansia candida Pers. sensu latu

Folk Names

Almizclillo, angel's trumpet tree, baumdatura, baumstechapfel, borrachera, (Spanish, "inebriator"),⁵⁵ campachu, campanilla, chamico, cimora, cojones del diablo, engelstrompetenbaum, floripondio, großer stechapfel, guar guar, hierba de los compañeros, huántac (Zaparo-Quechua), huanto, huánto (Quijo), huántuc (Quechua), huarhwar, isshiona (Zaporo), kecubong (Bali),⁵⁶ maícoma, mai ko, mai ko' mo, mataperro (Spanish, "dog killer"), misha huarhwar, misha rastrera blanca, qotu (Quechua), saharo, tecomaxochitl (Nahuatl),⁵⁷ toé, tree stramonium, trombeteiro (Brazil)

History

All of the angel's trumpets are from South America. They are now known only as cultigens and not as wild plants. It has still not been determined which wild plants yielded the known species and hybrids. This implies that the plant must have long played a role in human cultures. For this reason, it is very likely that angel's trumpets were already being used for ritual and psychoactive purposes in prehistoric times. *Brugmansia arborea* is from the Andes region. The earliest description of the Indian use of this potent hallucinogen is probably that of Bernabé Cobo (1653) (Bastien 1987, 115*). The species "was first described in 1714 by Louis Feullée, and Linnaeus's description is based upon his illustration" (Stary 1983, 96*).

Distribution

This relatively rare species has an extensive range, from Ecuador to Peru and Bolivia and into northern Chile. It grows wild in the Bolivian province of Bautista Saavedra, in the lower valleys of Camata (Bastien 1987, 114*).

Cultivation

This angel's trumpet, like all other *Brugmansia* species, is most easily propagated by cuttings. A sharp

knife is used to cut off the end of a branch, some 20 cm in length, which is then stripped of all but the newest leaf buds. The cutting is then placed in water. Roots appear after two to three weeks. Soon thereafter, it can be planted in nutrient-rich soil. Because the plant does not tolerate frost, in central Europe it can be grown only in pots.

The plant is grown for pharmaceutical purposes (**scopolamine** production) in the Andes region, Brazil, the southern United States, and India (Lindequist 1992*). The angel's trumpet also enjoys a wide distribution as an ornamental.

Appearance

The treelike perennial bush can grow as tall as 5 meters in height. It produces trumpet-shaped (sometimes double), five-pointed flowers that are white or cream-white in color and hang slightly to the side. At night, these exude an exhilaratingly sweet scent. The long calyx is single and deeply incised (an important diagnostic feature). The smooth fruits, when they do develop, are berrylike and contain large brown seeds. They are almost spherical (another important diagnostic feature). Most angel's trumpets only rarely or never produce fruits. The leaves, which frequently grow along the same side of the stalk, are oblong-elliptic and pointed at the ends and can be of varying lengths. In the tropics and temperate zones, angel's trumpets blossom throughout the year. The flowers wilt after about five days.

Brugmansia arborea is easily confused with the white-blossomed ***Brugmansia aurea*** and ***Brugmansia candida***.

Many plant lovers, gardeners, anthropologists, and even botanists confuse all *Brugmansia* species with the thorn apple (*Datura*). The two genera, however, can be easily distinguished by the position of their flowers. The flowers of all species of *Brugmansia* hang more or less straight down, while the flowers of the *Datura* species point more or less upward, often steeply. In addition, no *Brugmansia* is known to produce a thorny fruit.

Depiction of an angel's trumpet or tree datura on an Incan drinking vessel. (Copy by C. Räscht)

The treelike angel's trumpet (*Brugmansia arborea*) is a common ornamental throughout the world. Especially in subtropical zones, it can attain a stately height and develop woody stems. (Photographed in Peru)

Psychoactive Material

- Leaves
- Fresh flowers (used to produce the homeopathic mother tincture)
- Seeds

Preparation and Dosage

The leaves are extracted in cold water or steeped in hot water. A psychoactive dosage is usually given as four leaves or one flower brewed into a tea. The crushed seeds may be added to **chicha** (Bastien 1987, 114f.*). The leaves are also used as one of the main ingredients of the **cimora** drink and as an additive to preparations of San Pedro (*Trichocereus pachanoi*). Dried leaves are smoked alone or in **smoking blends** together with other ingredients, e.g., *Cannabis indica*.

Extreme caution should be exercised when ingesting any species of *Brugmansia*. Angel's trumpets are the most potent hallucinogens in the plant kingdom, producing hallucinations that are no longer recognized as such. South American shamans urgently warn unknowledgeable people against using these plants. Angel's trumpets are used for psychoactive purposes almost exclusively by experienced shamans. Overdoses can result in states of delirium that can last for days and have aftereffects that persist for weeks. Proper dosage presents an additional problem. People react very differently to the **tropane alkaloids**. In other words, the same dosage can produce completely different effects in different people. In the toxico-logical literature, one can read that heavy overdoses can be fatal; such cases, however, are only poorly documented (cf. *Brugmansia suaveolens*).

In contrast to internal ingestion, smoking the dried leaves is relatively harmless. Smoking an amount that corresponds to one to two cigarettes produces only subtle effects. The *Brugmansia* effects become more obvious when the leaves are combined with hemp products (*Cannabis indica*, *Cannabis sativa*).

Ritual Use

The Indians regard angel's trumpet as sacred. The priests of the Andean peoples smoked the leaves so that they could make prophecies, divine, and diagnose. Many Andean peoples use the seeds as an additive to the **chicha** (maize beer) that is drunk at village festivals and religious rituals.

“The Indians use [the angel’s trumpet] to get drunk, and when they take too much, they completely lose their senses, so that they cannot see or hear with open eyes. They are accustomed to exploit this for evil purposes. Not long ago, it happened that one of my friends was given *chamico* so that he could be robbed. When he awoke, he was so angry that he ran around naked, with only his shirt, and fell into a river. They seized him and kept him locked up until, after two days, he reawakened from his condition. Juice from the leaves, mixed with vinegar and applied above the liver, mitigates mild fever and is very good for high fever. A *mate* [= tea] of this solution heals chronic fever.”

BERNABÉ COBO

HISTORIA DEL NUEVO MUNDO [HISTORY OF THE NEW WORLD] (1653; CITED IN BASTIEN 1987, 115*)

Artifacts

It is astonishing that relatively few artifacts or artistic renditions are associated with angel’s trumpet. Where such objects do exist, it is usually almost impossible to determine which species is being represented (cf. *Brugmansia candida*). Angel’s trumpets are frequently depicted in the paintings of the American artist Donna Torres. Jürgen Mick has masterfully portrayed *Brugmansia arborea* in his comic story *Träume* [Dreams] (Carlsen, Hamburg, 1993).

Medicinal Use

In Peru, the leaves of this and other angel’s trumpets are used in the treatment of tumors (Chavez V. 1977, 231*). It is possible that the seeds may have been used for anesthetic purposes in pre-Columbian times, perhaps in combination with coca leaves (*Erythroxylum coca*) (Bastien 1987, 115*).

A number of potencies of *Datura arborea* hom. *HAB34* and *Datura arborea* hom. *HPUS78* are used in homeopathy in accordance with the medical description. The mother tinctures are produced by extracting the flowers in strong spirits (Lindequist 1992*).

Constituents

All parts of the plant contain **tropane alkaloids**. The leaves contain 0.2 to 0.4% total alkaloids, of which 0.01% is hyoscyamine, 0.13% is **scopolamine**, and 0.07% is **atropine**. The stems contain only 0.16% total alkaloids; the seeds contain chiefly hyoscyamine. The roots also contain the alkaloids (–)-3,6-ditigloyloxytropine, 7-hydroxy-3,6-ditigloyloxytropine, tropine, and pseudotropine. **Coumarins** and **scopoletin** are both present in all parts of the plant (Lindequist 1992, 1140).

Effects

Brugmansia arborea induces strong parasympatholytic effects (Jacinto et al. 1988). Characteristic symptoms include mydriasis (dilation of the pupils), often persisting for days, along with an extreme dryness of the mucous membranes. Depending upon the dosage and individual reactions, there can also be profound hallucinations with a complete loss of reality, delirium, coma, and death through respiratory paralysis (Lindequist 1992*).

Angel’s trumpets are said to have potent narcotic effects. In Peru, intoxicating a person against his or her will is known as *chamicado*, which means “touched by the angel’s trumpet” (Bastien 1987, 114*).

Commercial Forms and Regulations

The seeds and plants of all *Brugmansia* species are available without restriction and can be purchased in many nurseries and garden shops. The mother tincture requires a prescription (Lindequist 1992*).

Scopolamine

Hyoscyamine

Scopoletin

It is strange that this most potent and most dangerous of all plant hallucinogens is not included on any list of illegal drugs, while such plants as ***Cannabis*** and ***Erythroxylum***, which by comparison are almost completely harmless, are prohibited. This situation is a strong indication that most current drug laws are not founded upon scientific knowledge (cf. Körner 1994*).

“His body was burning with heat, his throat parched with dryness, and for the first time, he recalled the cup of Huacacachu [= *Brugmansia*] that he had ingested. Then he knew that he had journeyed through the land of visions, and not through the desert, as he had thought . . .”

Brugmansia aurea Lagerheim

Golden Angel's Trumpet

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

There is a yellow- and a white-blooming form. Several mutations have also been observed: “The clones of *Brugmansia aurea* are often of bizarre appearance. They are frequently infected by viruses” (Plowman 1981, 441).

Synonyms

Datura aurea (Lagerh.) Saff.

Schultes and Raffauf have recently suggested that ***Brugmansia candida*** is a synonym for *Brugmansia aurea* (1990, 421*). On the other hand, *Brugmansia aurea* is also regarded as a synonym for *Brugmansia candida*.

Folk Names

Borrachero, floripondio, gelbe baumdatura, golden angel's trumpet, goldene baumdatura, goldene engelstropfete, golden tree datura, guantu, huandauj, kiéri (Huichol),⁵⁸ kiéri-nánari (Huichol, “root of the kiéri”), yellow tree datura

History

Golden angel's trumpet was first discovered and described at the end of the nineteenth century by the Swedish botanist Nils Gustaf von Lagerheim (1860–1926) (Lagerheim 1893). In South America, its ethnobotanical significance is similar to that of ***Brugmansia candida*** (Plowman 1981).

Distribution

The original range of *Brugmansia aurea* extended from Colombia into southern Ecuador. It is not known when the species was introduced into Mexico. In the Andes, it is primarily found in altitudes between 2,000 and 3,000 meters (Plowman 1981).

“The aim and purpose of the Brugmansia inebriation was—as a rule—to establish contact with the gods or the spirits of the ancestors. With their help, one could try to positively influence one's own future and that of the tribe. In the inebriated state, one saw oneself transported into a different level of consciousness that made it possible to communicate with the supernatural powers, to ask them for help, and to receive their teachings. Brugmansias were the keys that opened the door to this other world.”

ULRIKE AND HANS-GEORG PREISSEL *ENGELSTROMPETEN* [ANGEL'S TRUMPET] (1997, 14f.)

Cultivation

See ***Brugmansia arborea***.

Appearance

This perennial, treelike shrub has a woody stem and is usually heavily branched. The smooth, margined leaves are oval-cuspidate. The calyx is simple and only slightly incised. The long, funnel-shaped, five-pointed, and normally luminously yellow flowers hang down at an angle. They are larger than the flowers of *Brugmansia arborea* and more stocky than the blossoms of *Brugmansia candida*. The smooth fruits are somewhat fatter and shorter than those of *Brugmansia candida*.

The white-blossomed form is very easily mistaken for *Brugmansia candida*.

Psychoactive Material

- Stems and stem pith
- Leaves
- Flowers
- Seeds

Preparation and Dosage

The Canelos scrape the green pith from split stems, press this, and ingest it when it is swollen with water (Whitten 1985, 155).

In Ecuador, the juice pressed from the pith of a 5 cm long, finger-thick piece of stem is used as a “prophetic” dose (Metzner 1992). The juice is drunk with some water.

The dried leaves and flowers can be smoked alone or in **smoking blends** (cf. *Brugmansia arborea*, *Brugmansia suaveolens*).

Ritual Use

The shamans of the Canelo Indians use angel’s trumpet to establish contact with their spirit helpers and animal spirits. With their aid, they are able to detect sorcerers who carry out harmful magic in secret and magically send “worms” and other diseases into their victims’ bodies (Whitten 1985). In Ecuador, the juice of the plant is ingested to induce prophetic dreams that can then be interpreted as portents concerning the next phase of one’s life (Metzner 1992).

The seeds are used as an inebriating additive to **chicha** (maize beer), which is consumed at village festivals and religious rituals.

In Mexico, the Huichol apparently use this angel’s trumpet in a manner similar to *Solandra* spp.

Artifacts

Kiéri plants are sometimes depicted in the visionary art of the Huichol (see *Solandra* spp.).

Medicinal Use

Identical to the use of *Brugmansia candida*

Constituents

Golden angel’s trumpet contains large amounts of **tropane alkaloids**. The total alkaloid content was found to be 0.9%, with the main alkaloid **scopolamine** (hyoscyne) making up some 80% of the mix (Plowman 1981, 440). In addition, apoatropine, 3 α -tigloyloxytropine-6 β -ol, tigloidine, 6 β -acetoxy-3 α -tigloyloxytropine, apohyoscyne, hyoscyamine/atropine, norhyoscyamine/noratropine, 6 β -hydroxyhyoscyamine, and tropine-3 α -ol are also present (el Imam and Evans 1990, 149*).

The luminous yellow-gold blossom of the relatively rare yellow angel's trumpet (*Brugmansia aurea*).

Effects

This species has been reported to produce intense dreams of a prophetic nature (Metzner 1992). Apart from this, the general effects are similar to those of *Brugmansia candida*.

Commercial Forms and Regulations

See *Brugmansia arborea*.

“Most of the ethnographic reports about tree daturas list the species used under the name *Brugmansia (Datura) arborea* (L.) Lagerh. This name is assigned without distinction to every white-flowered *Datura*. While this species is indeed used with great pleasure, it is one of the rarer species. It usually grows in the higher regions of Ecuador and south toward Bolivia. *Brugmansia aurea* Lagerh. is used much more commonly. This plant grows at altitudes between 2,000 and 3,000 meters, primarily in the northern Andes of Venezuela and in the south toward Ecuador, where it is frequently found along roadsides, rivers, and drainage ditches. The flowers are also sometimes golden yellow.”

TIMOTHY PLOWMAN “BRUGMANSIA (BAUM-DATURA) IN SÜDAMERIKA” [BRUGMANSIA (DATURA TREE) IN SOUTH AMERICA] (1981, 439)

Brugmansia x candida Persoon

White Angel's Trumpet

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

This quite variable angel's trumpet may be a natural hybrid between *Brugmansia aurea* and *Brugmansia versicolor* (Giulietti et al. 1993). There is a white form and a form that produces peach-colored flowers.

A form cultivated by the Sibundoy Indians that has tiny, stunted leaves has been described under the name *Datura candida* (Pers.) Saff. cv. Munchira; the “normal” form was referred to as *Datura candida* (Pers.) Saff. cv. Biangan (Schultes 1979b, 147f.*). Additional forms include *Datura candida* cv. Quinde, *Datura candida* cv. Andres, *D. candida* cv. Ocre, *D. candida* cv. Amaron, and *D. candida* cv. Salaman (Bristol et al. 1969).

A form used commercially and ornamentally is known by the name *Datura candida* cv. Flintham Hall (Imam and Evans 1990*).

Methysticodendron amesianum, which Richard Evans Schultes (1955) described as a new genus and species, is now known to be nothing more than a “monstrous” cultivar (Bristol 1965, 272*). It may be best described as *Brugmansia x candida* f. Culebra.

From Peru, the following forms, all of which are used for psychoactive purposes (cf. *Trichocereus pachanoi*, *cimora*), have been described:

Brugmansia x candida f. Cimora oso

Brugmansia x candida f. Cimora galga

Brugmansia x candida f. Cimora toto curandera

Synonyms

Brugmansia candida Pers.

Datura affinis Saff.

Datura arborea Ruíz et Pav. non L.

Datura aurea x *D. versicolor*

Datura candida (Pers.) Saff.

Datura x candida (Pers.) Saff.

Datura pittieri Saff. *Methysticodendron amesianum* Schultes

Folk Names

Almizclillo, amarón, andaqui, biangán, biangán borrachera, borachero, borrachera, borrachera de agua, borrachero (Spanish, “inebriator”),⁵⁹ borracherushe, buyés, buyés borrachera, buyés borracherushe, cacao sabanero, cambanda, campana (Spanish, “bell”), campanilla (Spanish, “little bell”),⁶⁰ cari, chamico,⁶¹ chontaruco, chontaruco borrachera, cimora,⁶² cucu, culebra, culebraborrachero (Spanish, “snake inebriant”), danta (“tapir”), danta borrachera, flor de campana (Spanish, “bell flower”), floripondio, floripondio blanco, goon’-ssi-an borrachero (Kamsá), guamuco blanco, guamuco floripondio, huama, kampaana wits (Huastec, “bell of the mountain”),

kampachu (Quechua), kampaña nichim (Tzeltal, “bell flower”), kin-de-borrachero (Inga), lengua de tigre (“tongue of the jaguar”), lipa-ca-tu-ue (Chontal), maikoa, mets-kwai borrachero (Masá, “jaguar inebriant”), misha, mitskway borrachero, munchira, mutscuai, ngunsiana, nitkwai boracero (Kamsá), nit-waí-boracero (Inga), palpanichium, po:bpihy (Mixe), queen of the night, quinchora borrachera, quinde, quinde borrachero, reinweißer stechapfel, Sta. Maria wits (Huastec, “St. Mary’s flower”), salamán, salamanga, salvanje, tecomaxochit (Náhuatl), trombita (Spanish, “little trumpet”), ts’ak tsimin (Lacandon, “horse medicine”), tu:tk-hiks (Mixe), white angel’s trumpet

History

In 1935, H. García-Barriga collected the first specimen of this species in the Sibundoy Valley of Colombia (located at an altitude of 2,200 meters). Later, numerous forms were described for the Sibundoy region on the basis of the Indian ethnobotanical classification of the angel’s trumpets. *Datura* (*Brugmansia*) *candida* cv. Culebra was originally thought to represent a different genus and was described by Richard Evans Schultes under the name *Methysticodendron amesianum* (Schultes 1955). This form has very long, thin leaves that look like snakes; for this reason, the Sibundoy Indians call this form *culebra-borrachero* and the Kamsá call it *mitskway-borrachero*, both of which mean “snake inebriant” (Schultes 1979b, 148f.*). It is not known when this ethnobotanically significant species spread into Central America.

Distribution

The plant is originally from Colombia or Ecuador (Franquemont et al. 1990, 99*) and is still common in these areas. It is usually found at altitudes between 1,500 and 2,500 meters. It was apparently introduced into Mexico in pre-Columbian times (Berlin et al. 1974, 280*).

Cultivation

Propagation can take place only by cuttings, although this is very simple. The stem is simply placed in the ground and watered (Bristol 1965, 276*). Apart from this, cultivation is the same as with *Brugmansia arborea*. Nitrogen-rich soils have been found to increase alkaloid production in the plant.

Appearance

Growing to heights of up to 8 meters, this treelike shrub always produces flowers but only very rarely produces fruits. The smooth fruits are slender, spindle-shaped, and pointed at the end. They are somewhat more slender and longer than the fruits of *Brugmansia aurea* (which is how the two species may be distinguished). This angel’s trumpet typically bears snow-white flowers that hang almost straight down, are often double, and can reach a length of more than 30 cm. In southern Mexico, the flowers of this species sometimes have a pink margin. The form of the flowers is so variable that it is often very difficult to make a definite species identification.

Brugmansia x candida is very often confused with *Brugmansia aurea* and has even been regarded as a synonym for the latter. It can also be mistaken for *Brugmansia arborea*.

Psychoactive Material

- Leaves
- Flowers

Preparation and Dosage

Shamans in Colombia use primarily cold-water extracts of the leaves. Normally, only pairs of leaves

—and even numbers of pairs—are used. Depending upon the size of the leaves, the Sibundoy Indians regard two to twenty-four (= twelve pairs) leaves per person as a shamanic dosage. For “normal” people, this dosage would likely result in extreme delirium and dangerous toxic symptoms.

In the Kamsá tradition, the “jaguar inebriant,” which is made from the fresh leaves of *Brugmansia x candida* f. *Culebra* (= *Methysticodendron amesianum*), can be produced and drunk only during a waning moon. No more than one hour before they are to be ingested, the leaves are plucked from the shrub, crushed, and placed in cold water for about half an hour. Directly before the extract is consumed, it is warmed a little and stirred, but never boiled. The liquid is then strained off. The shamans never drink all of the liquid at once but, rather, take a few sips at a time over a period of some three hours. This procedure evidently enables them to achieve the dosage that is appropriate for them. If the shaman has not fallen into trance after three hours, a helper will prepare another drink and give small sips of it to him until the desired state of consciousness has been achieved (Schultes 1955, 9).

Northern Peruvian *curanderos* (folk healers) drink a decoction of the leaves to induce a clairvoyant trance. The freshly pressed juice of the leaves and/or flowers is also ingested alone or mixed with **alcohol** and sugar (Bristol 1965, 285*).

In Peru, at least three cultivated forms (see above) are used as one of the main ingredients in the psychoactive drink known as **cimora** and as additives to preparations of San Pedro (*Trichocereus pachanoi*).

The dried leaves and flowers can be smoked alone or mixed with other plants such as *Cannabis indica* and *Nicotiana rustica* to produce **smoking blends** (cf. *Brugmansia arborea*).

Ritual Use

In Colombia (Sibundoy), extracts of the leaves are drunk at shamanic and religious ceremonies of the Kamsá and Inga Indians, primarily to learn about methods for performing witchcraft, divination, prophecy, and shamanic therapy.

Among the Kamsá, the form described as *Methysticodendron amesianum* is known as *mets-kwai borrachero* or *mitskway borrachero*, the “jaguar inebriant” (Schultes 1955, 10). Corresponding to the strongest of all shamanic animals, this plant thus represents a very potent shamanic vehicle (cf. *Nymphaea ampla*, *Solanum spp.*). The shamans of the Kamsá use this agent almost exclusively for divination and prophecy. They normally turn to it only when faced with a truly difficult case, for it can occur that the body of the shaman who has used it lies in a comatose or delirious state for two to three days while his soul explores the secret corners of nonordinary reality. During this procedure, an assistant is always present. He does not merely watch over the shaman’s body but also pays heed to any messages the shaman may utter (Schultes 1955, 8f.).

In modern Mexico, angel’s trumpets are used as alternatives to the herbaceous thorn apples (*Datura innoxia*, *Datura stramonium*) (Heffern 1974, 100*). In some Mixe settlements, angel’s trumpets are used for divination and diagnosis (Lipp 1991, 187*). Three flowers is the suggested effective dosage, although six flowers may be administered if the desired effects are not achieved with three. The fresh flowers are macerated in hot water and then pressed with a cloth (190).

The Huastec, who live on the Gulf of Mexico, believe that a person who has eaten *Brugmansia candida* leaves “sees” reality (Alcorn 1984, 624*). The Tzeltal, who live in the Selva Lacandona (Chiapas, Mexico), smoke the dried leaves (with or without tobacco, *Nicotiana rustica*) when they wish to perform divinations (Rätsch 1994c*).

Cultivated plants of *Brugmansia x candida* often develop double flowers.

“Our ancestors were accustomed to it, so it is said,
to drink many medicines, even more than we do.
By drinking these medicines they could see, so it is said,
the forms in which things appear. And once they drank yagé
and angel’s trumpets,
and suddenly, so it is said,
a falcon flew past,
and the bird fell dead in the courtyard.
And then they said: O God,
what is going to pass?
And as they asked this,
the best among the drinkers of medicine answered:
People from another world will come,
flying, and they come to drive us from our land.”

FRANCISCO TANDIOY

IN *VON DEN WURZELN DER KULTUR* [FROM THE ROOTS OF CULTURE]
(RÄTSCH 1991b, 161*)

The leaves of the cultivated “snake plant” angel’s trumpet (cv. Culebra) are often grossly deformed.

Artifacts

The Mexican art nouveau artist Saturnino Herrán (1887–1919) painted a fresco, *Nuestros dioses*, in the center of which Coatlicue, the Aztec earth goddess, is portrayed adorned with angel’s trumpets

(López Velarde 1988, 113). During the art nouveau movement, glass lamp shades were manufactured in the shape of angel's trumpet flowers (cf. *Brugmansia arborea*). In a cloth print (Paris, 1896) based upon a design by Alphonse Mucha, *Brugmansia x candida* appears as a floral element playfully surrounding a young woman.

The prophetic powers of the angel's trumpet are portrayed in a theater piece by Francisco Tandioy (McDowell 1989, 139).

Medicinal Use

In the Sibundoy Valley, the fresh flowers and leaves of *Methysticodendron amesianum* are heated in water and applied as a plaster to treat tumors, swelling, swollen knees, et cetera. Medicine men sometimes bathe patients suffering from fever and chills in a warm decoction of the leaves and flowers (Schultes 1955, 9f.).

In Colombia, preparations of *Brugmansia candida* are used to treat muscle cramps, erysipelas (a skin inflammation), swollen inflammations, and colds. The Tzeltal Indians of Chiapas (Mexico) use the leaves to treat diseases that are caused by “winds” in the body.

Constituents

All forms of *Brugmansia x candida* contain **tro-pane alkaloids**. The primary constituent is **scopolamine** (hyoscyne); also present are meteloidine and hyoscyamine. The Culebra form (= *Methysticodendron amesianum* Schultes) contains hyoscyamine, scopolamine, and **atropine**; L-scopolamine makes up 80% of the plant's total alkaloid content (Bristol 1965, 286*). The young leaves have the highest concentration of alkaloids, up to 0.56% total content (Griffin 1976). The cultivar Flintham Hall was found to contain 0.55% total alkaloids, with scopolamine the primary constituent. Also present are 6 β -acetoxy-3 α -tigloyloxytropene, tigloidine, 6 β -tigloyloxytropene-3 α -ol, 3 α -tigloyloxytropene-6 β -ol, hyoscyamine/ atropine, norhyoscyamine/noratropine, 6 β -hydroxyhyoscyamine, and tropane-3 α -ol (el Imam and Evans 1990, 149*).

Effects

The Sibundoy Indians say that they encounter numerous giant snakes in the visions they receive while under the influence of this powerful magical plant. One Sibundoy provided the following description of his first encounter with the “snake plant”:

The first time, I drank six leaves [of the Culebra form] at night. I became drunk. I saw forests full of trees, people from other places, animals, tree stumps, meadows full of all kinds of snakes which came towards me at the edge of the pasture—all in green—to bite me. As the inebriation became stronger, the house began to lean against the rest of the world, as did the things in the house. . . . But the snakes still wanted to kill me. (Bristol 1965, 283*)

Apart from this, the effects of this plant should not differ much from those of the other species of *Brugmansia* (see *Brugmansia arborea*).

Commercial Forms and Regulations

Brugmansia x insignis (Barbosa Rodrigues) Lockwood ex Schultes

Magnificent Angel's Trumpet

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

The Siona make a distinction among at least four “species” of this plant, the names of which refer to totemic and shamanic elements (Vickers and Plowman 1984, 29*):

muhu pehí—“thunder angel’s trumpet”

semé pehí—“Paca angel’s trumpet”

sesé pehí—“white-lipped peccary angel’s trumpet”

tākiyai pehí—“*tāki*-cats angel’s trumpet”

Synonyms

Datura insignis Barb. Rodr. in Vellozia

Datura x insignis Barb. Rodr.

Datura suaveolens x *D. versicolor*

Folk Names

Ain, ain-va-i (Kofán), angel’s trumpet, danta borrachera, floripondio, guando, hayapa, huanduj, jayapa, ku-a-va-u, ku-wá-oo (Inga, “pink angel’s trumpet”), magnificent angel’s trumpet, maricaua, muhu pehí, pehí (Secoya), pimpinella borrachera, saaro (Matsigenka), sacha-toé, toa-toé, tree-datura, ts’ak tsimin (Lacandon, “tapir medicine”), wandú (Quechua), xayápa (Mashco)

History

The Amazon Indians of Ecuador use the stem of this angel’s trumpet as a hallucinogen. The Mashco, who live in the southwestern region of the Amazon (Peru), are composed of two tribes (Huachipaire and Zapiteri). Their most important shamanic plant is the magnificent angel’s trumpet, which they call *xayápa*.

Distribution

This hybrid of *Brugmansia suaveolens* and *Brugmansia versicolor* was likely the result of cultivation. The plant is from the West Amazon, and many Indians plant it in their house gardens (Vickers and Plowman 1984, 29*). The species has spread into other tropical areas. It is frequently found growing wild in the Selva Lacandona (Chiapas, Mexico).

Cultivation

In Amazonia, this angel’s trumpet is propagated with cuttings. The Indians take a piece of stem or branch approximately 50 cm long and simply stick this into the moist ground (Califano and Fernández Distel 1982, 131).

Appearance

This species is most likely the result of a cross between *Brugmansia suaveolens* and *Brugmansia versicolor* (Schultes 1977b, 124*) and looks exactly like an intermediate stage between the two species. It is most easily recognized by its flowers. They are convex, like those of *Brugmansia suaveolens*, but not as obese, and they hang almost straight down, although not as steeply as those of *Brugmansia versicolor*.

In the tropics, *Brugmansia* x *insignis* can grow into a proper and heavily branching tree that can reach a height of over 5 meters. In Amazonia, it blossoms between November and April. The flowers exude a potent perfume in the evening. This cultivar almost never develops fruits (Califano and Fernández Distel 1982, 131).

In addition to the yellowish-reddish blooming form, there is also a form with luminously yellow blossoms that is easily mistaken for *Brugmansia aurea*. This species is also easily confused with *Brugmansia suaveolens* and *Brugmansia versicolor*.

Psychoactive Material

—Stems

—Leaves

—Flowers

“The origin myth of the Huachipaire has the following to say about *xayápa* [*Brugmansia* x *insignis*]: Xayápa was a man who had come to the settlement and announced that he would remain as a medicine. He then changed himself into a plant.”

MARIO CALIFANO AND ALICIA FERNÁNDEZ DISTEL

“THE USE OF A HALLUCINOGENOUS PLANT AMONG THE MASHCO (SOUTHWESTERN AMAZONIA, PERU)”
(1982, 135)

Preparation and Dosage

The Secoya grate the stem and boil it for an entire day. They then pour off the decoction and boil it down some more. Unfortunately, no precise information about dosages is known, as use of the plant is restricted to knowledgeable shamans (Vickers and Plowman 1984, 29*).

The Siona and Secoya also use this angel’s trumpet as an **ayahuasca** additive. The leaves are burned to ashes in a pot and powdered. This powder is mixed into the finished ayahuasca to potentiate the visions (Vickers and Plowman 1984, 29*). The leaves are also used as an ayahuasca additive in the area of Loreto (Peru) (Schultes and Raffauf 1990, 422*).

The cultivar *Brugmansia x insignis* cv. Orange produces beautiful trumpet-shaped yellow flowers.

Brugmansia x insignis is a highly significant shamanic plant among the peoples of the rain forests of northern South America and southern Mexico. (Wild plant, photographed in the Selva Lacandona, Mexico)

The Kofán drink an infusion of the leaves for psychoactive purposes. An infusion of six leaves in 200 ml of water is sufficient to induce a hypnotic state (Schultes and Raffauf 1990, 422*). The Kofán also drip juice pressed from fresh flowers into the nostrils of their hunting dogs “so that they can hunt better” (421).

The Mashco prepare a hallucinogenic drink from this plant. Both the drink and the plant itself are known as *xayápa*. The Mashco take stalks of various thicknesses, cut these into pieces about 70 cm in length, and carry them into the ritual house, which is located outside of the settlement in the jungle. There, the bark is peeled from the pieces of stalk, pounded, and boiled in water for several hours. The long period of boiling yields a thick concentrate that possesses “enough hallucinogenic power.” The preparation of *xayápa* is usually carried out by a knowledgeable—typically older—person who also assists the *xayápa* drinker during his journey (Califano and Fernández Distel 1982, 135). The shamans of the Huachipaire Mashco also ingest the drink in the form of an **enema** (140).

Ritual Use

The Huachipaire Mashco have several rules associated with the ritual consumption of the *xayápa* drink that must be observed without exception: Ingestion must take place at night; the drinker must lie on the ground or a platform, uncovered, with open arms, and be able to observe the nocturnal sky above; the liquid must be drunk with the lips directly from the pot without touching the pot; the assistant or assistants may not speak to the drinker, even when the latter encourages them to do so; when the sun rises, the drinker must be dipped completely naked into the water of a nearby stream or river so that the last effects of the drink dissipate. In the weeks following ingestion, the drinker must adhere to a specific diet. In no case may he consume certain fishes and birds, bananas, and sugarcane,

lest he fall victim to fever, skin spots, or stomach ailments. The drink is customarily ingested to localize a lost or stolen object, discern the future, heal illnesses, or renew the body. The Mashco believe that under the influence of *Brugmansia*, the body is renewed or rejuvenated and thereby healed of all diseases (Califano and Fernández Distel 1982, 135f.). A longer life can thus be expected.

In Colombia and Peru, shamans also ingest preparations of angel's trumpet for diagnostic purposes (Schultes and Raffauf 1990, 422*).

Artifacts

See *Brugmansia arborea*.

Medicinal Use

The fresh leaves are tied to inflamed or painful areas. The freshly pressed plant juice is also used to treat pains. An infusion of the leaves is drunk as a sedative (Schultes and Raffauf 1990, 421f.*).

Constituents

This angel's trumpet contains the **tropane alkaloids atropine, scopolamine**, and hyoscyne. The bark appears to be particularly rich in alkaloids (Califano and Fernández Distel 1982, 134).

Effects

The Mashco granted permission to anthropologists Mario Califano and Alicia Fernández Distel to try the *xayápa* drink several times under their instruction and supervision. They drank approximately one quarter of a liter of the bitter, almost viscous drink. This resulted in a series of hallucinations pertaining to the “social life that we had experienced a few days earlier,” and they saw family members and friends approach them as if from a different world. The effects lasted a total of twelve hours and were characterized by visual hallucinations, illusory feelings, acoustic and olfactory hallucinations, and a profound dryness of the mouth. They occasionally fell into periods of sleep from sixty to ninety minutes long, with prophetic dreams, but they also experienced nervous discomfort and euphoria (Califano and Fernández Distel 1982, 137f.).

The Lacandon (Chiapas, Mexico) say that horses who have eaten the leaves of this angel's trumpet become inebriated “as if they were drunk.”

“The pith [of this angel's trumpet] gives visions of the future and makes it possible for one to hear the words that a person has said to other people.”

Brugmansia sanguinea (Ruíz et Pavón) D. Don

Bloodred Angel's Trumpet

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

One form from Sibundoy that has heavily serrated leaves has been described under the name *Datura sanguinea* Ruíz et Pav. cv. Guamuco (Schultes 1979b, 148).

Datura vulcanicola [syn. *Brugmansia vulcanicola* (Barclay) Lockw.], a species originally described by A. S. Barclay (1959), is now regarded as a subspecies: *Brugmansia sanguinea* ssp. *vulcanicola* (Riviera et al. 1989). The variety [or cultivar β] *flava* Dunal is a yellow-blooming variety (= *Brugmansia lutea* = *Datura rosei*) cultivated primarily in Colombia. A form with pure red flowers occurs in the highlands of southern Colombia and northern Ecuador and is referred to as *Brugmansia sanguinea* cv. Sangre. In Sibundoy, there is a cultivar *Brugmansia sanguinea* cv. Guamuco.

A form recently discovered in eastern Ecuador (Pelileo, Napo Province) at an altitude of approximately 2,500 meters appears to be an intermediate between *Brugmansia sanguinea* and *Brugmansia sanguinea* ssp. *vulcanicola* (possibly it is a hybrid between the species and the subspecies).

In southern Chile, there is also a form whose flowers are almost entirely green; the outer margin of the calyx is slightly red, and occasionally almost purple.

Synonyms

Brugmansia bicolor Pers.

Brugmansia lutea Hort. ex Gardeners

Brugmansia vulcanicola (Barclay) Lockwood

Datura vulcanicola Barclay

Folk Names

Belladonna tree, bloodred angel's trumpet, blutroter stechapfel, borrachero, borrachero rojo, bovachero, campanilla encarnada, chamico, el quantug (Ecuador), floripondio, floripondio boliviano, floripondio encarnado, guamuco (Kamsá, Inga),⁶³ guamuco floripondio, guamucu borrachera (Inga), guando, quantug, guántug, huaca (Quechua, “grave”), huacacachu, huántug, humoco, koo-wá-oo, misha colorada, misha curandera, misha huarhwar, misha rastrera, perecillo, poroporo, puca campancho (Quechua, “red Brugmansia”), puca-campanilla, qotu (Quechua), tonca, tonga, yerba de huaca

History

In Colombia, this sacred plant was used in pre-Columbian times in ritual contexts in the cult of the sun. It was apparently this species of angel's trumpet that José de Acosta mentioned in 1590 under the name *floripondio*. The incredible effects of the *tonga* drink, prepared from *Brugmansia sanguinea*,

were first described in 1846 by the Swiss Johann J. von Tschudi (Hartwich 1911, 519*). Today, shamans in Ecuador continue to utilize the plant as a hallucinogen. In Peru, the seeds are still used as popular additives to **beer**, **chicha**, and coffee (cf. *Coffea arabica*).

This angel's trumpet is now also known as *floripondio boliviana* because its flowers have the same colors as the Bolivian flag: red, yellow, and green (Bastien 1987, 114*).

Distribution

This rather cold-resistant species is distributed throughout the Andes, from Colombia to Ecuador, Peru, and Bolivia and into southern Chile. It is usually found around 2,000 meters above sea level. On Chiloé, an island off the southern coast of Chile, it is found at altitudes as low as sea level. In Charazani, Cochabamba, and the area of La Paz (Bolivia), it is frequently cultivated as an ornamental (Bastein 1987, 114*).

The subspecies *Brugmansia sanguinea* ssp. *vulcanicola* is found only in the mountainous region around the Puracé volcano in Colombia at altitudes above 3,000 meters (Rivera et al. 1989).

Cultivation

This species is propagated through seeds or cuttings. Of all species of *Brugmansia*, this species is most easily grown from seed. It is best to pre-germinate the seeds, e.g., in moist cloths or in thoroughly moistened soil in seedbeds or greenhouses. The seedlings should be transplanted with care (into pots where the climate is too cold for outdoor planting).

This angel's trumpet is cultivated commercially in Ecuador to produce **scopolamine** for the pharmaceutical industry and thus represents one of the world's primary sources of this compound (Rivera et al. 1989).

Appearance

This perennial, heavily branching angel's trumpet forms a woody stem and can grow from 2 to 5 meters in height. The margins of the gray-green, hairy leaves are coarsely serrated and are usually smaller than those of other *Brugmansia* species. The bloodred angel's trumpet does not exude a scent at night, an important criterion for recognition. The blossoms do not produce any perfume, which enables the species to be very clearly identified. The flowers are normally greenish at their base, yellow in the middle, and red at their margin. But there are also green-red, pure yellow, yellow-red, and almost entirely red varieties.

Iconographic element from the pre-Columbian Tello obelisks; possibly a representation of the bloodred angel's trumpet (*Brugmansia sanguinea*) with its characteristically shaped fruits.

The oval-obese, pointed fruits have a smooth surface and are usually half-covered by the dried calyx. This species produces fruits more regularly than does any other species of *Brugmansia*. In contrast to the normal form, the subspecies *vulcanicola* produces smooth seeds.

This angel's trumpet is the most easily identifiable of all *Brugmansia* species. Nevertheless, it is still occasionally confused with *Brugmansia aurea* and *Brugmansia suaveolens*. It has even been mistaken for *Iochroma fuchsioides*.

Psychoactive Material

—Leaves

—Fruits/seeds

Indians of the Ecuadoran highlands believe that this angel's trumpet provides a toxic or inebriating honey when bees collect its nectar.

Preparation and Dosage

The seeds are used as an additive in preparations of *Trichocereus pachanoi* (cf. **cimora**) and to fortify **chicha**. The fruits or seeds are boiled to produce a decoction known as *tonga*. Only shamans are allowed to drink *tonga*, for it is said that it would cause normal people to lose their mind. For information about dosages, see *Brugmansia arborea*.

The folk healers (*curanderos*) of northern Peru add the leaves and flowers to their San Pedro drinks (cf. *Trichocereus pachanoi*) so that they may “see” better. The woody stems are used to produce magic wands for *mesa* (or table; a temporary altar used by *curanderos*) rituals (Giese 1989, 251*).

The dried leaves may be smoked alone or in **smoking blends**. They are also a component of South American asthma cigarettes, which are smoked to relieve the symptoms of asthma.

Ritual Use

In pre-Spanish and late colonial times, the priests in the sun temple of Sogamoza (north of Bogotá, Colombia) ingested *tonga* during religious rituals (Lockwood 1979, 149). During the pre-Spanish period, the Chibchas gave the widows and slaves of deceased rulers a mixture of *Brugmansia*, **chicha** (maize beer), and tobacco extract (*Nicotiana tabacum*) so that they would be sedated but still alive as they were buried along with the deceased (Lockwood 1979, 150). Contemporary shamans and diviners still use *tonga* to induce a prophetic trance, to diagnose diseases, and to localize lost objects as well as to divine the future.

In the Darién and Chocó regions, the seeds were boiled to produce a decoction that was administered with **chicha** to children so that they could enter a clairvoyant state in which they would receive the power to “see” gold and treasures (Lewin 1980 [orig. pub. 1929], 182*).

In many parts of South America (e.g., southern Chile), the seeds may be secretly mixed into a person's coffee (cf. *Coffee arabica*) to harm, induce aphrodisiac effects in, or make fun of him or her. Depending upon the dosage, the victim may fall into a coma, become sexually aroused, or carry out comical stereotypical acts (cf. *Scopolia carniolica*).

Artifacts

This or other species (cf. *Brugmansia arborea*) appear to be represented on various objects of the pre-Columbian Chavín culture (Mulvany de Peñaloza 1984*).

An Indian drawing of a woman under a *borrachero* tree has been incorrectly interpreted as a depiction of *Brugmansia vulcanicola* (Schultes and Hofmann 1992, 128*). The species shown is in fact *Iochroma fuchsioides*.

In Sri Lanka, the beautiful flowers are sometimes depicted on batiks.

Medicinal Use

In the Colombian Sibundoy Valley, flowers of the bloodred angel's trumpet, leaves of the Culebra form of *Brugmansia* x *candida*, and the stems and leaves of *Phenax integrifolius* Webb. are macerated in water and made into a plaster for treating rheumatism. Heated leaves are also bound over swollen infections, and an infusion of the leaves is used to wash inflamed areas (Schultes and Raffauf 1990, 422*). The leaves are also used in Peruvian folk medicine for treating inflammations (Chavez V. 1977, 189*). The healers of the Callawaya use the leaves externally to treat rheumatism and arthritis (Bastien 1987, 114*).

The typical flower shape and color of *Brugmansia sanguinea*

The seeds of *Brugmansia sanguinea* are similar to the seeds of *Datura innoxia* but are considerably larger (two to three times as large).

The relatively rare *Brugmansia sanguinea* ssp. *vulcanicola* of Ecuador

A shaman with a lance and animal spirit (bird) receives a branch with angel's trumpet flowers and fruits from a woman. (Taken from a Keru lacquer picture of the colonial period, late sixteenth century, South America)

Constituents

The entire plant contains **tropane alkaloids**. The flowers contain chiefly **atropine** and only traces of **scopolamine** (hyoscine). The seeds contain approximately 0.17% total alkaloids; of this, 78% is scopolamine. The alkaloids apohyoscine, hyoscyamine, choline, tropine, and pseudotropine and two unknown alkaloids have also been detected (Leary 1970). The roots contain the highest alkaloid concentration as well as 0.08% littorine (Evans and Woolley 1969). This angel's trumpet produces a psychoactive or toxic **honey**.

The subspecies *Brugmansia sanguinea* ssp. *vulcanicola*, which is native to Colombia, is especially rich in scopolamine and atropine. The flowers contain the highest concentrations of alkaloids (0.83%), followed by the fruits (0.74%), while the leaves contain only 0.4% (Rivera et al. 1989). This is probably the most potent of all *Brugmansia* species.

Effects

All parts of the plant produce strong hallucinations and delirium. The overall effects of this species are the same as those of the other *Brugmansia* species (cf. ***Brugmansia arborea***).

Commercial Forms and Regulations

See ***Brugmansia arborea***.

The ripe fruit of *Brugmansia sanguinea*.

The yellow-blooming variety *Brugmansia sanguinea* var. *flava* is also known by the names *Brugmansia lutea* and *Datura chlorantha*.

A green-blooming variety of *Brugmansia sanguinea*. (Photographed in southern Chile)

The fruit of *Brugmansia sanguinea* produces a large number of seeds. In South America, these are often used to fortify maize beer.

Brugmansia suaveolens (H.B.K.) Berchtold et Presl

Aromatic Angel's Trumpet

“The natives call it *Huacacachu*, *yerba de Huaca*, or *Borrachero* and prepare from its fruits a potent narcotic drink known as *tonga*. Its effects are terrible. I once had the opportunity of seeing them in an Indian who wanted to contact the spirits of the ancestors. The horrible sight of this scene has burned itself so deeply into my memory that I will never forget it. Shortly after consuming the *tonga*, the man fell into a dark brooding, his eyes stared dully at the ground, his mouth was tightly, almost convulsively shut, his nostrils gaped widely, cold sweat covered his forehead and earthly pallid face, the jugular veins of his throat were swollen as thick as a finger, his chest rose slowly and gaspingly, his arms hung rigidly alongside his body. Then his eyes moistened and filled with great tears, his lips twitched slightly and convulsively, his carotid pounded visibly, his respiration accelerated, and his extremities made repeated automatic movements. This state may have lasted for a quarter of an hour, and then all of these manifestations increased in intensity. His now dry but completely reddened eyes rolled wildly in their sockets. All of his facial muscles were contorted in the most horrible fashion. A thick white foam emerged from between his half-opened lips. The pulse on his forehead and throat beat with terrible rapidity. His breath was shallow and unusually accelerated and was no longer able to lift his chest, which exhibited only a slight vibration. Copious amounts of sticky sweat covered his entire body, which was continuously shaken by the most horrible convulsions. His limbs were twisted in the most terrible way. A low, unintelligible murmuring alternated with a piercing and heart-rending scream, a muffled crying, and a deep groaning or moaning. Long did this terrible state last, until the severity of the symptoms diminished and calmness appeared. Immediately, women hurried over, washed the Indian's entire body with cold water, and laid him comfortably onto several fleeces.

“There followed a peaceful sleep that lasted for several hours. That evening, I saw the man again as he was just describing his visions and his conversations with the spirits of his ancestors to a circle of attentive listeners. He appeared to be very exhausted and worn out, his eyes were glazed, his body slack, and his movements sluggish.

“In earlier times (and still today among the wild tribes), only the physicians and magicians made use of the thorn apple (Peruvian thorn apple = angel's trumpet) to induce ecstasy when performing their conjurations, in which they pretended that this had enabled them to enter into a closer relationship to the gods and, as they put it, ‘to speak confidentially with the powerful spirits.’ But after Christianity suppressed the magicians and the belief in one god had spread widely, at least in appearance, the Indians themselves stated that they used the *tonga* to establish contact with the gods of their ancestors and to obtain from them insights into the treasures that were hidden in the graves (*huacas*). Hence the name: *huacacachu* (grave plant). The Mestizos use the plant for this purpose much more frequently than do the Indians, who have an unlimited awe of and veneration for the graves of their ancestors. The Cholos (mixtures of Indians with Chinos, Chinos are a mix of mulattos and Mestizos, Mestizos are a mix of whites and Indian women) very often give the pressed juice of the fruits of the thorn apple, mixed with *chicha* (an alcoholic drink, usually from maize), to the women as an aphrodisiac.”

JOHANN VON TSCHUDI *REIZESKIZZEN* [TRAVEL SKETCHES] (1846, 2:21f.)

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, *Brugmansia* Section

Forms and Subspecies

One form with a very large calyx has been described under the name *Datura suaveolens* β *macrocalyx* Sendtn. The Shuar and Achuar know of several “species” of this *Brugmansia*; these cannot, however, be botanically distinguished (Bennett 1992, 493*, Descola 1996, 88*).

Synonyms

Datura gardneri Hooker

Datura suaveolens Humb. et Bonpl. ex Willd.

Folk Names

Ain-vai (Kofán), almizclillo, angel's trumpet, aromatic angel's trumpet, baikua, bikut, borrachero, campana, canachiari (Shipibo), chinki tukutai maikiua (Achuar, “angel's trumpet to blow on small birds”), *datura d'Egitti*, *datura d'Egypt*, duftende engelstrome, fleur trompette, flor de campana, floripondia, floripondio blanco, guando, huanduc (Quechua), ishauna (Zapara), juunt maikiua

(Achuar, “large angel’s trumpet”), maikiua (Achuar), maikiuwa (Achuar/Shuar), maikoa (Jíbaro), maikua, maikuna, ohuetagi (Huaorani), peji (Secoya), sprengels engelstropete, toá, toé, toé canachiari (Shipibo), trompeta del juicio, ts’ak tsimin (Lacandon, “horse medicine”), tsuaak, tsuak, tu-to-a-vá-a (Kofán, “white angel’s trumpet”), vau (Kofán), wahashupa (Sharanahua), weiße engelstropete, wohlriechender stechapfel, yawa maikiua (Achuar, “dog’s angel’s trumpet”), yumi maikiua (Achuar, “heaven’s water angel’s trumpet”)

History

In South America, aromatic angel’s trumpet has apparently been used for ritual and medicinal purposes since pre-Columbian times. It is possible that this species may have been known even in pre-Spanish Mexico; there, it continues to possess a certain significance as a hallucinogenic shamanic plant. This angel’s trumpet was first described by Alexander von Humboldt (1769–1859). Because of its beauty and its bewitchingly delicious scent, it is now the most commonly cultivated species of *Brugmansia*. Among the Jíbaro Indians, it has important meaning as a ritual inebriant (Descola 1996*).

Distribution

Aromatic angel’s trumpet is found throughout the Andes and Cordilleras as well as Central America. Through cultivation, it has spread into other regions of the world. It is now part of the flora of Nepal and can be found in the Himalayas at altitudes of up to 1,700 meters (Polunin and Stainton 1985, 289*).

Cultivation

The simplest method of cultivation is through cuttings (see *Brugmansia arborea*). This angel’s trumpet can also be grown from seed. In northern climates, sowing (possible throughout the year) should be done in pots on a window ledge at temperatures of 20 to 25°C (time to germination is two to three weeks). A sterile, porous substrate, e.g., sandy, loose soil, works best. The soil must be kept well moistened. The plant should be transplanted while still small into a large pot filled with peat-rich soil or into the garden. Prune back in late fall and allow to overwinter in the cellar. Water the plant thoroughly in the spring. Leaves will appear again quite quickly. The plant requires much water and thrives best in semi-shaded areas.

Appearance

This large perennial bush with woody stems is often heavily branched and can grow as tall as 5 meters. It has very large, usually smooth-margined leaves that are oval and pointed at the ends. The flowers, which can grow as long as 30 cm, hang down at an angle and are usually pink. The calyx and corolla each have five points (an important point for classification). During the evening and at night, the flowers exude a bewitching and inebriating scent. The fruits, which form only very rarely, are short and spindle-shaped with an irregularly gibbous surface and contain large (approximately 1 cm) light brown seeds. This species also occurs in a form with pure white blooms (e.g., in Argentina). In the Himalayas, only the white-blooming form is found (Polunin and Stainton 1985, 289*).

This angel’s trumpet is easily mistaken for *Brugmansia x insignis*.

Psychoactive Material

- Leaves
- Flowers
- Stems

- Juice pressed from the fresh stems
- Seeds

The typical flower of *Brugmansia suaveolens*. (Photographed in Chiapas, Mexico)

A rare pure-white-blooming form of *Brugmansia suaveolens*. (Photographed in northwest Argentina)

Preparation and Dosage

The fresh leaves, seeds, and flowers may be eaten fresh or drunk in the form of an infusion. This tea is sometimes mixed with alcoholic beverages. The fresh flowers are also added to milk and drunk (Hall et al. 1978, 251). To produce an aphrodisiac tea, pour hot water over one fresh flower and allow this to steep for ten minutes. The fresh leaves can be added to white rum, tequila, or other types of spirits (**alcohol**). The leaves also can be made into a decoction or used as an **ayahuasca** additive (Schultes and Raffauf 1990, 422*). For information about dosages and dangers, see ***Brugmansia arborea***.

In the Himalayas, the dried leaves are used in tantric **smoking blends** in the same manner as those of ***Datura metel***.

Ritual Use

This species is the most commonly used *Brugmansia* in the upper Amazon region. The Jíbaro or

Shuar and Achuar drink a tea of the plant they call *maikuna* to obtain a vision that can help them acquire an *arutam wakani*, “visionary soul” (cf. *Nicotiana tabacum*). Once acquired, this soul will be sent forth to make inquiries in the “other world” (Bennett 1992, 493*). Among the Achuar, the visions of the *arutam* are especially important because they restore to a warrior (the former hunter of shrunken heads) the power that he has lost as a result of ritual war killing. To do this, the warrior will go to a secluded place deep in the forest and consume angel’s trumpet juice as well as tobacco juice by himself, away from all others. The effects allow him to see an *arutam* soon thereafter:

Arutam is initially a vision, the fruit of a change in consciousness induced by fasting, the repeated ingestion of tobacco juice, and especially the high doses of scopolamine that are liberated in the thorn apple [sic] [207] preparation. . . . The circumstances under which *arutam* appear [are] exceptionally stereotypical. Exhausted by the inebriation, physically weakened by a lack of food, the senses focused completely on the desired encounter, the supplicant waits alongside the path until he suddenly perceives the rustling of a distant wind, which swells into a hurricane and descends with all its power over the clearing, while a strange figure or a monster slowly approaches: Perhaps a gigantic jaguar whose eyes spout fire, it might also be two intertwined giant anacondas, an overpowering harpy, a sneering bunch of armed strangers, a dismembered human body whose limbs crawl along the ground, or a flaming head that falls from the skies and rolls around twitching. . . . The wind calms down as quickly as it had arisen, and out of the sudden quiet steps an old man. It is *arutam*. . . (Descola 1996, 318f.*)

The Jíbaro drink the freshly pressed juice of the stems to become brave and to peer into the future. Unruly children are given some of this drink so that they will learn how to behave properly while delirious (Harner 1984, 143ff.*). The Kofán and Achuar give the plant to their dogs to improve their hunting abilities (Descola 1996, 88*; Schultes 1981, 34*).

The shamans of the Tzeltal of southern Mexico smoke the leaves “in order to see things,” i.e., for divination and divinatory diagnosis of the causes of illness. But they warn: People who smoke too much will see demons and ultimately “go crazy.”

In Nepal, the leaves of this angel’s trumpet together with those of *Cannabis indica* are smoked by sadhus and tantric practitioners for meditation or for yoga exercises (cf. also *Aconitum ferox*).

Artifacts

A white-blooming *Brugmansia suaveolens* is portrayed on a still life with flowers (1833) by Johan Laurentz Jensen (1800–1856). (See also *Brugmansia arborea* and *Brugmansia candida*.)

Medicinal Use

In Latin America, the leaves of this *Brugmansia* are very commonly used in folk medicine as an external treatment for wounds, rashes, and ulcers (Berlin et al. 1990, 33ff.*). The Achuar also use the leaves to treat battle wounds and snakebites (Descola 1996, 88*). Use of the flowers and leaves, and sometimes also the seeds, as aphrodisiacs is found throughout the world. Even the scent is regarded as an aphrodisiac.⁶⁴

Some Lacandon Mayans use angel’s trumpet as a remedy to treat their animals. As one tribe member said, “That is a medicine for the chickens. I treat my chickens with it when they have a rash on the eyes. I take the stem and rub it over it, then they quickly get healthy” (Rätsch 1994b, 60*).

“This plant is not a joke!”

A SHUAR INDIAN

(BENNETT 1992, 488*)

Constituents

The **tropane alkaloid** constituents of this *Brugmansia* species have a characteristic composition that chemically distinguishes this plant from all other *Brugmansia* species. The aboveground herbage contains **scopolamine** (hyoscine), apohyoscine, norhyoscine, **atropine**, and noratropine as well as high concentrations of the tigloyesters of these substances. The roots contain scopolamine, meteloidine, atropine, littorine, 3 α -acetoxytropine, 6 β -(α -methybutyryloxy)-3 α -tigloyloxytropine, 3 α ,6 β -ditigloyloxytropine-7 β -ol, 3- α -tigloyoxytropine-6 β -ol, tropine, and cuscohygrine. The principal alkaloid in the corolla of the flowers is norhyoscine (Evans and Lampard 1972). The leaves contain 0.09 to 0.16% alkaloids. Some of the esters also occur in the genera *Solandra* and *Datura* (Evans and Lampard 1972). The alkaloid content is highest during the flowering period (Roth et al. 1994, 294*).

Effects

In Colombia, it is commonly believed that the scent of aromatic angel's trumpet induces sleep and intense dreams often with erotic overtones. In southern Colombia, where there are entire boulevards of aromatic angel's trumpet trees, people suffering from sleep disorders walk past the scented trees in the evenings. In Peru, it is thought that those who sleep under an aromatic angel's trumpet will become permanently insane (Schultes 1980, 115*). “Even the scent of the flowers is said to possess narcotic properties and induce headaches as well as nausea” (Roth et al. 1994, 294*).

The hallucinations evoked by aromatic angel's trumpet can last for up to three days (Bennett 1992, 493*). Overdoses can result in anti-cholinergic delirium (Hall et al. 1978). The toxicological literature contains reports of five deaths alleged to have resulted from an overdose of *Brugmansia suaveolens* (Roth et al. 1994, 294*).

Commercial Forms and Regulations

See *Brugmansia arborea*.

Brugmansia versicolor Lagerheim

Amazonian Tree Datura

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Brugmansia Section

Forms and Subspecies

Presumably none

Synonyms

Datura versicolor (Lagerh.) Saff.

Folk Names

Amazonian datura, Amazonia tree datura, bunte engelstrompete, canachiari (Shipibo), sachá-toé, toé, tree datura

History

Although this angel's trumpet appears to be an important Amazonian shamanic plant, almost no ethnobotanical or ethnopharmacological studies of it have been carried out to date. This may be due at least in part to the fact that the uses of the plant that have been noted in ethnographic reports may have been listed under incorrect botanical names. It is very likely that a great deal of the information recorded for ***Brugmansia suaveo-lens*** and ***Brugmansia*** x ***insignis*** actually pertains to *Brugmansia versicolor*.

This plant first became known to botanists when the Swedish botanist Nils Gustaf von Lagerheim (1860–1926), who was also the first to describe ***Brugmansia aurea***, discovered it in Ecuador in 1895.

Distribution

This angel's trumpet is from the northwestern Amazon region (the basin of Guyaquil) and is adapted to the tropical climate. It is found primarily in Ecuador (Zander 1994, 226*) but is also common in northern Peru (Schultes and Raffauf 1990, 424*).

Cultivation

Propagation is performed through cuttings (as with ***Brugmansia arborea*** and ***Brugmansia*** x ***insignis***).

Appearance

This perennial plant grows into a treelike shrub that can attain a height of 3 meters. The large, trumpet-shaped flowers have smooth corollas and hang straight down (an important characteristic for identification). The flowers are usually various shades of pink and yellow (hence the name *versicolor*). The calyx is simply dentate. The smooth fruit capsule is thin, spindle-shaped, and approximately 15 cm in length and, like the flower itself, hangs straight down. The leaves have a smooth margin and are oval with a pointed end.

Amazonian tree datura is easily confused with ***Brugmansia*** x ***candida*** and ***Brugmansia*** x ***insignis***.

Crossing ***Brugmansia aurea*** with *Brugmansia versicolor* yielded the hybrid ***Brugmansia** x **candida*** (Schultes and Hofmann 1980, 267*).

Psychoactive Material

—Fresh stalks

—Leaves

Preparation and Dosage

A shamanic dosage consists of 1 to 2 ml of the juice pressed from fresh stalks. The dried leaves and flowers can be smoked alone or in **smoking blends**. For more about dosages and dangers, see ***Brugmansia arborea***.

Ritual Use

This species is one of the most important shamanic plants in the Amazonian regions of Ecuador and Peru. In spite of this, almost nothing is known about its usage, which is presumably quite similar to the usage of ***Brugmansia aurea***, ***Brugmansia** x **insignis***, and ***Brugmansia suaveo-lens***. In the Peruvian Amazon, *Brugmansia versi-color* is used as an **ayahuasca** additive and is cultivated in home gardens specifically for this purpose (Ott 1993, 222*).

Artifacts

See ***Brugmansia arborea***.

Medicinal Use

It is possible that this plant is used in folk medicine as a means of birth control (Schultes and Raffauf 1990, 424*).

Constituents

The entire plant contains **tropane alkaloids**. Chemical studies are lacking.

Effects

It is said that the scent of this species not only induces sedative effects but also can, at high dosages (e.g., when a person sleeps underneath this angel's trumpet at night), result in temporary or permanent insanity. A myth of the Juruna tribe tells how under certain circumstances the scent can also lead one to become a shaman:

One day Uaiçá went hunting. In the forest, he saw many, yes, very many dead animals lying beneath a tree. Uaiçá stood and looked, unable to comprehend how this could happen. As he was thinking about it, he walked around the tree. No sooner had he walked beneath the tree than he felt dazed, and he immediately fell down and slept. He had many dreams. He dreamt of singing people, of the tapir and all the other animals. In a dream, he also saw Sinaá, an ancestor of the Juruna. He spoke long with him. When Uaiçá awoke, he immediately went back home, for it was late and the sun was already setting. The following day, he returned to the tree, where he again fell down and went to sleep. He dreamed of the same things: of Sinaá, singing people, animals, and his people. For several days, Uaiçá came to the tree, under which he always had the same dreams after he had fallen asleep. He had fasted since the first day. He ate nothing. During the last visit, Sinaá told Uaiçá in a dream: 'Do not come under this tree any more. This is enough.'

“After Uaiçá woke up, he scraped off a little of the bark of the tree and went to the riverbank.

There he made a tea from the bark and drank of it. Then he was inebriated, and he jumped into the water and caught fish with his hands. . . . Uaiçá never went back to the tree. He now drank the tea he had brewed from the bark scrapings, and in this way he acquired many abilities.” (Karlinger and Zacherl 1976, 172 f.*)

Apart from this, the effects of this plant should not differ from those of other *Brugmansia* species.

The tropical *Brugmansia versicolor* can be recognized by its vertically hanging flowers.

A cultivated form of *Brugmansia versicolor* with a double trumpet flower

“Perhaps the Brugmansias would have become extinct long ago if they had not impressed so many people with their ornamental value. These decorative and yet easily cultivatable plants are making their ways into ornamental gardens with increasing frequency—both planted in the ground and as potted plants, depending upon the geographical situation. It would be wonderful if the survival of an interesting genus of plant could be ensured at least in this manner.”

ULRIKE AND HANS-GEORG PREISSEL *ENGELSTROMPETEN* [ANGEL’S TRUMPETS]
(1997, 17)

Brugmansia spp. and Hybrids

Angel's Trumpets and Hybrids

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, *Brugmansia* Section

Because angel's trumpets are such beautiful plants, they have attracted the enthusiastic attention of gardeners all around the world. There is hardly a tropical or subtropical region in which one will not find angel's trumpets being used as ornamentals. As a result of the now global distribution of these plants, even specialized botanists (including myself) are no longer able to keep track of the genus and the hybrids that have been produced from it (cf. Lockwood 1973).

It is a difficult enough task to distinguish among the species discussed above, not to mention the local varieties. The situation is made more confusing by the utter taxonomic confusion and the multitude of popular names. The many commercial names of plants and seeds that can be obtained from nurseries and seed dealers are more the result of the seller's imagination than botanical nomenclature.

To truly untangle the taxonomy of angel's trumpets, extensive comparative genetic studies would be necessary. These, however, are both expensive and time-consuming and would presumably not justify the economic benefits that would result.

Below may be found some of the names that have appeared in the literature. These refer either to very little known species, subspecies, or varieties or to cultivated forms and hybrids. Only three types can in fact be distinguished on the basis of the actual flower shape: *Brugmansia* x *candida* (=

B. aurea), *B. sanguinea*, and *B. suaveolens* (cf. Schultes 1979b*). For this reason, the following taxa have been assigned to these types (most species and hybrids are sterile, so the shapes of the fruits cannot be used for classification purposes):

Brugmansia x *candida* type:

—*Brugmansia dolichocarpa* Lagerh. [syn. *Datura dolichocarpa* (Lagerh.) Saff., *Datura carpa*]

This form is very similar to ***B. versicolor***.

—*Datura (Brugmansia) cornigera* (Hook.) Lagerh.

A form with very large flowers; described for the Valley of Mexico (Safford 1921, 183).

—*Datura (Brugmansia) mollis* Saff.

A yellow-flowering form from Ecuador; apparently synonymous with ***B. x candida***.

—*Datura rubella* Saff.

Described only for an herbarium specimen from Ecuador (Safford 1921, 185).

Brugmansia sanguinea type:

—*Datura (Brugmansia) chlorantha*

Yellow-blooming form; presumably identical to ***B. sanguinea***.

—*Datura pittieri* Saff.

A form of ***B. sanguinea*** that produces light-colored blossoms.

—*Datura (Brugmansia) rosei* Saff.

Reddish-blooming form of ***B. sanguinea*** from Ecuador; also used as a name for a cross between ***Datura innoxia*** and ***B. aurea*** (Lockwood 1973, 280).

—*Brugmansia vulcanicola* (Barclay) Lockw. [syn. *Datura vulcanicola* A.S. Barclay]

See ***B. sanguinea***.

***Brugmansia suaveolens* type:**

—*Datura affinis* Saff.

Nonsterile form that produces an oval fruit, from the area of Quito, Ecuador; apparently synonymous with ***B. arborea*** or ***B. suaveolens***.

—*Datura suaveolens* x *Datura candida* cv. Flintham Hall

—*Brugmansia longifolia* Lagerh. [syn. *Datura longifolia* (Lagerh.) Saff.]

Presumably a long-leafed, white-blooming form of ***B. suaveolens***.

Today, most botanists accept four species of angel's trumpets: *B. arborea*, *B. aurea*, *B. sanguinea*, *B. suaveolens*. All the other names refer to forms, subspecies, hybrids, and races (D'Arcy 1991, 94; Schultes 1979b, 141*). It may be that only *B. aurea*, *B. sanguinea*, and *B. suaveolens* are true, independent species.

Crosses of *Brugmansia suaveolens* and *Brugmansia versicolor* are frequently encountered. These often yield spectacularly beautiful flowers in various colors (especially white and yellow). Several of the crosses and hybrids have been affected by certain viruses that do not kill the plant but simply alter the form of its flowers. Some of the cultivars are not amenable to more precise specification.

Crosses with Other Genera

Some botanists have succeeded in producing crosses between the species *Datura* and *Brugmansia*. The following hybrids have been successfully produced (Lockwood 1973, 280):

Datura innoxia* (fem.) x *Brugmansia aurea

Datura innoxia* (fem.) x *Brugmansia suaveolens

Synonyms with Other Species

Some of the nightshades that have been described under the name *Brugmansia* are now assigned to the genus *Juanulloa*:

—*Brugmansia aurantiaca* Hort. ex Walpers is an outdated synonym for the nightshade *Juanulloa parasitica* Ruíz et Pav.

—*Brugmansia coccinea* Hort. ex Siebert et Voss. is a synonym for *Juanulloa aurantiaca* Otto et A. Dietr.

—*Brugmansia floribunda* Paxton (= *Brugmansia parviflora* Paxton) is a synonym for a *Juanulloa* species.

Some species of the genus *Juanulloa* are used as **ayahuasca** additives.

This flower of *Brugmansia suaveolens* x *versicolor* has been deformed by a virus.

As a result of the long history of cultivation and the numerous hybrids that have been produced, many angel's trumpets have developed into forms that are impossible to assign to a specific species.

The hybrid *Brugmansia suaveolens* x *versicolor* is a popular garden ornamental.

A virus has produced this mutated form of a *Brugmansia* species cultivar, which develops “glovelike” flowers.

Brunfelsia spp.

Manaca, *Brunfelsia*

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Salpiglossidae Tribe

Forms and Subspecies

Today, forty to forty-five species of *Brunfelsia* are botanically accepted (D'Arcy 1991, 78*; Schultes and Raffauf 1991, 34*). Several of these have importance as medicinal or ornamental plants or as additives to psychoactive preparations (Plowman 1977).

The genus *Brunfelsia* is named after the German physician, botanist, and theologist Otto Brunfels (ca. 1489– 1534), one of the fathers of botany. Brunfels produced an important work on herbalism, *Contrafayt Kreuterbuch*, in 1532. (Contemporary woodcut)

Species used for psychoactive purposes:

—*Brunfelsia chiricaspi* Plowman

Borrachero, chiricaspi, chiric-caspi,⁶⁵ chiri sanango, covi-tsontinba-ko (Kofán), sanango, yaí uhahai (Siona, “jaguar Brunfelsia”)

—*Brunfelsia grandiflora* D. Don ssp. *grandiflora*⁶⁶ [syn. *B. calycina* Benth. var. *macrantha* Bailey, *B. tastevinii* Benoist]

Borrachera, chinikiasip (Shuar), chiricaspi, chiric sanango, keya-honi, mucapari (Shipibo-Conibo)

—*Brunfelsia grandiflora* D. Don ssp. *schultesii* Plowman

Bella unión, borrachero, chipiritsonbinka (Kofán), chiricaspi chacruco (Quechua), chiricaspi picudo, chiricaspi salvaje, chiricsanango, huha hay (Siona), sanango, uhahai

—*Brunfelsia uniflora* (Pohl) Benth.⁶⁷ [syn. *Brunfelsia hopeana* (Hook.) Benth., *Franciscea uniflora* Pohl]

Bloom of the lent, boas noites, (“good nights”), camgaba, camgamba, (“tree of the gambá-opossum”), Christmas bloom, flor de natal, (“Christmas tree”), gerataca, good night, jerataca, jeratacaca (“snake bite medicine”), manaca, manacá, mercurio dos pobres (“poor man’s quicksilver”), Paraguay jasmine, Santa María, umburapuama (“medicine tree”), vegetable mercury, white tree

—*Brunfelsia maritima* Benth.

Borrachera (“inebriator”)⁶⁸

—*Brunfelsia mire* Plowman

Borrachera

History

The genus *Brunfelsia* was named for the German physician, botanist, and theologist Otto Brunfels (1489–1543). When the Portuguese arrived in northern Brazil, they were able to observe the use of *Brunfelsia uniflora* among the Indians. The inhabitants of the Amazon manufactured arrow poisons from extracts of the root. The *payés*, or shamans, used the root for healing and in magical activities (Plowman 1977, 290f.). The first description of the plant (*Brunfelsia uniflora*) was published in 1648 in Piso’s *De Medicina Brasiliensi*.

Today, *Brunfelsia uniflora* enjoys the greatest phytomedicinal and pharmaceutical importance in Brazil and is grown in plantations as the stock plant for the manaca root drug. The word *manaca* is derived from *manacán*, which means “the most beautiful woman of the tribe” and alludes to the bush’s beauty (Plowman 1977, 290). Because of their attractive flowers and colors, several *Brunfelsia* species (*B. americana*, *B. australis*, *B. uniflora*, *B. pilosa*) are now grown in tropical gardens throughout the world or raised as potted ornamentals.

Distribution

The genus *Brunfelsia* is originally from northern (tropical) Brazil and the Caribbean Islands. Because most of its species are so beautiful, the genus has spread as an ornamental into all of the tropical zones of the world. It has also been successfully propagated in the frost-free areas of the Mediterranean region (Bärtels 1993, 180*).

The species with ethnomedical significance are all from the Amazon, where they are planted by many of the Indians. *Brunfelsia chiricaspi* is found only in primary forest (Plowman 1973a, 258f.; 1977, 305).

Cultivation

Most species of *Brunfelsia* are propagated by cuttings, root pieces, or scions. In cultivation, they rarely produce fruits. Brunfelsias require a tropical climate and thrive best in loose soil. *Brunfelsia chiricaspi* is not cultivated (Plowman 1977, 305).

Indoor plants (*B. uniflora*, *B. pauciflora*) must be watered regularly with water that has been allowed to stand. Between April and August, they should be fertilized every fourteen days.

Appearance

The species discussed here are very similar in appearance and are all easily mistaken for one another. They usually form evergreen shrubs that can grow as tall as 3 meters. The leaves are alternate and elliptical in shape, and they taper to a point. Their upper side is leathery and dark green, while their underside is pale green. The flowers, which are typically borne on short stalks, are almost always

violet but are sometimes white or in rare cases yellow (*Brunfelsia americana*) or creamy white (*Brunfelsia undulata*). Often, a plant will bear both white and violet flowers simultaneously. The fruits, which only rarely develop, are round green berries. The seeds are relatively large.

The flowers fade after only a few days. The flowers of the species *Brunfelsia pauciflora* are dark violet the first day, light lilac the second, and almost white on the third day. As a result, this popular ornamental species is also popularly known by the name *yesterday, today, and tomorrow*.

At night some species (e.g., *Brunfelsia americana*) exude a sweet scent that has inebriating effects and is reminiscent of the scent of *Brugmansia suaveolens*. In tropical regions, brunfelsias bloom throughout the year. As potted plants in temperate zones (central Europe), the flowering period lies between spring and late summer.

Those species that are cultivated as ornamentals are quite similar in appearance to and are easily confused with those used for psychoactive purposes. Even a trained botanist can have difficulty identifying the species. The species *Brunfelsia hopeana* (= *B. uniflora*) and *Brunfelsia pilosa* Plowman, for example, are almost always regarded as one and the same (Plowman 1975, 47). For this reason, it can be assumed that the species' identifications provided in the ethnobotanical literature are not reliable. Accordingly, as a rule this monograph will not differentiate among species that are used for the same purpose (unless absolutely accurate data are available).

Brunfelsia maritima is deceptively similar to *B. grandiflora* and has even been confused with the latter in herbarium specimens. *B. grandiflora* is also frequently confused with *Brunfelsia latifolia* (Pohl) Benth. and *Brunfelsia bonodora* (Vell.) Macbr. (Plowman 1977, 298).

Brunfelsia grandiflora ssp. *schultesii* Plowman is distinguished from *B. grandiflora* ssp. *grandiflora* solely on the basis of its much smaller flowers and fruits. There is no ethnobotanical distinction made between the two subspecies or forms; both are known as *chiricaspi*, "cold tree," and each is used in the same manner (Plowman 1973a; 1977, 299).

Psychoactive Material

—Leaves

—Stems

—Roots (manaca roots, *manacá*, radix manaca, radix brunfelsiae)

In Brazil, several species are used as sources for manaca roots: *Brunfelsia uniflora*, *Brunfelsia australis*, and *Brunfelsia* spp.

Preparation and Dosage

There are a variety of traditional and pharmaceutical preparations of the raw drug. Leaves can be steeped in hot water (Schultes 1966, 303*). Leaves and stalks can also be decocted in boiling water. As little as 100 mg/kg of an extract of manaca root (*B. uniflora*) is sufficient to produce pharmacological effects (Iyer et al. 1977, 358).

For medicinal purposes, *Brunfelsia grandiflora* can be prepared in several ways. Scrapings of the bark can be added to cold water or **chicha** (maize beer). The bark of other trees (*remo caspi*: *Pithecellobium laetum* Benth.; *chuchuhuasi*: *Heisteria pallida* Engl.; *huacapurana*: *Campsiandra laurifolia* Benth.) can be added to potentiate the dosage. Unfortunately, the amount of bark used to make the extract is not known. The root can also be added to **alcohol**. Here, 50 g of the root cortex is added to 1 liter of *aguardiente* (cane sugar spirits). One shot glass of this is taken before every meal (Plowman 1977, 300).

The Jíbaro produce a type of **ayahuasca** using *Banisteriopsis* spp., *Brunfelsia grandiflora*, and a botanically unidentified vine known as *hiaji*. First the *Banisteriopsis* pieces are boiled for fourteen

hours, after which the other ingredients are added and the entire mixture boiled down until a thick solution results (Plowman 1977, 303).

When used for psychoactive and magical purposes, the wild-growing *Brunfelsia chiricaspi* is preferred over the cultivated varieties of *Brunfelsia grandiflora* (Plowman 1973a, 259).

Brunfelsia can also be smoked. Men and women of the Yabarana roll cigarettes out of manaca bark and tobacco (*Nicotiana tabacum*) (Wilbert 1959, 26 f.*).

The typical yellow flowers of *Brunfelsia americana*.

Brunfelsia australis can have both white and violet flowers simultaneously.

The South American *Brunfelsia grandiflora* ssp. *grandiflora* is one of the shamanic plants known as *chiricaspi*.

Brunfelsia grandiflora ssp. *schultesii*, named for the botanist Richard Evans Schultes, is a rare shamanic plant.

Ritual Use

In Ecuador, Amazonian Indians use *Brunfelsia grandiflora* as a hallucinogen. The shamans of the Shuar drink a tea of the leaves and stems in order to induce “strong feelings” that they can then use for healing purposes (Bennett 1992, 493*). The Siona scrape the bark of *B. grandiflora* ssp. *schultesii* and drink a cold-water extract of this. Two mouthfuls are said to be an effective dosage (Vickers and Plowman 1984, 29f.*). They drink the extract “to obtain visions and alleviate pains.” The *Brunfelsia* extract is often drunk prior to the ingestion of **ayahuasca** or combined with yoco (cf. ***Paullinia* spp.**) (Plowman 1977, 305). The shamans of the Kofán drink *Brunfelsia grandiflora* to diagnose diseases. The shamans of the Lama Indians, who live in northern Peru, regard *B. grandiflora* as a spiritual leader. They consume it during their initiation and receive from it special powers that they can use to heal as well as to cause diseases (Plowman 1977, 303).

Both subspecies of *Brunfelsia grandiflora* are used as **ayahuasca** additives and are said to potentiate its effects (Schultes and Raffauf 1991, 34*). In Iquitos, urban *ayahuasqueros* say that

Brunfelsia grandiflora makes ayahuasca more powerful and induces acoustical effects “like rain in the ear.” During a new moon, the Witoto on the Río Ampiyaco (Peru) add brunfelsia to ayahuasca (they add pieces of the bark to cold ayahuasca) to obtain power (Plowman 1977, 303).

The beautiful *Brunfelsia maliformis* from Jamaica is one of the rarest members of the genus.

Fruits and seeds of *Brunfelsia grandiflora* ssp. *schultesii*.

The prostrate shamanic plant *Brunfelsia mire* is almost unknown and has been little studied.

Brunfelsia pauciflora var. *calycina* is a popular ornamental from Brazil.

Brunfelsia pauciflora cv. *Floribunda compacta*, a plant found in tropical gardens.

The green fruit of *Brunfelsia plicata*, from Jamaica.

Brunfelsia uniflora is the source of the manaca root drug.

Artifacts

Apparently none; cf. **ayahuasca**.

Medicinal Use

In Brazil, the manaca root is used as a remedy for syphilis and as an abortifacient (Bärtels 1993, 180*). It is used in folk medicine to treat rheumatism, syphilis, yellow fever, snakebites, and skin diseases (Iyer et al. 1977, 356). It is a very important fever medicine; *chiricaspi* means “cold tree” and refers to the plant’s ability to lower body temperature (Schultes and Raffauf 1991, 34*).

The stalks of *Brunfelsia grandiflora* are grated and added to cold water. The resulting solution is rubbed over or massaged into areas affected by rheumatism. A cold-water extract is also drunk to treat arthritis and rheumatism (Plowman 1977, 300).

A homeopathic preparation made from manaca roots was introduced around 1862. *Franciscea uniflora* (essence of fresh root), as it was known, was an important agent for a time (Schneider 1974, 1:198*).

Constituents

In the older literature, the constituents were listed as brunfelsia alkaloids with such names as franciscaine, manacine, brunfelsine (Brandl 1885), and even mandragorine (cf. ***Mandragora officinarum***)—all obsolete names for the “only little understood chemical components” of the roots (Schultes 1979b, 154*).

The species *Brunfelsia uniflora*, *B. pauciflora*, and *B. brasiliensis* contain the non-nitrogenous compound **scopoletin** (= 6-methoxy-7-hydroxycoumarin). The alkaloid cuscohygrine, which also occurs in *Atropa belladonna* and *Erythroxylum coca*, has been isolated from an unidentified species of the genus (Mors and Ribeiro 1957; Schultes 1979b, 155*).

Brunfelsia uniflora and *B. pauciflora* contain the alkaloids manacine and manaceine as well as aesculetine. The concentration of manacine is highest in the bark (of *B. uniflora*), reaching 0.08% (Roth et al. 1994, 175*).

Effects

The peculiar effects of the manaca root were described at an early date: heavy salivation, slackness, general sedation, partial paralysis of the face, swollen tongue, and blurred vision. There were also more drastic reports: “wild deliria and persistent feeble-mindedness.” “One kind of *manacá* has the property of causing intoxication, blindness, and the retention of urine during the day; but after having drunk the infusion of the root or bark of this tree, a man is always happy in his hunting and fishing” (Plowman 1977, 292).

Laboratory studies of the **scopoletin** extracted from *Brunfelsia uniflora* (= *B. hopeana*) have demonstrated clear depressive effects upon the central nervous system (Iyer et al. 1977, 359). “Manacine stimulates glandular secretion and kills by respiratory paralysis. Manacein has similar effects” (Roth et al. 1994, 175*).

Brunfelsia chiricapi is said to be the most psychoactively potent of all brunfelsias. However, the effects do not seem particularly alluring. They begin within just a few minutes and are first manifested as tingling, numbness, et cetera (similar to when an arm or leg has fallen asleep). These are followed by a profound sensation of coldness and an inability to move, foaming at the mouth, shaking, and nausea. Aftereffects include dizziness and exhaustion. The feelings of dizziness and weakness persist into the following day (Plowman 1977, 306f.). Plowman, one of the few researchers to have actually tried the drink, compared the overall effects to those of **nicotine** (on nonsmokers). He assumes that brunfelsia is added to **ayahuasca** in order to achieve a higher concentration in the body or a stronger effect upon bodily processes. The shamans could then use the resulting condition to heal specific ailments.

Jonathan Ott (per oral communication with the author) notes that he almost died as a result of a self-experimentation with brunfelsia. To date, there are no reports of pleasant visionary experiences. However, for understandable reasons, few psychonauts have dared to explore the depths of the brunfelsia state.

Commercial Forms and Regulations

Some brunfelsias (usually *Brunfelsia pauciflora* and *Brunfelsia uniflora*) are sold in nurseries as ornamentals. Manaca root is officinal in Brazil and is listed in the Brazilian pharmacopoeia. In principle, manaca roots are available without restriction.

“The juice of this plant [*Brunfelsia grandiflora*] plunges them [the Indians] into a kind of intoxication or stupefaction which lasts a little more than a quarter of an hour and from which they acquire magical powers, enabling them to heal all sorts of diseases through incantations. While the effects of the drink act on their brains, they are unable to fall asleep. They believe they see all kinds of fantastic animals: dragons, tigers [= jaguars], wild boars, which attack them and tear them to bits, etc. This action of *honi* lasts four or five hours depending on the quantity ingested.”

PATER C. TASTEVIN IN “*BRUNFELSIA* IN ETHNOMEDICINE” (PLOWMAN 1977, 302)

The first illustration of the Brazilian manaca root *Brunfelsia uniflora* (= *Brunfelsia hopeana*). (Engraving from Piso, *De Medicina Brasiliensi*, 1648)

Calea zacatechichi Schlechtendal

Aztec Dream Grass, Zacatechichi

Family

Compositae (Aster Family); Subfamily Heliantheae, Galinsoginae Tribe/Subtribe

Forms and Subspecies

A number of varieties have been described (Flores 1977, 12 ff.):

Calea zacatechichi var. *calyculata* Robinson

Calea zacatechichi var. *laevigata* Standley

Calea zacatechichi var. *macrophylla* Robinson et Greenman

Calea zacatechichi var. *rugosa* (DC.) Robinson et Greenman

Calea zacatechichi var. *xanthina* Standley et L.O. Williams

Calea zacatechichi var. *zacatechichi*

There is also said to be a form that occurs only in Guadalajara (Flores 1977, 15).

Synonyms

Aschenbornia heteropoda Schauer

Calea rugosa Hemsley

Calea ternifolia Kunth var. *ternifolia*

Calydermos rugosus DC.

Folk Names

Ahuapatli, amula, atanasia amarga, Aztec dream grass, bejuco chismuyo, betónica, chapote,⁶⁹ chichicxihuitl (Nahuatl, “bitter plant”), chichixihuitl, cochitzapotl, dream herb, falso simonillo, hierba amarga, hoja madre (“leaf of the mother”), iztactzapotl, jaral, jaralillo, juralillo, mala hierba, matasano, oaxaqueña (“the one from Oaxaca”), paiston, poop taam ujts, prodigiosa, pux lat’em (Huastec), sacachcichic, sacachichic, sacatechichi, simonillo, techichic, tepetlachichixihuitl (Nahuatl, “bitter plant of the mountains”), thle-pelacano, thle-pela-kano (Chontal, “leaf of god”), tsuleek’ ethem (“raccoon’s trachea”), tzicinil, tzikin, xikin (Maya, “dove’s plant”),⁷⁰ xtsikinil, x-tzicinil, yerba amarga (“bitter plant”), zacachichi, zacachichic, zacate amargo (Mexican, “bitter grass”), zacatechi, zacatechichi, zacate de perro (Mexican, “dog grass”)

Zacachichic (*Conyza filaginoides* Hieron.), the false zacatechichi, was probably used as dream grass. (From Hernández, 1942/46 [Orig. pub. 1615]*)

History

This Compositae was used for magical and medicinal purposes in pre-Columbian times. It is possible that *Calea zacatechichi* helped Aztec magicians (*nagualli*) travel deeper into Tlálocan, the realm of dreams.

The Aztec name *zacatechichi* is translated as “bitter grass.” The first botanical description of the plant comes from the nineteenth century (1834). Its psychoactive use was first described by Thomas MacDougall (1968). Research into its pharmacology and phytochemistry did not begin until relatively recently (Flores 1977).

Distribution

Aztec dream grass grows primarily in the highlands of central Mexico (1,500 to 1,800 meters in altitude), in the mountainous regions of Oaxaca, Veracruz, and Chiapas, in Jalisco and Morelos, and in the lowlands of Yucatán (Barrera Marin et al. 1976*; Martínez 1987*). The plant also occurs in Costa Rica in association with pines (*Pinus* spp.) and oaks (*Quercus* spp.) (Schuldes 1995, 23*). It is more easily found in pure pine forests (Flores 1977, 12).

In Mexico, the closely related species *Conyza filaginoides* DC. is also known as *zacatechichi* (Schultes 1970, 48*).

Cultivation

Dream grass can be grown from germinated seeds. The dried fruit husks should be removed prior to planting. It is best planted in good topsoil and watered thoroughly.

Appearance

The herbaceous, branched plant grows to a height of approximately 1.5 meters and in rare cases to 3 meters. It has small, oval leaves that are crispate (curled) on the edges and forms small yellow or occasionally whitish flowers. The undersides of very young leaves are violet. The plant is difficult to

recognize and is easily mistaken for a number of other plants. Its most noticeable feature is its intense green color. It sometimes occurs in small fields that distinguish themselves from the surrounding vegetation through their green luminescence.

Dream grass is very easily confused with the closely related *Calea cordifolia*, which also bears yellow flowers.

Inflorescence of the Aztec dream grass (*Calea zacatechichi*)

The entire aboveground herbage provides the dream-inducing raw drug of *Calea zacatechichi*.

Psychoactive Material

—Leaves and stems, before the fruits ripen

Preparation and Dosage

The dried drug is used to prepare a tea, either an infusion or a decoction. The dried leaves and stems can also be smoked in a pipe or in the form of a cigarette (MacDougall 1968, 105).

When used for folk medicinal purposes—e.g., to treat malaria—a total of 10 g of dried herbage is made into a tea and drunk three times a day (Schultes 1970, 49*).

In Mexico, an alcohol extract of the leaves of the closely related *Calea urticifolia* (Mill.) DC. var. *axillaris* (DC.) Blake was formerly drunk as an inebriant (von Reis Altschul 1975, 324*).

Ritual Use

Although the Aztecs and other Mesoamerican peoples were almost certainly using the plant ritually in pre-Columbian times, very little information is contained in the sources. Dream grass is probably identical with *chichixihuitl*, “bitter herb,” an inebriating plant mentioned in sources from the colonial period.

The Chontal Indians of Oaxaca, whose language is related to Mayan, call the plant *thlepela-kano*, “leaf of god,” and venerate it as a plant of the gods. The *curanderos* (healers) of the Chontal boil crushed fresh leaves to produce a powerful and astringent brew that they drink in order to produce visions and clairvoyant, dreamlike states. They also lie down in a partially or fully darkened room and smoke a cigarette of dried leaves. The *curanderos* report having altered, dreamlike states in which they can hear the voices of the gods and spirits, recognize the causes of illnesses, look into the future, and locate lost or stolen objects. This form of divination is known as oneiromancy (divination through dreams).⁷¹ The Chontal healers consider a handful of dried herbage (approximately 60 g) an effective dosage.

The fresh herbage is sometimes placed under the pillow to induce dreams.

Artifacts

As of this writing, no artifacts are known.

Medicinal Use

Colonial medical texts from Yucatán indicate that crushed fresh leaves were used to prepare an herbal plaster to treat a swollen scalp. Steamed leaves were applied to treat skin diseases (Roys 1976, 290, 295*). Today, the Yucatán Maya still use dream grass as an herbal medicine (Barrera M. et al. 1976). During the Aztec period, the plant was also used to treat “cold stomach” (Flores 1977, 8).

The herbage is used in Mexican folk medicine as a laxative and febrifuge. Teas made from the plant are used as appetite stimulants (once the bitter taste has disappeared from the mouth) and stomach tonics and are also beneficial for diarrheal diseases (Mayagoitia et al. 1986, 230). The herbage also finds folk medicinal use in the treatment of headaches and diabetes, as a stimulant, and for menstrual complaints (Argueta V. et al. 1994, 1407*; Jiu 1966, 252*).

Constituents

The herbage contains a complex of horrible-tasting bitter principles consisting of several sesquiterpene lactones: germacranolide⁷² (1 β acetoxy-zacatechinolide, 1-oxo-zacatechinolide), germacrene 7, caleicine I and II, caleocromene A and B, caleine A and B, zexbrevine and analogs, and budleine A and analogs (Argueta V. et al 1994, 251*; Bohlmann and Zdero 1977; Herz and Kumar 1980; Lara Ochoa and Marquez Alonso 1996, 123f.*; Mayagoitia et al. 1986, 231; Quijano et al. 1979). The flavones acacetin and O-methylacacetin have also been found (Herz and Kumar 1980). Several studies have indicated the presence of an alkaloid (?) of unknown structure that has mild psychoactive and central sedative properties. According to Díaz (1979, 79*), there are different chemical races of the plant, of which one is psychoactive while the other(s) are not. This would explain why Chontal healers distinguish between “good” and “bad” specimens of the plant.

The active ingredients are water soluble. They may also be alcohol soluble, as tinctures are also used (cf. Schuldes 1995, 23*).

Effects

The subtle psychoactive effects on humans are best described as dream-inducing or oneirogenic. *Calea* also appears to promote sleep. Animal studies have demonstrated that cats quickly fall asleep when administered a dosage equivalent to that which induces dreaming in humans (Mayagoitia et al.

1986, 230).

A group of Mexican researchers headed by José Díaz conducted a double-blind experiment using a placebo and a preparation of *Calea zacatechichi* and registered a significant increase in the number of meaningful dreams in the subjects who had ingested *C. zacatechichi* (Mayagiotia et al. 1986). The geomancy researcher Paul Devereux, whose Dragon Project investigates dream activity in ancient cultic sites, is planning to conduct an additional study of the induction of waking dreams by *Calea zacatechichi*.

Germacranolide

A decoction made with a heaping tablespoon (approximately 25 g) of dried, chopped herbage, together with one standard joint, is regarded as an effective dosage for producing oneirogenic effects. After consuming the two, the person should lie down in a darkened room or go to bed:

After some 30 minutes, sensations of relaxation and calmness begin. The heartbeat is perceived more consciously. The stated amount of 25 grams clears the thoughts and the senses. (Schuldes 1995, 23*)

Some subjects have reported experiencing marijuana-like effects (cf. ***Cannabis***) after smoking a cigarette made with *Calea*. I personally cannot (yet) confirm such an effect. The only effects I have noticed are an increase of blood flow to the head and mild sensations of being “high.”

The effects described in the literature are not reliable (cf. Ott 1993, 422*). To date, no side effects have been reported.

Commercial Forms and Regulations

In Mexico, the dried herbage is occasionally found in markets or herb shops. It is more rarely found in international specialty stores. There are no regulations concerning its use.

“I played tamboura in a concert of classical Indian music after I had drunk the *Calea zacatechichi* tea. As I did, I dove into the sound of the tamboura. My teacher describes the tamboura as a ‘river,’ the water, the bearer of the music (the tablas are the currents, the voices are the spirit). I had always regarded the river as only a surface, and that with my tamboura playing I would form the surface upon which the others could flow. But the *Calea* literally brought a new depth into this picture. I was not only the carrying wave upon which the other musicians could drift along . . . I saw that we all played under water this time, all dove down to the depths of the ocean. . . .”

Calliandra anomala (Kunth) McBride

Red Powder Puff

Family

Leguminosae (Legume Family): Mimosaceae

Forms and Subspecies

None

Synonyms

Calliandra grandiflora (L'Hér.) Benth.

Folk Names

Cabellito, cabellitos de ángel, cabellitos de una vara, cabello de angel, cabellos de ángel, cabeza de angel (Spanish, “angel’s head”), canela, chak me’ex k’in (Lacandon, “the red beard of the sun/of the sun god”), ch’ich’ ni’ (Tzotzil, “bloody nose”), clagot, coquito, engelshaupt, hierba de canela, lele, meexk’in, pambonato, pombotano, red powder puff, saqaqa (Totonac), tabardillo, tepachera, tepexiloxóchitl, texoxóchitl, timbre, timbrillo, tlacoxilohxochitl, tlacoxiloxochitl (Aztec), tlamacatzcatzotl, tzonxóchitl, u me’ex k’in, xiloxóchitl

History

The spectacular red powder puff is originally from Mexico, where it was already being used for medicinal purposes in pre-Spanish times. The first reports about the plant are from Francisco Hernández, made in the fifteenth century. The Aztecs are said to have used the plant as a narcotic (Emboden 1979, 4*).

Both *Calliandra anomala* and the genus *Calliandra* as a whole have been little studied, even though the genus encompasses several interesting medicinal plants and very attractive and beautiful ornamental shrubs.

Distribution

Calliandra anomala occurs in the tropical zones of Central and South America. In Mexico, it is primarily found in Chiapas, Veracruz, Oaxaca, Morelos, Chihuahua, and Sinaloa (Martínez 1994, 319*).

Cultivation

The shrub can be propagated from seeds or cuttings. The seeds must be pre-germinated to ensure success. The plant requires a warm to moist/hot climate; it does not tolerate cold or frost (Grunner 1991, 19*).

Appearance

This branched shrub can grow as tall as 6 meters, although it usually attains a height of only 3 to 4 meters. The finely pinnate leaves are opposite. The bark is thick and covered with short hairs and has an olive-colored sheen. The characteristic inflorescences develop at the tips of the branches. The

actual white flowers are inconspicuous and arranged in rings around the branch. From these sprout the enormously long, luminously red filaments that give the inflorescence the appearance of a powder puff. In the tropics, the bush blooms throughout the year. The fruits, which usually appear in February, are long, flat pods that contain several flat seeds.

The genus encompasses some 110 species that are found primarily in the tropical zones of the Americas (Anzeneder et al. 1993, 53*; Bärtels 1993, 144*). The species *Calliandra fulgens* Hook. and *Calliandra tweedi* Benth. also produce red filaments and can thus have a similar appearance.

Psychoactive Material

—Bark (cortex calliandrae)

—Resin (sap)

—Root

—Buds/flowers (cabellitos)

Preparation and Dosage

Calliandra anomala was used as a pulque additive (see **Agave spp.**) and may have been used as an additive to cacao (**Theobroma cacao**).

The plant can allegedly be used to manufacture a **snuff**: “Several days after several incisions were made into the bark, the resin that had appeared was collected, dried, powdered, mixed with ashes, and sniffed” (Schuldes 1995, 24*). The powdered root has an irritating effect upon the mucous membranes of the nose (it is a sneezing powder, similar to **Veratrum album**). To date, no other effects have been reported.

The total daily dosage should not exceed 120 g; in one known case of overdose, a dog died following a dosage of 90 g (Martínez 1994, 320*).

The closely related species *Calliandra angustifolia* and *Calliandra pentandra* are used in South America as **ayahuasca** additives.

Ritual Use

In Aztec mythology and cosmology, *Calliandra* is associated with the heavenly realm of the dead (the House of the Sun in Heaven) and with the nourishment for reborn souls:

The third place to which one went was in the House of the Sun in Heaven. Those who had fallen in battle went there, those that had either died right in battle, so that they were carried away on the battlefield, that their breath ceased there, that fate found them there, or those that were brought home so that they could be sacrificed later, whether in the *Sacrificio gladiatorio* or by being thrown alive into the fire, or stabbed to death, or thrown onto the cactus [**Coryphantha spp.**], or in battle, or bound with pine chips—all of these go to the house of the sun. . . . And where those who had fallen in battle dwell, there are wild agaves [**Agave spp.**], thorny plants, and groves of acacias [**Acacia spp.**]. And he can see all of the offerings that are brought to them, that can make it to him. And after they have spent four years in this manner, they change into birds with bright feathers: hummingbirds, flower birds, into yellow birds with black, hollow depressions around their eyes; into chalk-white butterflies, into downy butterflies, into butterflies (as large) as drinking vessels, which suck **honey** from all types of flowers, the flowers of the *equimitl* [**Erythrina spp.**], the tzompantli tree [**Erythrina americana**], the *xiloxochitl* [*Pseudobombax ellipticum* H.B.K.; cf. **amapola**], and the *tlacoxilohxochitl* [*Calliandra anomala*]. (Sahagun, in Seler 1927, 301f.*)

It is possible that the shrub may have had a ritual significance among the Maya, for the Lacandon of Chiapas still refer to it as *chäk me'ex k'in*, “the red beard of the sun god.”

The astonishing flower of the tropical *Calliandra anomala*. (Photographed in Palenque, Chiapas, Mexico)

Various *Calliandra* species are used as ayahuasca additives in shamanic contexts.

Artifacts

None known

Medicinal Use

The Aztecs trickled the sap of the plant into the nose in order to induce a hypnotic sleep (Argueta V. et al. 1994, 251*; Emmart 1937*). To treat coughs, the root was chewed or peeled, ground, and taken in water with **honey** (Emboden 1979, 4*). The root is still used in folk medicine today to treat diarrhea, fevers, and malaria. A cold-water extract of the root is used as an eyewash (Martínez 1994, 320*). In Mexico, the shrub is becoming increasingly important in the treatment of diabetes (Argueta V. et al. 1994, 251*).

The Tzotzil Indians (Chiapas, Mexico) use this and other species of *Calliandra* to treat severe diarrhea. They macerate the root in water, boil the result, and drink three to five cups of this extract daily (Berlin and Berlin 1996, 212).

Around 1900, the bark of two Mexican species (cortex calliandrae, cortex pambotani) was used in Europe to treat marsh fever (Schneider 1974, 1:215*).

Constituents

The root drug contains quantities of tannins, fat, a resin called glucoresina, a glycoside called calliandreine, an **essential oil**, and minerals (Martínez 1994, 319f.*). The bark is said to contain harmane (per oral communication from Rob Montgomery). It is rumored that the bark also contains **N,N-DMT**. Felix Hasler and David Volanthen did not find any DMT in an analysis of *Calliandra* stem cortex material from southern Mexico. If DMT is in fact present in the stem cortex, it would have to be in amounts less than 0.1%. The root cortex has not yet been studied.

Calliandra angustifolia and *Calliandra pentandra* have been found to contain harmane and **N,N-DMT**. The closely related *Calliandra houstoniana* contains an alkaloid; this species is also the source of a gum resin that has industrial use (Cioro 1982, 74*). The leaves of *Calliandra portoricensis* Benth. contain saponines, tannins, flavonoids, and glycosides (Aguwa and Lawal 1988). Rare derivatives of pipecolic acid as well as derivatives of piperidine also occur in the genus (Marlier et al. 1979; Romero et al. 1983).

Effects

The effects of the resin have been characterized as hypnotic and sleep-inducing (Emboden 1979, 4*). It is unknown whether anyone has had psychoactive experiences with the plant.

The related species *Calliandra portoricensis* has sedative effects upon the nervous system (Adesina 1982; Berlin and Berlin 1996, 213).

Commercial Forms and Regulations

See under *Ipomoea* spp.

Camellia sinensis (Linnaeus) O. Kuntze

Tea Plant

Family

Theaceae (outdated: Ternstroemiaceae; Camelliaceae) (Camellia Family); Subfamily Theoideae (Camellioidae), Theeae (Camellieae) Tribe

Forms and Subspecies

The two basic forms (or races?) differ ecologically and especially economically. Assam tea is the source of black tea, China tea of green and brown tea. Whether the Assam tea plant is a variety (*Camellia sinensis* var. *assamica*), a subspecies (*Camellia sinensis* ssp. *assamica*), or a species in its own right (*Camellia assamica*) has still not been definitively clarified. Most authors presume that there are two varieties: *Camellia sinensis* var. *sinensis* and *Camellia sinensis* var. *assamica* (Teuscher 1992, 629). Numerous hybrids have been produced from both sorts; crosses have also been undertaken to produce higher yields.

Various species from the same genus are occasionally used as tea surrogates (i.e., *Camellia kissi* in Tibet and Nepal, *Camellia japonica* in Japan).

Synonyms

Folk Names

Arbre à thé, caha (Sanskrit), cajnoe derevo (Russian), cay (Hindi), cha, châ (Hindi), ch'a, chai, châ'î sabz (Persian), charil, gur gur cha, herba thee, kaiser-thee, ojandonnassame tzshe, syamaparni (Sanskrit), tè, tea plant, tea-shrub, teebaum, teepflanze, teyila (Malayalam), têylai (Tamil), théier, tzshe noky

History

The earliest written reference to the tea plant is contained in a document from 221 B.C.E., according to which the Chinese emperor Tschingschi-huang-ti had introduced a tax on tea (Temming 1985, 9).

Legend has it that Bodhidharma, a disciple of the Buddha, brought tea from India to China together with the Buddhist teachings (ca. 519 C.E.). There, it was enthusiastically received and passed on to Southeast and East Asia. The first handbook on tea was written by the Chinese Lu-Yü (740–804).

In 801, the Buddhist monk Saichô brought the tea plant to Japan (Okakura 1979, 34). The Zen monk Esai wrote the first Japanese book on tea (and its healing properties) during the early thirteenth century (Iguchi 1991).

The European Engelbert Kämpfer provided the first botanical description of the tea plant after visiting Japan in 1712. Tea arrived in Europe in 1610, when Dutch merchants brought it from Japan to Amsterdam (Gilbert 1981). The very first European description of the beverage, in Johan Neuhof's *Reisebericht* [Travel Report] (1655– 1657), praised its psychoactive effects:

The power and effect of this drink is / that it dispels immoderate sleep; but afterward those in particular feel very good / who have overburdened their stomachs with food / and have loaded the brain with strong beverages: for it dries and removes all other moisture / and dispels the rising vapors or fog / which provoke sleep; it fortifies the memory / and sharpens the mind. (In Temming 1985, 14)

An oversized tea plant in front of a tea field and a typical Chinese pagoda. (1669 copperplate engraving, printed in Amsterdam)

Botanical illustration of the Chinese tea plant. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

Distribution

The tea plant is originally from the triangle of countries formed by South China, Assam (northeastern India), and Cambodia. Today, it is planted in almost all tropical and subtropical regions of the world. The economically most important areas in which the plant is cultivated are in China, Japan, India, Sri Lanka, and Indonesia. Growing areas in Australia (North Queensland), KwaZulu-Natal, East Africa (Kenya), southern Brazil, the Caucasus Mountains, and the Seychelles (Mahé) are also gaining in importance. The place that is most renowned for its tea is Darjeeling, a small country in the Himalayas that culturally is a part of Nepal but politically is a protectorate of India (Vollers 1981).

“The spirit of tea is like the spirit of the Tao; it flows spontaneously, wanders here and there, and resists every compulsion.”

JOHN BLOFELD

DAS TAO DES TEETRINKENS [THE TAO OF TEA DRINKING]
(1986, 9)

Cultivation

The tea plant is usually propagated from cuttings, although it can also be grown from seed. The plant requires an average annual temperature of 20°C and a minimum of 1,300 mm of precipitation. The plant does not require any particular type of soil (for more on cultivation, see Franke 1994, 85–94). The first harvest can be had three years after propagation, but large harvests will not be produced until after six to seven years. The plant is harvested throughout the year, sometimes at short intervals (ten to fourteen days).

Appearance

This evergreen tree can grow as tall as 10 meters; in cultivation, it is maintained as a bush some 1.5 meters in height. It has elliptical, dentate, and leathery leaves that can grow as long as 10 cm. The flowers have five white petals and yellow pistils. The fruit is in capsules that may be monolocular, bilocular, or trilocular.

Psychoactive Material

—The young leaves (folia theae, thea folium); the best qualities are from young, small leaves from sorts that are planted in favorable altitudes (Darjeeling).

The processing method determines the type of tea. Green tea consists of unfermented, dried leaves (thea viridis folium), black tea of fermented leaves (thea nigrae folium), and oolong (also known as white or brown tea) of semi-fermented leaves.

Steps in processing include plucking, drying using hot steam or wilting, rolling of the wilted leaves, fermenting, and firing or roasting.

Preparation and Dosage

Tea is prepared by brewing the leaves in boiling or hot water, resulting in a simple infusion. Steeping time varies by sort. Darjeeling tea should not be steeped for longer than one minute, while heavily fermented black teas can be steeped for up to three minutes and oolong teas up to ten. With green teas, the amount of time is dependent upon the quality. The best sorts (e.g., Japanese gyokuro) require only thirty seconds, and they can be reinfused several times. Black tea should always be prepared with water that has reached a rolling boil, fine green teas should be brewed with hot water that is only between 60 and 70°C. Steeping tea for too long a time releases the bitter tannins.

Dosages of tea vary among individuals. Some people can tolerate up to thirty-five cups of tea per day, while others can handle little more than one cup at breakfast. One tea bag per cup yields approximately 60 mg of caffeine. The yield is lower with loose tea (only about 40 mg of caffeine is obtained from the same weight).

The renowned Tibetan butter tea, which is also made in Mongolia, is prepared from brick tea (pressed black tea leaves bound together with ox blood). Shavings from the brick are boiled in a mixture of milk and water (1:2) and flavored with rice, ginger (see *Zingiber officinale*), orange peel, various spices, and salt. Finally, a piece of yak butter (not rancid butter, as is often incorrectly stated) is added to the souplike tea. The entire mixture must then be churned in a special tubular vessel until an emulsion results.

Tea is sometimes combined with other plants to alter its aroma. Moroccan tea, a mixture of green Chinese tea and the North African nana mint (*Mentha x nana*), is quite typical. This tea is brewed strong and heavily sweetened (in Morocco, it is drunk primarily during usage of kif; cf. *Cannabis sativa*). In Yemen, tea is aromaticized with twigs of *Catha edulis*. In eastern Asia, oolong tea is often mixed with the flowers of *Chrysanthemum* spp.

A number of plants have been or are utilized as stimulating tea substitutes; mate (*Ilex paraguariensis*) is an especially popular alternative. *Ilex cassine*, *Ilex guayusa*, *Ilex vomitoria*, other *Ilex* species, coca (*Erythroxylum coca*), and *Ephedra* spp. have also been used. The African rooibos tea consists of the leaves of the leguminous *Aspalathus linearis* (Burm. f.) R. Dahlgr. ssp. *linearis*, which is devoid of **caffeine** and other stimulating constituents (Rehm and Espig 1996, 257*).

One of the many cultivated sorts of the tea plant that was bred to produce Japanese green tea (*Camellia sinensis* cv. Yutaka midori)

A Tibetan woman making the notorious butter tea

The tea plant (*Camellia sinensis*) with its typical fruit capsules.

Ritual Use

The legend of the origin of tea explains both its stimulating effects and its ritual significance: A pious monk—according to some versions, Bodhidharma, a disciple of the Buddha—was constantly falling asleep while meditating in the cloister. Angered by the fact that he could not keep his eyes open, he abruptly cut off his eyelids and cast them away. The first tea plant grew from the ground where they had fallen, its leaves resembling the eyelids. Other monks witnessed this miracle, collected some of the leaves, and poured water over them. They immediately noticed the animating power of the new beverage, and from that time forward, they always drank tea before meditating (Temming 1985, 9).

Customs surrounding the use of tea, some of which exhibit marked cultic or ceremonial qualities, have developed all across the world (Goetz 1989). In China, tea was initially drunk by Taoists and Buddhists to aid them in their meditations and sexual practices. This tradition evolved into the Chinese tea ceremony (Blofeld 1986), which culminated in the Japanese tea cult:

For us, the tea cult became more than simply an idealized form of drinking; it is a religion of the art of living. Tea drinking gradually became a pretext for venerating purity and refinement, it became a sacred act through which host and guest came together to create the greatest bliss. (Okakura 1979, 35)

The tea path (*cha-no-yu*) is a true entheogenic ritual in which a ceremonial master not only prepares the substance but also determines the spiritual direction of the circle. At the beginning of the ritual, which is conducted in a special house (teahouse) or a room furnished especially for the occasion, incense sticks (joss sticks based on aloe wood, *Aquilaria agallocha*) or special mixtures of various fumigatory substances (see **incense**) are burned. The tea is prepared in a ritual fashion: Powdered green tea (*macha*) is added to hot water (approximately 60°C) and whipped with a tea whisk in a tea vessel made of stone (*chawan*) until it froths. The dosage per person is “three and one-half sips.” The guests must ritually wash themselves before the ceremony (ablutions) and be prepared for philosophical discussion if the occasion should arise (Ehmcke 1991; Hammitzsch 1977; Iguchi 1991; Sadler 1992; Soshitsu Sen XV 1991; Stauffelbiel 1981):

Certainly, the tea path is not the path for many, even though many follow the path. Only a few knowers attain its ultimate goal—finding in the tea path a path to their true selves. They are liberated from their concerns about the transitoriness of all that is earthly, they take part in the eternal, they find their way back to nature, because they are in harmony with all living beings.

(Hammitzsch 1977, 125)

Similarly to the manner in which **wine** has shaped Occidental philosophy, Eastern philosophy has been borne on the wings of the spirit of tea:

Teaism is the art of shrouding beauty in order to discover it, and to suggest something which one does not dare reveal. It is the delicate secret of laughing softly and yet inscrutably about one's self, and is thus the good mood itself—the smile of philosophy. (Okakura 1979:19)

Tea has long been prepared as an aphrodisiac (cf. Stark 1984, 109*) and plays an important role in the Chinese and Japanese arts of love (Soulié 1983).

The Japanese name for a tea mortar is *cha-usu*. This word also refers to a particular aspect of erotic play: The man lies on his back, and the woman squats over him and places his “tea pestle” (*kine*) into her “tea mortar” (Heilmann 1991, 46). In many Taoist and similarly erotic rituals, drinking tea is a required practice.

Tea leaves are an ingredient in the initiatory drink of the Afro-American Candomblé cult (see **Madzoka medicine**).

Artifacts

Tea has influenced not only the Taoist and Zen Buddhist philosophies but also the associated arts (Soshitsu Sen XV 1991). For example, there are numerous depictions of Taoist saints drinking tea.

There are also many Chinese and Japanese marriage pictures and other erotic representations (*shunga*) that depict often intimately intertwined lovers drinking tea as they are having sex (Heilmann 1991; Marhenke and May 1995*; Soulié 1983). These erotic interludes are often shown taking place in the teahouse (following the tea ceremony).

The Japanese tea path has produced countless artifacts, especially those intended for use in conducting the ceremony (Ehmcke 1991). In 1989, the Japanese director Hiroshi Teshigahara produced a motion picture entitled *Rikyu, the Tea Master*. The film clearly portrays both the subtleties and the difficulties of the tea path (the film music was composed by the Japanese avant-gardist Toru Takemitsu).

A Taoist saint drinking tea while riding a dragon through the fields of bliss. (Chinese woodcut)

Although this American band calls itself The Tea Party, it is likely they are referring not to true tea but, rather, to a cozy *Cannabis* session. It is difficult to imagine that this cover illustration is meant to represent the effects of a tea party. (CD cover 1993, EMI Records)

“Tea is better than wine, for you drink it without inebriation.”

CHINESE SAYING (FIFTH CENTURY)

Medicinal Use

Before tea began its triumphant march through the world as an agent of pleasure, it was used primarily for medicinal purposes. In traditional Chinese medicine, the “foam of liquid jade” is regarded as an excellent panacea. It was first mentioned as a medicine in a Chinese herbal from the sixth century and was recommended particularly for people who slept too much (Leung 1995, 241f.*). In the Chinese literature, tea was attributed with the following properties:

promotes the circulation of blood into all parts of the body; aids clear thinking and mental wakefulness; promotes the excretion of alcohol and other harmful substances (fats and nicotine) from the bodily organs; strengthens the body’s resistance to a broad spectrum of diseases; accelerates the metabolism and the absorption of oxygen by the organs; prevents loss of teeth; cleans and invigorates the skin, which contributes to the maintenance of a youthful appearance; prevents or slows down anemia; purifies the urine and promotes its excretion; resists the effects of the summer heat; is good for the eyes and makes them more shiny; promotes digestion; soothes discomfort in limbs and joints; prevents harmful mucous secretions; alleviates thirst; combats tiredness or attacks of depression; enlivens the spirit and brings about a general feeling of well-being; increases life expectancy. (Blofeld 1986, 209)

In Japan, “newborn tea”—*gyokuro*, literally “precious dew,” referring to the first harvest of the year—is generally attributed with potent healing properties and is regarded as a rejuvenant. Many Japanese drink green tea together with a shot of **sake** or whiskey (**alcohol**) when they have a cold.

Strong infusions of tea are suitable for external application in treating skin ailments (athlete’s foot, skin eruptions, inflamed abrasions).

Constituents

Depending upon their source and fermentation process, tea leaves contain 0.9 to 5% **caffeine** (previously: theine or teine), which occurs freely or bound with glycosides; 0.05% theobromine; some theophylline ($C_7H_8N_4O_2$); the purine derivatives xanthine, methylxanthine, and adenine; 5 to 27% tanning agents (tannin, polyphenoles, gallic acid, and catechin derivatives); and chlorophyll (only in fresh or unfermented leaves). Also present are vitamins (A, B₂, C, D, P, nicotinic acid), minerals (e.g., manganese), and carbohydrates (dextrin, pectin), as well as traces of **essential oils**, which are responsible for the aroma (the fresh leaves contain some four to five times as much essential oil as dried or fermented leaves; Aleijos 1977, 103). The greatest amounts of essential oil are found in the so-called flying tea from Darjeeling (the first harvest of the year, which is exported by air freight; cf. Vollers 1981).

“One drinks tea to forget the noise of the world.”

LIN YUTANG

WEISHEIT DES LÄCHELNDEN LEBENS [WISDOM OF THE SMILING LIFE] (1960)

Effects

Because of the often high amounts of **caffeine** it can contain (up to 4.5%), tea has strong excitant and stimulant effects. The tanning agents are strongly astringent and “tanning” and are used as dyes in tanning hides. The stimulating effects of tea manifest themselves more slowly than those of coffee (see *Coffea arabica*) but also persist longer, as the caffeine often must first be liberated from the bond to the tanning agents and the glycosidic compounds. The tannic acids form toxic alkaloids and stimulate the digestion of fats. The essential oil has euphoriant as well as calming effects upon the nerves (Aleijos 1977, 106; Blofeld 1986, 212). The essential oil as such has stimulating effects very much like those of caffeine.

Japanese studies on the pharmacology and pharmacokinetics of green tea have demonstrated that the national drink of Japan has anti-carcinogenic effects, lowers cholesterol levels, and has hypoglycemic properties. It also hinders the development of arteriosclerosis. Numerous longitudinal studies in Japan have shown that drinkers of Japanese green tea develop cancer significantly less frequently than those who do not drink tea (Blofeld 1986, 214; cf. also Scholz and Bertram 1995).

The relatively high amounts of vitamin P in tea have positive effects upon high blood pressure and heart diseases.

A recent study of the medicinal effects of black tea revealed that the hot-water extract (what is normally drunk as “tea”) has antiulcerogenic effects (Maity et al. 1995). Theaflavine has bactericidal properties (Vijaya et al. 1995).

Strong tea has general detoxifying properties and is a useful antidote for alcohol poisoning, overdoses of hashish and opium, and nicotine or heroin withdrawal (Blofeld 1986, 211).

Tea is also used in homeopathy, both as a mother tincture and in various dilutions (*Thea chinensis* hom. *HAB34*, *Thea sinensis* hom. *HPUS78*). According to the homeopathic medical description, tea is used among other things to treat stomach weakness, headaches, circulatory problems, states of excitation, and ill feelings (Teuscher 1992, 638f.).

Commercial Forms and Regulations

Tea is sold in various forms on the international market. Different qualities of black tea and green tea (*sencha*), including oolong from specified areas, are available. Mixtures (e.g., English tea, East Friesian tea; cf. Haddinga 1977) as well as perfumed or aromatized teas (e.g., vanilla, Earl Grey, cinnamon) are also available. The most commonly sold type of tea in the world is bag tea (black tea).

There are also such specialized teas as Japanese powder tea (*macha*), Tibetan brick tea, Chinese cake tea, rice tea (*genmaicha*), et cetera (Adrian et al. 1983, Maronde 1973).

Tea is an agent of pleasure that is sold freely throughout the world and is usually classified as a foodstuff.^{[23](#)}

“With its aroma and clear foam

Tea resembles the nectar of the immortals.

The first cup swept the cobwebs from my thoughts,

the entire world appeared in a gleaming light.

The second freed the spirit like purifying rain,

the third made me one with the immortals. . . .”

CHIAO-JÊN (A POET OF THE T’ANG DYNASTY)

“THE TAO OF TEA”

Cannabis indica Lamarck

Indian Hemp

Family

Cannabaceae [= Cannabinaceae; also Cannabiaceae, Cannabidaceae] (Hemp Family); *Cannabis* is sometimes classified within the Moraceae Family (cf. Zander 1994, 165*)

A Preliminary Note on the Botany of *Cannabis* spp.

Contemporary botanists are of two minds regarding the genus *Cannabis* (Clarke 1981; Schmidt 1992; Small et al. 1975). One school regards the genus as monotypic and suggests that there is only one species, *Cannabis sativa*, which can be divided into several varieties and numerous sorts (Anderson 1980; Small and Cronquist 1976; Stearn 1974). The other group adheres to the concept of three species (Emboden 1974a, 1974b, 1981b, and 1996; Schultes et al. 1974).

This encyclopedia subscribes to the division of the genus into three species.

Illustration of *bangue*, the Indian hemp plant (*Cannabis indica*). (Woodcut from Garcia da Orta, *Colloquies on the Simples and Drugs of India*, 1987)

Forms and Subspecies

Wild or feral Indian hemp is sometimes referred to as *Cannabis indica* Lam. var. *spontanea* Vavilov (Schmidt 1992, 641).

Synonyms

Cannabis foetens Gilibert

Cannabis macrosperma Stokes

Cannabis orientalis Lam.

Cannabis sativa α -kif DC.

Cannabis sativa ssp. *indica* (Lam.) E. Small et Cronq.

Cannabis sativa var. *indica* Lam.

Folk Names

Azalla, azallû (Assyrian), bandsch, bang, banj, bengali, bengué, bhamgi (Tamil), bhang, bhanga, black prince, bota, cánamo de India (Spanish), canapem indiana (Italian), canhamo, canhamo da India, cannabis, can xa, caras, charas, charras, churrus, doña Juanita, gai ando (Vietnamese), gañajâ, gañca, gangué, ganja, gánzigùnu (Assyrian), garda (Kashmiri), ghariga, ghee (“clarified butter”), gunjah, haschischpflanze, hemp, hierba santa (Spanish, “sacred herb”), Indian hemp, juanita, jvalana rasa, kamashwar modak, kañcavu, kancha, keralagras, kerala grass, kimbis (Mesopotamia), konopie indyjskie, kumari asava, la amarilla, lai chourna, la mona, la santa rosa (Spanish, “the sacred rose”), liamba, madi, maguoon, manali, maría rosa, marihuana, marijuana, mariquita, mazar-i-sharif, menali, misarai, mustang gold, parvati, qunnab, qunubu (Assyrian), ramras, rosamaría, santa rosa, shivamuli, siddhi (Bengali, “miraculous ability”), soft hemp, tara-kola, the herb, true hemp, utter, vijaya (Sanskrit, “the victor”), yaa seep tit (Thai, “drug”), zacate chino

Many of these names are also used for ***Cannabis sativa*** and hemp hybrids (see ***Cannabis x and hybrids***).

History

We do not know with certitude when Indian hemp was first cultivated, when it was first used as a medicinal and pleasure plant, or where its ritual use began (Abel 1980; Merlin 1972; Schultes 1973). It is very likely that it was used in prehistoric times in the Indus Valley and in Mesopotamia. Its psychoactive effects were obvious from the beginning and were utilized for both ritual and medicinal purposes. Some authors are of the opinion that *Cannabis indica* was the miraculous Arian drug **soma** (Behr 1995). It is certain that hemp was used as a soma substitute during the post-Vedic period. In India, its use as a medicine has been documented as far back as 1400 B.C.E. In northern India and the Himalayas, hemp has been utilized since prehistoric times in shamanism (cf. ***Cannabis ruderalis***, ***Cannabis sativa***), the tantric cult, yoga, and magical contexts. Many of these uses have continued into the present day (Chopra and Chopra 1957; Sharma 1977).

The story of the Assassins, those “fanatic treacherous murderers,” has been reworked often to demonstrate the “horrible effects” of hashish (e.g., Meck 1981; Nahas 1982). It has been argued that *assassins* itself means “hashish people” or “hashish eaters.” The leader of this group supposedly used hashish, produced from the resin of hemp plants, to make his followers pliable, so that they would blindly carry out any murderous order. However, “[n]owhere, whether in any of the Oriental or any of the Occidental sources, is there even a suggestion that a captive Assassin made mention of the use of hashish or any other drugs” (Gelpke 1967, 274).

Indian hemp first came to the attention of Europe in the nineteenth century (Martius 1855). In 1811, an illustrated book was published in Paris that depicted the customs of the Hindus. It contained numerous scenes of Indians enjoying hemp from various water pipes and other smoking devices (Solvyns 1811). Indian hemp and the hashish it provides were immediately adopted for medicinal use; artists also discovered that hemp could be a source of inspiration, while occult circles tested it for use in inducing clairvoyant states (Hoye 1974; Meyrink 1984). The studies of the French psychiatrist Moreau de Tours (1804–1884) proved to be very influential, from both a medical and a cultural perspective (Scharfetter 1992). As a result of his published work, a number of artists, poets, and Bohemians were inspired to found the Club de Hashishins in Paris (Haining 1975; Müller-Ebeling 1992b). The renowned **Oriental joy pills** were also circulating in Marseilles at this time.

The systematic demonization of what is actually the most harmless inebriant and agent of pleasure

known is the work of drug policies promulgated in and by the United States (cf. Herer and Bröckers 1993). The illegal status of hemp is a recent phenomenon and is based not upon scientific data but upon sociopolitical goals and economic structures (Hess 1996). In recent years, even judges have begun to push for the decontrol of *Cannabis* products on the basis of the individual's "right to inebriation" (Neskovic 1995).

Today, hemp is the most commonly consumed of all illegal drugs in the world, although its users typically classify hemp products not as drugs but as agents of pleasure (Drake 1971; Haag 1995). Wherever hemp is used, a hemp culture has developed along with it (Giger 1995; Novak 1980; Rätsch 1996a; Vries 1993). In the 1990s, hemp experienced a renaissance when its potential as a useful economic crop with outstanding ecological qualities was rediscovered (Galland 1994; Herer and Bröckers 1993; Hesck et al. 1996; Rätsch 1995b; Robinson 1996; Rosenthal 1994; Sagunski et al. 1995; Wasco 1995).

Distribution

The range of *Cannabis indica* is limited to northern India, Afghanistan, Pakistan, and the Himalayas (Macmillan 1991, 421*). It is difficult to assess whether the hemp that was used in ancient Mesopotamia was in fact *Cannabis indica*. Only in the Himalayas has it been observed growing wild. A large occurrence of wild plants can be found in Taratal, near the Dhaulagiri massif; the wild plant is known as *tara khola* (Haag 1995, 75). On the other hand, *Cannabis indica* and hybrids that have been produced from it are now grown throughout the world (cf. ***Cannabis* x and hybrids**).

Cultivation

All species of *Cannabis* can be grown from both seeds and cuttings (clones). Propagation from cuttings requires some skill, a green thumb, and considerable luck, but it does ensure purely female descendants (see ***Cannabis* x and hybrids**).

The seeds can be germinated either in seedbeds or in germinating pots. They can be presprouted by placing them in moist and warm (21°C) paper towels placed in a dish and kept in a dark location. This method provides the clearest indication as to which of the seeds are the most vigorous. The seed coat will open in just a few days, after which the seed can be placed into the soil (0.5 cm deep). The young seedlings do not tolerate direct sunlight and must not be allowed to dry out. A seedling can be transplanted as soon as it has sprouted its first pair of leaves. In central Europe, it is best to begin germination in April (at home or in a greenhouse). The young plants should not be placed outdoors (i.e., on a balcony or in a garden) until the middle of May. It is also possible to sow or scatter the seeds directly onto the ground in May, although the success rate of such a method is considerably lower. In the Himalayas, *Cannabis indica* is self-sowing.

Cannabis plants need relatively copious amounts of water to grow. For this reason, they must be watered regularly. Branching can be induced by occasionally pinching off the new leaves at the ends of the branches. Flower formation can be promoted by partially defoliating the plant from time to time. As soon as hemp begins to flower, it should no longer be heavily watered. Large amounts of light and only a little water will help ensure that the inflorescences are rich with resins. Opinions about fertilizer use vary considerably.

Appearance

Indian hemp typically grows to a height of only about 1.2 meters. It is heavily branched, which gives it a conelike appearance not unlike that of a Christmas tree. Because of its many oblique side branches, this species forms many more (female) flowers than the other hemp species do, which makes it particularly attractive for the production of psychoactive products. The aril is heavily

articulated, in contrast to its more smooth appearance in *Cannabis sativa* (cf. Clarke 1981, 158). The seeds are somewhat darker and smaller than those of *Cannabis sativa*. Apart from its size and the heavily branched appearance, the main distinguishing feature of the species is the shape of its leaves, which are usually much broader and more oval than those of the other two species. Indian hemp is almost always dioecious. The male plants are somewhat more slender and taller than the female plants.

This plant is very easily confused not only with the other hemp species, but also with other plants, such as false hemp (*Datisca cannabina* L.), which is remarkably similar and has even been mistaken for Indian hemp in herbariums (Small 1975).

A typical leaf of Indian hemp (*Cannabis indica*).

Produced from *Cannabis* leaves, bhang is sold openly in Varanasi, the sacred city of Shiva, the god of hemp and hemp use. One ball represents a weak dose, two produce moderate effects, and three induce profound psychoactive effects.

Indian hemp (*Cannabis indica*) is distinguishable primarily by its short stature and Christmas-tree-like appearance. (Female wild plants, photographed in the Himalayas, Nepal)

Psychoactive Material

- Female flowers/inflorescences (ganja)
- Leaves (bhang)
- Herbage of flowers and leaves (*cannabis indicae herba*, *herba cannabis indicae*, *summitates cannabis*)
- Seeds
- Resin (*resina cannabis indicae*, *charas* = *churrus*, hashish)
- Oil from the resin (hashish oil)
- Oil from the seed (hemp oil)

Preparation and Dosage

There are many ways to prepare *Cannabis indica*. For psychoactive use, the most popular parts are the female flowers and the resin. The leaves of the female plant are also used. Male plants are practically useless. All products can be either smoked or eaten (drunk) (Rippchen 1995). The most common method of use is to smoke the dried flowers of the female plant, which should be harvested before the seeds form and slowly dried in the shade.

The most valuable products of the plant are the resin and the resin glands that are rubbed off the female flowers. The resin can be harvested or obtained in a number of ways (Gold 1994). The most valuable resin is obtained by rubbing the female inflorescences with the hands. The resin and some of the resin glands stick to the surface of the hands and collect there as more flowers are rubbed. The result can be scratched or scraped from the hand. Kneading the collected material produces a soft, aromatic, black or deeply dark olive green mass known in the Himalayas as *charas* (= *charras*, *chura*, *churrus*). *Charas* can be mixed either into various foods (pudding, cakes, cookies, etc.) or with other herbs to produce **smoking blends**.

In India, Pakistan, Afghanistan, and Nepal, the resin is graded into different sorts, depending upon the source and the intended use: Kashmiri or Dark Brown Kashmiri, Manali or Finger Hashish, Rajasthani (resin mixed with other pieces of the plant), Indian Gold or Black Gold (high-grade resin gilded with gold leaf), Black (soft, pure resin), Bombay Black (resin to which opium, *Papaver somniferum*, or **morphine** has been added), Parvati, (hand-rubbed resin), Pakistani or Brown Pakistani (brown resin), Afghani or Black Afghani (hand-rubbed resin), and Moldy Afghani (inferior quality).

After *charas*, the most potent product is the nonrubbed, deleafed dried female inflorescence. This

product is usually called ganja and is either smoked alone or mixed with other herbs (e.g., *Datura metel*, *Turnera diffusa*, *Brugmansia suaveolens*, *Amanita muscaria*, *Nicotiana rustica*, *Aconitum ferox*). Ganja can also be eaten or drunk.

A third psychoactive *Cannabis indica* product is bhang. The term *bhang* refers to the small, resinous leaves of the plant as well as to drinks that are prepared from them. Bhang is prepared from watery hemp leaves, i.e., leaves that have been soaked in water, ground, and mixed with sugar and molasses (this method is typical for the region around Varanasi/Benares). But bhang can also be made with milk products:

The drink called *bhang lassie* (*thandai*, *poust*, *siddhi*, *ramras*), which is made of yogurt, water, **honey**, pepper [cf. *Piper spp.*], and hemp flowers, symbolizes the sacred Ganges and can be obtained for pennies throughout India even today. It is equally venerated by pilgrims and by participants in marriage ceremonies and temple festivals. When **alcohol** is added to bhang, it is called *loutki*; if opium tincture [see *Papaver somniferum*] is also added to the preparation, then the Indians call the drink *mourra*. Bhang mixed with ice cream produces *gulfi*, also called *hari gulfi* (green ice), which is particularly popular in northern India. (Haag 1995, 78)

On occasion, the leaves will be drunk only with water or milk; such drinks, known as *thandai*, are consumed for refreshment (Morningstar 1985). Ganja can also be used to brew **beer** (Rosenthal 1996).

The two most important products of *Cannabis indica* are the dark resin rubbed from its female flowers (charas) and the dried female inflorescences (ganja).

The hashish produced in Lebanon is known as red Lebanese.

Moroccan hashish is also known as green hashish. It is produced by pressing finely chopped and sifted female flowers.

Bhang Recipe (Nepal)

Required ingredients:

- hemp flowers (ganja)
- spices (e.g., cardamom, turmeric, nutmeg [*Myristica fragrans*], cloves, pepper [*Piper spp.*], cinnamon)
- sugar or **honey**
- milk (water buffalo)

Optional ingredients:

- poison nut (*Strychnos nux-vomica*)
- opium (*Papaver somniferum*)
- thorn apple seeds (*Datura metel*)
- ground nuts (e.g., almonds)
- ghee (clarified butter)

Finely chop the hemp flowers and mix with the spices (and optional ingredients).

Dissolve sugar or honey in the milk, then mix in the hemp and the spices.

For tantric **smoking blends**, hemp flowers (ganja) are sometimes mixed with cobra venom—the cobra is a sacred animal and a symbol of Shiva. Crystallized cobra venom²⁴ is mixed with chopped hemp flowers or hashish and smoked in a chillum. Other tantric mixtures contain *Aconitum ferox*, *Datura metel*, *Brugmansia arborea*, opium (see *Papaver somniferum*), tobacco (*Nicotiana tabacum*), or henbane (*Hyoscyamus niger*).

Around 1870, Indian cigarettes were made in Paris from the following ingredients:

- 0.3 g belladonna leaves (*Atropa belladonna*)
- 0.15 g henbane leaves (*Hyoscyamus niger*)
- 0.15 g thorn apple leaves (*Datura stramonium*)
- 0.5 g Indian hemp leaves, impregnated with opium extract and cherry laurel infusion (*Prunus laurocerasus* L.)

This recipe is reminiscent of **witches' ointments** as well as modern **smoking blends**. Another recipe for Indian cigarettes mentions paper impregnated with a tincture of *Cannabis indica*, opium (see *Papaver somniferum*), and *Lobelia inflata*.

In Cambodia, the wood of the botanically unidentified **shlain** tree is added to hemp flowers and leaves in order to increase their effects when smoked (cf. Räscht 2001, 51*).

The psychoactive dose when smoking *Cannabis indica* is approximately twice as high as when eating it; around 50% of the THC is taken into the smoke. A normal dosage is between 5 and 10 mg of THC. This corresponds to about 0.25 g of smoked flowers or 0.1 g of smoked charas (resin). These guidelines should be used with care, however, because THC content can vary considerably (Schmidt 1992, 650). The products of *Cannabis indica* are generally more potent than those of *Cannabis sativa*.

Ritual Use

Hemp has been a drug of shamans since ancient times (Eliade 1975, 376ff.*; Knoll-Greiling 1950; Sebode and Pfeiffer 1988, 16). Shamans are generally attributed with the discovery of pharmacologically efficacious plants, including the discovery of hemp and its multitude of uses (Merlin 1972). In central and east Asia, hemp was already in use during the Neolithic period. Our word *shaman* originated in the same area. In the Tungusic language, *shaman* refers to the healing and prophesizing master of consciousness (Sebode and Pfeiffer 1988, 7). The earliest literary and ethnohistorical evidence for hemp is contained in shamanic texts from ancient China (Li 1974a, 1974b).

In Nepal, shamanism has been and continues to be of great importance for many indigenous peoples who have had only limited contact with Western medicine. Most of the peoples of Nepal practice a religion that draws from various sources. Here, elements from the Vedic period, the ancient Bön religion of Tibet, Tibetan Lamaism, and a variety of schools of Hinduism have blended into a harmonious whole. Shamans can be found in almost every village. They are usually called *jakri*, a word that means “magician” (both male and female). These shamans inhabit a polytheistic cosmos in which the Buddha is as much at home as are the ancient Bön demons and the Vedic and Hindu gods:

The Chillum Cult

The word *chillum* (pronounced *tschillum*, and sometimes spelled *chilam*) refers to a conical tube for smoking hemp. The smoking of chillums is an ancient tradition that is still alive in the Himalayas and India (Knecht 1971; Morningstar 1985). Generally speaking, the Himalayan region is the most tradition-rich area of the world as far as hemp is concerned (Fisher 1975; Sharma 1972, 1977). It is not known how long chillums have been in use. It is also not clear whether the chillum is an ancient invention of the Himalayan peoples or is derived from the head (upper part) of the Muslim hookah (the traditional Oriental water pipe) (Morningstar 1985, 150).

The chillum is the typical smoking device of sadhus and yogis, who use it constantly in their rituals of worship, meditation, and yogic practice (Bedi 1991; Gross 1992; Hartsuiker 1993).

When Western travelers (“hippies”) journeyed to India and Nepal in the 1960s, they quickly learned about the indigenous use of the chillum and hemp by sadhus. They brought back to the West both the smoking device and the knowledge of its proper use. Soon, large numbers of Indian and Nepalese chillums were being imported by shops specializing in Indian articles and by “head shops.” Many

Western hashish smokers possess one or more chillums and know how to use them in a traditional manner.

A chillum is smoked not alone, by one person, but in a smoking circle (*chilam chakri*). One person fills the chillum with the smoking mixture (e.g., hashish and tobacco, hashish and marijuana, or hashish and ***Datura metel***) and then hands it to the next person in the circle for lighting. The chillum is lit with two matches (which represent the masculine and the feminine poles of the universe). Before lighting the mixture in the chillum, the person holds the chillum against his or her forehead (the third eye) and utters a short formula (*japa*), usually “Bum Shankar!” This consecrates the smoke to the Hindu god Shiva. Hemp smokers regard both Shiva and his son Ganesha as the gods of hemp smoking. After the chillum has been started, it is passed around the circle, usually in a clockwise direction. When the chillum is “through,” its owner taps out the remnants of the smoking mixture and carefully cleans it with a piece of cloth.

Chillum smoking is a relatively elaborate process that demonstrates the profound respect the consumer has for the plant as well as for the Asian tradition, and often reveals a religious attitude toward hemp smoking. Most Europeans who use chillums today learned about its use not while in India or Nepal but from other hemp smokers. The European tradition of chillum smoking can now look back upon more than thirty years of tradition, and chillum use is being passed on from one generation to the next (Rätsch 1996a).

According to shamanic tradition, Indra, the original Vedic god, discovered Cannabis and sowed it in the Himalayas so that it would always be available to humans, who could attain joy, courage, and greater sexual desire through the herb. (Haag 1995, 78)⁷⁵

The shamans venerate Shiva, whose roots can be traced back to the Vedic Rudra. They regard him as the primordial first shaman, who had a perfect understanding of the shamanic arts and who taught this to certain chosen people. One Nepalese name for Shiva is *vijaya*, “the victorious”; in the Vedic scriptures, hemp is referred to by the same name. Shiva is also known as Bhangeri Baba, “the lord of hemp” (Storl 1988, 83, 198, 201). According to shamanic tradition, it was he who discovered hemp and sowed it in the Himalayas so that humans would always have access to it. Shiva also gave people the various recipes for its use: “In Nepal, ascetics, shamans, and magicians have been consuming small amounts of this agent since ancient times in order to induce trance states” (Gruber 1991, 144).

Smoking is the most common method of consuming the various hemp products (Knecht 1971). Hemp leaves, the female flowers (*ganja*), or bits of the sticky, aromatic resin (*charas*) are stuffed into a chillum, either alone or mixed with thorn apple leaves (***Datura metel***), henbane (***Hyoscyamus niger***), aconite (***Aconitum ferox***, ***Aconitum spp.***), or tobacco (***Nicotiana tabacum***). The chillum, a symbol and an attribute of Shiva, is then held to the forehead and consecrated to the god with the words *Bum Shankar*, “hail to the benefactor” (Morningstar 1985).

In Nepal, hemp is often drunk in the form of bhang (Müller-Ebeling and Rätsch 1986, 20*). The shamans of the Himalayas drink bhang in order to induce the states of trance or ecstasy that they require for their healing rituals. They offer bhang at the phallus-shaped shrines of Shiva (sacred stones, lingams). The offerings actuate the healing powers of the god, for no one loves hemp and the state it produces as much as Shiva himself. The inebriated god sends forth his healing power, which the shaman channels and transmits to the patient. Although it is usually only the shaman who smokes ganja or drinks bhang during the shamanic healing sessions, hemp is also used as a medicine. By smoking hemp, and by virtue of his gifts, a shaman who is devoted to Shiva can produce an especially efficacious medicine:

A traditional hookah, a simple water pipe for consuming hashish or marijuana. (Drawing by C. R  tsch)

Smoking is an unbecoming, a dissolution, a process of death. In this small, spinning pyre, the husks of delusion that entwine us burn to ash. The rotting corpses of our transgressions, the cadavers of old karma, roast therein and are transformed to snow white ash. . . . The bolt to the door of the “transcendent” is shattered; the demonic hordes of Shiva, the ethereal images of natural forces and the shapes of souls, dance before the eyes of the initiate. The dead and the gods appear! In an even deeper samadhi, all manifestations, all appearances, cease, and it simply is. In total absorption, Shiva sits on Kailash, the holy mountain, the mountain of snow, the mountain of ash. . . . After the chillum has been smoked all the way to the end and the meditation is over, the shaman takes the ashes and rubs them onto his forehead or he places them on his tongue as prasad, for the sacred white powder is regarded as the best medicine. (Storl 1988, 204, 205*)

Hemp is the most important ritual drug of Indian and Nepalese Tantrists. They call it *vijaya*, “the victorious,” and regard it as “the only true aphrodisiac” (Bharati 1977, 209). For this reason, hemp preparations are used in the erotic rituals for couples, during which the two lovers are transformed into the gods Shiva and Parvati (Aldrich 1977). The *sadhaka* (or Tantrist) places a bowl with a hemp preparation in front of himself on a mandala and asks the tantric “goddess of the divine nectar” to consecrate the hemp. After this, he carries out several ritual gestures (*mudras*) over the vessel. He then speaks a mantra to the guru, the teacher, in order to offer him the libation. Finally, he touches his heart and drinks the drink to honor the god, usually Shiva, he has chosen for this purpose (Bharati 1977, 207f.).

During one tantric ritual that is still conducted in northern India today, hemp (bh  ng) is transformed into *amrita*, the drink of the gods (cf. **soma**):

1. As an act of preparation and ritual purification, the leaves of the Cannabis plant are rubbed with black pepper [cf. **Piper spp.**], water is added, and the mixture is filled into a stone vessel.
2. A *yantra* (ritual diagram) of a circle, square, and triangle is drawn. The primordial feminine energy *ardhar shakti* is venerated in this *yantra*.
3. The vessel with *bh  ng* is placed upon the *yantra*. This is followed by meditation and recitation.

4. Using a *mantra* (a kind of magical formula), *vijaya* (the name of the goddess) is called into the *bhang* container and welcomed.
5. Using a particular *mantra* (magical formula), *bhang* is transformed into *amrita* (a drink of the gods).
6. With a ritual gesture of veneration [*mudra*], the vessel full of *bhang* is raised to the forehead and a prayer in honor of the *guru* (religious teacher) is uttered.
7. The *bhang* preparation is ingested.

The activity described is accompanied by recitations and ritual gestures (*mudras*). (Moser-Schmitt 1981, 545)

Since the post-Vedic period, Brahmans have been using hemp as an adjunct to meditation and to promote concentration as well as to deepen their understanding of the sacred texts (Rig Veda, Atharva Veda, Puranas, etc.). Orthodox Brahmans from the area of Varanasi (= Benares) and Allahabad (Uttar Pradesh) still regularly ingest *bhang* every Friday (Bharati 1977, 207).

In Mesopotamia, and especially among the Assyrians, hemp was burned as a sacred **incense** (Bennett et al. 1995, 15, 19). The Scythian hemp ritual is discussed under *Cannabis ruderalis* (cf. also “**Trees with Special Fruits**”). In the Occult movement, hemp was used as a visionary incense (Bennett et al. 1995, 280ff.; Meyrink 1984).

On the Caribbean island of Jamaica, Indian hemp is at the center of the Rastafari cult, a movement that arose in the twentieth century and is said to have its roots in Ethiopia (see Räscht 2001, 137–42). The ritual music of the Rastas is reggae, and their sacrament is hemp (ganja). One leader of the Rastas summarized the cultural meaning of hemp in the following manner:

We use this herb as medicine and for spiritual experiences. It helps us to overcome illness, suffering, and death. . . . We use our herb in our church—as incense for God, just as the Roman Catholics use incense in their church. We burn our incense in order to venerate our God through spiritual experience. . . . It gives us spiritual comfort, we praise God in peace and love, without force. . . . When we are depressed, when we are hungry, we smoke our little herb and we meditate on our God. The herb is a true comfort to us. (In Kitzinger 1971, 581)

In the Rastafarian community, the first inebriation produced by smoking ganja has the character of an initiation. The young smoker is supposed to receive a vision that will mark him as a full member of the community and reveal his path through life (Rubin and Comitas 1976). “Ganja is the most strongly shared experience among the brothers” (Gebre-Selassie 1989, 156). The Rastas, it should be noted, eschew **alcohol**, which may be used only as a solvent for ganja and be consumed in medicines. Alcohol inebriation is viewed as reprehensible, harmful, aggression promoting, and asocial (Blätter 1990, 1993).

In Mexico, an Indian cult calls hemp *la santa rosa*, “the sacred rose,” and venerates it as a sacred plant. The cult members chew hemp flowers at their meetings and use the psychoactive effects to intuitively speak sacred words, for divination, and as an expression of the divine (Williams-Garcia 1975). This hemp cult may have its roots in a pre-Columbian use of other psychoactive plants (possibly *Salvia divinorum*).

Artifacts

A Sumerian necklace from Ur incorporates a number of elements that are strongly reminiscent of *Cannabis* leaves (Emboden 1995, 99*). An ancient depiction of bull killing suggests that hemp may very well have played a role in the Mithraic mysteries. From the wounds of the bull that Mithras killed

as a sacrifice to create the world, blood is shown flowing in the shape of a hemp leaf (Bennett et al. 1995, 146; cf. *Peganum harmala*, *haoma*).

Evidence of the effects of hemp consumption on art (painting) is not as obvious as with other psychoactive plants. This is certainly due to the fact that the effects of hemp are only rarely visionary in nature. With many artists, it is also impossible to state whether their works were influenced by hemp or other psychoactive substances because the artists themselves refuse to discuss the matter (Müller-Ebeling 1992b).

Hemp provided Aubrey Beardsley, one of the greatest artists of the art deco movement, with inspiration during his short life (1872–1898). He described Warden’s Extract of Cannabis Indica, available at pharmacies, as “my mental nourishment” (Behr 1995, 185). It is very likely that other art deco artists created their works while under the influence of hemp; information about this, however, is scant (Müller-Ebeling 1994). Consequently, it is not surprising that elements of the art deco style reemerged in the psychedelic art of the 1960s.

Hashish had a significant influence upon surrealism (Breton 1968). Other artists were also inspired by hemp. Picasso (cf. *Artemisia absinthium*) was quite familiar with hashish and was of the opinion that it made one happy and stimulated the imagination. In contrast, Alfred Kubin experienced its effects on more of an existential level and felt compelled to transform his hashish visions into art (Behr 1995, 208f., 244f.). A recent work by the American artist Alex Grey, known for his psychedelic visions in *Sacred Mirrors*, has hemp as its theme, featuring a hemp goddess for the “Cannabis Cup” (Rätsch 1995d, 306).

Since the 1960s, hemp, hemp leaves, hemp consumption, smoking paraphernalia, and caricatures of hemp smokers and of persecution by the police have all been the subjects of posters and postcards.

In the art of the Rastafarian movement, the hemp plant is sometimes depicted as a sacred tree. Many Rasta pictures clearly have been inspired or influenced by the heavy hemp consumption of the painter (e.g., Ivan Henry Baugh, Jah Wise) (Haus der Kulturen der Welt 1992).

It is possible that numerous Sanskrit texts were inspired by hemp consumption. It is certain that hashish inebriation had an enormous influence on the *Tales of a Thousand and One Nights* (cf. *Papaver somniferum*).

“The gods gave people hemp out of compassion so that they could attain enlightenment, lose their fear, and retain their sexual desire.”

RAJA VALABHA (SEVENTEENTH-CENTURY SANSKRIT TEXT)

“To the Hindu the hemp plant is holy. A guardian lives in the bhang leaf. . . . To see in a dream the leaves, plant, or water of bhang is lucky. . . . A longing for bhang foretells happiness. . . . It cures dysentery and sunstroke, clears phlegm, quickens digestion, sharpens appetite, makes the tongue of the lisper plain, freshens the intellect, and gives alertness to the body and gaiety to the mind. Such are the useful and needful ends for which in his goodness the Almighty [Shiva] made bhang. . . . [T]he quickening spirit of bhang is the spirit of freedom and knowledge. In the ecstasy of bhang the spark of the Eternal in man turns into light the murkiness of matter. . . . Bhang is the Joy-giver, the Skyflier, the Heavenly-guide, the Poor Man’s Heaven, the Soother of Grief. . . . No god or man is as good as the religious drinker of bhang.”

HEMP DRUG COMMISSION REPORT (1884)

IN *THE BOOK OF GRASS* (ANDREWS AND VINKENOOG 1968, 145)

Hashish inebriation inspired the literary efforts of many nineteenth-century authors. The works of Charles Baudelaire (*Paradis artificiels*), Fitz Hugh Ludlow (*The Hasheesh Eater*), Maurice Magre (*La nuit de haschish et d’opium*), Walter Benjamin (*Über Haschisch*), Leo Perutz (*Der Meister des letzten Tages*), and Ernst Jünger (*Annäherungen*) all rank among the classics of world literature (Kimmens 1977).

The poets of the Beat generation—Jack Kerouac, Gary Snyder, Allen Ginsberg, Paul Bowles—regarded hashishuse as an important source of inspiration, and their work has provided us with

numerous examples attesting to this fact. For the authors of the psychedelic generation—Robert Anton Wilson, Robert Shea, Tom Robbins, Mohammed Mrabet, Stephen Gaskin, Hunter S. Thompson, Tom Wolfe—smoking hashish was an obvious source of inspiration. The smug novel *Budding Prospects: A Pastoral*, from the best-selling author T. Coraghessan Boyle (1984), relates the turbulent story of the attempts of several hippies to grow hemp and the paranoia that accompanies their efforts. The Rastafarian movement and its hemp consumption, and the inseparably related reggae, has also been the subject of literary treatments (e.g., Thelwell 1980, Zahl 1995).

Even more than such literature, underground comics have clearly been inspired by hemp and drawn for readers who are under the plant's influence while they are reading them. One series of comic books, featuring the stories of various authors and illustrators, was even called *Dope Comix*. The works of artists Robert Crumb and Gilbert Shelton (*The Fabulous Furry Freak Brothers*) are among the classics of this genre. The tales of the Freak Brothers were quickly translated into German, and they became a true underground hit (1975). The motto of the three permanently stoned Freak Brothers expresses the sentiments of many hemp users: "As we all know, dope will get you through times of no money better than money will get you through times of no dope!"

The German counterpart of the American Gilbert Shelton is Gerhard Seyfried. His comics and caricatures (*Wo soll das alles enden* [Where Will It All End?] and *Freakadellen und Bulletten* [Freak Sandwiches and Pig Burgers]) provide a clear and amusing document of the German underground during the 1970s and 1980s. Seyfried has recently produced a poster about hemp (1994). During the 1990s, Walter Moers's comics and caricatures about *das kleine Arschloch* ("the little asshole") enjoyed considerable popularity. In one volume titled *Sex, Drogen und Alkohol*, Moers provides a biting satirical characterization of the effects of a variety of psychoactive substances, including hashish. While the underground comics primarily give expression to typical "stoner" humor, the more "artistically serious" comics (e.g., Edition Comic Art) reveal a different side of the hashish state. The French comic artist Moebius, who gained renown primarily as a result of his collaboration with the filmmaker Alejandro Jodorowsky (*Montana Sacra*) and their joint opus *John Difool* (better known as *Der Incal*), has created worlds that his readers perceive as "extremely psychedelic." The artist himself has stated that marijuana provided him with a source of inspiration and that he learned things from his experiences with inebriated states, but also that he has now grown out of these (Moebius 1983).

Some comics focus exclusively on the topic of hemp, e.g., the works of Pete Loveday (*Highter Breiter: Der definitive Hanf Comix*, Edition Rauschkunde, 1995; *Russell' Big Strip Stupor-market*, John Brown Publishing, 1995). The collected works of Harold Holmes bear the seal "Cannabis-Friendly Comicx"—this pertains especially to *Der Abenteuer von Harolod Hedd* (Raymond Martin Verlag, 1995). From time to time, hemp also appears in children's comics, albeit in disguise. In Bud Sagendorf's *Popeye*, the wondrous plant is camouflaged as spinach. The favorite food of the Frenchman Peyo's Smurfs (who live in fly agaric mushrooms) is "sarsaparilla" (cf. ***Veratrum album***). In Voss's *Der Drogenbaum* [The Drug Tree], the plant turns into an autonomous thinking being (Volksverlag, 1984).

Hemp has also left its mark upon movies. Many movies from the first half of the twentieth century, such as *Reefer Madness*, were intended as deterrents but are unintentionally comical. Other "stoner" films that have appeared since the 1960s are intentionally humorous. Like the Freak Brothers of the comic world, the films of Cheech and Chong push marijuana use to satirical heights. The film *Up in Smoke* (1978) is a true cult classic of the hemp culture. The film *Rembetiko* (1985), which brings the Greek hemp and music scene of the 1930s and 1940s to life with much music and hashish, is well worth watching. *The Harder They Come*, a film based upon Michael Thelwell's novel of the same name (1980), provides deep insight into the world of Rasta and reggae.

The music that is associated with smoking hemp and with marijuana and hashish is as varied as the cultural landscape of our planet (Rätsch 1995a). Although there is no hemp music per se, much traditional and ethnic music has been related to the ritual ingestion of hemp products for centuries. This includes both classical Indian music and Jajouka, the ecstatic music of Morocco (Welte 1990). Rembetiko, also known as rebetiko, is sometimes called the Greek blues, but it is actually a folk music from the 1930s and 1940s that was influenced by Oriental elements and was played primarily in Greek cafés by those under the influence of hashish (Dietrich 1987; cf. also Rätsch 2001, 92–93*).

At the dawn of the twentieth century, hashish was a well-known drug of fashion, as were opium and cocaine. (“Hashish,” fantasy from Schlosser and Wenisch; illustration from the periodical *Das Magazin*, January 1930)

Some music has been inspired and composed as a result of smoking hemp, while other music is played while directly under its influence. Some music draws upon texts from the hemp culture, and some is played for an audience whose members are inebriated as they listen. The musical excursions into the world of hemp-influenced consciousness are as multifarious as the possibilities of using the hemp plant. Indeed, the perception of music is profoundly affected by *Cannabis* (Fachner et al. 1995). This new listening experience has also produced new music (Mezzrow 1995; Shapiro 1988). Jazz, for example, has been profoundly affected by these new listening experiences. And the reggae that has developed in Jamaica is a “pure stoner music” (Epp 1984).

Today, an increasing number of hemp leaves are gracing the covers of CDs as well as the rainbow-colored CDs themselves. The hemp leaf has become a political symbol of the underground and the counterculture. The leaf signals both a disaffection with current political and social systems and a peaceful way of achieving inebriation and enjoying music. Some bands even name themselves after the plant and its products: Bongwater, Gunjah, Hash, The Smoke (Calm 1995).

For information about smoking devices and other paraphernalia, see *Cannabis sativa*.

Medicinal Use

In ancient times, the Assyrians were especially known for using Indian hemp (*azallu*, *qannapu*, *ganzigunnu*) and hashish (*martakal*) in their medicine (Thompson 1949, 220ff.*). Numerous cuneiform texts attest to this fact. Hemp root was prescribed for difficult births. For abdominal pains,

the entire plant was boiled and administered as an **enema**. Hemp oil or hemp in petroleum was rubbed onto swollen stomachs. The roasted seeds were administered for treating *arimtu*, a disease causing a type of shaking in the extremities. Crushed hemp seeds, mixed with the seeds of a ***Mesembryanthemum*** species, were given to “suppress the spirits” that were responsible for causing (probably) some type of depression. A mixture of hemp and cereal flour was used as an antidote. Mixed with other plants and with “pig oil,” hemp was applied as a small anal compress. Hemp was also used in **beer** (*kurunnu*); this brew was drunk to treat diseases that had been caused by witchcraft (Thompson 1949, 221f.*). It is possible that the Assyrians adopted the practice of inhaling hemp smoke from the Scythians (cf. ***Cannabis ruderalis***), who long had trade relationships with the Assyrians before eventually contributing to their destruction. The Assyrians inhaled hemp smoke to relieve worries, cares, and sadness (Thompson 1949, 220*). Since these afflictions often hide behind the masks of demons, it is very likely that hemp was also used in exorcisms.

Discography of Hemp Music (a small selection)

Traditional and Ethnic Hemp Music

Jilala and Gnaoua—Moroccan Trance Music. SUB CD013-36. Sub Rosa Records, 1990. (Recorded by Paul Bowles.)

L’Ensemble Traditionnel de l’Orissa. *L’Inde—Musique traditionnelle de danse Odissi*. ARN 64045. Arion Records, 1975.

Maroc—Festival de Marrakech. PS 65041. Playasound Records, 1989.

The Master Musicians of Jajouka, featuring Bachir Attar. *Apocalypse Across the Sky*. 314-510857-2. Axiom Records, 1992. (Includes accompanying text by William S. Burroughs.)

Rembetica: Historic Urban Folk Songs from Greece. CD 1079. Rounder Records, 1992. (Historical original recordings [from the 1930s] from the legendary *tekedes* [hashish cafés])

Rembetiko—Original Filmmusik. CD CMC 013009. PROTON/Videorent, 1985.

Songs of the Underground. The Greek Archives. Vol. 5. F.M. Records 631.

Reggae

Big Blunts—Smokin’ Reggae Hits. Vols. 1, 2, and 3. Tommy Boy Records, 1995ff.

Culture. *International Herb*. 44006. Shanachie Records, 1992.

Dub Syndicate. *Stoned Immaculate*. ON-U LP56. On-U Sound Records, 1991.

Inner Circle. *The Best of Inner Circle*. 74321 12734 2. Island Records, 1992.

Peter Tosh. *Bush Doctor*. 1C 064-61 708. EMI Electrola Records, 1978.

Peter Tosh. *Legalize It*. CDV 2061. CBS/Virgin Music, 1976.

Tougher Than Tough: The Story of Jamaican Music. 4 CDs. Island Records, 1993.

Zion Train. *Natural Wonders of the World in Dub*. WWLP/CD5. Zion Records, 1994.

Jazz, Pop, Rock, Metal, Ambient/Techno/Trance, etc.

Alex Oriental Experience. *Studio Tapes 1976–78*. WR 08517122. Wiska Records, 1996.

Black Crowes. *The Southern Harmony and Musical Companion*. 512 263-2. Def American Records, 1992.

Blue Cheer. *Oh! Pleasant Hope*. 1971/LMCD 9.51080 Z. Line Records, 1991.

Cannabis Weekend. Dope Records, 1995.

Children of the Bong. *Sirius Sounds*. 540394-2. Ultimate Records, 1995.

Cypress Hill. *Black Sunday*. CK 53931. Ruffhouse/Columbia Records, 1993.

Dr. John, The Night Tripper. *Remedies*. AMCY-231. Atlantic, 1970.

Dope on Plastic. Vols. 1, 2, and 3. React CDs, 1994ff.

Embryo. *Turn Peace*. EFA 01045-26. Schneeball Records, 1990.

Freaky Fuckin Weirdoz. *Senseless Wonder*. PD 75331. RCA Records, 1992.

Give ’em Enough Dope. Vols. 1, 2, and 3. CD 001/310. Wall of Sound, ca. 1995ff.

Godfathers. *Dope, Rock ’n’ Roll and Fucking in the Streets*. GFTR CD 020. Corporate Image, 1992.

The Golden Dawn. “*Power Plant*.” LIK 24. Reissue Charly Records, 1988.

Gong. *Camembert Electrique*. CD LIK 64. Charly Records, 1990.

Gong. *Flying Teapot*. CD LIK67. Charly Records, 1973, 1990.

Green Piece. *Northern Herbalism*. CD 003. Kiff Records, 1996.

Hasch stoppt Hass—Alkohol killt. Vince Records 019, ca. 1995.

Hans Hass Jr. *Magic Ganja*. AIM0085. Aquarius Records, 1996.

Hempilation: Freedom Is Normal. Capricorn Records, 1995.

Highzung. LC-8248. Rockwerk Records, 1992.

Idjo. *Argile*. 3055-2. Schneeball/Indigo, 1995.

Jefferson Airplane. *Long John Silver*. NL89133. RCA Records, 1978.

Joint Venture. *Dinger*. Fun Beethoven Records, ca. 1994.
Marijuana's Greatest Hits Revisited. 7-5042-2. Rehash Records, 1992.
MC5. *High Time*. R2 71034. Orig. Atlantic, 1971; reissue Rhino Records, 1992.
New Riders of the Purple Sage. *Adventures of Panama Red*. CK 32450. Columbia Records, 1973.
David Peel and The Lower East Side. *Have a Marijuana*. LECD 9.01050. Elektra, 1968; Line Records, 1991.
Pro Cannabis—Tranceformed Ambient Collection. DO CD 01. Dope Records, 1994; distributed by EFA. (Featuring Robert Anton Wilson.)
Rausch. *Glad*. 848546-2. Vertigo, 1991.
Reefer Songs—23 Original Jazz and Blues Vocals. Jass CD-7. Jass Records, 1989.
The Sky Is High . . . 25 jazzige Reefer Songs der 30er und 40er Jahre. LC 4590. Transmitter, 1995.
Snow Bud and The Flower People. *Green Thing*. FH-339D. Flying Heart Records, 1991.
Sweet Smoke. *Just a Poke*. LC 0162 EMI. Electrola Records, 1970.
Tad. *Inhaler*. 74321 16570 2. Giant Mechanic Records, 1993.
Ten Years After. *Stonedhenge*. 820 534-2. Decca, 1969; reissue Dream, 1989.
U.S. Homegrown. COA 70003-2. City of Angels, 1995.
Witthüser und Westrupp. *Der Jesus Pilz—Musik vom Evangelium*. 2021098-7. Pilz Records, 1971.
Zentralpark. *Haschisch in Marseille*. Peace Records, 1995.

Spoken Word (and related)

Cheech and Chong. 9 3250-2. Warner Bros. Records, 1972.
Cheech and Chong. *Greatest Hit*. WB K 56 961. Warner Bros. Records, 1981.
Cheech and Chong. *Up In Smoke*. 7599-27367-2. Warner Bros. Records, 1978. (Soundtrack from the film of the same name.)
Mick Farren's Tijuana Bible. *Gringo Madness*. CDWIK 117. Ace Records, 1993.
Mohammed M' Rabet. *The Storyteller and The Fisherman*. SUB CD015-38. Psalmodia Sub Rosa Records, 1990. (Translated and read by Paul Bowles [cf. Mrabet 1995].)

Since the beginnings of Ayurvedic medicine, *Cannabis* products have been an indispensable part of that tradition's medicinal trove. The leaves (bhang) are ingested for cramps, earaches (otalgia), lower abdominal complaints, diarrhea (including bloody dysentery), body pains, and hemorrhaging. The crushed leaves are used as **snuffs** to treat headaches and other ailments. The resin (charas) is used especially as an aphrodisiac, usually combined with opium (***Papaver somniferum***), poison nut (***Strychnos nux-vomica***), thorn apple seeds (***Datura metel***), and spices (cf. **Oriental joy pills**). In Nepal, hemp is used as a tonic, stomach medicine, and pain and sleeping agent. Sick people are prescribed hemp drinks for a variety of ailments, including depression, lack of appetite, inconstancy, and altitude sickness, a frequent occurrence in the Himalayas (Morningstar 1985). In Kashmir, the roasted leaves and flowers of the female plant are mixed with **honey** and used as sleeping pills (Shah 1982, 298*).

Immigrants from India introduced the plant into the Caribbean and taught the peoples there about its many uses. As a result, in Jamaica ganja has become an important part of bush medicine and Rasta medicine. It is used as a general remedy and restorative (Witt 1995, 80ff.), as an efficacious means of relaxing, and also as an analgesic in the same manner that aspirin is used in Germany or the United States (Kitzinger 1971, 581). The Zionist-Coptic Church of Ethiopia encourages the Jamaican Rastas in such use, declaring that “the *Herb* may definitely be grown for its use as an asthma medicine, as a remedy for glaucoma, and for joint inflammations; also to aid in the treatment of cancer, as well as for economic use in the clothing industry and for producing paper to use, for example, in the manufacture of Bibles” (Gebre-Selassie 1989, 161). Ointments produced from crushed leaves and fat are applied externally to treat pain. A poultice is used to treat open wounds and internal pains. Newborns are sometimes rubbed with a mush made of hemp. Hemp tea is a popular prophylactic as well as therapeutic drink for practically all complaints. It is especially effective in treating eye weakness and night blindness (West 1991).

In the nineteenth century, Europeans discovered the analgesic properties of Indian hemp (Martius 1855; O'Shaughnessy 1839). This led to the development of a number of anodynes that were made from *Cannabis indica* and marketed both in Europe and in the United States (Edes 1893; Mattison

1891). In central Europe, the seeds were mixed with an extract of henbane (see *Hyoscyamus niger*) and used to treat gonorrhea (V. Robinson 1930, 39). Around the beginning of the twentieth century, numerous cigarettes and medicinal smoke powders based on *Cannabis indica* were utilized to treat asthma, lung ailments, neuralgia, and sleep disorders (cf. **incense, smoking blends**).

Homeopathic medicine uses *Cannabis indica* (*Cannabis indica* hom. *HAB34*, *Cannabis indica* hom. *HPUS78*) in accordance with the medical description to treat a wide variety of ailments, including asthma, impotence, lack of appetite, sexual exhaustion, nightmares, and nervous disorders (Boericke 1992, 187*; Schmidt 1992, 644).²⁶

The American physician Lester Grinspoon has noted that *Cannabis* has shown great promise as a medicine to treat the following ailments: depression, pain, headaches, migraines, menstrual cramps, paralysis, traumatic injuries, spasms, epilepsy, asthma, glaucoma, the side effects of cancer therapy, and AIDS (Grinspoon 1996; Grinspoon and Bakalar 1995; cf. also Roffman 1982). Overall, more and more physicians are expressing the wish that hemp products be made available for therapeutic purposes so that they can prescribe them for their patients (Clarke and Pate 1994; Grotenhermen and Karus 1995; Iversen 1993). Even psychiatry is beginning to revise its opinion of the plant (Baumann 1989; Hess 1996). But it is especially those patients who have had very good experiences with illegal self-medication who are demanding the (long overdue) legalization of *Cannabis* products (Corral 1994; Rathbun and Peron 1993). Studies have been designed to assess the medicinal use of *Cannabis* as an adjunct in AIDS therapy (Doblin 1994), and voters in California, Arizona, and other states have passed initiatives supporting the legalization of medical marijuana (ADH 1997).

Numerous record and CD covers feature hemp leaves (e.g., *ProCannabis*) or suggest *Cannabis* use (*Marijuana's Greatest Hits*). Music and texts make frequent references to the plant. (CD covers: 1995, Dope Records; 1992, Rehash Records)

Constituents

The resin, the female inflorescences, and the leaves of hemp all contain an **essential oil** and other substances, primarily cannabinoids, more than sixty of which are already known structurally and pharmacologically (Brenneisen 1986; Clarke 1981; Hollister 1986; Mechoulam 1970; Schmidt 1992).

The main active constituent is delta-9-tetrahydrocannabinol (Δ^9 -THC, corresponding to Δ^1 -THC, abbreviated as **THC**). The resin (hashish) contains the four primary components, the so-called cannabinoids: Δ^1 -tetrahydrocannabinol (THC) with three variants, two of which—cannabidiol (CBD) and cannabinol (CBN)—result as artifacts only when the resin is stored. These substances are responsible for the psychoactive effects of hemp. The structures of some thirty other cannabinoids with only mild or no psychoactive effects have been described. The resin also contains various sugars, flavonoids, alkaloids (choline, trigonelline, piperidine, betaine, proline, neurine, hordenine, cannabissativine), and chlorophyll. The THC content can exhibit considerable variation. Some plants (fiber hemp) contain very little or none, while in others it can constitute as much as 25% of the resin. Four to 8 mg is regarded as an efficacious psychoactive or analgesic dosage (Schmidt 1992).

The characteristically scented **essential oil**, which imparts hemp with its typical bouquet, contains eugenol, guaiacol, sesquiterpenes, caryophyllene, humulene, farnesene, selinene, phellandrene, limonene, and other substances.

The constituents of the seeds, lignans, et cetera, are similar to those of *Cannabis sativa*.

Effects

The primary effect of consuming hemp is a mild to profound sense of euphoria accompanied by rich associative and imaginative abilities, a stimulated imagination, and a sense of physical well-being. Very often, the effects of hemp are also perceived as aphrodisiac or erotic (Amendt 1974; Blätter 1992; Cohen 1982; Lewis 1970).^z When cannabis is smoked, these effects are manifested within ten minutes; when eaten or drunk, in forty-five minutes to two hours. The euphoric phase lasts for one to two hours, after which a calming effect becomes predominant. The effects often culminate in a more or less dream-rich sleep. Hemp products can also potentiate the effects of other substances (e.g., of such nightshades as *Atropa belladonna*, *Brugmansia* spp., *Datura* spp., *Hyoscyamus niger*, and, of cocaine, nicotine, opium [*Papaver somniferum*], ayahuasca, ayahuasca analogs, and *Piper methysticum*). The effects of cannabis are generally contrary to those of tobacco (*Nicotiana tabacum*). Nicotine suppresses the effects of THC, while THC potentiates the effects of nicotine (cf. smoking blends).

When larger quantities of hashish are eaten or drunk, visionary states, enlivened imagination, hallucinations, and even near-death experiences can be the result (Baudelaire 1971; Benjamin 1972; Cohen 1966; Haining 1975; Hofmann 1996; Kimmins 1977; Ludlow 1981; Robinson 1930; Tart 1971). Overdoses can lead to circulatory problems, anxiety, and vomiting. In Nepal, strongly brewed tea (cf. *Camellia sinensis*) is recommended for overdoses. In the European drug scene, a high dose of vitamin C is a recommended first-aid step. Dangerous symptoms, not to mention deaths from *Cannabis* overdoses, are unknown (Grinspoon and Bakalar 1994; Hess 1996; Hollister 1986; Mikuriya 1973; Schmidt 1992).

The effects of *Cannabis* products are primarily the result of the principal constituent, **THC**. THC has euphoric, stimulant, muscle-relaxing, anti-epileptic, antiemetic, appetite-stimulating, bronchodilating, hypotensive, antidepressant, and analgesic effects. Cannabidiol (CBD) has no psychoactive effects but does have sedative and analgesic effects. Although cannabinol (CBN) is mildly psychoactive, it serves primarily to lower intraocular pressure and as an antiepileptic. Cannabigerol (CBG) is not psychoactive but does have sedative and antibiotic effects and also lowers intraocular pressure. Cannabichromene (CBC) has sedative effects and promotes the analgesic effects of THC (Grotenhermen and Karus 1995, 7). The lignans contained in the seeds suppress allergies.

The official, state-sanctioned and -supported psychiatry is dominated by the strangest notions and preconceptions about the long-term effects of frequent or chronic *Cannabis* use; for example, it is hypothesized that hemp is a “gateway drug” and that it contributes to a so-called amotivational

syndrome (Täschner 1981). These “psychiatric symptoms” are pure invention and have no empirical basis (cf. Hess 1996). A politically independent, sociological study of the long-term effects of chronic hemp use yielded an interesting picture: “The chances that a person will think and work creatively and productively while under the influence of hemp increase with increasing experience with hemp” (Arbeitsgruppe Hanf and Fuss 1994, 103). Many studies of long-term use have demonstrated that *Cannabis* products are among the most harmless psychoactive agents of pleasure that humans have thus far discovered (cf. Blätter 1992; Grinspoon 1971; Hess 1996; Michka and Verlomme 1993; Schneider 1995).

Recent discussions have focused on the influence of *Cannabis* upon driving behavior. Lawmakers have based their legislation on the erroneous assumption that the effects of hemp are more dangerous than those of **alcohol**—even though a number of studies have shown that drivers under the influence of hashish drive considerably slower and with greater care than either sober or drunk drivers (Karrer 1995; Robbe 1994, 1996).

Commercial Forms and Regulations

Hemp products containing THC were banned in most countries as a result of the Single Convention on Narcotic Drugs (1961) and are therefore not allowed to be marketed. There are only a few exceptions: “When signing the Single Convention, Bangladesh, India, and Pakistan retained the right to permit the non-medical use of opium and cannabis” (Haag 1995, 174).

“The great disappointment of that which we know is what YOU encounter, terrible Bhairava,
the heads of hope hang bloody around YOUR loins.
I greet YOU, YOU who first placed into the earth the seeds of ganja,
from which my knowledge of YOU grows.
The lord of the burning pyres, may my smoke be as limitless as YOU, Uma [=Unmatta Bhairava].
Lowering my hemp-red eyes toward within, I experience YOU while inebriated, and I have left the world behind me.
Bom Shankar! In YOUR honor do I raise my dschillum [= chillum] to my brow,
so that I may merge with YOU. Om nama Shiva!”

NEPALESE HYMN TO SHIVA (FIFTEENTH CENTURY)

IN VON HANF IST DIE REDE [SPEAKING OF HEMP] (BEHR 1995, 44)

THC

“*Ong Hrîng*. Ambrosia which is derived from Ambrosia, you who causes Ambrosia to rain down, make Ambrosia for me again and again. Bring Kâlîkâ under my control. Give me *siddhi*, the miraculous abilities [= hemp]; *svâhâ*.”

MANTRA FOR CONSECRATING VIJAYA (= HEMP)

IN TANTRA OF THE GREAT LIBERATION (MAHANIRVANA TANTRA) (AVALON 1972, 73)

In Germany, the *Betäubungsmittelgesetz* (Law on Narcotic Drugs) does not allow *Cannabis* to be used as medicine (Körner 1994, 56).⁷⁸ Thus prohibition applies even to hemp preparations devoid of active constituents: “Homoeopathic drugs and preparations are subject to the stipulations of the *Betäubungsmittelgesetz* and thus are not open to trafficking” (Schmidt 1992, 653).

Only the seeds are explicitly allowed to be sold without restriction (Körner 1994, 38, 56*). Many countries now allow the cultivation of fiber hemp (see ***Cannabis sativa***) or varieties with very low THC contents for industrial use.

However, many sorts of hashish from around the world, numerous sorts of marijuana (especially the potent hybrids from Holland, Acapulco gold, Thai sticks, etc.; cf. ***Cannabis x and hybrids***), and, more rarely, hash oil are available on the black market. Holland has its “coffee shops” (cf. ***Coffea arabica***) and bars where the police tolerate the sale of small quantities of hemp preparations (cf. Haag 1995). The legal situation for hemp consumers varies greatly from one country to another, and even within countries. While much of Europe now regards hemp consumption as a minor offense (Bührer n.d.), some Southeast Asian countries (Malaysia, Singapore, the Philippines) may impose the death penalty on convicted hemp consumers.

“I found myself in a wondrous inner world. I existed alternately in different places and in different conditions. Once I steered my gondola through a moonlit Venetian canal, and then mountain upon mountain rose before my eyes, and the magnificence of the rising sun bathed the icy peaks in purple light. And then I spread my feathered leaves out like a giant fern in the primordial silence of some untouched tropical jungle and swayed and nodded softly in the scented breeze above a riverbed, upon whose waves equally thick clouds of music and perfume arose. My soul transformed itself into a plant being and was strangely and unimaginably enraptured.”

FITZ HUGH LUDLOW *THE HASHEESH EATER* (1857)

“Core, throw hemp into the wine! Let us drink of the juice of rapture!”

URSULA HAAS, LIBRETTO TO THE OPERA BY ROLF LIEBERMANN *FREISPRUCH FÜR MEDEA* [ACQUITTAL FOR MEDEA]
(1994/95)

Dried parsley leaves are sometimes smoked as a hemp substitute. Whether this produces psychoactive effects is an open question.
(Woodcut from Lonicerus, *Kreuterbuch*, 1679)

The seeds of *Canavalia maritima*, a plant used as a marijuana substitute.

In California, the dried herbage of wild dagga (*Leonotis leonurus*) is smoked as a marijuana substitute. Careful cultivation may be able to increase the psychoactivity of the stock plant.

The inhabitants of the Atacama Desert (northern Chile) smoke the dried, resinous herbage of *pupusa* or *chachalana*, a desert plant that has not yet been botanically identified, as a marijuana substitute.

Marijuana Substitutes

These are plant drugs that are smoked in place of *Cannabis* flowers in order to induce an identical or similar effect. (After Ott 1993* and Schultes and Hofmann 1995*; modified and expanded)

<i>Botanical Name</i>	<i>Popular Name</i>	<i>Drug</i>	<i>Place/Culture</i>
<i>Alchornea floribunda</i> M.-A.	niando	root	Africa
<i>Anethum graveolens</i>	dill	herbage	U.S.A.
<i>Argemone mexicana</i>	prickly poppy	leaves	Mexico
<i>Artemisia mexicana</i>	estafiate	herbage	Mexico
<i>Calea zacatechichi</i>	zacatechichi	herbage	Mexico, U.S.A.
<i>Canavalia maritima</i> (Aubl.) Thouars ⁷⁷ [syn. <i>Canavalia obtusifolia</i>] (Leguminosae)	frijolillo	leaves	Mexico
<i>Capsicum frutescens</i> (cf. <i>Capsicum</i> spp.)	paprika	rotten fruits	U.S.A.
<i>Catharanthus roseus</i>	periwinkle	leaves	Florida
<i>Cecropia mexicana</i> Hemsl. ⁷⁸ [syn. <i>Cecropia obtusifolia</i> Bert.]	chancarro	leaves	Mexico (Veracruz)
<i>Cestrum laevigatum</i> Schlecht. (cf. <i>Cestrum parqui</i>)	maconha	leaves	Brazil
<i>Cymbopogon densiflorus</i>	lemongrass	flower extract	Tanzania
<i>Daucus carota</i>	carrot	herbage	U.S.A.
<i>Helichrysum</i> spp.	strawflower	herbage	
<i>Helichrysum foetidum</i> (L.) Moench		herbage	Zulu/Africa
<i>Helichrysum stenopterum</i> DC.		herbage	Africa
<i>Hieracium pilosella</i>	håret høgeurt	herbage	Denmark
<i>Hydrangea paniculata</i>	hydrangea	leaves	U.S.A.
<i>Hydrangea</i> spp.	hydrangea	flowers, leaves	U.S.A.

<i>Lactuca sativa</i> L.	lettuce	leaves	U.S.A.
<i>Lactuca serriola</i>	wild lettuce	leaves	U.S.A.
<i>Lactuca virosa</i>	wild lettuce (thickened juice)	lactucarium	U.S.A.
<i>Leonotis leonurus</i>	wild dagga	herbage	Hottentots
<i>Leonurus sibiricus</i>	marijuanillo	herbage	Mexico (Chiapas)
<i>Mimosa</i> spp. ⁷⁹	dormilona	herbage	San Salvador
<i>Musa x sapientum</i>	banana	inner peel	cosmopolitan
<i>Myristica fragrans</i>	nutmeg	seed, aril	U.S.A., Europe
<i>Nepeta cataria</i>	catnip	herbage	cosmopolitan
<i>Nepeta</i> spp.	catnip	herbage	cosmopolitan
<i>Petroselinum crispum</i>	parsley	flowering herbage	U.S.A., Europe
<i>Piper auritum</i>	gold pepper	leaves	Belize
<i>Sceletium tortuosum</i>	kougoed	herbage, roots	South Africa
<i>Sida acuta</i> Burm. chichibe	malva amarilla,	herbage	Mexico, Belize
<i>Sida rhombifolia</i> L.	escobilla	herbage	Mexico ⁸⁰
<i>Turnera diffusa</i>	damiana	herbage	cosmopolitan
<i>Zornia latifolia</i> DC. (Leguminosae) ⁸¹	maconha brava	desiccated leaves	Brazil
<i>Zornia diphylla</i> (L.) Pers. yerba de la víbora ⁸²	maconha brava,	leaves	Brazil
Unidentified	<i>Pupusa/Chachalana</i> ⁸³	herbage	Atacama/Chile
	canna	herbage	South Africa

It is thought that the fruits of the bay bean (*Canavalia maritima*) had a ritual or magical significance in ancient Peru. This painting on a Moche vessel may be a depiction of these fruits. It is uncertain whether they actually produce psychoactive effects.

Cannabis ruderalis Janischewsky

Weedy Hemp

Family

Cannabaceae (= Cannabinaceae) (Hemp Family)

Forms and Subspecies

None

Synonyms

Cannabis intersita Sojak

Cannabis sativa L. ssp. *spontanea* Serebr. ex Serebr. et Sizov

Cannabis sativa L. var. *ruderalis* (Janisch.)

Cannabis sativa L. var. *spontanea* Mansfield

Cannabis spontanea Mansfield

Folk Names

Anascha, konopli, mimea, momea, mumeea, penka, penscha, ruderalhanf, russischer hanf, weedy hemp, wilder hanf, wild hemp

History

Weedy hemp was already being used for shamanic and ritual purposes in central Asia in prehistoric times. The description that Herodotus (ca. 500–424 B.C.E.) provided us about the ancient Scythian⁸⁶ use of hemp in purification and burial rituals has been confirmed by archaeological findings in the Altai Mountains of Mongolia. The Scythians also smoked hemp for pleasure (Rocker 1995). This small, wild hemp is still used in Mongolia for shamanic and medicinal purposes. Recently, a Scythian shaman was found in an undisturbed and frozen grave in the Altai Mountains. Among the goods found with her were hashish and other hemp products (*Stern* no. 18, 1994, 194ff.).

This hemp species was first described in 1924 by the Russian Janischewsky. Today, it is primarily used to breed low-growing varieties of hemp that contain THC (see ***Cannabis* x and hybrids**).

Distribution

Cannabis ruderalis now grows wild from the Caucasus Mountains to China. Its species name expresses its preference for so-called ruderal places, i.e., rocky locations, scree, and rubbish sites. *Cannabis ruderalis* originally occurred in the wild only in southeastern Russia (Emboden 1979, 172*). It is likely that the Scythians introduced it into Mongolia, where it then became wild.

Cultivation

See ***Cannabis indica*, *Cannabis* x and hybrids**.

Appearance

This hemp species grows to a height of only 30 to 60 cm. It has few if any branches and rather small leaves. The inflorescence is small and forms only on the end of the stalk. The seed coat has a fleshy

base.

Psychoactive Material

—Female flower

—Seeds

—Resin

Preparation and Dosage

The female inflorescences are dried and smoked or inhaled as a kind of **incense**. The flowers are also suitable for use as a fumigant in sweat lodge rituals (cf. Bruchac 1993), both alone and in combination with *Artemisia absinthium*, *Artemisia mexicana*, or other *Artemisia* species.

A shamanic incense with psychoactive effects can be mixed using equal parts of hemp flowers, the tips of juniper branches (*Juniperus communis* L., *Juniperus recurva*, *Juniperus* spp.), thyme (*Thymus* spp.), and wild rosemary (*Ledum palustre*).

In Russia, sedative, aphrodisiac, and analgesic foods are prepared from hemp, saffron (*Crocus sativus*), nutmeg (*Myristica fragrans*), cardamom, **honey**, and other ingredients (cf. **Oriental joy pills**).

Ritual Use

The oldest known literary evidence of the use of hemp is from Herodotus. In a comprehensive chapter of his *History*, he describes the social structure, religion, mythology, and customs of the Scythians. Their burial or death ritual is particularly significant:

When they have buried the dead, the relatives purify themselves as follows: they anoint and wash their heads; as to their bodies, they set up three sticks, leaning them against one another, and stretch, over these, woolen mats; and, having barricaded off this place as best they can, they make a pit in the center of the sticks and the mats and into it throw red-hot stones.

Now, they have hemp growing in that country that is very like flax, except that it is thicker and taller. This plant grows both wild and under cultivation, and from it the Thracians make garments very like linen. Unless someone is very expert, he could not tell the garment made of linen from the hempen one. Someone who has never yet seen hemp would certainly judge the garment to be linen.

The Scythians take the seed of this hemp and, creeping under the mats, throw the seed onto the stones as they glow with heat. The seed so cast on the stone gives off smoke and a vapor; no Greek steam bath could be stronger. The Scythians in their delight at the steam bath howl loudly. This indeed serves them instead of a bath, as they never let water near their bodies at all. But their women pound to bits cypress and cedar and frankincense wood on a rough rock and mix water with it.⁸⁷ When they have made of the wood and the water a thick paste, they smear it all over their bodies and faces. A wonderful scent pervades them from this; a day later they take off the plaster, and they have become shining clean. (Herodotus 4.73–75; 1987, 307*)

It seems obvious that the hemp seeds were still attached to the inflorescences, for how else could a “smoke and a vapor” have resulted that would make the Scythians “howl loudly” in their delight? Herodotus is describing a cult activity in which the relatives of the deceased would accompany the soul of the dead to the next world while in a shamanic trance. The ritual was intended to benefit both the soul of the deceased and the souls of those remaining behind. Hemp loosened the barriers of death and enabled people to take part in the immortality of the soul; it allowed a collective way to overcome

grief. Meuli (1935) has characterized this ritual use of weedy hemp as a “family shamanism” devoid of any pronounced specialization (Jettmar 1981, 310). Similar rituals are known to have occurred among other peoples (e.g., the Assyrians; cf. *Cannabis indica*) and tribes of antiquity (the Thracians and Massagets). The Massagets, a nomadic tribe from central Asia, camped together around fires into which certain “fruits” had been thrown. After inhaling the smoke, the participants sprang up elatedly (312).

Artifacts

The deeply frozen Scythian burial mounds of Pazyryk Kurgan (Altai Mountains, Mongolia) have yielded leather bags containing hemp seeds together with vessels for burning incense (cf. **incense**). The bags are 2,400 years old. The rather small seeds indicate that they came from wild-growing plants—most likely *Cannabis ruderalis* (Clarke 1996, 104). The Russian archaeologist S. I. Rudenko excavated a number of bronze incense vessels, over which a felt-covered frame still stood (Rudenko 1970). The report on the excavation noted:

In the southwest corner of the grave chamber of Parzyryk Kurgan II, a bundle of six staffs was found. Below this stood a rectangular bronze vessel on four legs, filled with broken stones. The lengths of the staffs was 122.5 cm, their diameter some 2 cm, at the lower end about 3 cm. A small strap that held the staffs together had been pulled through openings 2 cm below the upper end of each staff. Glued to all of the staffs was a narrow spiral strip of birch bast. North of this, in the western half of the chamber, a second bronze vessel was found, of the type of a Scythian kettle. It too was full of stones. Over this were spread six of the same type of staff, partially broken and thrown about when robbers had broken in. These, together with the incense vessel, were covered by a large leather wrap.

In addition to the stones already mentioned, both vessels were found to contain a large quantity of hemp seeds (*Cannabis sativa* L. of the variety *C. ruderalis* Janisch). Hemp seeds were also in one of the leather bottles described previously, which was attached to one of the poles of the hexapod that stood over the vessel in the form of a Scythian kettle. The stones in the incense vessels had been scorched and a portion of the hemp seeds blackened. In addition, the handles of the kettle that had been used as an incense vessel were wrapped around with birch bast. Clearly, the vessel had been so heated by the glowing stones that it could not be picked up with bare hands. . . . Consequently, we have here complete sets of those utensils that were necessary to carry out the purification ritual that Herodotus so precisely recorded in reference to the Pontic Scythians. Sets of utensils for inhaling hemp were present in all of the Pazyryk kurgans, without exception. Even though the vessels and the wraps had been stolen by plunderers, with the exception of Kurgan II, the staffs remained in all of the kurgans. It follows that the smoking of hemp was practiced not only during the purification rituals but also in daily life. . . . Here, both men and women smoked. (In Jettmar 1981, 311)

Scythian incense vessels for inhaling hemp smoke, found in prehistoric graves in the High Altai (Mongolia). (From Rudenko, *Frozen Tombs of Siberia*, 1970)

Medicinal Use

A Mongolian medicine known as *bagaschun*, said to be a kind of cure-all and apparently made from hemp, juniper (cf. ***Juniperus recurva***), and bat guano, is known from the Altai region. This preparation is also known as *mumio* and is highly esteemed as a tonic in Russian folk medicine (Rätsch 1991).

Today, *Cannabis ruderalis* grows throughout the entire region once inhabited by the Scythians. It is still used in Russian and Mongolian folk medicine to treat depression. Recently, the Mongolian Academy of Sciences sponsored a project to document the shamanic, folk medical, and Lamaistic knowledge of medicinal plants. It was found that in the Mongolian tradition ***Cannabis sativa*** and *Cannabis ruderalis* are used for different medicinal purposes. *Cannabis sativa* is usually used as a source of oil, whereas *Cannabis ruderalis* is esteemed more for its psychoactive properties (Mr. Günther, Ulaanbaatar, pers. comm.). It is very likely that Mongolian shamans in the Altai use *Cannabis ruderalis* as well as juniper to induce shamanic trances (Jettmar 1981).

“A colleague of mine at work is a ‘Russian-German’ from Tadjikistan. As we were first smoking something together a few days ago during lunch, he told me the following: ‘Where I come from, no one buys hashish or grass. It grows wild everywhere. To harvest, we only needed to ride through the pastures of hemp on our horses. After just a half hour, the legs of the horses were covered with resinous plant parts. All we needed to do was scrape it off.’ ”

DIETMAR. B.

IN *HANFKULTUR WELTWEIT* [HEMP CULTURE WORLDWIDE]

(HAAG 1995, 51)

Constituents

This hemp species contains more or less the same cannabinoids as are found in ***Cannabis indica*** and ***Cannabis sativa***. The amount of **THC**, however, is considerably lower. Only 40% or less of the

cannabinoids that were measured could be identified as THC; in *Cannabis sativa*, the THC content is around 70% (Beutler and Der Marderosian 1978, 390).

Effects

Cannabis sativa Linnaeus

Fiber Hemp

Family

Cannabaceae (= Cannabinaceae) (Hemp Family)

Forms and Subspecies

In the mid-nineteenth century, the renowned botanist Alphonse-Louis-Pierre Pyramus de Candolle (1806–1893) attempted to standardize the taxonomy of *Cannabis* and proposed the following varieties:

Cannabis sativa var. α *Kif* DC. (Moroccan hemp)

Cannabis sativa var. β *vulgaris* DC. (fiber hemp)

Cannabis sativa var. γ *pedemontana* DC. (wild hemp)

Cannabis sativa var. δ *chinensis* DC. (Chinese hemp, giant hemp) [= *C. chinensis* (Del.) A. DC., *C. gigantea* Del. ex Vilm. = *C. sativa* cv. Gigantea]

According to Clarke (1981, 159), this species can be subdivided into the following subspecies and varieties (although it is certainly not a good idea to propose a subspecies *indica* as well as a variety *indica*):

Cannabis sativa var. *sativa* (the common, cultivated fiber hemp)

Cannabis sativa var. *spontanea* (has smaller seeds, occurs wild)

Cannabis sativa ssp. *indica* (very rich in cannabinoids) [= ***Cannabis indica***]

Cannabis sativa var. *indica* (fruits smaller than 3.8 mm)

Cannabis sativa var. *kafiristanica* (short fruits)

It has also been suggested that the species can be divided into four phenotypes (chemotypes) (cf. Clarke 1981, 160). In my opinion, however, there is no justification for such a division, as any one population can exhibit considerable variation in cannabinoid content (Hemphill et al. 1978; Latta and Eaton 1975). Two chemotypes have been described for Africa (Boucher et al. 1977).

Fiber hemp (*Cannabis sativa*), also known as *ta-ma*, is one of the oldest food, ritual, and medicinal plants of Chinese culture. (Illustration from the *Chih-wuming-shih-t'u k'ao*)

The (ancient) Chinese character (*ma*) for *Cannabis sativa*.

History

The oldest archaeological evidence for the cultural use of hemp points to it originally having been used in shamanic contexts (cf. ***Cannabis indica***, ***Cannabis ruderalis***). Hemp seeds, which could be identified as those of *Cannabis sativa*, were recovered in the Neolithic linear band ceramic (*linearbandkeramik*, or LBK) layers of Eisenberg in Thuringia, Germany (Renfrew 1973, 163*; Willerding 1970, 358*). The layers were dated to around 5500 B.C.E. Hemp seeds have also been found in the excavations of other, somewhat more recent Neolithic layers, such as those in Thainigen (Switzerland), Voslau (Austria), and Frumusica (Romania) (Renfrew 1973, 163*). These finds date from a period of peaceful, horticultural, pre-Indo-European cultures who venerated the Great Goddess (Gimbutas 1989) and knew of shamanism (Probst 1991, 239). The linear band ceramics that lend their name to this Stone Age cultural epoch are decorated with graphics representing the archetypical motifs and patterns of hallucinatory or psychedelic themes (Stahl 1989).

In Bavaria, finds of clay pipe bowls with wooden stems, discovered during excavations of the barrows of Bad Abbach-Heidfeld, indicate that cannabis or its products were being smoked more than 3,500 years ago, possibly together with sleeping poppy or opium (***Papaver somniferum***) (Probst 1996, 174). There is also evidence from the early Germanic period:

Hemp remnants from the prehistoric period of northern Europe were uncovered in 1896 when the German archaeologist Hermann Busse opened an urn grave in Wilmersdorf (Brandenburg). The vessel that was found dates from the fifth century B.C. and contained sand mixed with plant remains. The botanist Ludwig Wittmaack (1839–1929) was able to identify fruits and fragments of the seed coats of *Cannabis sativa* L. among these. (Reininger 1941, 2791)

Woodcut of a male hemp plant from the herbal of John Gerard (1633). At that time, the botanically male plant was thought to be the female.

Among the Germanic peoples, hemp was sacred to Freya, the goddess of love, and apparently was used as an inebriant in ritual and aphrodisiac contexts. Like Indian hemp (*Cannabis indica*), the German fiber hemp did and does have inebriating effects:

But here as well, the fresh plant also possesses an extremely potent, unpleasant, often intoxicating scent, and it is known that dizziness, headache, and even a kind of drunkenness frequently result if a person spends too much time in a blooming hemp field. It has also been observed that roasting hemp, as it is called, produces a similarly intoxicating scent. (Martius 1996, 31)

Fiber hemp was mentioned as a source of food several times in the ancient Chinese *Shih Ching*, the Book of Songs (ca. 1000–500 B.C.E.) (Keng 1974, 399f.*). The Egyptians probably learned of hemp at about the same time.

The useful and medicinal hemp plant was very well and very widely known in ancient times. Theophrastus provided a botanically correct description of the plant under the name *dendromalache*. As many ancient authors (e.g., Varro, Columbarius, and Gellus) attest, hemp was known and esteemed in antiquity as a good source of fiber, and it was planted widely. Pliny wrote extensively about hemp, which he called *cannabis*.

Concerning the origin of the term *cannabis*, we know that there was a classical Greek expression *cannabeizein*, meaning “to inhale hemp smoke.” Another word from that period is *methyskesthai*, “to become inebriated through drug use”; Herodotus used this word to describe the inebriation that the inhabitants of an island in the Araxes (Araks) produced using smoke (cf. *Cannabis ruderalis*, **trees with special fruits**). Hemp’s ability to improve mood did not escape Democritus (460–371 B.C.E.), the “laughing philosopher,” who called the plant *potamaugis*. He noted that when this plant is drunk in wine (cf. *Vitis vinifera*) together with myrrh (*Commiphora molmol* Engl.), it produces delirium and visions. He was especially struck by the immoderate laughter that invariably followed such a drink. Galen (ca. 130–199 C.E.) wrote that in Italy it was customary to serve small cakes containing hemp for dessert. These would increase the desire to drink, although eating too many had stupefying effects

(6:549f.). It was considered a sign of good manners to offer guests hemp, for it was regarded as a “promoter of high spirits” (cf. **Oriental joy pills**).

It is likely that hemp spread from Arabia and Egypt into the rest of Africa at an early date. Numerous pipes and smoking devices have been found in archaeological contexts, some of which still contain remnants of **THC** (Van der Merve 1975). It appears that the introduced hemp, with its better effects, supplanted the use of indigenous smoking herbs (*Leonotis leonurus*, *Sceletium tortuosum*) (Du Toit 1981, 511).

As human culture spread around the world, hemp went along (see Rätsch 2001*). In many places, e.g., Morocco and Trinidad, hemp cultivation has come to have an irreplaceable economic importance for the indigenous peoples (Joseph 1973; Lieber 1974; Mikuriya 1967).

Distribution

Cannabis sativa is from either central Europe or central Asia. But as an anthropophilous species, it already had become widespread during the Neolithic period. Today, it is found almost everywhere in the world and has adapted to very different soil types and climate zones. It is unknown as a wild plant.

Cultivation

See *Cannabis indica* and *Cannabis x* and hybrids.

Appearance

Fiber hemp can vary considerably in appearance. Like the other *Cannabis* species, it usually occurs in two sexes, but it can also be hermaphroditic in cultivation. It has few if any branches and has the largest leaves of the three species. The individual “fingers” of the leaves are long, lanceolate, and very slender (an important feature for recognizing the plant).

Cannabis sativa is sometimes confused with the anaphrodisiac monk’s pepper (*Vitex agnuscastus* L.; Verbenaceae), the leaves of which are remarkably similar to those of *Cannabis sativa*. An illustration from the Viennese Dioscorides that has appeared in many publications as the “oldest representation of the hemp plant” (e.g., Fankhauser 1996) is in fact *Vitex agnus-castus*.

Psychoactive Material

- Female flowers
- Resin glands
- Resin
- Red hemp oil (hash oil, cannabis resinoid)
- Seeds (*cannabis sativae fructus*, *fructus cannabis*, *semen cannabis*, hemp fruits, hemp grains, hemp seeds)
- Leaves

Preparation and Dosage

It is primarily the dried female inflorescences and the resin or resin-rich preparations that are used for psychoactive purposes; these are smoked or ingested (cf. *Cannabis indica*).

The inflorescences are usually referred to as marijuana (= marihuana) or “grass.” Well-known sorts of Colombian marijuana from *Cannabis sativa* include Santa Marta Gold (= *Muños de oro*; yellow-brown color), Blue Sky Blonde (yellowish color), Red Dot (= *Punto rojo*; yellow color with reddish specks), and Mangoviche Grass. Panama Red, from Panama, and Maui Wau, from Hawaii, are legendary.

Cannabis sativa is just as well suited as *Cannabis indica* and *Cannabis ruderalis* for producing

hashish. In Mexico, hashish, the pressed resin, is known as *marijuana pura* (“pure marijuana”) and is obtained in the following manner: “All you need is to walk wearing the heavy leather pants typical of the rancheros through the field with the diabolical flora and a knife, which is used to scrape off the resin that has adhered to the pants, and then roll it into little balls” (V. Reko 1936, 65*). Numerous kinds of hashish are obtained from *Cannabis sativa*: Green Turkish (sometimes adulterated with henna, *Lawsonia inermis* L. [syn. *Lawsonia alba* Lam.]), Yellow (from Syria), Yellow Lebanese, Red Lebanese, Zero-Zero (pure resin gland powder, pressed), Black Moroccan (hand-rubbed resin), Green Moroccan (pressed resin glands and flowers),⁸⁹ and Pollen (unpressed resin glands; has nothing to do with flower pollen).

It is also possible to make hashish at home. The female inflorescences should be chopped into large pieces and then rubbed on gauze over a bowl. A fine dust consisting of the valuable resin glands and fine resinous leaf tips will collect in the bowl. This powder should be dried and pressed, and then the hashish is ready. Using this method, between 30 and 50 g of hashish can be obtained from 1 kilo of plant material (plant tips with inflorescences) (Haller 1996).

Red hemp oil (= hashish oil) is produced as a resinoid by extracting the female inflorescences and then evaporating the solvent (ethanol; cf. **alcohol**). The essential oil of hemp, which smells slightly of fresh hemp flowers, is obtained by steam distillation.

Cannabis sativa is often used as an additive in alcoholic beverages. In former times, it was used in place of *Humulus lupulus* as an additive in **beer** (cf. *Cannabis indica*). Since 1996, a hemp beer is again being produced in Switzerland that is freely available (at least in that country). In South America, hemp flowers are added to drinks made with *Trichocereus pachanoi* (cf. **cimora**). Democritus’s famous recipe for a hemp **wine** is suitable for internal use: Macerate 1 teaspoon of myrrh (*Commiphora molmol*, cf. **incense**) and a handful of hemp flowers in 1 liter of retsina or dry Greek white wine (cf. *Vitis vinifera*). Strain before drinking. Hemp can also be used to make liquors. Mexicans “chop up the flowers and the top parts of the stalks, rub these with sugar and chili [cf. *Capsicum* spp.], and mix everything in a glass of milk or mescal (agave liquor) [see *Agave* spp.]” (V. Reko 1936, 64*).

The female flower of *Cannabis sativa* forms the THC-rich resin on its hairs.

The male flower of fiber hemp (*Cannabis sativa*).

A rare African form of *Cannabis sativa*, with red stalks.

“It’s true that marijuana is a fantastically effective aphrodisiac, and the person who understands pot can weave together a symphony of visual, auditory, olfactory, gustatory, tactual sensitivity to make lovemaking an adventure which dwarfs the imagination of the pornographers.”

TIMOTHY LEARY
THE POLITICS OF ECSTASY (1998, 213*)

Ritual Use

Our present state of knowledge does not allow us to state with certainty when and where the ritual use of *Cannabis sativa* began (cf. ***Cannabis indica***). In central Europe, it may already have been in use in shamanic contexts during the Neolithic period (Probst 1991; Stahl 1989). It is certain that shamans in ancient China knew of hemp, which they used to produce a shamanic state of consciousness so they could divine and heal. Ancient Chinese literature is filled with information about hemp's medicinal use. In the earliest sources on the Chinese use of herbs, it is said that chronic use of *ma-fen* ("hemp fruits") will enable one to "see devils" that can then be pressed into service. Unfortunately, these sources do not say how the hemp was ingested, i.e., whether it was eaten, drunk, or burned as incense (Li 1975*).

Hemp products had a cultic significance among the ancient Greeks. The Greek archaeologist Sotiris Dakaris, who has been investigating the oracle of the dead at Acheron since 1959, discovered "bags full of black clumps of hashish" in Ephyra (Vandenberg 1979, 24*). It is entirely possible that the temple sleepers at Acheron were administered a hemp preparation so that their dreams would be especially vivid. It is also possible that hemp, as "Scythian fire" (cf. ***Cannabis ruderalis***), was used as an **incense** in the cult of Asclepius, the god of healing.

Remnants of hemp were recovered from the ancient Egyptian grave of Amenophis IV (Akhenaten; 1550–1070 B.C.E.) in Tell el-'Amârna. Hemp pollen has been identified on the mummy of Ramses II. Egyptian mummies were stuffed with hashish (Balabanova et al. 1992). Thus, the ritual use (death cult) of hemp during the dynastic period in Egypt (New Kingdom) has been demonstrated for the second millennium B.C.E. (Manniche 1989, 82f.*). This has also made it possible to identify the ancient Egyptian word *šmšmt* as "hemp." In Egypt, hashish continues to possess a ritual significance as a socio-integrative element at social events. People smoke out of the water pipe together after meals and at concerts and dance performances (Sami-Ali 1971).

In medieval Islamic society, hemp products were used primarily as sacred plants to support meditation in various Sufi and dervish orders. The plant became so closely identified with its mystical use by the Sufis that it became known as the "hashish of the poor"[= Sufis] (Rosenthal 1971, 13).

In South Africa, where the plant is known as *dagga*, hemp is now usually smoked for hedonistic purposes. In times past, however, it played an important role in numerous tribal rituals (Du Toit 1958, 1975, 1980; Morley and Bensusan 1971; Watt 1961). Its smoke was inhaled for divination, and it was sometimes smoked collectively for healing dances (cf. ***Ferraria glutinosa***, **kanna**). *Dagga* was often used ritually together with other psycho-active plants (see ***Mesembryanthemum spp.***, ***Sceletium tortuosum***, ***Tabernanthe iboga***).

In Switzerland, the hemp fields in the *allmend* (the collective fields of a community) were once the site for various pagan and erotic rituals that the authorities interpreted as "witches' dances" or the "witches' sabbath" (Lussi 1996).

In modern Germany, ritualized hemp use based upon traditional shamanic patterns (cf. ***Cannabis indica***) is becoming increasingly common. Because of the legal situation, however, these so-called hemp healing circles have not yet been described in any detail.

Artifacts

Pipes intended for hemp smoking have been found in Gallo-Romanic graves (Brosse 1992, 181*). Celtic and Germanic graves have yielded inflorescences of *Cannabis sativa* (cf. ***Papaver somniferum***).

A large number of smoking devices have been invented in Africa. In addition to water pipes with hoses (so-called *argile*), these include horn pipes, earth pipes, and gourd pipes (Du Toit 1981, 518ff.).

When it comes to smoking devices, creativity knows no limits. Numerous pipes have been devised

and used to smoke hemp. In addition to standard tobacco pipes and Oriental water pipes (hookahs), devices have been developed specifically for smoking hemp. There are pure pipes, bonges (water pipes, made out of laboratory glass, plastic, or ceramics), ka-booms (smoking tubes with extra airflow), and others in a wide variety of designs. One astonishing invention comes from California, where an ocean creature, the sea urchin (*Clypeaster rosacea*), produces a shell that can be made into a natural and ideal pure pipe. Apart from the shell, all that is needed is a small screen, which is placed in the sea urchin's oral cavity. The smoke is drawn through its anal opening. Consequently, in the local counterculture it has become customary to speak of "ritual analingus." Recently, Nick Montefiore and James Hassal developed a high-tech pipe the size of a credit card and made entirely of metal (for pure smoking). When it came on the market, it was immediately awarded the BBC Designer Prize.

Most of the time, however, hemp products and the **smoking blends** prepared from them are smoked in the form of a self-rolled cigarette, a so-called joint (called also spliff, doobie, reefer, number, etc.). A joint is made using either the same commercial rolling papers that are used to roll cigarettes or special commercial rolling papers that differ from normal rolling papers principally in that they are larger. In 1986, the cigarette company BAT sponsored an exhibit in Paris entitled *Les papiers du paradis* [The Papers of Paradise]. The catalogue for the exhibit made it very clear that most of the rolling papers were intended for use in rolling joints.

For modern treatments of *Cannabis sativa* in painting, music, literature, comics, and films, see *Cannabis indica*. In art, no distinction is made among the different *Cannabis* species.

"[Hemp] preparations have a stimulating and invigorating effect upon the nervous system in small doses. This is why the physician will prescribe it for great exhaustion and debility following physical exertion. Larger amounts are sedative. For this reason, it is sometimes administered in the place of morphine. It is also a good agent for diseases of the urinary apparatus."

E. W. ZIMMERER

KRÄUTERSEGEN [HERBAL BLESSINGS] (1896, 53*)

Medicinal Use

For additional information on medicinal use, see also *Cannabis ruderalis* (and see Rätsch 2001*).

The medical pyramid inscriptions and papyri of the ancient Egyptians indicate that hemp was used as a medicine in myriad ways. One translation reads, "A treatment for the eyes: celery; hemp; is ground and left in the dew overnight. Both eyes of the patient are to be washed with it early in the morning" (P. Ramesseum II, 1700 B.C.E.). This recipe has been interpreted as a treatment for glaucoma, which was common in ancient Egypt. This interpretation is very revealing, for ophthalmologists still have not developed a medicine better than hemp for treating glaucoma (cf. *Cannabis indica*).

Hemp was introduced into New Spain (Mexico, Peru) in the early colonial period. Since that time, it has been prized as a stimulant. Hemp, mixed with *aguardiente* (alcohol made of sugar-cane; cf. **alcohol**), is used both internally and externally as a remedy for scorpion stings and tarantula bites (Bye 1979a, 145*).

At the beginning of the early modern period, all of the "fathers of botany" were in agreement that hemp possessed a "warm and dry nature" and could therefore dispel gas and flatulence. They wrote that it provided a good medicine for ear ailments. The use of the boiled root as a wrap for painful limbs is also frequently mentioned. The most important information about this early medicinal use comes from Tabernaemontanus, whose *Kräuterbuch* [Book of Herbs] is one of the most comprehensive works of its kind. It says, "Those women who have cramps in the womb / for them hemp should be burned / and held to the nose" (1731, 937*). This is apparently the first written reference to medicinal hemp smoking (to treat uterine cramps) in the German-language literature.

In the nineteenth century, so-called Indian cigarettes were sold in European pharmacies. These were smoked to treat asthma, lung and larynx ailments, neuralgia, sleeplessness, et cetera (cf. ***Cannabis indica***). They were made from hemp leaves that had been soaked in an extract of opium (***Papaver somniferum***), together with belladonna leaves (***Atropa belladonna***), henbane leaves (***Hyoscyamus niger***), thorn apple leaves (***Datura stramonium***), and sometimes ***Lobelia inflata*** or cherry laurel schnapps (***Prunus laurocerasus*** L.). Such mixtures are reminiscent of the recipes for both **witches' ointments** and **smoking blends** (including **kinnikinnick**). The recommended dosage was one cigarette as needed (Fankhauser 1996, 156f.).

Hemp has been a part of the homeopathic materia medica since its inception. Homeopathy was established as a medical method by the physican Samuel Hahnemann (1755–1843), who wrote the following about hemp (***Cannabis sativa***):

Until now, hemp has been usefully applied for acute gonorrhea and several types of jaundice. This organotropic tendency is found again in testing the symptoms of the urinary organs. In Persian inns, the herb is used to alleviate tiredness among those who are traveling on foot. Here, too, there are suitable symptoms for testing. For a long time, I administered hemp juice in the mother tincture, in the dosage of the smallest portion of a drop. But now I find that the dilution C30 is able to more highly develop these medicinal powers. (Buchmann 1983, 19f.*)

In the homeopathic doctrine of medicine, it has become customary to distinguish between ***Cannabis sativa*** and ***Cannabis indica***, as the medical descriptions and symptom pictures of the two species vary considerably. ***Cannabis sativa*** (***Cannabis sativa*** hom. ***HPUS78***, ***Cannabis*** hom. ***HAB34***) is prescribed primarily for urine retention as well as diseases of the urinary tract (gonorrhea, inflammation of the penis) and the respiratory organs. A substitute is ***Hedysarum ildefonsianum***, a Brazilian species of sweet clover (Boericke 1992, 190*).

Hemp seed oil is now used in folk medicine to treat neurodermatitis. It is applied to the affected areas of the skin (this treatment is said to be amazingly successful).

Constituents

The chemistry of ***Cannabis sativa*** is very complex but is now quite well understood (Lehmann 1995). The main psychoactive constituent is **THC** (cf. ***Cannabis indica***), which is contained primarily in the resin and the female flowers and, in lower concentrations, in the leaves. The most highly concentrated product is hashish oil, which contains approximately 70% THC. The resin contains up to 25% THC. Studies of older material have demonstrated that, even when stored for long periods, THC only very slowly oxidizes into the much less active CBN (Harvey 1990).

The **essential oil** contained in the plant, and especially the hashish, contains caryophyllene oxide. This odoriferous substance has been used to train police dogs to detect the drug (Martin et al. 1961; Nigam et al. 1965). Hemp's essential oil usually either is devoid of THC or contains only trace amounts.

Persian water pipe for using hashish. (From Neander, *Tabacologia*, 1626)

The seeds contain an oil rich in lignan, proteins, and the enzyme edestinase (St. Angelo and Ory 1970). The growth hormone zeatin has been found in immature seeds (Rybicka and Engelbrecht 1974). The seeds also contain the alkaloids cannabamine A, B, C, and D, piperidine, trigonelline, and L-(+)-isoleucine-betaine (Bercht et al. 1973). Hemp seed oil, which is obtained by cold pressing the seeds, is very rich in unsaturated fatty acids (vitamin F).

The pollen contains Δ^9 -THC as well as THCA, an alkaloid-like substance, flavones, and phenolic compounds (Paris et al. 1975).

The leaves of *Cannabis sativa* have been shown to contain choline, trigonelline, muscarine, an unidentified betaine, and, astonishingly, hordenine, a β -**phenethylamine** alkaloid present in many cacti (El-Feraly and Turner 1975). The leaves of Thai and African populations have yielded water-soluble glycoproteins, serine-O-galactoside, and hydroxyproline (Hillestad and Wold 1977; Hillestad et al. 1977).

The roots of *Cannabis sativa* have been found to contain friedelin, epifriedelinol, N-(*p*-hydroxy- β -phenethyl)-*p*-hydroxy-*trans*-cinnamamide, choline, and neurine as well as the steroids stigmast-5-en-3 β -ol-7-on (= 7-keto- β -sitosterol), campest-5-en-3 β -ol-7-on, and stigmast-5,22-dien-3 β -ol-7-on (Slatkin et al. 1975).

The male hemp plant in blossom. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Effects

Cannabis x and Hybrids

Hemp Hybrids

Family

Cannabaceae (= Cannabinaceae) (Hemp Family)

Hemp connoisseurs regard any marijuana (= female hemp flowers) that contains more than just a few seeds as inferior in quality. They prefer those psychoactive, **THC**-rich sorts that form no or few seeds. These are known as *sinsemilla*, literally “without seeds” (Mountain Girl 1995). When producing *Cannabis* crosses or sorts, a fundamental distinction is made between hybrids that can be grown outdoors and those that thrive only under conditions of artificial light (so-called indoor sorts).

Crosses between ***Cannabis indica*** and ***Cannabis ruderalis*** are popular, as they are very small as well as very potent. Crosses with *Cannabis ruderalis* are well suited for growing outdoors, as they flower early regardless of the length of the day.

Because of pressure from law enforcement, cannabis intended for smoking is being grown in closed rooms with ever greater frequency. The cultivation of highly potent sorts in greenhouses is now especially common in the Netherlands (Jansen 1991).

Most marijuana growers no longer use seed to produce new plants; they use cuttings (clones) of female plants instead. To take a cutting, a sharp knife is used to separate a vigorous 8 to 10 cm long shoot from the mother plant. The leaves are removed and the shoot is immediately placed in a container of lukewarm water. Then the shoot is placed in a watered piece of rock wool that is full of holes. To promote root formation, a root hormone may be added to the water. Shoots will most readily develop roots if they are kept in a warm room (soil temperature between 21 and 24°C) with very high (at least 80%) air humidity (e.g., in a small, heated greenhouse). Once the shoots have formed roots, they may be planted in soil in pots.

The most important factor affecting the formation of THC-rich flowers is the amount of light the plants are exposed to: “When two clones of a female hemp plant grow in two totally different surroundings, i.e., one perhaps in shade and the other in full sun, their genotypes remain identical. But the clone grown in the shade will grow tall and slender and mature late, whereas the clone exposed to sunlight will remain small and bushy and mature much sooner” (Clarke 1997, 28f.).

One important goal of cultivation is shortening the time it takes for the THC-rich inflorescences to develop without producing seeds. For this reason, many sorts or hybrids are evaluated by the amount of time between seed germination and the full development of the resinous flowers. For example:

Skunk Special	flowers after 9 weeks
Super Skunk	flowers after 7 weeks
Big Bud	flowers after 9 weeks
California Orange Bud	flowers after 9 weeks
California Indica	flowers after 7 weeks
Misty	flowers after 10 weeks
NL Shiva	flowers after 9 weeks
Shiva Shanti	flowers after 7–8 weeks

NL Masterkush	flowers after 10 weeks
Haze	flowers after 11 weeks
Afghaan	flowers after 8 weeks
Durban Poison	flowers after 9 weeks
Hindu Kush	flowers after 6–7 weeks
Northern Lights	flowers after 7–8 weeks
Jack Herer	flowers after 10 weeks

Spectacular results were achieved in experiments in which *Cannabis sativa* was grafted onto *Humulus lupulus* and *Humulus japonicus*. Here, four-week-old hops seedlings were cut straight across. The stems were split, and a cannabis stalk that had also been split was placed into each hops seedling's stem, after which the two were tied together with cellulose. Over 30% of these grafted plants survived and developed into large plants. When THC-rich hemp is grafted onto *Humulus*, it continues to produce high quantities of constituents. Unfortunately, this does not occur when hops is grafted onto cannabis (Crombie and Crombie 1975).

There is a very rich literature on methods for cultivating all sorts and hybrids of hemp, including Behrens 1996, Frank and Rosenthal 1980, Starks 1981, and Stevens 1980. High-tech methods have been developed to provide optimal watering to hemp fields in dry or very dry areas (prairies, deserts). Special hydroponic techniques have been developed for indoor growing (Storm 1994).

There is now a vigorous trade in legal seeds (cf. *Cannabis indica*) of particular sorts and crosses for growing both indoors and outdoors.

As the very wide leaves indicate, this *Cannabis* sort, bred for the (still illegal) production of high-quality marijuana, was derived primarily from *Cannabis indica*.

“Since every cannabis sort is genetically unique and exhibits at least a few genes that cannot be found in other sorts, these unique genes are lost forever when a sort dies out. If genetic problems should appear as a result of excessive inbreeding of commercial sorts, then these new sorts might not be as resistant to previously unknown threats from the environment. Then, for example, it would be possible for

a plant disease to spread with great speed and simultaneously befall and destroy several fields. For a farmer, the loss of a large part of the crop means immense financial losses. In this way, entire sorts can disappear forever.”

ROBERT C. CLARKE *HANF* [HEMP] (1997, 14*)

History

Archaeological discoveries indicate that the prehistoric Hohokam (1150–1350 C.E.) used the saguaro for a variety of purposes (Hodge 1991, 48; Nabhan 1986, 32). The cactus has continued to play a central role in the cultures of the Southwest into the present day. In 1540, Spanish conquistadors, marching to the north under the command of Coronado, first mentioned the cactus as well as the wine produced from it under the name *pitahaya* (Bruhn 1971, 324). It was first described in a botanical publication in 1848, under the name *Cereus giganteus*. The genus name used today was coined to honor Andrew Carnegie, a passionate desert researcher (Hodge 1991, 6).

Distribution

The giant saguaro is native to Arizona, Southern California, Baja California, and northern Sonora (Mexico).

Cultivation

Propagation by seed is possible, but it is extremely difficult and rarely successful. Because of this, most attempts to restore the saguaro forests of Arizona have met with failure (Hodge 1991, 35ff.). The fruits cannot be picked by hand but must be collected using a long pole (2 to 5 meters long), to the end of which is attached another pole (*kuibit*) (Bruhn 1971, 325). The cactus requires an extreme desert climate with very high summer temperatures. It tolerates frost and snow in winter (Nabhan 1986, 16f.).

Appearance

The cactus can grow to a height of more than 12 meters. It has a main trunk and eight to twelve side branches that rise vertically. The skeleton has twelve to twenty-four ribs. The white flowers emerge from green, scaly buds on the tips of the trunk and branches. The flowers have luminously yellow stamens and pistils. The cactus does not flower until it is between fifty and seventy-five years old

(Bruhn 1971, 323). The fruits are 6 to 9 cm long and contain a crimson flesh, in which some 2,200 seeds are found.

The cactus occasionally takes on a deformed appearance. Such specimens are known popularly as “monarchs with crowns” (Hodge 1991, 31ff.).

The saguaro (*Carnegiea gigantea*) is the largest of all column cacti. In Arizona, entire saguaro forests can be seen. (Photographed in its natural habitat)

“Ready, friend!
Are we here not drinking
The shaman’s drink,
The magician’s drink!
We mix it with our drunken tears and drink.”
PAPAGO DRINKING SONG IN *SINGING FOR POWER* (UNDERHILL 1993, 35)

The cactus can live 150 to 175 years and attain a weight of six to ten tons. Its high water content (80 to 95%) enables the cactus to flower and fruit regularly, even during yearlong droughts (Bruhn 1971, 323). Flowering time is normally in the spring. Pollination occurs through bats and birds as well as other agents (Hodge 1991, 16). The **honey** that is collected from the flowers has no psychoactive effects. In Arizona, it is regarded as a culinary specialty.

Psychoactive Material

—Fruit (pitahaya, tjúni, a-a, a-ag, nol-bia-ga)

Preparation and Dosage

In the area in which the cactus is found, fermented drinks (beerlike or **wine**) made from its fruits are known as *tiswin*, *sawado*, *saguaro*, *haren*, *ha’-san na’vai* (“saguaro drink”), and *na’vait*. Among the O’odham (= Papago), the wine is known as *nawait*.

Boiling the fruit flesh yields a sweet brown syrup (*sítoli*) that can be either eaten as is or fermented.⁹⁰ When a fermented beverage is made from this syrup or from fresh fruits with water, the **alcohol** content is only 5% or less (Hodge 1991, 47f.). Thus, the beverage is not a wine but a rather beerlike drink (very similar to the South American **chicha**). Fermentation takes about seventy-two hours. Possible additives are unknown (Bruhn 1971, 326). The Serí Indians of northern Mexico also

brewed a fermented drink from saguaro fruits. Known as *imám hamáax*, “fruit wine,” it was made by crushing the fruits in a basket and mixing the result with water. Fermentation was complete after a few days. They more rarely produced a true wine without water (Felger and Moser 1991, 247*).

Ritual Use

The Tohono O’odham (= Papago) venerate the saguaro as a sacred tree. They explain that it arose from drops of sweat that fell from the eyebrows of I’itoi, the older brother of the tribal pantheon, in the morning dew and condensed into pearls. According to a different origin myth, the cactus was once a boy. When his mother was not watching, he became lost in the desert and fell into a tarantula hole. He reemerged as a cactus. This may explain why, after a child is born, the O’odham bury the placenta next to a saguaro. Doing so is said to secure the child a long life. On the vernal equinox, the O’odham sing special songs throughout the night to aid the cactus fruits in their development (Hodge 1991, 47).

The O’odham make cactus wine in July (= *harsany paihitak marsat*, “saguaro harvest month”) for their annual rain ceremony, which was established by I’itoi, the Older Brother (Bruhn and Lundström 1976, 197). The wine consumed in the ceremony is made from fruits or syrup contributed by all the families (Bruhn 1971, 326). The ritual is both a conjuration of rain—an extremely important ceremony in the desert—and a socially integrative tribal celebration and harvest festival. In a kind of sympathetic magic, all the members of the tribe drink copious amounts of *nawait*. They do this in imitation of nature, for “the earth drinks water” so that the plants, and especially the cacti, can thrive. During the festival, songs and texts are presented that describe the life cycle of the cactus, the proper ways of harvesting the fruits, and the influence the cactus spirit has upon the “rain house” in which the weather is made (Underhill 1993, 21ff.). The elders of the tribe pray to the four directions. During the festival, a person is not allowed to ask for a drink but must wait until one is offered (Hodge 1991, 48).

As is the case in the ceremonies of many tribes of the Southwest, a ceremonial clown appears at the festival and makes fun of the ritual. The O’odham ceremonial clown (Naviju dancer) is regarded as a personification of the saguaro. And in general, the giant cactus is construed as an “Indian” (Bruhn 1971, 327).

The Serí, who live in the Sonoran Desert of Mexico, share the O’odham belief that the cactus was originally a person. For this reason, they also bury the placenta of a newborn at its roots so that the child will enjoy a long life (Felger and Moser 1991, 248*; Lindig 1963).

To date, we know of no psychoactive use of the cactus flesh or an alkaloid-rich preparation made from it. It is possible that there might have once been such a use, for the saguaro is also regarded as a peyote substitute (see *Lophophora williamsii*).

Artifacts

Representations of the giant cactus in varying degrees of abstraction are found as graphic elements in the baskets that are woven out of yucca (*Yucca* spp.), catclaw (*Acacia greggii*), and other desert plants (Hodge 1991, 47). A figure of the Naviju dancer, the personification of the cactus, is on display at the Arizona State Museum in Tucson.

The saguaro cactus is depicted on numerous Western paintings and has become something of a symbol of the Wild West.

The O’odham artist Leonard F. Chana has produced an acrylic painting, *When the Clouds Come*, that depicts the harvest of the saguaro fruit. (It was published as a postcard by Indigena Fine Art Publishers in 1995.) The Luiseno–Hunkpapa Sioux painter Robert Freeman has immortalized the cactus in his painting *Lady in Waiting* (1990).

The O’odham and other tribes have a number of songs that praise the cactus; some of these have been recorded, translated, and published. Some songs, especially the dream songs, are said to have

been inspired by the effects of the wine (Bruhn 1971, 327; Densmore 1929; Underhill 1993).

“The dreams and feelings that are experienced in inebriation are generally attributed to a supernatural origin and are considered essential for certain undertakings. Among the Pima and the Papago, drunkenness in the context of the annual rain dance held great significance. A fermented drink was obtained from the juice of saguaro, pitahaya, or nopal cactus fruits. In a kind of sympathetic magic, they believed that drinking alcohol would induce clouds to form, which would soon burst and satiate the world with water.”

SERGE BRAMLEY

IM REICHE DES WAKAN [IN THE REALM OF THE WAKAN]

(1977, 82*)

Carnegine

Salsolidine

The skeletons of decayed cacti are used as raw materials for numerous products. They also serve as fence posts and are now used throughout the world as window decorations (to suggest a Wild West ambience).

Medicinal Use

The Mexican Serí Indians cut a piece from the trunk of the living cactus, remove the thorns, and heat the cactus flesh over hot wooden coals. The flesh is then wrapped in a cloth and applied to rheumatic or painful areas (Bruhn and Lundström 1976, 197; Felger and Moser 1974, 421*). Apart from this, no ethnomedical or folk medicinal uses have been recorded.

Constituents

Saguaro flesh has been found to contain the β -**phenethylamines** carnegine, gigantine, salsolidine, 3-methoxytyramine, 3,4-dimethoxyphenethylamine, arizonine, and dopamine (Bruhn and Lundström 1976; Mata and McLaughlin 1982, 96*). The alkaloids carnegine, gigantine, and salsolidine are closely related to the constituents of peyote (*Lophophora williamsii*) (Bruhn 1971, 323). The main alkaloid is salsolidine (= norcarnegine), which makes up some 50% of the total alkaloid content. This alkaloid was first discovered in a *Salsola* species (Chenopodiaceae) and also occurs in *Pachycereus*

pecten-aboriginum (Bruhn and Lundström 1976, 199). Altogether, the cactus contains 0.7% alkaloids (Bruhn 1971, 323).

The entire air-dried fruit contains approximately 7% sugar and 13% protein. The fruit syrup consists of up to 63% sugar. The seeds contain high amounts of tannin and are approximately 16% protein (Bruhn 1971, 324f.).

Effects

The sap, which flows from the cactus when it has been wounded, is very bitter. When ingested, it typically produces nausea and dizziness (Bruhn and Lundström 1976, 197).

In laboratory tests with monkeys and cats, the alkaloid gigantine was found to induce hallucinations (Bruhn and Lundström 1976, 197). It is interesting to ponder, however, how we are able to recognize that animals that are incapable of speech are having hallucinations.

All that has been reported about the effects of saguaro wine is that it produces “good feelings” (Bruhn 1971, 327).

Commercial Forms and Regulations

The cactus is listed as an endangered species and is protected. In Arizona, only saguaro honey is available.

Catha edulis (Vahl) Forsskål ex Endlicher

Khat

Family

Celastraceae^{[91](#)} (Bittersweet Family); Subfamily Celastroideae, Celastreae Tribe

Forms and Subspecies

Khat farmers of Ethiopia make a distinction between two varieties: *ahde*, “white,” and *dimma*, “red,” in reference to the color of the leaves. The red leaves are said to be more potent (Getahun and Krikorian 1973, 359ff.). Apart from this, no varieties or forms have been described botanically (Brenneisen and Mathys 1992, 730).

Synonyms

History

The use of psychoactive khat leaves is very old, with roots that definitely predate coffee (*Coffea arabica*) drinking. It is very likely that khat was first chewed as an agent of pleasure and a stimulant^{[93](#)} in Ethiopia. The plant was first included in a list of medicines in 1222; it is also mentioned in the book *The Wars of ‘Âmda Syon I* (‘Âmda Syon I was a Christian king who ruled in the early fourteenth century) (Getahun and Krikorian 1973, 356). A history book by Al-Maqrîzî (1364–1442) notes the following about Abyssinian plants: “Among them is a tree that is called *gât*. It does not bear fruit, people eat its leaves, and these resemble the small leaves of the orange tree. They expand the memory and in doing so call the forgotten back into mind. They give pleasure and diminish the desire for food, sexuality, and sleep. For the inhabitants of that land, not to mention the educated, the consumption of this tree is associated with great longing” (Schopen 1978, 46f.).

The Sufis and the wandering dervishes played a great role in the early spread of khat use (Schopen 1981). They regarded the ingestion of the leaves as a sacred activity and used khat to achieve mystical experiences, believing that “[i]n doing so, you see things of rare knowledge that belong to God’s magnificence” (Schopen 1978, 52).

The name *khat* is apparently derived from the Arabic *kut*, “sustenance or driving principle,” or

from the place name Kafa (in Ethiopia), which is also thought to be the source of the word *coffee*. Most folklore suggests that both the khat bush and the practice of chewing khat are from Yemen. It is said that the goatherd Awzulkernayien observed how his goats ate the leaves of a shrub, after which they behaved in a frisky manner. The goatherd then tried the fresh leaves, whereupon he immediately felt more awake and stronger than he ever had before. Before turning in to sleep that night, he chewed a few more of the leaves he had brought with him. He was unable to sleep the entire night and spent it instead in prayer and meditation. Following this, khat was proclaimed to be a sacred tree and regarded as a wondrous medicine (Getahun and Krikorian 1973, 353f.).

According to a different legend, two saints who often prayed throughout the night were constantly falling asleep or fighting to avoid sleep. They prayed to God that he would give them a means to prevent them from falling asleep. An angel appeared to them and showed them a plant to eat that would help them remain awake and pray through the night (Getahun and Krikorian 1973, 356).

Charles Musès has proposed the theory that khat was already regarded as a “food of the gods,” “divine food,” or “food of existence” in ancient Egypt and was used for magical purposes. The plant is thought to have been known as *kht* in Egyptian (Musès 1989). Others have suggested that the Homeric **nepenthes** was in fact khat. It has also been suggested that khat was the magical medicine Alexander the Great used to miraculously heal his troops. Even the smoke of Delphi (cf. *Hyoscyamus albus*) was said to have come from khat leaves and to have been inhaled as a psychoactive **incense** (Elmi 1983, 164).

The plant was described in 1775 by the Swedish botanist Pehr Forsskål (1732–1763), who lived in Yemen for many years and eventually died there. Pharmacognostic and chemical studies of the khat bush began in the German-language areas at the end of the nineteenth century (cf. Beitter 1900 and 1901). In the 1920s and 1930s, a variety of pharmaceuticals and agents of pleasure made from khat (e.g., Catha-Cocoa Milk; cf. *Theobroma cacao*) were sold in London (Brenneisen and Mathys 1992, 735). The beginnings of ethnographic khat research (in Yemen) began in the 1970s with the groundbreaking work of Armin Schopen (1978). It was only during the early 1980s that Swiss scientists discovered the actual psychoactive constituent, the amphetamine-like cathinone (Kalix 1981).

Distribution

The bush is very likely from the area around Lake Tana (Harar) in Ethiopia. From there, it spread to East Africa (via Kenya), Tanzania, Aden, Arabia, and Yemen (Getahun and Krikorian 1973). The khat bush can thrive in quite different ecological zones and can be found in both tropical and cooler mountain regions. The wild khat bush grows in the tropical rain forest of the Gurage country in Shewa, Ethiopia. It is cultivated in Arabia, Zambia, and Somalia, and even as far away as Afghanistan (Getahun and Krikorian 1973, 357).

Cultivation

Because the plant only rarely produces seeds in cultivation, khat is best propagated by cuttings (approximately 35 cm long) from the young branches. Propagation is best performed in a dry, hot climate (Grubber 1991, 43*). The cuttings—usually two—are placed in a hole filled with water. Khat can be planted at any time of the year, so long as the young plants can be provided with sufficient water. The bushes are planted in rows about 1 meter apart. Sorghum is often planted between the rows.

Propagation can also occur using seeds, but this is never done in the areas under cultivation (Getahun and Krikorian 1973:364).

Khat requires a climate that is the same as or similar to the climate required for growing coffee (*Coffea arabica*), i.e., approximately 1,200 mm of precipitation. As a mountain plant, the bush can

tolerate a mild frost. The first harvest may be taken from the bush when it is three years old, although typically it is not taken until after five to eight years. Khat planting is done primarily by males (Getahun and Krikorian 1973, 365; R. Schröder 1991, 126*). Khat bushes are often inhabited by an insect of the genus *Empoasca*, although this does not cause damage. In fact, a greater number of young shoots (the best merchandise) are formed as a result of the insect eating the plant (Getahun and Krikorian 1973, 367).

Important areas of cultivation are found especially in Ethiopia and Yemen and now also in northern Madagascar, Afghanistan, Turkistan, and even Israel. Some 60% of the fertile areas of Yemen are used for planting khat (Brenneisen and Mathys 1992, 732).

Appearance

This evergreen, fast-growing bush can grow into a tree as large as an oak (15 to 20 meters tall); under cultivation, it usually is kept to a height of 3 to 5 meters or, in rare cases, 7 meters (Getahun and Krikorian 1973, 356). The more the bush is trimmed, the more rapidly young shoots appear.

On blooming branches, the leaves are always opposite, but they can be alternate on young branches and plants (Brennesien and Mathys 1992, 730; Krikorian 1985). The leaves have a serrated margin and a shiny, slightly leathery upper surface. Young leaves at the ends of branches are light green; older leaves are dark green. The leaves sometimes take on a red hue. The small, star-shaped flowers are white and are borne in clusters in axillary cymes. The fruit capsules are 7 to 8 mm long and have four chambers. When they mature, they open up like small flowers (Krikorian 1985).

The genus *Catha* consists of only a few species (Wang 1936), probably a maximum of three. The two others are *Catha transvaalensis* Codd. [syn. *Catha cassinoides* N.K.B. Robson] and *Catha abbottii* Van Wyk et Prins;⁹⁴ *Catha spinosa* Forssk. nows bears the botanically valid name *Maytenus parviflora* (Vahl) Sebsebe (Brenneisen and Mathys 1992, 730). These African bushes can all be mistaken for khat, although they themselves have no ethnopharmacological significance.

Psychoactive Material

- Leaves (*Catha-edulis* leaves, khat leaves)
- Fresh leaves and twigs, and also the leaf buds
- Dried leaves (khat tea)

Every day, large segments of the population of Yemen chew the light green leaves of the khat bush (*Catha edulis*) as a stimulant and inebriant.

The small fruits of *Catha edulis*.

Preparation and Dosage

The fresh leaves should be chewed as soon after harvesting as possible. They should be no more than two days old. They require no further treatment and do not need to be mixed with any other substances. A person simply takes as many of the leaves into the mouth as possible, then chews the leaves for some ten minutes before either spitting them out or swallowing them (Getahun and Krikorian 1973, 371). The juice of the chewed leaves is swallowed periodically (Schopen 1978, 85). The longer the constituent-rich juice is retained in the mouth, the more pronounced the effects. In Yemen, fresh leaves are also pounded in mortars.

The fresh leaves and branch tips are (more rarely) brewed or boiled into a tea. In South Africa, infusions of khat are known as bushman's tea. In Yemen, roasted khat leaves were once used to prepare "coffee" (Schopen 1978, 86). They also can be ground, mixed with honey or sugar, and made into candies (Getahun and Krikorian 1973, 357). In Somalia, the leaves are sometimes dried in the sun and then crushed. Cardamom, cloves, and water are then mixed with the powder to produce a paste that is taken as a quid. Fresh or dried khat branches are added to tea (*Camellia sinensis*) for flavor. In Ethiopia, khat is even used to make **mead**: "The qât infusion is fermented with **honey**. This produces a brown, bitter, meadlike drink with mild inebriating effects" (Schopen 1978, 85).

In Arabia (Yemen), dried leaves are smoked both alone and with other substances, especially hashish (*Cannabis indica*; cf. also **smoking blends**) (Getahun and Krikorian 1973, 357). Dried leaves that are still green are used as a (medicinal) **incense**. The dried leaves may also be ground and formed into balls using a binding agent; when ingested, such preparations give strength to pilgrims bound for Mecca. Dried leaves can also be mixed with water to prepare a paste for ingestion by old people without teeth (Getahun and Krikorian 1973, 366).

Leaves that have been damaged by frost take on a dull ashen color and should not be used, as they are said to cause headaches (Getahun and Krikorian 1973, 367).

It is generally said that tobacco (*Nicotiana tabacum*) should be smoked along with khat, as it will potentiate the effects of the khat (Schopen 1978, 86).

Only the leaf buds, the young leaves, and the ends of the branches contain sufficient constituents. The main psychoactive component breaks down rapidly when the material is dried. In contrast, it can remain unchanged for months if the fresh leaves are frozen (Brenneisen and Mathys 1992, 732).

Between 100 and 200 g of leaves are typically consumed during a khat session (R. Schröder 1991, 127*). Ethiopian khat farmers eat between ¼ and ¾ kg of khat leaves in the morning—of the finest quality, to be sure (Getahun and Krikorian 1973, 374).

Cathinone, the primary active constituent, is some three times less toxic than amphetamine. An alcoholic extract of khat, in a dosage of 2 g per kilogram of body weight, has been demonstrated to have lethal effects on mice (Brenneisen and Mathys 1992, 738). One gram of khat leaves contain 3.27 mg of cathinone/cathine (Ahmed and El-Qirib 1993, 214).

Ritual Use

Most Muslims who live in areas where khat is grown regard both the bush and its leaves as sacred and utter a prayer of thanks before they use it (Getahun and Krikorian 1973, 356). In Ethiopia, traditionally only the older men chewed khat, and then only in conjunction with religious rites. They chewed the leaves and drank coffee so that they could remain awake for the long prayers. Often, they also smoked hashish on these occasions. Over the course of time, people began to chew khat leaves while watching over the sick, at marriages and funerals, and during business negotiations. Today, khat leaves are chewed by men and women of all ages, including students and children (Getahun and Krikorian 1973, 371f.).

Ethiopian dervishes use khat as part of their religious healing ceremonies. They chew consecrated leaves and then spit upon the ill before pronouncing prayers and magical formulae over them (Schopen 1978, 87).

In Yemen, the ritual use of khat is widespread for certain festivals and religious events: engagements, marriages, burials. Most Yemenites chew khat every day in a social round whose structure adheres to precisely defined ritual forms. Because of their socially integrative nature, these rounds play a central role in Yemenite society (Schopen 1978). The participants come together in the afternoon, during the "blue hour." Most are men, but women occasionally take part as well. These daily khat rounds take place in the main rooms of private houses as well as in special khat rooms in

the offices of the government, large companies, et cetera. The participants pluck fresh leaves from the twigs and stuff these into their mouths. The leaves are then moistened with saliva and chewed thoroughly. A pitcher of water is passed around continuously, “for the alkaloids work only when the cell juice of the leaves that have been mixed with saliva gets to the stomach by drinking” (R. Schröder 1991, 127*). Because tobacco (or, less often, hashish) smoking is regarded as an absolutely essential part of chewing khat, cigarettes, pipes, or the hoses of large water pipes are also passed around. The participants often sing and make music together. The activities change as the effects of the khat run their course. At first, the members of the round converse excitedly with one another about contemporary political topics, current events, gossip, and Islam. As the effects begin to diminish some two hours later, the participants weary and the conversations dwindle. At this time, the circle breaks up (Schopen 1978, 1981).

“We don’t have anything else to do so we sit and chew chat.”

AN ETHIOPIAN IN “CHAT: COFFEE’S RIVAL FROM HARAR, ETHIOPIA” (GETAHUN AND KRIKORIAN 1973, 374)

“Let the jewels of qât go around, emerald leaves of the small leaves.

Its ingestion sweetens my heart,

its sight my eye, my condition and my times are pleasant because of it.

Its hearts [i.e., the leaves]

bear the secrets that they place in our hearts.

They then flow into the most secret of thoughts.

[Qât is] the Burâq of the ascension of my heart,

as soon as it needs it.

Gabriel is my heart,

who travels to the highest heaven.

.....

Its use, say the Mursidûn [Sufis],

is like the enlightenment of the mysteries,

the seclusion of the forty days.

I have never wanted to ascend into the heaven of

my view in the universe, unless

I can make qât my ladder”

ABDALLÂH IBN AL-IMÂM SARAF AD-DÎN *QASÎDE* (SIXTEENTH CENTURY) (IN SCHOPEN 1978, 85)

Artifacts

In Yemen, numerous Arabic-language poems both glorify and criticize khat use (Schopen 1978). It is possible that many aspects of Arabic art have been influenced by the use of khat. The samar music of Yemen is composed specifically for the afternoon khat rounds and is played and sung during these social gatherings. At least one album of samar music that was recorded on-site has been released internationally: *Music from Yemen Arabia: Samar* (Lyrichord Discs, LLST 7284).

In Tanzania, the wood of the khat bush is used to manufacture spoons and combs (Schopen 1978, 86).

Medicinal Use

Khat is generally used only infrequently as a medicine. The leaves are mentioned in only two Arabic pharmacopoeias. Khat is said to calm the stomach and cool the intestines and is recommended for the treatment of depression and melancholy (Schopen 1978, 87). In Yemen, it is used also as an appetite suppressant (Fleurentin and Pelt 1982, 96f.*). More rarely, the fumes of burning khat are inhaled for the treatment of headaches (Schopen 1978, 88).

In Africa, khat root is used to treat influenza, stomach problems, and diseases of the chest (Getahun and Krikorian 1973, 357).

In Ethiopia, it is believed that khat can cure 501 diseases and afflictions, as the numerical value of

its Arabic name, *ga-a-t*, is 400 + 100 + 1 (Getahun and Krikorian 1973, 370). Khat is also used there as an aphrodisiac (Krikorian 1984), as well as to treat depression and melancholy. A khat leaf is applied to the forehead as a remedy for headaches. Among the Masai and Kipsigi tribes, the leaves are used to treat gonorrhea. It is also said that regular consumption of khat provides protection against malaria. In Saudi Arabia, khat is used to treat asthma and fever (Brenneisen and Mathys 1992, 735).

Constituents

During the early phase of khat research, it was thought that the leaves contained **caffeine**, an assumption that none of the studies was able to verify. Later, katin (= cathine) or “celastrina” was regarded as the active principle (Krikorian and Getahun 1973, 379). Soon thereafter, it was suggested that **ephedrine** was responsible for the plant’s effects. Some investigators claimed that *d*-norpseudoephedrine was also present (Krikorian and Getahun 1973, 387). The constituents primarily responsible for the stimulating effects upon the central nervous system (CNS) are the khat phenylalkylamines or khatamines (phenylpropylamines) cathinone and cathine (= *S,S*-[+]-norpseudoephedrine) (Brenneisen and Geisshüsler 1985). Other CNS stimulants, the phenylpentylamines merucathine, pseudomerucathine, and merucathinone, are present in small amounts, and there is also some *R,S*-(-)-norephedrine (Brenneisen and Geisshüsler 1985, 293; Brenneisen et al. 1984). The actual primary psychoactive and stimulating constituent is cathinone (= *S*-(-)-cathinone or *S*-(-)-[α]-amino-propiofenone) (Brenneisen and Mathys 1992, 731; Kalix 1992).

The amount of constituents present in the fresh leaves can vary considerably, depending upon provenance, place of cultivation, age, and quality (Geisshüsler and Brenneisen 1987). The alkaloid content varies between 0.034% (leaves from Harar, Ethiopia) and 0.076% in leaves from Aden. Surprisingly, leaves from khat bushes grown in the United States and Europe have been found to contain little or almost no alkaloids (Krikorian and Getahun 1973, 379, 388). In leaves from Ethiopia, the cathinone content was measured as approximately 0.9 mg per leaf (fresh weight) (Halket et al. 1995, 111).

The flavonoid glycosides myricetin-3-*O*-β-*D*-galactoside, dihydromyricetin-3-*O*-rhamnoside, myricetin-3-*O*-rhamnoside, and quercetin-3-*O*-β-*D*-galactoside have been found in air-dried leaves and branch tips (Al-Meshal et al. 1986). These substances are similar to those contained in ***Psidium guajava***.

Fresh leaves contain several polyphenolics (El Sissi and Abd Alla 1966). They are also rich in vitamins (especially vitamin C, but also thiamine, niacin, riboflavin, and beta-carotene) and minerals (Mg, Fe, Ca) as well as tannins, catechol tannins, sugars (mannitol, glucose, fructose, rhamnose, galactose, xylose), flavonoids, glycosides, amino acids (phenylalanine, choline, etc.), and proteins (Krikorian and Getahun 1973). There are also reports of an **essential oil** (Qédan 1972).

Effects

The primary effect of khat is an increase in energy and wakefulness (Widler et al. 1994). Khat chewing initially induces a cheerful mood, gaiety, and euphoria, together with a certain talkativeness. This state of arousal diminishes after about two hours. The stimulating effects usually begin with a tingling sensation on the head. It is said that khat “produces a social delirium” (Remann 1995, 79). The effect of the leaves is often compared to that of a “combination of **caffeine** and **morphine**” (R. Schröder 1991, 125*).

Sufis and dervishes use khat to produce an ecstatic state, but khat “will not induce this if the greatest intention is not present. If it does not appear, then you are negligent” (Schopen 1978, 200). In other words, ecstatic effects occur only when set and setting are taken into consideration.

“For centuries, khat has been used traditionally in Islamic cultures and tolerated by the Koran as a part of religious and social life. Consuming khat in groups is especially popular, as this is said to increase the ability to communicate and stimulate the fantasy and power of imagination. When working, khat is consumed individually, primarily for its performance-enhancing and hunger-suppressing effects.”

RUDOLF BRENNESIEN AND KAROLINE MATHYS CATHA

(1992, 735)

Cathinone

Cathine

Cathinone, the main active constituent, has been described as a “natural amphetamine” and has correspondingly similar effects (Kalix 1992). Cathinone interacts with the neurochemistry of dopamine (Pehek et al. 1990) and frees catecholamine at the synapses (Kalix 1992). It has the identical or at least very similar pharmacological properties and the same sympathomimetic effects as amphetamine (Kalix 1992; Widler et al. 1994). However, the effects of the leaves appear to be conditioned by the synergistic effects of cathinone and the other constituents (Krikorian and Getahun 1973, 278). Khat, or the mixture of substances contained in the leaves, also has interesting cholesterol-lowering effects (Ahmed and El-Qirib 1993, 215).

Apart from its psychoactive effects, khat also has an antidiabetic effect. Long-term chronic use can cause stomach problems, undernourishment, and nervousness. Ethiopian Christians claim that “insanity” is prevalent among Muslims because of their constant khat use (Krikorian and Getahun 1973, 378). A World Health Organization (WHO) document from 1964 notes, “Physical dependence (in the sense in which this is understood for morphine and substances with morphine-like effects or of the barbiturate type) does not occur [with khat], even when some tolerance to the effects has been acquired” (cited in Getahun and Krikorian 1973, 375).

Commercial Forms and Regulations

In Ethiopia, khat is divided into three commercial grades, depending upon the size and age of the leaves as well as their taste and tenderness: *kudda* (first quality), *uretta* (second quality), and *kerti* (third quality). In Kenya, a distinction is made between the qualities *giza* (best) and *kangeta* (lower quality). The best quality, *giza-bomu*, does not even make it to market because the plantation owners themselves consume it (Geisshüsler and Brenneisen 1987, 276). Some two hundred different sorts are recognized in Yemen (Schopen 1978, 66ff.). All the attempts to suppress khat use in Yemen or even to replace it with chewing gum (!) have—quite rightly—failed (Schopen 1978, 11).

Today, khat leaves are used in all those areas of the world in which ethnic groups from the

traditional khat countries have settled. To serve them, shipments are sent by air freight daily to France, Italy, England, Switzerland,² and even the United States. Around the world, some two to eight million portions of khat are chewed every day. The average price for a bundle of 50 g is approximately ten dollars (Brenneisen and ElSohly 1992, 99, 109).

In Arabia, the dried leaves are sold in supermarkets for use as tea (R. Schröder 1991, 127*). In contrast, the fresh leaves are forbidden, as they are in Djibouti (Brenneisen and ElSohly 1992, 111).

Upon the recommendation of WHO, cathi-none in its pure form was made an internationally controlled substance listed in Schedule I of the U.N. Convention on Psychotropic Substances (Brenneisen and ElSohly 1992, 109).

On the black market, one can occasionally find so-called khat pills (Nexus). Although the label often indicates that these pills contain extracts of *Catha edulis*, they actually consist of pure 2-CB, a synthetic phenethylamine with empathogenic effects (Schulgin and Schulgin 1991, 503ff.*).

“At exactly two o’clock in the afternoon, the proud Yemenite people roll down their store blinds and leave work to go straight to their inebriation, the qat inebriation. I have rarely seen a people who are as full of themselves as the Yemenite people are with qat. I have seldom encountered a people that could puff up its cheeks so mightily. With qat. Show me your cheeks, and I will tell you if you are from Yemen. Fat cheeks appear to be the primary physical effect of this people’s drug.”

MICKY REMANN

DER GLOBALTROTTEL [THE GLOBE-TROTTING MORON]
(1995, 79)

“The most common method of consuming khat is to chew it. As a part of the religious social life, khat was traditionally used in the Islamic cultures. Today, khat sessions are still subjected in part to strict, ritualized customs. . . .

“Khat use induces a general state of well-being. The consumers become cheerful, excited, and talkative. Problems appear to be more easily dealt with, the sense of space and time partially disappears, without hallucinations being produced. All tiredness vanishes and, as a result of the anorexic effect, all feelings of hunger as well.”

Cestrum nocturnum Linnaeus

Night-Blooming Jessamine

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Cestreae Tribe

Forms and Subspecies

One variety has been described for Mexico: *Cestrum nocturnum* L. var. *mexicanus*.

Synonyms

Cestrum hirtellum Schlechtendal

Chiococca nocturna Moc. et Sessé

Folk Names

Akab-xiu (Mayan, “night plant”), ak’ab-yom, äk’a’yo’om (Lacandon, “night foam”), arum ndalu (Javanese), dama de noche, ejek tsabalte’, galán de noche, galán de tarde, hammerstrauch, hedeondilla, hedioncilla, hediondilla, hierba de zorillo,⁹⁵ hierba hedionda, huele de noche, iyyocxibitl, iscahuico (Totonac), ishcahuico’ko, it’ib to’ol (Huastec), lady of the night,⁹⁶ mach-choch, minoche, mocxus, nachtschaum, nachtschaumbaum, night-blooming jasmine, night-blooming jessamine, orquajuda negro, palo huele de noche, parqui, pipiloxihuitl, pipiloxohuitl (Náhuatl), putanoche (“whore’s night”), scauilojo (Totonac), tzisni sanat, tzisnutuwan, tzon tzko kindi t oan (Amuzgo), zitza kiwi (Totonac)

In Peru, one *Cestrum* species that has not been botanically identified is known locally as *hierba santa*, “sacred herb.”

History

Most *Cestrum* species are indigenous to the Amazon basin, and many occur in the Andes (Hunziker 1979, 70). It is unknown whether these psychoactive plants were used for ritual or medicinal purposes during pre-Spanish times, but it is possible. To date, no traditional psychoactive use has been documented. Overall, little ethno-botanical and ethnopharmacological research has been conducted into the genus *Cestrum* (cf. *Cestrum parqui*).

Distribution

The shrub is indigenous to the West Indies, Central America, and South America; in Mexico, it occurs in Coahuila, Guerrero, Oaxaca, Veracruz, and Chiapas (Martínez 1994, 437*). As a result of cultivation, it is also found in Southern California (Enari n.d., 22).

Cultivation

Propagation can occur with seeds or cuttings. The seeds are either pre-germinated or sowed in seedbeds. The cuttings (approximately 20 cm long) are separated from the branch tips and placed in water until roots develop. They can then be planted in soil. The plant does not tolerate frost or a cold climate and requires considerable water. In central Europe, it can be grown only as a houseplant or in a greenhouse. In tropical regions, the bush often is planted for the scent it produces at night (Morton

1995, 130*).

Appearance

This perennial bush can grow as tall as 4 meters. It bears shiny leaves. The 2 to 3 cm long, funnel-shaped flowers are greenish white and grow in clusters. At night, they open and exude a sweet, delicious scent that is very intense and penetrating. The white fruits are round but slightly oval and grow to 2 cm in length. The bush can bloom three or four times a year (Morton 1995, 130*). When rubbed, the fresh leaves release a scent similar to that of the fresh leaves of *Datura innoxia* and *Datura stramonium*.

Today, 175 to 250 species are recognized in the genus *Cestrum* (D'Arcy 1991, 78*; Hunziker 1979, 70). Many species are easily confused with one another. *Cestrum nocturnum* is easily mistaken for *Cestrum diurnum* L. (dama de noche, day jessamine), a species originally from the Antilles. It can also be confused with the Guatemalan species *Cestrum aurantiacum* Lindl., which develops magnificent yellow flowers.

Cestrum nocturnum is occasionally crossed with *Cestrum diurnum* L., as the hybrid (*Cestrum nocturnum* x *diurnum*) is more easily adaptable to nontropical climates. *Cestrum nocturnum* can be confused with many other yellow-blooming species of the genus (cf. *Cestrum parqui*).

Inflorescence of the tropical night-blooming jessamine *Cestrum nocturnum*, a typical night-scented plant.

Many *Cestrum* species are easily confused with one another. (*Cestrum aurantiacum*, from southern Mexico)

“In the beginning Hachäkyum, our true lord, created the night foam tree, for Hachäkyum was to create Kisin, the lord of death. He created Kisin.

“He planted the night foam tree, for when it was night, the flowers of the night foam tree were to open and Kisin was to blossom out of these. Kisin, the lord of death, was born there of the night foam tree.”

FROM THE LACANDON CREATION MYTH

(IN MA'AX AND RÄTSCH 1994, 41)

Psychoactive Material

—Leaves

—Flowers

Preparation and Dosage

When dried, the leaves may be smoked alone or in **smoking blends** (cf. *Cestrum parqui*). Fresh or dried leaves can be decocted into a tea (Argueta et al. 1994, 830*). No information concerning dosages is available.

Ritual Use

In the mythology of the Lacandon of Naha', who have preserved the pre-Hispanic cosmology of the Maya (cf. **balche'**) into the present day, the lord of death (Kisin) was born from a flower of *Cestrum nocturnum*. It is possible that the ancient Maya may have used the plant in necromantic rituals. Apart from this, we do not yet know of any traditional use of the plant for psychoactive purposes.

Artifacts

None

Medicinal Use

The Yucatec Maya use decoctions of the plant as medicinal baths to treat cold sweats as well as a curious illness known as *ak'ahkilka* (“night sweats”) (Pulido S. and Serralta P. 1993, 61*).

In Mexican folk medicine, an extract of the leaves is used as an antispasmodic, especially in the treatment of epilepsy (Martínez 1994, 438*). It is frequently used to treat headaches and illnesses resulting from *susto*, “fright” (Argueta et al. 1994, 830*).

Constituents

The composition of the powerful scent is as little understood as are most of the constituents (Morton 1995, 130*). Chemical studies of *Cestrum nocturnum* are lacking (Aguilar Contreras and Zolla 1982, 56*). The sapogenin steroids tigogenine, smilagenine, and yuccagenine have been found only in the leaves (Arbain et al. 1989, 76; Argueta et al. 1994, 830*).

The characteristic constituents of the genus *Cestrum*, i.e., those that are chemotaxonomically relevant, are saponines (Schultes 1979b, 151*). Alkaloids, tanning agents, and glycosides are also present in the genus (Wong 1976, 137*). Many species contain alkaloids of the **nicotine** type (Schultes and Raffauf 1991, 36*). *Cestrum diurnum* contains a principle that behaves like **atro-pine** and produces the same effects (Morton 1995, 24*). The saponines yuccagenine (0.5%) and tigogenine (0.04%) are found in the entire plant (Frerichs, Arends, and Zörnig, *Hagers Handbuch* 1980, 821*).

Effects

Simply inhaling the scent of this plant deeply is said to be sufficient to induce psychoactive effects (Argueta et al. 1994, 830f.*). The berries as well as the leaves are also reputedly able to induce hallucinations (Aguilar Contreras and Zolla 1982, 56*; Enari n.d., 22).

One child reportedly experienced profound hallucinations after consuming several fruits of *Cestrum diurnum* (Morton 1995, 24*).

Commercial Forms and Regulations

In the tropical regions of the Americas, young bushes are sold in tree farms.

A Mexican species of the genus *Cestrum* is known in Aztec as *iyacxihiuitl*, “stink tree.” The name refers not to the scent of the

flowers but to the typical inebriating nightshade scent of its leaves. (From Hernández, 1942/46 [Orig. pub. 1615*])

Cestrum parqui L'Héritier

Willow-Leafed Jessamine, Palqui

“The juice of *hediondilla* heals wounds. I saw how the natives used it to heal a boy’s dog bite. A heated solution is used to bathe the feet in order to free them of brackish slime and heal all kinds of inflammations and immoderate heat.”

BERNABÉ COBO

HISTORIA DEL NUEVO MUNDO (1653) (IN BASTIEN 1987, 117*)

“In Chile, it is said of a well-known personality: ‘He is as famous as palqui.’ ”

CARL HARTWICH

DIE MENSCHLICHEN GENUßMITTEL [THE HUMAN AGENTS OF PLEASURE] (1911, 523*)

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Cestreae Tribe

Forms and Subspecies

None

Synonyms

Cestrum salicifolium H. et B.

Cestrum virgatum Ruiz et Pavón

Folk Names

Alhuelahuen, chilenischer hammerstrauch, duraznillo negro, green cestrum, hediondilla (“stinking”),⁹⁷ paipalquen, paique, palquin, palki, palqui, palqui blanco, palquin, parqui, parquistrauch, willow-leafed jessamine, yerba santa

History

Since pre-Columbian times, the Mapuche of southern Chile have used this plant for medicinal and probably ritual purposes. The Spanish missionary Bernabé Cobo described the medicinal use of a plant known as *hediondilla* in his *Historia del Nuevo Mundo* (1653) (Bastien 1987, 117*). Louis Lewin provided an early description of the use of the wood and leaves as a tobacco substitute (cf. *Nicotiana tabacum*) among the Cholos Indians (Lewin 1980 [orig. pub. 1929], 411*). Palqui generally appears to have been smoked prior to the introduction of tobacco (Hartwich 1911, 48, 523*):

According to Ochsenius [1884], the Chonos (sic) Indians on the island of Chiloe smoke the herbage of another nightshade known as *palquin* (*Cestrum parqui* L'Hérit.) when tobacco is lacking. It is possible that this is a remnant of a smoking custom that is older than [that of] tobacco. (Hartwich 1911, 48f.*)

Distribution

The plant is from central Chile but had spread as far as Peru, Argentina, Uruguay, and Brazil at an

early date (von Reis and Lipp 1982, 267*). In Chile, it occurs as far south as Osorno and Chiloé (Hartwich 1911, 523*; Montes and Wilkomirsky 1987, 164*). It has now been introduced into the Mediterranean region as well as California (Zander 1994, 179*).

Cultivation

Propagation is best achieved using seed. The plant is sometimes grown as an ornamental.

Appearance

The bush, which can grow as tall as 1.5 meters, has narrow, lanceolate, pale green leaves. The yellow, tubular, five-pointed flowers are located in panicles or clusters at the ends of the branches. In South America, the flowers bloom in October and November, and they exude a strong, inebriating scent. The plant produces small, oval-round berries (approximately 5 mm in length) that take on a shiny black color as they mature.

The palqui bush is easily confused with *Cestrum aurantiacum* Lindl. Other similar species include *Cestrum elegans* (Brongn. ex Neum.) Schlecht., *Cestrum ochraceum*, and *Cestrum laevigatum* Schlecht. (Roth et al. 1994, 209*).

Psychoactive Material

—Leaves

—Bark

—Wood

Preparation and Dosage

The leaves of *Cestrum parqui* are dried, chopped, and smoked alone or in **smoking blends**, e.g., with ***Cannabis sativa***. Three or four leaves per person is a good starting dosage. The leaves are an ingredient in psychoactive fumigations using ***Latua pubiflora*** (cf. also **incense**).

A decoction of leaves and bark or a bark tea (infusion) is drunk for folk medicinal purposes.

In Brazil, the dried leaves of the closely related species *Cestrum laevigatum* Schlecht. are known as *maconha* and are smoked as a marijuana substitute (Schultes and Hofmann 1992, 38*).

The willow-leaved jessamine (*Cestrum parqui*) in blossom.

This delicate jessamine (*Cestrum elegans* (Brongn. ex Neum.) Schlechtend. [syn. *C. purpureum* (Lindl.) Standl.]) is from Mexico. Like many other *Cestrum* species, it contains psychoactive and toxic constituents.

Ritual Use

In southern Chile, this sacred plant is used in shamanic healing activities. The plant possesses the

virtue or power known as *contra*, which resists attacks by sorcerers or black shamans (*tué-tué* or *chonchones*). Since illnesses are often produced by other shamans, they can best be healed by a shaman with the aid of palqui. The stems are used to make wooden crosses that are attached to the windows or outer walls of houses as a magical protection against disease demons. A tea also protects from *susto* (“fright”) and *mal de ojo* (“evil eye”) and is drunk during purification ceremonies (*limpia*) (Hoffmann et al. 1992, 172*).

The shamans of the Kamsá (Sibundoy, Colombia) refer to one *Cestrum* species as *borrachero andoke*. They press the leaves of the plant in water and drink the resulting solution so that they can see things as if under the influence of **ayahuasca** (Schultes and Raffauf 1991, 36*).

Artifacts

The stems are made into wooden crosses and amulets.

Medicinal Use

The Mapuche of southern Chile drink an infusion of the leaves to treat smallpox, tuberculosis, and leprosy; to treat herpes, to wash out wounds (Houghton and Manby 1985, 99f.*); and also to treat fever (Montes and Wilkomirsky 1987, 164*; Schultes 1980, 114*). A tea or decoction of the bark is ingested as a powerful analgesic and sleeping agent (Hoffmann et al. 1992, 171f.*). The leaves and the freshly pressed juice of the plant are used especially in the treatment of ant bites. In Chile, it is said that “wherever the devil has put ants, there God has planted a palqui tree” (Mösbach 1992, 105*). In the Andes, the leaves are used primarily to treat wounds (Bastien 1987, 116f.*).

The Colombian Sibundoy Indians drink a tea prepared from the closely related species *Cestrum ochraceum* Francey [syn. *Cestrum ochraceum* var. *macrophyllum* Francey] to treat headaches, pain, swelling, fever, and rheumatism (Bristol 1965, 267*). It is said that the patient will fall into a mild state of delirium if he drinks (too much) of the tea (Schultes 1981, 34*; Schultes and Raffauf 1991, 36*). In Brazil, *Cestrum laevigatum* is used as a sedative (Frerichs, Arends, Zörnig, *Hagers Handbuch* 1980, 820*). On the Brazilian coast, the leaves are smoked as a marijuana substitute (cf. ***Cannabis indica***) (Schultes 1979b, 151*).

Constituents

Cestrum parqui contains solasonine, a glycosidic steroidal alkaloid, and solasonidine (Montes and Wilkomirsky 1987, 164*; Schultes 1979b, 151*). The bitter alkaloid parquine has the empirical formula $C_{21}H_{39}NO_8$ and produces effects like those of **strychnine** or **atropine** (Roth et al. 1994, 209*). A triterpene and fitoesterol are also present. The leaves and fruits contain tigogenin, digallogenin, digitogenin, and ursolic acid (Montes and Wilkomirsky 1987, 164*). The fruits contain at least three alkaloids. Solasonine is the primary active constituent (Hoffmann et al. 1992, 172*). The alkaloid is found in the leaves as well as the wood (Hartwich 1911, 523*).

Cestrum parqui and *Cestrum laevigatum* contain gitogenin and digitogenin.

Effects

Pharmacologically, the extract has an atropine-like effect (Montes and Wilkomirsky 1987, 164*; cf. **atropine**).

Smoking *Cestrum parqui* leaves produces effects that are clearly psychoactive and are reminiscent of the effects of smoking ***Brugmansia*** leaves. However, no dryness of the mouth occurs. The effects are relatively weak and are perceived as a mild euphoria and physical relaxation.

Commercial Forms and Regulations

In Chile, the dried leaves are available at most herb stands and in shops that sell natural medicines. Apart from this, the plant is not sold.

Solasonine

The dried leaves of *Cestrum parqui* can be smoked as a mild inebriant.

A cultivated variety of jessamine, known by the name *Cestrum rubrum*. It also contains psychoactive constituents.

The fruits of *Cestrum rubrum*.

Literature

See also the entry for *Cestrum nocturnum*.

Cinnamomum camphora (Linnaeus) Siebold

Camphor Tree

Family

Lauraceae (Laurel Family); Subfamily Lauroideae, Cinnamomeae Tribe, Cinnamominae Subtribe

Forms and Subspecies

Distinctions were previously made among different forms, varieties, and even species that are now understood simply as chemical races (Morton 1977, 103f.*). The variety *Cinnamomum camphora* var. *linaloolifera*, which is especially rich in sesquiterpenes, is still important. Most of the distinctions are geographical in nature (Chaurasia 1992, 896):

Cinnamomum camphora ssp. *formosana* (Taiwanese camphor)

Cinnamomum camphora ssp. *japonicum* (Japanese camphor)

Cinnamomum camphora ssp. *newzealandae* (New Zealand camphor)

Synonyms

Camphora camphora Karst.

Camphora officinarum Nees

Cinnamomum camphora Fries

Cinnamomum camphora (L.) Nees et Eberm.

Cinnamomum camphora Presl et Eberm.

Cinnamomum camphoriferum St. Lag.

Laurus camphora L.

Laurus camphorifera Salisb.

Persea camphora Spr.

Folk Names

Alcanfor (Spanish), baum-camphera, borneo-campher, borneo-kampfer, camfora (Italian), campherbaum, camphero, camphor laurel, camphor tree, camphre, camphrier du japon, chang (Chinese), chang-shu, cusnocy (Old Japanese), cutakkarpuram (Malay), gaara-boon (Tai), ga bur (Tibetan), gaburi (Mongolian), gum camphor, japaansche kamferboom (Dutch), kafr (Czech), kamfer, kamferboom (Dutch), kámforfa (Hungarian), kampferbaum, kampferlorbeer, kanfur (Arabic), kapor, kapur, kâpûr, karpura, karpurah (Sanskrit), karpuram (Tamil), kuso-noki (Japanese), laure à camphre, laurocanfora (Italian), re

History

In China and Japan, camphor has been obtained from the camphor tree since at least the ninth century C.E. (Morton 1977, 105*). In Asia, camphor has been a much praised aphrodisiac⁹⁸ and remedy since ancient times (Warrier et al. 1994, 2, 81*).

Arabs were using camphor as early as the eleventh century for all types of medical purposes (Bärtels 1993, 123*). The first camphor tree was brought to Europe in 1676 and planted in Holland (Morton 1977, 103*). Since 1910, camphor has been produced synthetically in Germany from α -

pinene (turpentine). In the Roaring Twenties, camphor often was used as an inebriant.

Distribution

The tree is indigenous to India, China, and Formosa (Taiwan). From there, it spread throughout the tropical zones of Southeast Asia. In the Mediterranean region, it is even grown as an ornamental (Bärtels 1993, 123*).

Cultivation

The camphor tree can be propagated from seed, cutting, scion, or rootstock. Cuttings that contain high amounts of camphor rarely develop roots on their own. The tree is usually grown from the seeds of twenty- to twenty-three-year-old mother trees. The seeds of younger trees are infertile. Seeds will germinate only when fresh, and only a very few of the planted seeds do so. The germination period is approximately ninety days. When the seedlings are six months old, they are trimmed for the first time and transplanted (Morton 1977, 104*). Trees that are older than thirty years yield the most camphor.

In the tropics (Sri Lanka, India), the tree thrives best at altitudes between 1,220 and 1,800 meters when precipitation is between 114 and 368 cm per annum.

Most commercial camphor tree plantations are on Taiwan, but there are others in India and in the Republic of Georgia (Morton 1977, 103*).

Appearance

This evergreen tree can grow as tall as 50 meters. It develops a gnarled stem (up to 5 meters in diameter) and a projecting crown. It has long-stemmed, leathery, smooth, oblong leaves that are shiny green on their upper surface and dull blue-green on their underside. When young, the leaves often have a reddish color. When rubbed, the leaves smell strongly of camphor; this is the most reliable method for identifying the tree. The greenish white flowers are small and rather inconspicuous. They form axillary panicles 5 to 7 cm in length. The fruits are small, one-seeded berries surrounded by a calyx (Chaurasia 1992, 896).

Because of its habitus, the tree is easily confused with the true or Ceylon cinnamon tree (*Cinnamomum verum* Presl [syn. *Cinnamomum ceylandicum* Bl.]). However, the leaves of the cinnamon tree smell (almost exaggeratedly) of cinnamon when they are rubbed. The genus *Cinnamomum* encompasses approximately 150 to 200 species, most of which occur in eastern Asia. Many of these resemble the camphor tree (Bärtels 1993, 123*; Chaurasia 1992, 884).

Botanical illustration of the Southeast Asian camphor tree *Cinnamomum camphora*, previously known as *Camphora officinarum*. (Engraving from Pereira, *De Beginselen der Materia Medica en der Therapie*, 1849)

Psychoactive Material

- Leaves
- Fruits (fructus camphora)
- Camphor (camphora; depositum in the oil cells, Japanese camphor)
- Camphor tree oil (cinnamomi camphorae aetheroleum, oleum camphorae, oleum cinnamomi camphorae, camphor oil, huile de camphre)

The so-called Borneo camphor (also known as *kapur*) is from the stock plant *Dryobalanops aromatica* Gaertn., a member of the resin-producing family Dipterocarpaceae. The odoriferous substance borneol is distilled from its wood. Crystals of pure camphor sometimes crystallize out of its trunk (Martin 1905).

There is also a safrole camphor (cf. *Sassafras albidum*) and a parsley camphor (= apiol; see *Petroselinum crispum*).

Preparation and Dosage

Actual camphor is obtained by careful distillation from small pieces of the wood. It crystallizes out and is ready to be used.

The information concerning dosages for internal use varies. Up to 10 g is said to produce pleasant inebriating effects. However, reactions differ from person to person⁹⁹: “Serious toxic effects occurred as a result of ingestion of 10 to 20 g of camphor; lethal poisoning from 6 g sub-cutaneous” (Fühner 1943, 237*).

In India and Nepal, camphor (*kapur*) is used primarily as a stimulating additive to **betel quids** and as an ingredient in **incense**.

The most important Japanese incense mixture for Buddhist services and ceremonies consists of five or seven coarsely chopped ingredients. The proportions can be varied as desired, so new scent

compositions are constantly being produced (cf. **incense**). The *shokoh*-5 mixture is a combination of:

Aloe wood	<i>Aquilaria agallocha</i>
White sandalwood	<i>Santalum album</i>
Cloves	<i>Syzygium aromaticum</i>
Cassia cinnamon	<i>Cinnamomum aromaticum</i>
Camphor	<i>Cinnamomum camphora</i> ssp. <i>japonicum</i>

The *shokoh*-7 mixture consists of the same five substances plus ginger (*Zingiber officinale*) and amber (Morita 1992).

The leaves of the Cambodian camphor tree (*Cinnamomum tetragonum*) are made into a stimulating drink (von Reis Altschul 1975, 78*).

Ritual Use

In Japan, camphor is an important ingredient in ritual **incenses**. It is also one of the most important incense materials in the traditional Tibetan Tantra cult (Yeshe Tsogyal 1996) and has enormous ritual significance, especially in southern India. In the region of Nordarcot is a sacred mountain known as Arunachala, “red mountain,” which is said to be hollow inside and inhabited by beings with extraordinary spiritual abilities. A large temple at the mountain is dedicated to a goddess of the same name:

Once a year, the priests celebrate her great festival. As soon as it begins in the temple, a gigantic flame is lit on the peak of the mountain [and] is fed by great quantities of butter and camphor. It burns for days and is visible for miles. (Brunton 1983, 153)

This cult is closely associated with Shiva, the god of ecstasy and inebriants, to whom camphor is also sacred:

According to our sacred legends, the god Shiva once appeared as a fiery flame at the peak of the sacred red mountain. For this reason, once a year the priests of the temple light the great fire to commemorate this event, which must have occurred thousands of years ago. I assume that the temple was built for this festival, as Shiva still protects the mountain. (Brunton 1983, 165)

In Varanasi (= Benares), Shiva’s sacred city, there is a shrine to Krishna in which a golden statue of the young god and lover is venerated. Offerings include flowers (e.g., *Cestrum nocturnum*), fruits (thorn apples; cf. *Datura metel*), and dyes. The incense that is burned at this site is camphor (Brunton 1983, 217).

In Malaysia, Borneo camphor had a ritual and magical significance for the indigenous Malay people:

Along with the Hantu belief and the conception that things in nature could be charmed was a peculiar custom which, however, was found only among the Jakun and was known only by the name camphor language (Bhasa Kapor). The natives used the term “pantang kâpûr” (Malay, “pantang” = forbidden) for this, which expresses the fact that it is forbidden to use the normal Malay language while they are searching for camphor. . . . In fact, the Jakun believe that a “bisân”

["woman"] or spirit watches over the camphor trees [*Dryobalanops aromatica*] and that it is impossible to obtain camphor before a person has made her kindly disposed to them. During the night, it gives off shrill sounds . . . , and this is evidence that camphor trees are near. To placate the camphor spirit, the Jakun give it a part of their food before they themselves eat . . . , eat some soil, and utilize the special language. . . . (Martin 1905, 972 f.)

Since the beginning of the twentieth century, reports of the psychoactive use of camphor have increased:

Indeed, since about two decades one encounters in the upper circles of English society camphor eating men and women, who ingest the agent in milk, alcohol, pills, etc. The same can be found in the United States and in Slovakia. Women maintain that it gives them a fresh complexion. But the true motive appears to be that they achieve a certain state of excitation or inebriation that admittedly, it seems to me, requires a special deposition. (Lewin 1980 [orig. pub. 1929], 302*)

Today, camphor is used in Amazonia by mestizo shamans in connection with **ayahuasca**.

Artifacts

In Japan, the aromatic camphor wood is carved into ritual masks, e.g., of *tengu* (see *Amanita muscaria*, **ibotenic acid**) for the *gagaku* dance festivals (since the second century).

Medicinal Use

Since very early times, the camphor tree has been one of the most important medicinal plants in the Chinese materia medica. In Chinese, the white, aromatic camphor resin is known as *long nao xiang*, "dragon brain."¹⁰⁰ The Yellow Emperor used it as a remedy for headaches and hemorrhoids:

We do not know whether the congealed camphor reminded them of a brain and was ascribed to the king of animals because it was so rare and precious, or whether the name is derived from the fact that camphor was reserved for the emperor, the "dragon." (Fazzioli 1989, 23)

In China and Tibet, the camphor tree was long regarded as the "king of far eastern medicinal plants," for "camphor is comparable to a 'wild man' (Yeti, the snow man of the Himalayas)" (Kaufmann 1985, 106*). In Nepal, camphor is used as a stimulant, vermifuge, and digestive agent (Singh et al. 1979, 188*).

In Ayurvedic medicine, camphor is prescribed for inflammations, heart weakness, coughs, asthma, spasms, flatulence, diarrhea, and dysentery (Warrier et al. 194, 2:81*). Camphor is often administered as a sedative, to cool off, so to speak, and for hysteria and nervousness:

Camphor increases *prana*, opens the senses, imparts clarity to the mind. . . . A pinch of camphor powder is sniffed when the nose is congested, for headaches, and to increase perception. During a *puja*, a religious service, camphor is burned as incense in order to purify the atmosphere and promote meditation. . . . To treat the respiratory tract, an infusion of camphor can also be boiled and the fumes inhaled. For internal use, only raw camphor should be used, not the synthetic camphor that is frequently sold in stores. (Lad and Frawley 1987, 179f.*)

In Western medicine, camphor is highly important in the treatment of coughs and colds and well as fits of shivering (Morton 1977, 106*; Pahlow 1993, 388*). In homeopathy, camphora is used in accordance with the medical description for such ailments as colic and spasms (Roth et al. 1994,

233*).

Constituents

All parts of the plant contain camphor oil and **essential oils** with sesquiterpenes (campherenone, campherenol, camphor derivatives); the white substance camphor (empirical formula $C_{10}H_{16}O$) is precipitated from this. The amount of camphor can vary considerably. The leaves of Indian camphor trees contain 22.2% camphor.

The composition of the essential oil is complex and varies according to location, climate, et cetera; azulene, bisabolone, cadinene, camphene, α camphorene, carvacrol, cineole (main component), π -cymol, eugenol, laurolicsine, Δ -limonene, orthodene, α -pinene, reticuline, safranal, safrole, salvene, and terpineol are some of the substances that have been identified. Safrole is often present in great quantities, and large amounts are contained in the wood. The highest concentrations of safrole are found in the roots (Morton 1977, 104*). The leaves also contain large amounts of safrole (cf. *Sassafras albidum*) (Chaurasia 1992, 896).

The heartwood of the stem contains sesquiterpenes and cyclopentenones (Takaoka et al. 1979). The alkaloids laurolicsine and reticuline are present in the roots (Chaurasia 1992, 896). The seeds contain primarily laurine and an oil whose composition is the same as that of coconut oil (cf. *Cocos nucifera*). The entire plant contains traces of caffeic acid, quercetin, camphor oil, and leucocyanidin (Chaurasia 1992, 896).

Effects

In the medical and toxicological literature, one repeatedly reads that high dosages of camphor can induce hallucinations (Morton 1977, 107*):

“Because the [camphor] tree can become several hundred years old and develop into an immense tree, it enjoys special veneration in China and Japan.”

ANDREAS BÄRTELS

FARBATLAS TROPENPFLANZEN [COLOR ATLAS OF TROPICAL PLANTS]

(1993, 123*)

“The king washed the jewel in purifying water, attached it to the top of a victory banner, enveloped it in the aromatic smoke of camphor and sandalwood, and spread an immeasurable series of offerings out in front of it. He then bathed, put on clean garments, and, after paying his respects to the gods of the four directions, spoke the following prayer: If this incomparable jewel that I have found truly is the perfect and precious wish-fulfilling jewel, so may everything humans and other beings wish for fall like a blessing rain!”

YESHE TSOGYAL

DER LOTUSGEBORENE IM LAND DES SCHNEES [THE LOTUS-BORN IN THE LAND OF SNOW]

(1996, 39f.)

Camphor

After ingestion of app. 1.2 g, the following can appear: a pleasant feeling of warmth of the skin and a general stimulation of the nerves, a need for movement, a tingling in the skin, and a peculiar, inebriation-like, ecstatic, mental excitement. “According to one such self-experimenter, the effects were clear and obvious with tendencies of the most beautiful kind.” This condition lasted for one and a half hours. After ingestion of 2.4 g, a need for movement was felt. All movements were easier. When walking, the thighs were raised higher than usual. Mental work was impossible. A flood of thoughts occurred, one idea wildly followed another, quickly, without one persisting. *The consciousness of the personality was lost.* (Lewin 1980 [orig. pub. 1929], 302f.*)

The inebriating effects of camphor are often compared to those of **alcohol**:

Following ingestion of larger amounts of camphor, nausea and vomiting can quickly remove the greatest part of the substance. When resorbed, mild toxic effects include central stimulation, dizziness, headache, a state of inebriation like that produced by alcohol, with sensory delusions and delusional ideas; kidney irritation occurs, rarely hematuria. With frequent use of camphor, “camphor addiction” can develop. (Fühner 1943, 237*)

Commercial Forms and Regulations

Since camphor is relatively easy to synthesize, pharmacies now offer almost only synthetic camphor (*Camphora synthetica* DAB 8). It is an open question as to whether this has the fine qualities of the natural product. In spite of its name, the so-called camphor oil available in pharmacies has had all of its camphor removed.

Shiva is the god of ecstasy and psychoactive plants. Here, he is shown inhaling the smoke of a sacred incense. Shiva is particularly fond of the psychoactive camphor. (Hindu devotional picture, detail; India)

“In Spain, the children carry a small linen sack containing camphor to ward off the evil eye. . . . In India, the child is bathed in smoke to protect against the evil eye. When a newly married Tamil couple returns from their procession through the streets, during which they are exposed to the looks of the crowd, a vessel is filled with camphor and pepper [***Piper spp.***], the camphor is lit, and the vessel with the burning camphor is swung around the heads of the newlyweds. . . . If a child in India has become ill as a result of the evil eye, then a piece of burning camphor is waved before him. If a Jewish child has developed a stomachache, headache, or fever because of the evil eye, or if a singer has suddenly become hoarse, then some camphor is placed before the door of the house and ignited, if the cattle have become ill from the evil eye, then camphor is burned in front of them.”

Cocos nucifera Linnaeus

Coconut Palm

Family

Palmae (Palm Family) (previously Arecaceae)

Forms and Subspecies

Numerous varieties and cultivars are grown in the tropics and subtropics (Stewart 1994, 88*). There are cultivars for ornamental purposes that have only a short trunk and develop inedible, small yellow fruits. One variety with green fruits is known as *Cocos nucifera* var. *viridis*. Only the tall-growing varieties (*Cocos nucifera* var. *typica* Nar.) are easily distinguishable from the dwarf forms (*Cocos nucifera* var. *nana* [Griff.] Nar.) (Franke 1994, 240*).

Synonyms

Cocos butyraceum

Cocos nana Griff.

Folk Names

Coconut, coconut palm, coco nut tree, coco palm, cocotero (Spanish), cocotier (French), cocus, dab (Bengali), green gold, ha'ari, hach kokoh, khopra (Hindi), kôkô, kokoh, kokosnußpalme, kokospalme, kuk, kuk-anâ (Ka'apor), mabang, mbang ntnag, naral (Marathi), narial (Hindi), narikela, narikelamu, narikera, nariyal (Sanskrit), narkol (Bengali), niu (Samoa), obi, ogop, palmeer-baum, palmenbaum, pol, suphala (Sanskrit), tenga, tengu (Kannada), tenkai, tennaimaram (Tamil), thengu, thenna (Malayalam)

In Europe, the coconut palm (*Cocos nucifera*) is regarded as a symbol of the tropics.

The coconut palm produces the inebriating palm wine in the interior of the young leaf shoots. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Coconut trees have been used culturally in India for three thousand to four thousand years. They first appear in European literature in the sixth century and became an officinal agent in Europe with the adoption of Arabic medicine (Schneider 1974, 1:341*). They were known by the names *nucēs indicae*, *carya indica*, and *Indian nut*. The name *cocos* means “grimace” and was given to the palm by the Spanish because of the “eye” where the nut is attached to the fruit (Bremness 1995, 49*).

In the older literature, the coconut palm was often characterized as “the most useful of all trees” because every part of it can be utilized (Meister 1677, 43*). This palm is a source of food, medicine, fibers, copra, and other raw materials as well as various inebriating beverages. **Palm wine** was even mentioned in ancient Sanskrit literature.

Culturally and economically, the coconut palm is one of the most important plants of the tropics. Coconut oil provides 8% of the world’s oil and fat supply. The oil is used to make a variety of products, including margarine (Udupa and Tripathi 1983, 64).

Distribution

Now pantropical, the coconut tree apparently came from Asia or Melanesia (Zander 1994, 194*). However, there were already coconut trees in Colima (Mexico) when the first Europeans arrived there (Dressler 1953, 129*).

Coconut trees represent the typical vegetation associated with the beaches of the islands of the Indian Ocean, India, Southeast Asia, Central and South America, the Caribbean, and Melanesia.

Cultivation

The natural propagation and distribution of coconut palms occurs through the coconuts, which fall into the water, are carried away, and are then washed up in suitable locations. The palm thrives in sand, preferably at or near the beach; it can tolerate up to 1% salt in the groundwater. For cultivation, the fruits can be laid out (in areas rich in rain, under a roof) with the narrow side facing down. Up to half of the coconut can be lightly buried in sand. After four to five months, the fruit will have developed roots and formed a shoot. After six to twelve months, the seedling can be planted in the desired location. The germination period can be shortened by wrapping the coconut in a plastic bag left somewhat open at the top (Rehm and Espig 1996, 87f.*).

Appearance

The slender, slightly leaning coconut palm can grow up to 30 meters in height. It develops pinnate leaves that can be as long as 6 meters. It has cream-colored panicles and large, solitary fruits (coconuts) that hang in thick clusters between the leaf stalks.

The coconut palm can be easily confused with the king coconut (*Cocos butyracea*), assuming that this is in fact a separate species.

Psychoactive Material

—Coconut

—Coconut milk (coconut water)

—Bleeding sap (toddy); **palm wine** (suri, tuaco, vino de coco)

Preparation and Dosage

The first detailed discussion (1677) of the manner in which **palm wine** is obtained from the coconut palm provides a precise description of the method that is still used throughout Southeast Asia and on the islands of the Indian Ocean:

Now follows the usefulness of the noble palmeer wine. . . . This wine, which is the juice of this tree, is called major by the inhabitants of Java, tuaco by those of the Malabars, and surii by the Dutch, and is tapped from the tree in the following manner: While the flower is still growing, one cuts the same at the front with a broad knife made for this purpose and places such shortened little branches in a piece of bamboo (this bamboo is a hollow tube almost as wide as a leg, which the inhabitants of India generally use to build their houses) or in a narrow pot, open at the top, which is standing in the sun. When they are visited by their warders, also known as divitores, [they] . . . use several steps that have been chopped in to climb quickly up. They pour the sura into a pober or Indian gourd attached to their persons at least twice every 24 hours, that is, early for what was collected during the night, and evenings, for what was collected during the day. . . . This sura or juice, when drunk immediately while fresh, is delicious and good and sweet beyond measure, especially that which comes from those grown around Cannanor or in the Kingdom of Calicut, on the coast of Cannera and Malabar, which tastes quite agreeable, almost as sweet as a newly pressed cider. But if you drink a little too much of this, you will very easily get drunk from it. (Meister 1677, 49*)

As a result of fermentation and enzymatic processes, palm wine changes considerably during the course of a single day:

The palm wine that is collected in the morning tastes like sweet cider until about 10 o'clock, however with the oily aftertaste of the coconut, it then begins to ferment and at around 12 o'clock foams over the edge of the bottle or bamboo vessel in which it is being kept in the open. In the evening, toward 3 o'clock, it is then an inebriating drink, a "fire water," as the natives call it. . . . If the palm grower wishes to hinder the fermentation, he takes some calcium from shells and mixes this into the palm juice. (Schröter, in Hartwich 1911, 627*)

If the palm wine is allowed to stand for a longer time, it ferments into palm vinegar. Production of the bleeding sap can be stimulated and increased by hitting the inflorescence with a special wooden stick or bone.

The alcohol that is distilled from the flower sap (*toddy*, *tonwack*) is known as *arrak* (Fernando 1970). On the Marquesas Islands, fermented coconut milk is distilled into a type of brandy (**alcohol**). On Rennel Island, one of the southernmost of the Solomon Islands, a drink obtained from coconuts is known as *kava kava ngang*i. In spite of its name, the drink contains no *Piper methysticum* (Holmes 1979).

Coconut flakes are an ingredient in **betel quids** as well as **Oriental joy pills**.

Ritual Use

In India, coconuts are thrown into the sea as offerings to placate the spirits of the monsoon. In Gujarat, the palm is venerated as a familial deity. Muslims toss pieces of coconut and limestone over the heads of newlyweds to dispel evil spirits. The Bengalis believe that coconuts have eyes and are able to see if someone is lying beneath the palm so they will not fall on that person's head (Gandhi and Singh 1991, 65*). Because coconuts are as large as a person's head, they are offered to the bloodthirsty goddess Bhadrakali ("auspicious black [goddess]"), a terrifying manifestation of Shiva's wife Parvati, in place of real human sacrifices (Gandhi and Singh 1991, 66*).

The Yoruba of Africa believe that at the beginning of creation, the coconut was a pure, loving, and virtuous person who was later transformed into the plant. For this reason, the palm is a sacred tree that is venerated and respected.

Coconut palm wine enjoys great ritual significance, especially in western New Guinea but also in other areas: “Drinking palm wine is part of certain idolatrous ceremonies, but in private life the palm wine drinkers are despised and are not as common as the habitual drunkards are among us” (Schröter, in Hartwich 1911, 627*).

For more on ritual use, see **palm wine**.

Artifacts

In Southeast Asia, coconuts are made into boxes for tobacco snuff (Meister 1677, 48*). In Oceania, half shells were and still are used to manufacture vessels for drinking kava (cf. *Piper methysticum*).

The wooden beating sticks—called *pudscha*—that were used to stimulate juice production were regarded as idols and venerated accordingly (Hartwich 1911, 627*).

Because the coconut palm is a symbol of tropical, South Seas romance, it is depicted on numerous pictures intending to invoke such an ambience. It is possible that there are art objects that were inspired by the use of coconut palm wine, but there are no reports about this.

Medicinal Use

On Samoa, the coconut is used in a multitude of ways as a remedy for stomach problems, constipation, open wounds, puerperal fever, gonorrhea, inflammations, eye ailments, problems associated with pregnancy, and stings by the very poisonous stonefish (*Synanceja* spp. and others) (Uhe 1974, 6f.*). It is used in similar manners in the folk medicine of other South Pacific islands. In Polynesia, coconut milk is used as a solvent for medicinal herbs (Whistler 1992, 82).

In India (Karnataka), a tea made from the tender flower buds is drunk every morning for three days to balance out all menstrual irregularities (Bhandary et al. 1995, 157*). The oily exudation of heated coconut shells is used in Ayurvedic medicine as a treatment for parasites (Venkataraman et al. 1980). Coconut milk is prescribed for gastritis, stomach ulcers, and heartburn (Udupa and Tripathi 1983, 64).

On the Malay Peninsula, the ground root is administered as an antidote for poisoning with *Datura metel* (Perry and Metzger 1980, 304*).

The Fang of Central Africa use the bark to obtain a medicine to treat toothaches (Akendengué 1992, 169*).

The use of coconut flakes and meat as aphrodisiacs^{[101](#)} and as treatments for venereal diseases is widespread. In Indonesia, coconut shells are burned and the ashes mixed with **wine** to treat syphilis (Perry and Metzger 1980, 404*). In Indonesia, a flaccid or sick “Venus rider” would dangle his damaged member through a hole in a fresh coconut and bathe it in the coconut milk to provide it with new vigor or to cure the venereal disease he had acquired (Meister 1677, 46*). In Islamic medicine, the penis is packed in a mush made from fresh coconut meat in order to give it new energy (Moinuddin Chishti 1984, 96*). In the Bahamas, the tender coconut flesh is mixed with nutmeg (*Myristica fragrans*) and ingested to heal “weakness” (Eldridge 1975, 314*).

Coconut oil, obtained from the dried endo-sperm of the seed, has great significance in the cosmetic industry.

“I [must] mention a kind of bat, which can easily grow as large as a proper, complete hen in its head and hair, long of mouth and short of ears, the wings, as smooth as those of our own bats, are as long as a fathom when you stretch them apart, the Dutch call them suiri-cats, the Portuguese murchsebes, and in the Malay language eansching duack. These monstrous bats, although very rarely seen, often came and hung with their sharp claws on the coconut tree leaves, from which the sura or palm wine is tapped, and inebriate themselves on this to such an extent that they would often remain the entire night until the sun had risen in order to get enough sleep, and could thus be encountered, and I brought down such a one with a good flint rifle, and my slaves then made themselves very merry when they ate this, and I too consumed it out of curiosity, as they are not poisonous but rather taste like the best chicken meat.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]
(1677, CH. 6, P. 3*)

Constituents

The plant contains an **essential oil**, wax, and oil. The bleeding sap, which ferments into **palm wine**, contains proteins, ashes, 15% sugar (saccharose), and enzymes (Perry and Metzger 1980, 304*; Rehm and Espig 1996, 74, 89*).

The milk of a still-green coconut fruit has been found to contain 1,3-diphenylurea, a compound that stimulates cellular growth (Wong 1970, 110*). Coconut flakes contain proteins, carbohydrates, and vitamin B complex.

Effects

Because of its low alcohol content, the **palm wine** obtained from the bleeding sap—even when consumed in large quantities—has stimulating, almost refreshing and invigorating effects that do, however, tend toward drunkenness. The effects of drinks fermented from the milk are different: “Fermented coconut milk has a high alcohol content: too much will result in toxic symptoms” (Udupa and Tripathi 1983, 64).

Commercial Forms and Regulations

Coconuts are available throughout the world wherever fruits and vegetables are sold. On the other hand, **palm wine** can be obtained only where it is made, as it is quite perishable. Arrak can be obtained throughout Southeast Asia but is only infrequently available in the West.

Coffea arabica Linnaeus

Coffee Bush

Family

Rubiaceae (Coffee Family); Subfamily Cinchonoideae, Coffeae Tribe

Forms and Subspecies

The variety *Coffea arabica* L. var. *abyssinica* A. Chev. (wild form) occurs in the mountain forests of Ethiopia. In principle, two varieties that were derived from early Arabic plantations are now under cultivation:

Coffea arabica L. var. *arabica* (= var. *typica* Cramer)

Coffea arabica L. var. *bourbon* (B. Rodr.) Choussy

A very large number of mutants and cultivated forms have been described. The following are of economic interest:

Coffea arabica L. cv. Caturra (stocky growth, productive)

Coffea arabica L. cv. Mundo novo (very good yield)

Coffea arabica L. cv. Catuai vermelho (red fruits)

Coffea arabica L. cv. Catuai amarelo (yellow fruits)

Coffea arabica L. cv. Mragogipe (gigantic form)

Coffea arabica L. cv. Mokka (very low growing)

The last of these cultivars, which is also known by the names *mokha* and *moka*, has also been described as a variety:

Coffea arabica L. var. *mokka* Cramer

Branch and “beans” (= seeds) of the coffee bush. (Copperplate engraving from Peter Pomet, *Der aufrichtige Materialist und Specerey-Händler*, Leipzig 1717)

Synonyms

Coffea laurifolia Salisb.

Coffea mauritiana Host. non Lamk.

Coffea vulgaris Moench

Jasminum arabicum laurifolia de Juss.

Folk Names

Arabian coffee, Arabica coffee, arabica-kaffee, arabischer kaffee, bergkaffee, bun (Yemen), buna (“wine”), buni (Ethiopian), cabi, café, caféier, cafeiro, cafeto, chia-fei (Chinese), coffa, coffee, coffee bush, coffee tree, common coffee, kaffeebaum, kaffeepflanze, kaffeestrauch, kahawa (Swahili), kahwa (Arabic), kahwe (Turkish), kahweh, k’hoxwéh (Navajo), koffie (Dutch), kopi, qahûa, qahwa (Arabic, “wine”), qahwe

History

Long before the first coffee was ever brewed, the berries of the coffee bush were being chewed in Africa for stimulating purposes (by about the sixth century). Coffee drinking was discovered long after khat chewing (see *Catha edulis*). The word *coffee* is sometimes derived from the Arabic word for wine,¹⁰² *gahwe*; but the Arabic name for coffee, *kahwa*, is more likely derived from the place-name Kafa (in Ethiopia). In Ethiopia, the story told to explain the discovery of coffee is almost identical to that told in Yemen to explain the discovery of khat. A goatherd watched as his goats scampered around excitedly after they had eaten from the coffee bush. He took some of the beans and gave them to the village priest, who then experimented with them until he experienced their stimulating power and was thus better able to recite the long prayers (Mercatante 1980, 171*). The first mention of coffee use in Yemen comes from the twelfth century (Meyer 1965, 137).

Coffee is highly esteemed among African Sufis, for it enables them to take part in their mystical rituals night after night without falling asleep and makes it easier for them to attain religious ecstasy. The Sufis and the wandering dervishes played a great role in the spread and popularization of coffee.

In the sixteenth and seventeenth centuries, coffee became known both in Europe and on the African Swahili coast (Sheikh-Dilthey 1985, 253). Coffee was enthusiastically received in Europe, where it was praised as a cure-all and used as an aphrodisiac (Müller 1981). The first complete botanical description of the plant was not made until the mid-nineteenth century (Meyer 1965, 142).

Today, coffee is probably the most commonly consumed stimulating beverage in the world (Morton 1977, 356*). As a result, the coffee bush is one of the most culturally important psychoactive plants that exist.

Because of its economic significance, coffee has often led to violent altercations and warlike actions. In the 1920s and 1930s, a veritable “witches’ war” broke out in Puebla (Mexico), during which over one hundred Nahuatl Indians lost their lives (Knab 1995*).

Distribution

The coffee bush apparently originated in Abyssinia, i.e., southwest Ethiopia (Schneider 1974, 1:343*). It is still indigenous to the region (Baumann and Seitz 1992, 927; Meyer 1965). Wild plants have also been observed in Sudan.

Cultivation

The coffee bush requires a tropical climate to thrive and does not tolerate frost. It must be raised in

partial or complete shade. Anyone who wants to grow the plant in the climate zone of central Europe must raise it as a potted plant or in a tropical greenhouse. The seeds are placed on peaty, sandy seed soil. They should be not covered with soil but, instead, gently pushed into the soil and kept continuously moist. The germination time is quite variable but usually requires between two and four weeks (at temperatures between 25 and 30°C). The germinated seeds or seedlings can be transplanted into a suitable pot. They should be fed frequently and well watered. In principle, sowing can be performed throughout the year, but because of the plant's biorhythms, it is best done between November and January. After a growing period of about three years, the plant produces its first fruits. These contain the coffee beans.

Coffee plantations are found in many tropical countries. Coffee is an economically important source of income for many so-called Third World countries. Outside of Africa, the most important coffee-growing regions are in Mexico (Chiapas), Guatemala, Nicaragua, Colombia, and Brazil. In tropical Africa, the closely related species *Coffea liberica* Bull. is grown as a source of coffee beans. Robusta coffee (*Coffea canephora*) is also cultivated on a large scale in Africa. *Coffea canephora* provides some 20% of the world's supply of coffee beans, while about 80% comes from *Coffea arabica* (Baumann and Seitz 1992, 928).

The seeds of the ripe fruits of the coffee bush (*Coffea arabica*) are referred to as coffee beans, even though the plant is not related to the Legume Family.

Appearance

The perennial coffee bush can grow to a height of about 4 meters. It is heavily foliated, with shiny leaves (6 to 20 cm long, 2.5 to 6 cm wide) that can persist for two to three years. The white, star-shaped flowers (calyx approximately 3 mm long) are in thick glomerules and exude a fine, delicious scent vaguely reminiscent of that of jasmine (*Jasminum* spp.). The green, oval fruits (berries) turn bright red when ripe (only the cultivar Catuai amarelo develops yellow berries).

The genus *Coffea* consists of some ninety species, many of which resemble the coffee bush. *Coffea arabica* is very similar to two tropical species, *Coffea congoensis* Froehn. and *Coffea eugenioides* S. Moore, and is easily confused with them (Meyer 1965, 138).

Other Coffea Species That Yield Coffee

Trade Name	Stock Plant
Congo Coffee	<i>Coffea canephora</i> Pierre ex Froehner [syn. <i>C. arabica</i> L. var. <i>stuhlmannii</i> Warb., <i>C. bukobensis</i> Zimm., <i>C. laurentii</i> De Wild., <i>C. maclaudii</i> A. Chev., <i>C. ugandae</i> Cramer, <i>C. welwitschii</i> Pierre ex De Wild.]
Robusta Coffee	<i>Coffea canephora</i> var. <i>canephora</i> [syn. <i>Coffea robusta</i> Lind.]
Nganda Coffee	<i>Coffea canephora</i> var. <i>nganda</i> Haarer [syn. <i>Coffea kouilouensis</i> Pierre ex De Wild.]
Liberian Coffee	<i>Coffea liberica</i> Bull ex Hiern

“Hot as hell, black as the devil, pure as an angel, sweet as love.”

A RECIPE FOR COFFEE

CHARLES MAURICE DE TALLEYRAND-PERIGORD
(1754–1838)

“If I am not allowed to drink my three little cups of coffee a day, then I become to my torment like withered-up goat meat.

Oh! How sweet does coffee taste,
more delightful than a thousand kisses,
milder than muscatel wine,
coffee, I must have coffee,
and if anyone would wish to refresh me
yes, then give me coffee.”

JOHANN SEBASTIAN BACH *SCHWEIGT STILLE, PLAUDERT NICHT*
[BE QUIET, STOP CHATTERING; THE COFFEE CANTATA, BWV 211]

TEXT: PICANDER [= HENRICI]

“I found out from a Sayha named Hâgga Fâyza that they both read the coffee grounds and then in a relaxed state allow two djinns to explain the meaning of the patterns and lines in the grounds and also use the dream oracle to receive information about their personal djinn servant.”

KORNELIUS HENTSCHEL *GEISTER, MAGIER UND MUSLIME* [SPIRITS, MAGICIANS, AND MUSLIMS]
(1997, 68)

Psychoactive Material

- Seeds (coffee beans, semen coffeae, coffeae semen, green coffee)
- Roasted coffee beans (coffeae semen tostae)

The roasted coffee beans must be kept well sealed, in the dark, and away from humidity.

Preparation and Dosage

After the ripe fruits (coffee cherries, coffee berries) have been harvested by hand, they are spread out in a layer 3 to 4 cm deep to dry in the sun. The drying fruits are raked often, sometimes several times a day. After three to four weeks, the fruits are completely dry. The beans now lie loosely in the fruit coat, which is then removed by rubbing with the hand or with machines (so-called hullers). To brew coffee, the seeds must be roasted. The green coffee beans are roasted for differing lengths of time and by different methods, either on clay or metal plates above a fire or with industrial machines. The roasting process gives the beans their aroma, an important factor in determining the market quality of the beans.

The roasted beans are coarsely ground and brewed for ten minutes in boiling water or boiled for several minutes in water. These methods are common in Africa and Scandinavia. More often, the roasted beans are ground and placed in a filter or a suitable coffee maker. Boiling water is then poured slowly over them.

A normal cup of coffee, brewed from 5 g of ground coffee and 300 cm³ of water, contains 70 to 80 mg of **caffeine** (Roth et al. 1994, 248*). Approximately 250 mg of caffeine is contained in a double espresso.¹⁰³ If the daily consumption of coffee is so great that a person is ingesting 1.5 to 1.8 g of caffeine daily, “caffeinism” may result (Baumann and Seitz 1992, 935). Still, some people are said to drink up to fifty cups of strong coffee daily. The French writer Voltaire was one such person (Huchzermeyer 1994).

In Africa, coffee is usually spiced with cardamom (*dawa ya chai*, “tea medicine”), and also with ginger roots (*Zingiber officinale*) when being made into medicinal drinks. In Africa, ten to twelve roasted coffee beans are brewed with water when the drink is intended for medicinal purposes. When the beans are chewed for medicinal purposes, children take one or two beans, while adults take from seven to fourteen beans (Sheikh-Dilthey 1985, 254).

The following ingredients are used to make a purgative that is administered on the day after giving birth:

- 5 cups of water
- “Very many” crushed coffee beans
- 2 betel leaves (*Piper betle*)
- 1 spoonful of dried dill herbage (*Anethum graveolens*)
- 1 teaspoon of Ajwan cumin (*Trachyspermum ammi* [L.] Sprague)
- 2 sticks of cinnamon (*Cinnamomum verum* Presl)
- 5 cardamom seeds (*Elettaria cardamomum* [L.] Maton)
- 5 cloves (*Syzygium aromaticum*)
- 2 teaspoons of molasses (from sugarcane)

All of the ingredients are chopped and boiled in the water. After filtering, about two cups remain (Sheikh-Dilthey 1985, 255).

In Ethiopia and other African countries, the dried and/or roasted leaves of the coffee bush may also be chopped and boiled in water. Milk is then added, and the product is drunk either sweetened or salted. In Ethiopia, an infusion of the leaves or fruit husks is known as *hoja* and is drunk with milk

(Wellman 1961).

A number of other stimulating plants are used as coffee substitutes, e.g., *Ilex guayusa*, but also the roasted seeds of *Abrus precatorius*. The roasted root tubers of chicory (*Cichorium intybus* L. var. *sativum* Lam. et DC.), which contain no stimulating or psychoactive constituents, are the source of chicory coffee (Rehm and Espig 1996, 255*). In Yemen and the surrounding countries, an infusion of dried khat leaves is used as a coffee substitute (see *Catha edulis*). Dandelion roots (*Taraxacum officinale* Weber), fig fruits (*Ficus carica* L.), sugar beet roots (*Beta vulgaris* L.), lupine seeds (*Lupinus* spp.), rye grains (*Secale cereale* L.), and barley grains (*Hordeum distichon* L.) are also used as coffee substitutes or counterfeits. Some *Psychotria* species are known by the name *wild coffee* and are said to have formerly been used in Jamaica and on other Caribbean islands as coffee substitutes.

Ritual Use

In East Africa, it is believed that spirits live in the coffee beans and that the beans therefore possess magical powers a person can draw upon through rituals and incantations. According to an Arab legend, the archangel Gabriel presented the first coffee to the ailing Muhammad for his recuperation (Brunngraber 1952, 128*). For this reason, coffee is sacred in Islam, and it is even used as a ceremonial drink. In Swahililand, copious amounts of coffee are drunk during all religious rites, at the evening readings of the Koran, and at the midnight worship services at the mosques (presumably so that people will not fall asleep during the sermons):

The greatest of the Islamic festivals on the Swahili coast is Maulidi al Nabi, the celebration of the prophet's birthday. . . . On this occasion, people of all ethnic groups gather in the bigger cities and take part in processions through the city that are led by groups of musicians singing religious songs in praise of Mohammed. When it gets dark, the processions meet in a great square in front of a mosque. In the light of the torches or light bulbs, wrapped in the scent of ubani (incense [cf. *Boswellia sacra*]), all of the praying people listen attentively deep into the night as the life story of Mohammed is recited in prose or poetry. As this is going on, spiced coffee is passed out and drunk by all who are present. (Sheikh-Dilthey 1985, 255)

The use of coffee to support prayers, meditations, and secret rituals was of great importance in many Sufi orders.

The customs associated with drinking coffee in Viennese coffeehouses also have a ritual character, though the coffee drinkers themselves do not usually regard them as rituals (Thiele-Dohrmann 1997; Weigel et al. 1978). In some circles, the magical use of coffee has been preserved in the form of reading coffee grounds, a traditional folk oracular method. For many Westerners, the act of preparing coffee in the morning has become a small, personal ritual that helps them prepare for the day. Many coffee drinkers are not “officially” available before they have had their morning coffee, i.e., coffee opens a person to the world. Afternoon coffee parties and coffee breaks at work also have a ritual and socio-integrative character.

Artifacts

As a stimulating and awakening work drug, coffee has certainly made an indirect contribution to the productive abilities of creative artists. Many musicians have been inspired by coffee. If the American composer Frank Zappa (1940–1993), whom many music lovers regarded as a psychedelic musician, is to be believed, coffee and cigarettes were his “basic food groups” and the foundation of his musical productivity. The greatest musical work devoted to coffee is the very worldly *Kaffeekantate* [Coffee Cantata] of Johann Sebastian Bach (1685–1750), which was composed to be played in coffee-

and teahouses as well as more traditional venues. The hymn “Cigarettes and Coffee,” by the rock bard Jerry “Captain Trips” Garcia (1942–1995) (featured in the soundtrack to the film *Smoke*, 1995), is quite well known, as is the crossover ballad “Caffeine” from the heavy metal band Faith No More (on the album *Angeldust*, 1992).¹⁰⁴

The recent anthology *Music for Coffeeshops* (Dreamtime Records, 1995), the maxi-single “Coffee Shop” (from the crossover band the Red Hot Chili Peppers, WEA, 1996), and the album *Locked in a Dutch Coffeeshop* (by Eugene Chadbourne and Jimmy Carl Black, ca. 1993) are referring not to true coffeehouses but to the renowned Dutch coffee shops in which hashish and other hemp products (*Cannabis indica*) are sold in a quasi-legal environment.

Medicinal Use

In Africa, roasted coffee beans are chewed to treat headaches, malaria, and general weakness (Sheikh-Dilthey 1985, 254). In Arabia, coffee grounds are eaten as a folk medicinal treatment for dysentery and applied externally to suppurating wounds and inflammations (Baumann and Seitz 1992, 930). Decoctions of roasted coffee beans are used in Haiti to treat hepatitis, liver ailments, edema, anemia, and conditions of weakness (Baumann and Seitz 1992, 934).

In the United States, paramedical circles have claimed that coffee **enemas**, administered every two hours, can heal cancer. This therapy is usually recommended to cancer patients by other cancer patients. This treatment is responsible for at least two deaths (Eisele and Reay 1980).

Botanical illustration of the coffee bush. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

In the seventeenth century, drinking coffee or tea was an enormously popular activity. Meetings, or lodges, clearly provided the ritual and collective space for a communal “inebriation” using stimulating beverages. (Copperplate engraving from *Die neueröffnete lustige Schaubühne menschlicher Gewohnheiten und Thorheiten*, Hamburg, 1690)

In homeopathic medicine, Coffea—Kaffee is an important agent obtained from a tincture of unroasted seeds (Schneider 1974, 1:245*). Preparations of roasted coffee beans (*Coffea arabica tosta hom. HAB1*) are also used in homeopathy, including for the treatment of neuralgia and sleep disorders (Baumann and Seitz 1992, 936).

Constituents

The green beans contain purine alkaloids. In addition to concentrations within a normal range of 0.58 to 1.7% **caffeine**, there are slight concentrations of theobromine (cf. *Theobroma cacao*), theophylline, paraxanthine, theacrine, liberine, and methylloberine. Also present are chlorogenic acids, in concentrations of 5.5 to 7.6%, of which 60 to 80% is 5-caffeoylquinic acid. A portion of the caffeine is bound to the chlorogenic acids. The beans contain approximately 16% coffee oil with diterpene alcohols. Coffee wax contains fatty acid derivatives of 5-hydroxytryptamine (Baumann and Seitz 1992, 931). Green coffee beans have also occasionally been found to contain concentrations of 3% caffeine (Roth et al. 1994, 248*).

Roasting the seeds has almost no effect upon their caffeine content, but the chlorogenic acids are reduced to about 10% of their original concentration. Roasting also creates new compounds, including nicotinic acid, 5-hydroxyindole, alkane, trigonelline, and polymer pigments, which are responsible for the brown coloration of the beans. The source of the characteristic coffee aroma, which plays such an important role in determining the commercial value, remains unknown. The average caffeine content of roasted coffee is around 1% (Baumann and Seitz 1992, 932 f.).

The red pigmentation of the fruits is the result of anthocyanins and the aglycone cyanidin. The hull (pulp) of the fruit contains large amounts of tanning agents (Baumann and Seitz 1992, 928).

Whether the leaves contain caffeine, other purines, or chlorogenic acids is unknown (Roth et al. 1994, 248*).

Effects

Coffee has strong stimulating effects and induces wakefulness, accelerates the pulse rate, and promotes perspiration. At a certain dosage, which varies from person to person and also depends upon the degree to which a person has become habituated to coffee, mental abilities are improved. Coffee often improves heart activity and urinary excretion. Very high dosages can produce profound disturbances in perception, trembling, nervousness, and sleep disturbances. The discussions about the

beneficial or harmful effects of coffee upon health are apparently not over and are constant subjects of the popular media and health advocates. The chlorogenic acids are responsible for coffee's "acid content"; in large quantities, they can make the stomach acidic, resulting in heartburn, stabbing pains, and, over a period of time, stomach ulcers (Roth et al. 1994, 248*).

A nutrition scientist has noted: "If we summarize the results of the rather comprehensive research into the acute effects of caffeine and the long-term effects of daily coffee, then coffee should be ranked among the most harmless of all drugs" (Huchzermeyer 1994).

Commercial Forms and Regulations

Viable seeds (in packages designed to prevent germination) are available in nurseries and seed stores. Coffee beans are subject only to the prevailing food laws. Various types of coffee are available; Colombian coffee, Turkish mocha, and Italian espresso are especially popular. Decaffeinated coffees, commercial goods that have been treated to remove the **caffeine**, are also offered.

Theobromine

Caffeine

Cola spp. (*Cola acuminata* and *C. nitida*)

Cola Tree

Family

Sterculiaceae (Cocoa Family); Sterculieae Tribe, Sterculiinae Subtribe

Forms and Subspecies

The two most important trees that provide cola nuts are so similar that they can be distinguished only on the basis of the structure of the nuts they produce:

Cola acuminata (P. Beauv.) Schott et Endl.—small cola tree

Characteristic:	Four- to six-part nut
Synonyms:	<i>Sterculia acuminata</i> Schott et Endlicher <i>Cola pseudoacuminata</i> Engl.
Variety:	<i>Cola acuminata</i> var. <i>trichandra</i> K. Schum.

Cola nitida (Vent.) Schott et Endl.—large cola tree

Characteristic:	Two-part nut
Synonyms:	<i>Cola vera</i> K. Schum. <i>Cola acuminata</i> Engl. <i>Cola acuminata</i> var. <i>latifolia</i> K. Schum. <i>Sterculia nitida</i> Vent.

Varieties: *Cola nitida* var. *alba* (white seeds/flowers)

Cola nitida var. *mixta*
Cola nitida var. *pallida*
Cola nitida var. *rubra* (red seed core)
Cola nitida var. *sublobata* (very large seeds)

Folk Names

Abata kola, abé, afata, ajauru, ajo pa, alie a uke, al mur, aloko, alou, ang-ola, apo, ashaliya, atara, ataras, atarashi, awasi, awedi, ballay cornu, b'are, 'bari, bar ni da mugu, bese, bese-fitaa ("white cola"), bese hene ("king's cola"), bese koko ("red cola"), bese kyem, bese-pa (Ghanese, "good cola"), besi, bichy nuts, bise hene, bise kyem, bise pa ("good cola"), bisi, bisihin, bisi tur, bissy, bitter cola, bobe, buesse, buessé, burduk'u, chigban, chousse, cola, colatier, cola tree, dabo, 'dan agyaragye, 'dan agyegye, 'dan badum, 'dan katahu, 'dan kataku, 'dan kwatahu, 'dan laka, 'dan richi, daushe, dibe, doe-fiah, ebe, ebi, e esele, egin-obi, ehousse, ehuese, ereado, erhesele, eseri, evbe

gabari, evbe gbanja, evbere, evbi, eve, evi, ewe, ewese, fakani, farafara, farsa, fatak, fecho, fetjo, gabanja, gandi, ganjigaga, gazari, ge, go, “nut”), godi (“tree”), godoti, gola, gonja, gooroo nuts, gor, gore, goriya, goro, gorohi, goron ‘yan k’asa, gotu, gotu kola, guere, guéré, guiti, guli, gura, gura nuts, guresu, gurésu, guro, gwanja, gwe, gwolo, hak’orin karuwa, halon, halou, hannunruwa, hapo, hure, huré, ibe oji, ibi, ibong, ihié, inkurma, jouro, kanu, kanwaga, kobe, kola, kolabaum, kolai, kola nut tree, kolaxame, ko-tundo, kui, kuruo, k’waryar goro, k’waryar yaraba, k’yank’yambishi, k’yanshe, labuje, labure, lou, maandin, mabanga, marsa, mbuesse, mbuessé, minu, na fo (“white cola”), nafo, na he (“red cola”), nahé, nata, ngoro, ntawiyo, ntawo, obi, obí (Yoruba),¹⁰⁵ obi abata, obi gbanja, obi gidi, oji, oji ahia, oji aniocha, oji anwe, oji inenabo, oji odi, oji ugo, ombene, oro, oue, oué, oure, ouré, sandalu, saran-waga, siga, suture, tino uro, togo, tohn-we-eh, toli, tolo, toloi, tshere, tugule, tugure, tugwi, tui, ture, tutugi, uro, vi, wa na, we-eh, we na, wé na, wobe ihie, wore, woroe, wuro, yétou

These folk names almost always apply to both *Cola* species (Ayensu 1978, 255*).

“To the extent that they have still preserved their own natural and cultural qualities, cola fruits and cola trees occupy a high position in profane and religious ceremonies of the populace. . . . The prophet is said to have rested under a cola tree and to have distributed cola nuts to his followers. . . . The thing with Mohammed is, of course, an unmitigated swindle, for the cola tree does not occur in Arabia or in East Africa, and the prophet was never in West Africa. . . . The Islamic missionaries played their part from an early date and surrounded the cola with mystical embellishments.”

RUDOLF SCHRÖDER

KAFFEE, TEE UND KARDAMOM [COFFEE, TEA, AND CARDAMOM] (1991, 116*)

Other *Cola* Species Used for Pleasure and Other Purposes

The genus *Cola* consists of fifty to sixty species, some of which have attained importance as agents of pleasure, medicines, or ritual drugs. In addition to *Cola acuminata* and *Cola nitida* (the most important members of the genus), the following species are also used. (From Seitz et al. 1992, 940.)

Name	Distribution	Use
<i>Cola anomala</i> K. Schum.	Cameroon	seeds chewed for pleasure
<i>Cola ballayi</i> Cornu ex Hekkel	Central and East Africa	seeds used in cult activities and for pleasure
<i>Cola cordifolia</i> R. Br.	Africa, Southeast Asia	seeds eaten, bark used as medicine
<i>Cola sphaerocarpa</i> A. Cheval.	Central and East Africa	seeds chewed for pleasure
<i>Cola verticillata</i> Stapf ex Cheval. (owe cola)	Congo, Ivory Coast	seeds used for pleasure

History

Indigenous to western Africa, the cola nut (*Cola nitida*, *Cola acuminata*) was originally reserved for the gods. During a visit to the earth, however, one of the gods left a piece behind and humans found it. Because of their stimulating powers, cola nuts were used for magic and as amulets and aphrodisiacs. Today, they still play a central role in the religious and social life of many West and Central African cultures.

Clusius provided the first description of cola in 1605. Europe first became aware of the cola nut in the second half of the sixteenth century. The first cola plantations were established in the West Indies around 1680 (Schröder 1991, 119*). Nevertheless, the stock plant long remained unknown (Schumann 1900). In 1865, the seeds were found to contain **caffeine** (Schneider 1974, 1:346*).

The original Coca-Cola was a potent psycho-tropic beverage made with an extract of cola nuts and

Coca leaves (*Erythroxylum novogranatense*).

Distribution

The genus *Cola* is originally from tropical West Africa. *Cola acuminata* is found from Togo to Angola, and *Cola nitida* from Liberia to the Ivory Coast and in Senegal and Nigeria. As a result of cultivation, both species have now spread into the tropical zones of the New World and Southeast Asia.

Cultivation

Propagation occurs using large, undamaged seeds from the center of the fruit. To germinate, the seeds are placed in well-moistened seedbeds or pressed directly into the ground; no other treatment is necessary. The seeds germinate after three to five weeks. The tree can also be propagated using cuttings taken from root shoots (Eijnatten 1981). The variety *Cola acuminata* var. *trichandra* K. Schum. is especially suitable for cultivation (Seitz et al. 1992, 941).

Cola is now also planted in the region of Bahia (Brazil) for use in the Afro-Brazilian Candomblé cult (Voeks 1989, 126*).

Cola trees require a moist, warm, tropical climate and thrive especially in rain forests. They prefer alluvial and humus soils.

Appearance

This evergreen tree, which can grow as tall as 25 meters, develops pale yellow, purple-striped flowers and star-shaped composite fruits with large, woody hulls. The alternate leaves of *Cola nitida* are shiny and light green in color, while those of *Cola acuminata* are leathery and dark green. The leathery/woody fruits (so-called follicular fruits) can weigh as much as 3 kg. Enveloped within a mucilaginous layer are the large (up to 3 cm) seeds, with two (*C. nitida*) or four to six (*C. acuminata*) seed leaves. These cola “nuts” turn reddish brown when they dry. In the tropics, *Cola* species bloom throughout the year, with the main flowering period occurring at the beginning of the rainy season.

The two species *C. acuminata* and *C. nitida* are easily confused with the tropical species *Cola quinqueloba* (K. Schum.) Garcke as well as with other *Cola* species.

Psychoactive Material

—Seeds (nuts, semen cola, semen colae, colae semen, cotyledones colae, embryo colae, nuces sterculiae, nux colae)

Preparation and Dosage

The cola nut is the dried seed heart that has had its hull, i.e., the seedling or embryo of the plant, removed. In the pharmaceutical trade, only the seeds of *Cola acuminata* and *Cola nitida* may be referred to as cola nuts (Seitz et al. 1992, 942).

The seeds are freed from the fruit by breaking open the follicles by hand. The white seed hull that they are attached to can be removed in various ways. The cola nuts may be soaked overnight in water, so that the swollen hulls can be pulled off the next day, or they may be allowed to dry in large piles for five to six days. As soon as the hull turns brown, it disintegrates. After this, the nuts need only be washed. Freshly harvested cola nuts are sometimes placed in a termite mound. The termites then eat the seed hull cleanly away but do not touch the cola nuts (Schröder 1991, 123*).

The rather low-growing cola tree (*Cola acuminata*).

The fruit of *Cola nitida*.

Botanical illustration of *Cola acuminata*. (From Meyers, 5th ed.)

Some of the bitter red and white seeds are chewed fresh (Bremness 1995, 50*), but most are placed in water (so that they will remain soft) or dried in the sun.

An average daily dosage is 2 to 6 g or 1 to 3 g three times daily (Seitz et al. 1992, 944). The nuts are also used to manufacture extracts, tinctures, and wine extracts. Depending upon the production method, these products can exhibit considerable variation in the amounts of active constituents they contain.

Ritual Use

In West Africa and the Sahel zone, all of life is heavily shaped by the cola nut (Uchendu 1964), which represents the most important socio-integrative element. Cola nuts are offered to every guest as a gesture of respect and deference, they are presented to a lover as a token of one's feelings, they are exchanged at the end of business negotiations to seal the contract, and they are offered to the ancestors, orishas, spirits, and gods. The stimulating nuts are ingested at all social and religious events. They are chewed or given to others at burials, name-giving ceremonies, baptisms, and sacrifices. In the royal courts (e.g., in northern Ghana), all political meetings and discussions begin with a communal chewing of cola. The nuts are placed at forks in the road as protective amulets, they are given to lepers and beggars as gifts, they are handed to physicians and healers as a welcoming greeting, and they are given to soothsayers as payment for divinations (Drucker-Brown 1995).

The social meetings at which cola nuts are ceremonially distributed and communally consumed are strongly reminiscent of the manners in which *Catha edulis* is used in Yemen, *Erythroxylum coca* and *Erythroxylum novogranatense* in South America, *Ilex cassine* and *Ilex vomitoria* in southeastern North America, *Ilex paraguariensis* in southern South America, *Piper methysticum* in Oceania, *Camellia sinensis* in Japan, *Cannabis sativa* in Morocco, and **betel** in Southeast Asia (cf. Graebner 1927).

Cola nuts have also attained a ritual significance in Latin America. They are one of the liturgical plants of the Candomblé cult and are an indispensable element in the initiation of new members into the cult (Voeks 1989, 126*).

In the Afro-American Santería cult (cf. **madzoka medicine**), a sacred liquid known as *omiero* is drunk at the initiation of a new cult member (*santero*). *Omiero* should consist of 101 herbs,

representing all of the orishas (Yoruba gods).¹⁰⁶ Yet because it is almost impossible to collect all of these plants, the number of sacred orisha herbs has been reduced to twenty-one. *Omiero* is prepared from these twenty-one herbs as well as the following ingredients: rainwater, seawater, river water, holy water, sacrificial blood, rum, **honey**, *manteca de corajo*, cocoa butter, cascarilla, pepper (***Piper spp.***), and cola nuts (González-Wippler 1981, 95). Alone, the presence of the many cola nuts, the rum (see **alcohol**), and the cocoa butter (see ***Theobroma cacao***) is enough to ensure that the preparation has stimulant or mild psychoactive effects. Unfortunately, the botanical identity of the twenty-one orisha herbs is not fully known. They do include *Solanum nigrum* (cf. ***Solanum spp.***, **witches' ointments**), lettuce (***Lactuca virosa***), cinnamon, and fern (see ***Polypodium spp.***), all of which could contribute to the drink's psychoactivity (González-Wippler 1981, 96).

Artifacts

The cola nuts themselves represent artifacts, as they were used as currency in Africa for a time (Schröder 1991, 116*).

Medicinal Use

The fruits have many folk medicinal uses, especially in Africa (Akendengué 1992, 171*). They are used primarily as a tonic and stimulant and to treat dysentery, fever with vomiting, and exhaustion (Ayensu 1978, 257*). Many African women chew cola nuts to avoid vomiting while pregnant and to treat or suppress emerging migraines (Seitz et al. 1992, 944). To a certain extent, cola is also regarded as an aphrodisiac (Drucker-Brown 1995, 132f.).

Cola Counterfeits and Cola Substitutes

The drug can be counterfeited by using the seeds of lower-quality (i.e., with less caffeine) *Cola* species as well as the fruits/seeds of false colas (some of which have no caffeine at all) (Seitz et al. 1992, 943).

Lower-Quality <i>Cola</i> Species		
<i>Cola anomala</i> K. Schum.		Cameroon
<i>Cola astrophora</i> Warb.	(kpadu cola)	Togo
<i>Cola digitata</i> Mast.		
<i>Cola lepidata</i> K. Schum.		
<i>Cola pachicarpa</i> K. Schum.		
<i>Cola supfiana</i> Busse	(avatimecola)	
False Colas		
<i>Coula edulis</i> Baill.	Oleaceae	West Africa
<i>Dimorphandra mora</i> Schomb.	Fabaceae	Guiana, Trinidad
<i>Garcinia cola</i> Heckel (bitter cola)	Guttiferae	Sierra Leone
<i>Garcinia floribunda</i> (bitter cola)	Guttiferae	Lagos
<i>Heritiera litoralis</i> Dryander	Sterculiaceae	Africa, Indonesia, Antilles
<i>Lucuma mammosa</i> Griseb.	Sapotaceae	Southeast Asia
<i>Napoleona imperialis</i> Beauv.	Lecythidaceae	Benim, Nigeria
<i>Pentadesma butyraceum</i> G. Don	Guttiferae	Kenya, West Africa

The so-called cola nuts are rust-brown in color when dry.

“Without the cola nut, for which, if circumstances called for it, the riding horse or the bed slave would be given up, there would be no courtship, no marriage contract, no dowry, no oath, no symbolic expression of friendship or enmity, and no provisions for the dead on their journey. For the people of A. E. N., the cola nut was also responsible for the Adam’s apple in men’s throats, as they explain in a legend. According to this, once, as the Creator was wandering on the earth looking after the people, he took a piece of cola nut that he was chewing out of his mouth and laid it on a tree drum. And because he forgot this when he departed, a man who had observed this forgetfulness was able to take possession of the delicacy. But the god remembered his absentmindedness and returned, whereupon the man tried to swallow the divinely tasting morsel. The creator, however, stopped him from doing so with a quick grab of his neck, and since that time, men bear this knotty deformation on their throats.”

RUDOLF BRUNNGRABER

HEROIN: ROMAN DER RAUSCHGIFTE [HEROIN: A NOVEL OF DRUGS] (1952, 127f.*)

In Europe, cola nuts were once utilized to treat migraine headaches, neuralgia, vomiting, seasickness, and diarrhea (Schneider 1974, 1:347*). Today, *Cola* preparations are consumed around the world for physical and mental exhaustion (see **energy drinks**). A mother tincture (*Cola* hom. *HAB*) is used in homeopathy (Seitz et al. 1992, 945).

Constituents

The composition of the constituents is the same in both species. The purines **caffeine** and theobromine (cf. *Theobroma cacao*) occur in all parts of the plant but are concentrated in the seeds and seedlings. Cola nuts from *Cola acuminata* contain up to 2.2% caffeine, and those from *Cola nitida* up to 3.5% caffeine. Both contain less than 1% theobromine (Brown and Malone 1978, 11*; Seitz et al. 1992, 942). Also present are the polyphenols leucoanthocyanidin and catechine and large amounts of starch (Seitz et al. 1992, 940). Caffeine and catechine are primarily present in the form of a caffeine-catechine complex (especially in fresh nuts) that previously was wrongly thought to be a glycoside and named colanine (Seitz et al. 1992, 941).

Effects

Cola nuts have pronounced powers to stimulate, to wake up a person and keep him awake, as well as tonic effects, i.e., they generally invigorate a person and promote concentration. The effects of freshly chewed nuts are more pronounced, as the caffeine-catechine complex they contain is broken down more rapidly. Since this complex decays as the seeds dry, the alkaloids are not as easily removed from the tissue and hence are more slowly absorbed. To date, no negative effects of *Cola* use during pregnancy have been observed (Seitz et al. 1992, 944).

Commercial Forms and Regulations

In Africa, numerous commercial goods are produced in different areas. Tinctures and refreshing beverages are manufactured in many countries. All *Cola* products are available around the world without restriction (Seitz et al. 1992). Only the pertinent food regulations need be taken into consideration.

The stimulating extract of the cola nut was mixed with an extract of coca to produce what is probably the most famous refreshing drink in the world: Coca-Cola. (Advertisement, late nineteenth century)

Coleus blumei Bentham

Coleus

Family

Labiatae (Lamiaceae) (Mint Family)

Forms and Subspecies

Numerous *Coleus blumei* hybrids are raised as indoor plants and ornamentals (Roth et al. 1994, 256f.*).

Synonyms

None

Folk Names

Buntblatt, buntnessel, coleus, coleus scutellaire, common coleus, el ahijado (“the godchild”), el nene (“the child”), la’au fai sei (Samoa), manto de la virgen (Peru), painted nettle, patharcheer, patharchur

History

Coleus is used primarily as an ornamental. Very little is known about its ethnobotany. Its psychoactive use among the Mexican Mazatecs was discovered in 1962 in connection with Gordon Wasson’s early research into *Salvia divinorum* (Ott 1993, 381*) and has been only rudimentarily investigated. Phytochemical studies of the plant have increased in recent years, but these have been focused primarily on enzymatic processes (Kempin et al. 1993; Petersen 1992, 1993).

Distribution

Coleus is from Southeast Asia and was not brought to the Americas until the colonial period at the earliest (Schultes 1970, 42*). Today, it is a pantropic ornamental.

Cultivation

Propagation occurs primarily through cuttings. A young shoot some 10 cm long or a young branch is separated from the mother plant and all leaves except the last pair at the end of the stem are carefully removed. The stem is placed in a glass of water. Within two weeks, the first roots will appear. After three to four weeks, the small plant can be transplanted into humus-rich soil. It should be watered well and not allowed to stand in direct sunlight. Because it does not tolerate any frost, in cold climates *coleus* can be kept only as a houseplant.

Appearance

This herbaceous or bushy plant can grow to a height of about 80 cm. The colorful green-red leaves are decussate and ovate-acuminate; they have serrated margins and a slightly sinuate upper surface. The small flowers grow in terminal racemes or panicles. The plant can bloom throughout the year in the tropics. As a house-plant, it usually blooms from June to September. The plant apparently never or only extremely rarely develops fruits.

There are a large number of *Coleus blumei* hybrids, some of which can be mistaken for other

Coleus species. The popular cultivar *Verschaffetii* is especially easy to confuse with *Coleus forskohlii* (Poir.) Briq [syn. *Coleus barbatus* Benth.]. A species from Borneo, *Coleus pumilus* Blanco [syn. *Coleus rehnelianus* Berger], also has a very similar appearance.

Psychoactive Material

—Leaves

Preparation and Dosage

The leaves are dried and smoked alone or mixed with other herbs (cf. **smoking blends**).

In the tropics, the leaves dry slowly but do not grow moldy like those of other plants. Psychoactive effects can appear when smoking as few as three leaves.

Ritual Use

The Mazatecs include coleus in the same “family” as *Salvia divinorum*, whereby *Salvia* is the “female” and coleus the “male.” They also make an additional distinction: *Coleus pumilis* Blanco [syn. *Coleus rehnelianus* Berger] is *el macho*, “the male,” while the two forms of *Coleus blumei* are *el nene*, “the child,” and *el ahijado*, “the godson” (Schultes 1970, 42*). The fresh leaves are used in exactly the same manner as those of *Salvia divinorum*, that is, they are chewed as quids. Mazatec soothsayers apparently use coleus only as a substitute for *Salvia divinorum*.

Artifacts

None

“Having magico-religious significance, *Coleus* is used as a divinatory plant. The leaves are chewed fresh or the plants are ground, then diluted with water for drinking.”

RICHARD E. SCHULTES AND ALBERT HOFMANN

PLANTS OF THE GODS

(1992, 69*)

In German, *Coleus blumei* is known as *buntblatt*, “colorful leaf.” As this photograph demonstrates, the name is very appropriate. (Photographed in Palenque, Mexico)

Coleus pumilis, a close relative of *Coleus blumei*, is also said to induce psychoactive effects. (Photographed in Palenque, Mexico)

Medicinal Use

On Samoa, the herbage is used to treat elephantiasis (Uhe 1974, 15*). In Southeast Asia, it is used to treat dysentery and digestive problems (Valdés et al. 1987, 474), and in Papua New Guinea it is used to treat headaches (Ott 1993, 381*). *Coleus* is also used as a medicinal plant in the San Pedro cult (cf. *Trichocereus pachanoi*).

The closely related species *Coleus atropurpureus* Benth. was once used to prevent conception (Schneider 1974, 1:349*).

Constituents

Coleus was recently found to contain salvinorin-like substances (cf. **salvinorin A**) of an as yet undetermined chemical structure (cf. **diterpenes**). It is possible that these diterpenes are chemically modified by drying or burning and transformed into efficacious substances. However, additional chemical and pharmaceutical research is needed to clarify this situation.

Rosmarinic acid has been biosynthesized in cell cultures of *Coleus blumei* (Häusler et al. 1992; Meinhard et al. 1992, 1993).

A diterpene (forskolin = coleonol) that is potently bioactive has been found in the related species *Coleus forskohlii* (Poir.) Briq. [syn. *Coleus barbatus* Benth.] (Valdés et al. 1987). It is possible that *Coleus blumei* may also contain forskolin or a similar substance. However, an initial investigation of Indian plants was unable to detect any forskolin (Valdés et al. 1987, 479).

Forskolin activates the enzyme adenylate cyclase, an intracellular neurotransmitter that can bind to various receptors. This means that forskolin is able to exert strong indirect effects upon neurotransmission (D. McKenna 1995, 103*). Whether this can result in psychoactive effects is unknown.

Effects

Some 30% of subjects who smoked dried Mexican *Coleus blumei* leaves reported effects similar to

those produced by smoking a small dosage of *Salvia divinorum* (increase in pulse rate, sensations of bodily heaviness, rolling sensations, lights dancing before the eyes). It may be that a particular bodily chemistry is required to react to the plant. It is also possible that the effects are perceived only after repeated attempts (as is the case with *Cannabis* and *Salvia divinorum*).

In the specialized literature, the psychoactivity of coleus is highly controversial:

Coleus can be found in every specialized book on inebriating drugs. . . . I myself, as well as a larger number of people that I know, [have] undertaken experiments with this plant, some of them using very large amounts of leaves. In no case was there any type of effect. . . . A communication from the ethnopharmacologist Daniel J. Seibert suggests the same. He was in the area of the Mazatecs, and wrote me that only one single Indian there maintained that coleus is psychoactive. All of the other Indians denied this. (Schuldes 1995, 78*)

Commercial Forms and Regulations

Living coleus plants can be obtained in virtually every nursery. The plant is not subject to any rules or legal regulations.

Coleus forskohlii in bloom. (Photographed on the Seychelles)

Convolvulaceae (Morning Glory Family)

Forms and Subspecies

There are three subspecies, as well as cultivars that are distinguishable on the basis of the color of their flowers; ‘Royal Ensign’, for example, is characterized by a nonclimbing, bushy growth pattern and gentian blue flowers.

Synonyms

None

Folk Names

Bunte ackerwinde, dreifarbiges winde, dwarf morning glory

History

Dioscorides may have known this vine by the name *helxine*; he states that “the juice of the leaves has, when drunk, power to loosen the stomach” (4.39).¹⁰⁷ However, the taxonomic history of this vine is by no means clear (Schneider 1974, 1:362*). It has been suggested that the plant may have been an ingredient in the Eleusinian initiatory drink (see **kykeon**). Ethnopharmacological research into the plant is needed.

Distribution

The plant is from southern Europe (Italy or Portugal) and occurs throughout the entire Mediterranean region as well as North Africa (Festi and Alliot 1990*; Schönfelder 1994, 158*). It has become naturalized in Denmark. In Germany, it is usually found only in botanical gardens.

Cultivation

Sowing is best performed between April and June. The germinated seeds (time to germination is fourteen to twenty days at 15 to 18°C) should be planted directly outdoors. This vine is also suitable for growing on a balcony. The plant loves calciferous soils and thrives best in a sunny location. Flower production can be promoted by providing only a little fertilizer. The blooming period is from July to September.

Appearance

This bushy, annual vine attains a height of only about 35 cm. The funnel-shaped, five-pointed, three-colored flowers (yellow inside, white in the middle, and blue on the margin) are solitary and long-stemmed (as are the leaves). The corolla is 1.5 to 4 cm in length. The stigma has two oblong lobes (this characteristic distinguishes the genus *Convolvulus* from *Ipomoea*).

Convolvulus tricolor is sometimes confused with *Ipomoea violacea* (even in the specialized literature), and especially its synonym *Ipomoea tricolor* (e.g., Bauerreuss 1995*; Roth et al. 1994*).

Psychoactive Material

—Seeds (semen convulvuli, vine seeds)

Preparation and Dosage

The crushed seeds are drunk in the form of a cold-water infusion. To date, dosages have not been reported.

Ritual Use

A traditional use of *Convolvulus tricolor* as a psychoactive substance is as yet unknown, although such a use is entirely possible. Some “closet shamans” believe that the seeds of this vine may have been an ingredient in **kykeon**, the initiatory drink of the Eleusinian mysteries.

Artifacts

None known

Medicinal Use

This vine may have been used in folk medicine as a laxative, similar to the use of scammony (*Convolvulus scammonia* L.) or greater bindweed (*Calystegia sepium* (L.) Br. [syn. *Convolvulus sepium* L.]) (Pahlow 1993, 353*). Scammony has been used as an aid in childbirth and to induce contractions in both ancient and modern times (Albert-Puleo 1979).

Constituents

The seeds may contain **ergot alkaloids**, ergoline, and other lysergic acid derivatives. Trace amounts of these alkaloids (0.001% of fresh weight) have been detected in plants from Denmark (Genest and Sahasrabudhe 1966).

The dwarf morning glory (*Convolvulus tricolor*) is indigenous to the Mediterranean region. It is sometimes confused with the Mexican morning glory (*Ipomoea violacea*).

Two vines from the genus *Convolvulus* that may be identical to *Convolvulus tricolor* L. and *Convolvulus scammonia* L. Both species contain alkaloids. (Copperplate engraving from Dioscorides, 1610)

The closely related field convolvulus (*Convolvulus arvensis* L.) contains **tropane alkaloids**, including tropine, cuscohygrine, and hygrine (Todd et al. 1995).

Another relative, *Convolvulus pseudocantabricus* Schrenk., is said to contain alkaloids with analgesic effects, substances very similar to those found in *Turbina corymbosa*. *Convolvulus scammonia* appears to contain **ergot alkaloids** (Albert-Puleo 1979).

Effects

The seeds may possibly have a hypnotic effect.

Commercial Forms and Regulations

The seeds are available in nurseries and seed shops and are not subject to any regulations.

Corynanthe spp.

Pamprama

“In the Central African Republic, a macerate of the branch bark [of *Corynanthe pachyceras*] is drunk in palm wine as an aphrodisiac and as an agent for staying awake. . . . In the coast land of the PR of the Congo (Mayombe) and in Gabon, the healers do not distinguish the bark from *Pausinystalia* bark (= the source of yohimbine); they also use it as an aphrodisiac and agent for staying awake.”

HANS DIETER NEUWINGER *AFRIKANISCHE ARZNEIPFLANZEN UND JAGDGIFTE* [AFRICAN MEDICINAL PLANTS AND HUNTING POISONS]

(1994, 701*)

Family

Rubiaceae (Coffee Family); Subfamily Cinchonoideae, Cinchoneae Tribe

The genus *Corynanthe* is composed of five or six species. It is very closely related to *Pausinystalia yohimba* and is often confused with it. The small trees of this genus occur in the tropical rain forests of western Africa. The species that have been studied to date (*Corynanthe pachyceras* K. Schum., *Corynanthe mayumbensis* [Good] N. Hallé) contain **indole alkaloids** of the corynanthein-yohimbine group (Chaurasia 1992, 1029). The bark (pseudocinchonae africanae cortex) of *Corynanthe pachyceras*¹⁰⁸ contains approximately 5.8% indole alkaloids, including corynanthine (= rauhimbine), corynanthidine (= α -yohimbine), corynanthein, dihydrocorynanthein, corynantheidin, corynoxin, corynoxin, and β -**yohimbine**. In the pharmaceutical trade, the bark is often used as a counterfeit or substitute for the true yohimbé bark (from *Pausinystalia yohimba*) (Chaurasia 1992; Neuwinger 1994, 701*).

The bark of *Corynanthe pachyceras* is used in the Ivory Coast to manufacture arrow poisons (Neuwinger 1994, 701*; 1997, 780*). In the former French Equatorial Africa, the bark is used to fortify fermented beverages (**beer**, **palm wine**). The bark extract has weak analgesic and local anesthetic effects. In animal experiments, it decreased the toxicity of amphetamine (cf. **ephedrine**) by 100%! In West Africa, the bark is esteemed as an aphrodisiac (Chaurasia 1992, 1031; Raymond-Hamet 1937).

(Advertisement, ca. 1920)

Coryphantha spp.

Coryphantha Species

Family

Cactaceae (Cactus Family); Cereeae Tribe, Coryphanthanae Subtribe

Species

The following species have been found to contain β -**phenethylamines** (often hordenine) with (presumably) psychoactive effects (Howe et al. 1977; Kelley H. et al. 1972):

Coryphantha cornifera (DC.) Lem.

Coryphantha durangensis (Rünger) Br. et R.

Coryphantha echinus (Engelm.) Br. et R. [syn. *Coryphantha cornifera* var. *echinus*]

Coryphantha elephantidens (Lem.) Lem.

Coryphantha greenwoodii H. Bravo

Coryphantha ottonis (Pfeif.) Lem.

Coryphantha pectinata (Engelm.) Br. et R.

Coryphantha vivipara var. *arizonica*

Ethnobotanically relevant species:

Coryphantha compacta (Engelm.) Britt. et Rose (peyote substitute)

Coryphantha macromeris (Engelm.) Britt. et Rose [syn. *Lepidocoryphantha macromeris*] (peyote substitute)

Coryphantha macromeris var. *runyonii*

Coryphantha palmeri Britt. et Rose (narcotic)

Coryphantha ramillosa Cutak

Folk Names

Biznaga de piña, donana, falscher peyote, huevos de coyote (Spanish, “the eggs [= testicles] of the coyote”), mulato (for *Coryphantha macromeris*), stachelkaktus, warzenkakteen

Distribution

Most members of the genus are from Mexico, although some occur from northern Mexico to Texas.

Cultivation

Like all cacti, these species can be grown from seed. *Coryphantha* thrives best in sandy and clayey soils and requires much sun and much water during the blooming period (but do not keep wet). No water at all should be given during the winter (Hecht 1995, 26*).

Appearance

The most ethnopharmacologically interesting of these cacti, *Coryphantha compacta*, is a slightly depressed spherical cactus with a maximum diameter of 8 cm. The whitish, 1 to 2 cm long thorns are

arranged in a radial pattern. Most *Coryphantha* species are spherical, heavily thorned ball cacti (Preston-Mafham 1995*) that often develop magnificent, sun-yellow flowers. They can be confused with some species from the genera *Ferocactus* and *Echinocactus*, as well as with ***Mammillaria* spp.**

Many species in the genus *Coryphantha* are spherical in shape and regarded as peyote substitutes. (*Coryphantha recurva*, photographed in Arizona)

Psychoactive Material

—Cactus flesh, fresh or dried

Preparation and Dosage

The thorns must first be removed, after which the aboveground portion is eaten fresh. The dosage is given as eight to twelve cacti (*Coryphantha macro-meris*) (Gottlieb 1973, 12*).

Ritual Use

Presumably the only ritual or shamanic use of *Coryphantha* species is (for some of them) as peyote substitutes (see ***Lophophora williamsii***).

Artifacts

None

Medicinal Use

Presumably similar to that of ***Lophophora williamsii***

Constituents

β-phenethylamines (hordenine, normacromerine, calipamine, methyltyramine and derivatives, synephrine, macromerine, metanephrine, tyra-mine) have been found in many *Coryphantha* species (Bruhn et al. 1975). Most species contain primarily hordenine (Howe et al. 1977; Mata and McLaughlin 1982, 97–100*; Ranieri et al. 1976).

Effects

Coryphantha compacta is “taken by shamans as a potent medicine and greatly feared and respected by the Indians” (Schultes and Hofmann 1992, 67*).

Commercial Forms and Regulations

Many species of the genus are available in cactus shops.

Coryphantha echinus, from northern Mexico, produces psychoactive effects.

Hordenine

“The goddess sits at the top of the round cactus,
our mother, butterfly of obsidian.
Look, there in the springlike fields,
nourished by the hearts of deer,
is our mother, queen of the earth,
adorned with fresh clay and new feathers.
From the four directions of heaven,
because she breaks lances:
she is transformed into a deer.
Across the stony ground
come Xiuhnelli and Mimich,
to see you.”

AZTEC PRAYER

Crocus sativus Linnaeus

Saffron Crocus

Family

Iridaceae (Iris Family)

Forms and Subspecies

A very late-blooming form has been described as the variety *Crocus sativus* L. var. α *autumnalis*. The saffron grown in Kashmir is referred to as *Crocus sativus* L. var. *cashmirianus* (Bowles 1952). The subspecies *Crocus sativus* ssp. *cartwrightianus* is said to be endemic in Greece (Baumann 1982, 158*).

The saffron crocus (*Crocus sativus*) is the source of the coveted and precious saffron spice, high dosages of which produce opium-like effects. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Synonyms

Crocus autumnalis Mill.

Crocus hispanicus

Crocus luteus L.

Crocus orientalis

Folk Names

Abir (Persian), crocus (Roman), gewürzsafran, hay saffron, karcom (Hebrew), karkom, karkum (Persian), kesar (Sanskrit), kesara (Hindi), kesari, krokos (Greek), krokus, kumkumkesari, plam phool (Pakistani), saffron, saffron crocus, safrankrokus, sn-wt.t (ancient Egyptian), z'afarân (Arabic/Yemen), zafran

History

The saffron crocus is one of the very oldest of all cultivated plants. A wild form is no longer known (Czygan 1989, 413). Saffron was first mentioned in conjunction with the name of a city on the Euphrates: Azupirano, “Saffron City” (ca. 2300 B.C.E.). The plant was already being cultivated on Crete and Thera (Santorini) during the Minoan period (Basker and Negbi 1983, 228). Because of the plant’s color, the Greek scholar Carl Ruck believes that in Archaic Greece the saffron crocus was used entheogenically as a substitute for fly agaric (*Amanita muscaria*), which was originally venerated as sacred and eaten ritually (Ruck 1995, 133*). The earliest written record of saffron is presumably in the *Iliad* and in the Old Testament Song of Songs. The first documentation for Kashmir is from the fifth century B.C.E. (Basker and Negri 1983, 228).

In the eighteenth and nineteenth centuries, saffron was used as an inebriant—certainly, a very expensive one—whose effects were said to be like those of opium (cf. *Papaver somniferum*). Although it is known that saffron has psychoactive properties, this aspect of the plant has been only little studied. The reason is the still very high price that true saffron commands (in comparison, **cocaine** is a veritable “middle-class” drug).

Because true saffron has always been extremely expensive, the coveted spice has often been counterfeited. Moreover, the name has been used for a wide variety of plants (Schneider 1974, 1:378*). In ancient times, saffron was an important source of dye, especially for coloring royal garments (Basker and Negbi 1983, 230). Saffron also played a role in perfumery, as Aristophanes has intimated (*The Clouds*, 1.51).

True saffron consists of the stigmas of *Crocus sativus*. (Photograph: Karl-Christian Lyncker)

In the tenth century, saffron was cultivated in Spain and from there exported into all the countries of Europe (Hooper 1937, 107*). The Upper Valais (Switzerland) is a renowned and venerable area of saffron cultivation. The so-called krummenegga (“saffron fields”) are located there, having been established in 1420 by knights returning from the Crusades. In 1979, following long years of neglect, a saffron guild constituted itself with the aim of reinvigorating saffron cultivation (Vonarburg 1995).

Distribution

Because the wild form is unknown, only the range of saffron culture can be given. This is established primarily in western Asia, Asia Minor, Turkey, Iran, Greece, India, and Spain.

Cultivation

Propagation occurs vegetatively by the separation of small tubers. The precise methods of cultivation

are usually kept secret for economic reasons.

Saffron is the most expensive spice in the world, which is why its cultivation has such great economic significance in the areas where it is grown. Twenty thousand stigmas yield a mere 125 g; according to a different calculation, 1 kilo of dried filaments requires some 60,000 flowers or 120,000 to 150,000 stigmas (Vonarburg 1995, 75).

Appearance

This perennial tuberous plant blooms in the fall. It has very narrow and elongated leaves. The violet-veined flower sits at the end of the stalk. It has three yellow stamens, a thin yellow style, and three long, red, funnel-shaped stigmas that project from the flower.

The saffron crocus is very similar to the meadow saffron (= autumn crocus; *Colchicum autumnale* L.)¹⁰⁹ and is easily confused with it, especially because this plant also blooms in the fall (Bowles 1952).

Psychoactive Material

—Saffron (crocus stigma, flores croci, crocus): the brick red stigma held together by a small piece of the style. The dried stigmas are approximately 20 to 40 mm long. They have a strong aromatic scent and a spicy-hot taste.

Two qualities are distinguished:

—Crocus electus (saffron tips, free of the remains of the styles)

—Crocus naturalis (with many pieces of styles)

The stigmas must be kept out of the light and stored in an airtight container, or the volatile essential oil will evaporate and the color will fade.

The entire flower is used for folk medicinal purposes.

Besides the Greek saffron, the Hippocratics mention an “Egyptian saffron” that was used externally. This likely is a reference to yellow safflower (*Carthamus tinctorius* L.), as the Egyptians themselves did not plant saffron (which they called the “blood of Hercules”). Instead, they imported it from Crete and southwest Asia. The saffron threads are often mistaken for or counterfeited by the petals of the safflower (*Carthamus tinctorius*) (Norman 1991, 33*). Curcuma (*Curcuma longa* L., Zingiberaceae) is known as saffron spice as well as Indian saffron. To add to the confusion, the autumn crocus is also known as meadow saffron (Basker and Nagbi 1983, 232).

Preparation and Dosage

In ancient times, saffron was used primarily as a wine additive (cf. *Vitis vinifera*) that provided an additional inebriating effect (Norman 1991, 33*). Saffron is an important ingredient in laudanum or tinctura opii crocata (cf. *Papaver somniferum*, **soporific sponge**). Saffron is also found in the so-called Swedish herb mixes (cf. **theriac**) as well as **Oriental joy pills** and other aphrodisiacs. In ancient China, saffron was used as an additive to **sake**.

A Greek papyrus from the Egyptian Arsinoites (third century B.C.E.) contains a recipe; unfortunately, there is no information about what the mixture should be used for:

The plaster of Dionysus: two drams of copper oxide, three obols of rosebud hearts (perhaps specifically *Rosa gallica*), three obols of saffron, one-half obol poppy juice (*Papaver somniferum*), three obols of white (acacia) gum (*Gummi arabicum*). Stir these (things) in wine as smoothly as possible (and) make ointments, apply. (In Hengstl et al. 1978, 272)

Perhaps this was some type of aphrodisiac ointment, for saffron has always enjoyed a reputation as an aphrodisiac and agent of love.

To date, no risks have been documented at a maximum daily dosage of 1.5 g. Twenty grams is given as a lethal dose, while 10 g can induce abortion (per *Monographie der Kommission E*; cf. Czygan 1989, 414).

Ritual Use

The roots of the ritual use of saffron, which was regarded as sacred, lie in Minoan Crete and Thera, and most likely in the entire range of the Minoan culture. As the many saffron frescoes in different shrines suggest, saffron had an important ritual significance on Crete and Thera. The saffron crocus was apparently associated with the priestly veneration of the Minoan goddess, with the worship of nature, and with fertility. Wall paintings from Thera make it clear that priestesses carried out the saffron harvest (Doulas 1992). It is possible that saffron was also involved in the ritual embalming and preparation of the dead in Egypt.

“To the Aither
—a smoking offering of saffron—
You high-reaching house of Zeus,
Indestructible in eternal power,
Bearer of the stars, the sun,
the moon,
Vanquisher of all, fire-breathing,
substance which ignites all life!
Far-illuminating ether,
most noble primeval substance of the universe,
magnificent first seed, bearer of light,
flaming from the fire of the stars—
To you sounds my pleading call:
Oh show your cheerful visage!”

ORPHIC HYMN

“Emperor Marcus Aurelius bathed in saffron water, because it beautified the skin and supposedly also increased male potency. The celebration halls were adorned with crocuses as an auspicious sign for the orgy that the carousal would hopefully turn into, and crocus flowers were placed in the hair.”

ANTHONY MERCATANTE

DER MAGISCHE GARTEN [THE MAGICAL GARDEN]

(1980, 51*)

“Saffron, which is often used in the home kitchen to color food dishes, takes the place of opium for children. It is frequently used as an analgesic and antispasmodic, as an agent to promote menstruation and uterine spasms, and externally for inflammations of the glands (breasts), panaritis, hemorrhoidal knots, some eye ailments, and facial pain. In high dosages, it induces abortion.”

HAGERS HANDBUCH DER PHARMAZIEUTISCHEN PRAXIS KOMMENTAR TO THE DEUTSCHE APOTHEKER BUCH, FIRST EDITION

Saffron was sacred to the goddess Hecate, for Orphic hymns invoked the ruler of the shadows as the “sea goddess in saffron robes.” In the Orphic mysteries, part of the cult of Dionysos (cf. *Vitis vinifera*), saffron was a ritual **incense** that was burned during the recitation or singing of hymns.

To date, we know of no traditional or ritual use of saffron as a psychoactive substance.

Artifacts

Both the saffron crocus and its harvest are subjects of Minoan wall paintings (Marinatos 1984). The saffron paintings from Thera (Santorini, Xestes 3, Room 3a, first floor) reflect the loving manner in which the plant was treated (Doumas 1992, 152ff.; Douskos 1980).

Garments dyed with saffron have been preserved from antiquity, the Middle Ages, and the early modern period. In contrast, the “saffron yellow” robes that Buddhist monks in Sri Lanka wear are not dyed with true saffron, as has been wrongly assumed (Basker and Negbi 1983).

The novel *Die Safranhändlerin* [The Saffron Merchantess], by H. Glaesener (1996), provides an amusing description of the world of the medieval spice trade.

The petals of the safflower (*Carthamus tinctorius*), which do not have any psychoactive effects, are a source of false saffron. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

Medicinal Use

Saffron is one of the oldest and most used medicines of the Hippocratics. It was said to be an effective antidote for drunkenness (see *Vitis vinifera*) and to increase male potency. According to Pliny, saffron was a panacea and an aphrodisiac: “It induces sleep, has a gentle effect upon the head, and whets the sex drive” (21.137). For this reason, saffron was also an important ingredient in love drinks in ancient Rome (Mercatante 1980, 50*). During the Renaissance, it was said that smelling a crocus in bloom “expands the heart and the tools of the mind and stimulates to coitus.”

Safranal

In the mystical medicine of Islam, the following is said about saffron: “It is an excellent agent for the blood and for strengthening the soul. It assuages joint pains and strengthens the sex drive in young men” (Moinuddin 1984, 99*).

Since the Middle Ages, saffron has been used as a remedy for “St. Anthony’s fire” (ergotism; cf. *Claviceps purpurea*). In Victorian England, it was used to treat constipation and found its way to the source of the problem as an **enema** (Mercatante 1980, 51*).

In Western medicine, saffron was once used as a nerve calmativ and to treat spasms and asthma, but it no longer has any medical significance. In folk medicine, saffron is still used as a sedative and antispasmodic (Czygan 1989, 414). In homeopathy, the mother tincture is prepared from the dried filaments (stigmas) and is used primarily to treat women and children (Vonarburg 1995, 76).

Saffron also found its way into traditional Chinese medicine, where it is used as a psycho-active remedy:

Among the ailments that are generally treated with saffron are depression, constricted feelings in the chest, fear, shock, confusion (mental and emotional disturbances), coughing blood, period pains and other menstrual complaints, blood congestion [accumulation of blood in the capillaries], and abdominal pains following childbirth. Long-term use of saffron can free one from depressions and feelings of anxiety and produce sensations of happiness. (Leung 1995, 186*)

In Baluchistan (Pakistan), 10 g of ground flowers (not just the pistils), which are known as *khakhobe*, are drunk mornings and evenings in a mixture of liquid yogurt as a remedy for dysentery (Goodman and Ghafoor 1992, 52*). In Yemen, saffron is still used as an aromatic stimulant (Fleurentin and Pelt 1982, 90f.*).

Constituents

Saffron contains 8 to 13% solid oil and up to 1% **essential oil**, as well as oleanolic acid derivatives, glycosides, the bitter substance picrocrocin (which when stored transforms into safranal, the aromatic substance that gives saffron its characteristic scent), and crystalline yellow dyes (α -crocin = crocetin-di- β -D-gentiobiosylester, crocetin, and others) (Czygan 1989, 414). Saffron also contains the vitamins riboflavin (100 μ g!) and thiamine (Bhat and Broker 1953). The essential oil has a rather complex structure (Zarghami 1970): “The principal component of the essential oil is safranal, which produces the scent typical of the drug. Safranal is first produced during drying, which is why this step merits particular attention during processing” (Pahlow 1995, 78*).

Effects

The psychoactive effects of saffron have been occasionally described as “spasms of laughter” and “delirium” (Vonarburg 1995, 76); “in its effects, saffron comes close to opium [cf. *Papaver somniferum*]; in low dosages, it excites, cheers, and produces laughter . . . , in contrast, in high dosages it sedates, promotes sleep, sopor” (Most 1843, 536*). The essential oil and its vapors also produce psychoactive effects, which have been described as “a sedative effect upon the brain, sleep-inducing, produc[ing] headaches [and] cheerful delirium, and paralyz[ing] motor nerves. Blindness. Peculiar orgasm” (Roth et al. 1994, 276). Actual reports of direct experiences with the drug are not available, presumably because of its high cost.

Saffron promotes protein digestion because it stimulates enzymatic activity. It also stimulates uterine activity and can thus have abortifacient effects. Saffron has the highest riboflavin content of any plant (as a percentage of weight) and as a result appears to lower cholesterol levels (Basker and Begbi 1983). The extract has stimulating and antispasmodic properties (Hooper 1937, 107*).

Commercial Forms and Regulations

Saffron was formerly an important officinal drug. Today, it is listed only in the ÖAB, Ph. Eur. 1/III and Ph. Helv. VI.* Because it is classified as a spice, saffron is freely available.

Saffron is very often counterfeited for sale. Red or yellow pieces of marigold (*Calendula officinalis* L.) flowers or dyer's saffron (= safflower; *Carthamus tinctorius* L.) are often sold as saffron (even in such producer countries as Greece and Spain). The petals of ***Tagetes* spp.** (American saffron) have also appeared in trade. Paprika powder (*Capsicum frutescens*) and curcuma (*Curcuma longa* L.) are frequently sold as ground saffron. The red coloration is often achieved using red sandalwood (*Pterocarpus santalinus* L.f.). Saffron powder may also be made heavier by the addition of very dense additives (barium sulfate, brick dust, glycerol) (Czygan 1989, 415).

Cytisus canariensis (Linnaeus) O. Kuntze

Canary Island Broom

“In some places, time really does appear to have stood still, which makes it much easier for a researcher with access to a time machine (in other words, an ability to imagine and a nonjudgmental surrender to clearly perceivable ‘power fields’) to journey into the past. In the Canary Islands, the spirit of Tara, the power of the Great Goddess and her female and male servants, can be felt everywhere, and the magic cap the Goddess uses to hide herself from the excesses of the modern, hectic world exhibits countless gaps. The secrets of the islands begin directly behind the loud tourist beaches.”

HARALD BRAEM

MAGISCHE RITEN UND KULTE [MAGICAL RITES AND CULTS] (1995, 128)

Family

Leguminosae (Legume Family); Subfamily Papilionoideae, Genisteae Tribe, Cytisinae Subtribe

Forms and Subspecies

The taxonomy of the genus *Cytisus* (= *Genista*) is rather confusing and ambiguous, especially with respect to the Canary Island species (cf. Kunkel 1993). One variety is occasionally described under the name *Cytisus canariensis* (L.) O. Kuntze var. *ramosissimus* (Poir.) Briq.

Synonyms

Cytisus attleyanus hort.

Cytisus canariensis Steud.

Cytisus ramosissimus Poir.

Genista canariensis L.

Folk Names

Canary Island broom, kanarischer ginster, kytisos, Spanish broom, spartion, spartium

History

Canary Island broom is from the island group of the same name. It may have been a ritual plant of the Guancha, the indigenous people of the islands who, in the fifteenth century, still possessed a Stone Age culture and venerated the Great Goddess (Tara) in painted ritual caves (see Braem 1995, 114–28). It was likely introduced into the New World at an early date, for many ships that were bound for New Spain stopped at the Canary Islands and, when they left, carried the islands’ native plants with them. Knowledge of the use of broom as an inebriant may have traveled along as well.

The bright yellow blossoms of Canary Island broom (*Cytisus canariensis*).

Yaqui shamans from northern Mexico use Canary Island broom for ritual purposes (Fadiman 1965). In the United States, the flowers are smoked as a tobacco substitute (cf. *Nicotiana tabacum*) (Fadiman 1965).

Distribution

The bush is endemic to the Canary Islands. As a result of cultivation (as an ornamental), it can now be found in the entire Mediterranean region and in North, Central, and South America.

Cultivation

Propagation can occur via seeds as well as cuttings. The seeds should be pre-germinated in January before planting. The bush does not tolerate frost (Grubber 1991, 19*).

Appearance

This evergreen bush can grow up to 2 meters in height. The small green leaves are tripartite. The aromatic, light yellow, labiate flowers develop on the upper ends of the branches. The plant flowers between May and July. The fruits are small pods (15 to 20 mm) that contain several small, beanlike seeds.

Canary Island broom is easily mistaken for other species of the genera *Cytisus* and *Spartium* (see *Cytisus* spp.).

Psychoactive Material

—Flowers

Preparation and Dosage

The flowers are dried and chopped. They can be rolled into cigarettes (joints) or placed in a pipe and

smoked by themselves or together with other herbs (cf. **smoking blends**). The flowers can also be used to prepare an aphrodisiac drink:

The flowers of the Canary Island broom are dried over a low flame, then brewed with water, filtered, and drunk. After ingesting this liquid, a person is transported into a state of total euphoria, which includes more intense sensations of sexual arousal along with more intense perception, and a great deal of calm and quiet. (Stark 1984, 56*)

One dosage is the amount of dried leaves contained in one to three normal cigarettes (joints) (Fadiman 1965).

Ritual Use

A Yaqui shaman discovered the psychoactive use of this plant. After ingesting another psychoactive plant (most likely peyote; see ***Lophophora williamsii***), he was shown in a vision that the flowers of the Canary Island broom should be smoked. Further study of the ritual use is needed.

Artifacts

None

Medicinal Use

None

Constituents

Canary Island broom contains large quantities of **cytisine** (Ott 1993, 407*) and other alkaloids. Detailed chemical studies are lacking (Schultes and Hofmann 1980, 153*).

Effects

Smoking the dried leaves produces effects that have been described as mildly psychedelic without unpleasant side effects or aftereffects (Allen and Allen 1981, 211*). A small dose (one cigarette per person) produced sensations of relaxation with positive feelings for some two hours. Higher dosages (two to three cigarettes) produced an increase in intellectual abilities (clarity, flexibility) as well as an increase in alertness. Although there have been reports of sharpened perception and greater intensity of colors, hallucinations have not been observed. Closing the eyes stimulated the imagination. The effects lasted a maximum of five hours. Apart from a (rare) slight headache the following day, no side effects or aftereffects have been reported (Fadiman 1965).

Commercial Forms and Regulations

The plant is available as an ornamental in nurseries.

“The magical beliefs have the following to say about broom: ‘Whoever has become ill as a result of enchantment with formulae, he must urinate down through an upside-down broom made of broom, and then he will become healthy.’ ”

G. W. GESSMANN

DIE PFLANZE IM ZAUBERGLAUBEN [THE PLANTS IN SUPERSTITION] (N.D., 43*)

Cytisus spp. and Relatives

Broom Species

Family

Leguminosae (Legume Family); Subfamily Papilionoideae, Genisteae Tribe, Genistinae (previously Cytisinae) Subtribe

The originally Old World genus *Cytisus* (= *Genista*) encompasses some fifty species, twenty-three to thirty-three of which are found in Europe (Wink 1992, 1124). Many species contain the alkaloids anagyrine, **cytisine**, lupanine, *N*-methylcytisine, and sparteine (Allen and Allen 1981, 210*). Chinolizidine alkaloids (of the sparteine type) are of chemotaxonomic significance (van Rensen et al. 1993).

Cytisus scoparius (L.) Link [syn. *Genista angulata* Poiret, *Genista glabra* Spach, *Genista hirsuta* Moench, *Genista scoparia* (L.) Lam., *Genista scoparius* DC., *Genista vulgaris* Gray, *Sarothamnus ericetorum* Gandoger, *Sarothamnus obtusatus* Gandoger, *Sarothamnus scoparius* (L.) Wimm. ex W.D.J. Koch, *Sarothamnus vulgaris* Wimm., *Spartium angulosum* Gilib., *Spartium glabrum* Mill., *Spartium scoparium* L.]—Scotch broom

The use of Scotch broom for inebriating purposes is allegedly based upon the observation that sheep behave in an excited and peculiar manner after eating the plant (Brown and Malone 1978, 8*).

For several years, dried Scotch broom flowers have been regarded as a “legal high” and used in **smoking blends**. Users have repeatedly reported mild euphoric effects and distinct synergistic effects when the flowers are mixed with other substances, especially ***Cannabis sativa***.

The common name of the plant is derived from the fact that its branches were once used to make brooms. Witches are said to have made their flying brooms from *Cytisus* (Ludwig 1982, 143*). Perhaps this use, and its association with witches’ flight, is what led to the plant’s psychoactive use (cf. **witches’ ointments**).

Broom flowers are used in folk medicine as a dehydrating agent and blood purifier. In phytotherapy, their sole use is as a decorative drug in tea mixtures (Wink 1992, 1128).

The aboveground parts of broom as well as its seeds contain the alkaloid sparteine (= lupinine), sarothamnine, and genisteine. **Cytisine** does not appear to be present (Brown and Malone 1978, 9*), although the flowers do contain phenethylamine derivatives (tyramine, etc.) (Wink 1992, 1127). For this reason, they should not be used in combination with MAO inhibitors (see ***Peganum harmala***, **ayahuasca analogs**). Sparteine binds to nicotinic acetylcholine receptors (Wink 1992, 1130). This property may account for the weak psychoactive effects.

Cytisine

Lupinine

“They joined together the flowers of oak, broom, and meadow queen and, with the help of their magic, created the most beautiful and perfect maiden in the world.”

FROM THE WELSH *MABINOGION* (MARKALE 1989, 142*)

***Cytisus* spp.—broom species**

Some *Cytisus* species contain **cytisine** and were apparently frequently smoked as tobacco substitutes (*Nicotiana tabacum*).

In colonial Peru, a plant that was used as a medicinal **incense** may have been a *Cytisus* species. The source notes, “Another herb, *chuquicaylla*, similar to broom, is used as a fumigant for fever” (in Andritsky 1989, 267*).

***Genista* spp.—broom**

Species of the genus *Genista* are easily confused with ***Cytisus canariensis*** and with *Spartium* spp. Dyer’s greenweed (*Genista tinctoria* L.) contains the alkaloid **cytisine**, as does the German broom (*Genistra germanica* L.): “Some alkaloids of *Genista* species exhibit hallucinogenic effects” (Roth et al. 1994, 372*). No information is available that would suggest that these plants were used traditionally for psychoactive purposes.

***Spartium junceum* L. [syn. *Sarothamnus junceus* Link, *Spartianthus junceus* (L.) Link]—Spanish broom**

Spanish broom is easily mistaken for Canary Island broom (***Cytisus canariensis***). Spanish broom has a rich alkaloid content and high concentrations of **cytisine**. It also appears to induce psycho-active effects:

The drug evidently has weak hallucinogenic properties: One artist repeatedly drank decoctions

of Spanish broom flowers as a “cardio-tonic,” as he believed that he was using *Cytisi scoparii* flos. He reported that afterward he experienced very intense dreams, during which he had seen very colorful images. . . . After ingesting a tea infusion of seeds and branch tips (dosage unknown), a woman is said to have experienced vomiting, disturbances of vision, and feelings of drunkenness. (Wink 1994, 771)

In the highlands of Ecuador, this originally European plant is known as *retama*. Drunk as a tea, it is said to have abortifacient or prophylactic effects. The dried flowers are smoked there to treat asthma (Schultes 1983a, 262*). In southern Peru, the flowers are ground and added to **chicha**, (brewed from maize) in order to make it “more inebriating” (Franquemont et al. 1990, 82*). The bush is also called *retama* in Peru and is ingested together with *markhu* (*Ambrosia peruviana* Willd.), *guaco* (*Mikania scandens* Willd.; see *Mikania cordata*), *Coca* (*Erythroxylum coca*), rosemary (*Rosmarinus officinalis* L.; cf. *Fabiana imbricata*), and *nijnd* (*Myrica pubescens* H. et B. ex Willd. var. *glandulosa* Chev.) to treat rheumatism (Bastien 1987, 131*).

A cultivated variety of broom.

The southern broom (*Cytisus australis*).

Spanish broom (*Spartium juncum*) occurs throughout the entire Mediterranean region. (Photographed on Crete)

Broom (*Spartium junceum*) was introduced into South America. This specimen was photographed in the Altiplano of Peru.

The dried flowers and leaves of two species of broom are smoked for inebriating purposes. The upper illustration shows Scotch broom (*Cytisus scoparius*), a very common plant in Germany, while the lower illustration is of Spanish broom (*Spartium junceum*), which is more common in southern Europe. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Datura discolor Bernhardt

Sacred Datura

This Italian techno-pop group took its name from the sacred datura plant. The album includes descriptions of hallucinations caused by “devil’s weed.” A path to eternity? (CD cover 1993, ZYX Music)

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Dutra Section

Forms and Subspecies

Presumably none

Synonyms

Datura thomasi Torr.

Folk Names

A’neglakya, desert datura, é’’ee kamóstim (Serí, “plant that makes one squint”), é’’ee karóokkoot (Serí, “plant that makes one crazy”), hehe camóstim, hehe carócot, heilige datura, heiliger stechapfel, holy datura of the Zuni, malykatu (Mohave), sacred datura, sacred thornapple, Thomas’ thornapple, toloache

History

The history of this potentially hallucinogenic species of *Datura* is shrouded in mystery. Although this genus is ethnopharmacologically highly interesting and has been the object of a great deal of research over the last century, many questions still remain (Avery 1959). There is also some taxonomic confusion (cf. *Datura* spp.). In the ethnobotanical literature, *Datura discolor* is usually listed as *Datura innoxia* or *Datura meteloides* (syn.). And indeed, the ranges of the two species overlap. Moreover, the ethnopharma-cological uses of both are almost identical, and the two species

share many folk names. In the American Southwest, however, it has become customary to refer to *Datura discolor* as sacred datura or holy datura of the Zuni and to *Datura innoxia* as toloache or devil's weed.

In the southwestern region of the United States, the thorn apple (*Datura discolor*) is known as sacred datura. (Photographed in Zion Canyon)

Distribution

The primary range of this relatively rare thorn apple species extends across the American Southwest and northern Mexico. The plant has also occasionally been reported to occur in the West Indies.

Because of its high alkaloid content, *Datura discolor* is grown commercially in Egypt as a source of pharmaceutical scopolamine (Saber et al. 1970).

Cultivation

As with all *Datura* species, *Datura discolor* is propagated from seeds. Often, the seeds must simply be scattered over the ground. Seeds also can be grown in seedbeds or germination pots. They should be gently pressed into the soil or germinating substrate (0.5 to 1 cm deep) and watered regularly. The germination period is relatively short (five to ten days). The seedlings are somewhat sensitive. They do not tolerate direct or intense sunlight or complete shade. They will not survive excessive watering, yet if the soil or substrate dries out, the seedlings will die. The seedlings quickly grow into small, robust plants, which can then be repotted or planted in the ground. At this time, the plants will tolerate more exposure to the sun.

While most *Datura* species require relatively large amounts of water, they need little other care. *Datura* is self-sowing, so once it has been in a garden, it will likely be seen again in subsequent years.

Although the daturas are originally from subtropical and tropical zones, they adapt well to the climate of central Europe. In this area, seedlings should not be transplanted into the open until mid-May. Wild, self-sowing plants quickly adapt to local ecological conditions.

Appearance

This annual plant develops a multibranched, bushy, prostrate, laterally growing herbage that is dark green in color, with soft, slightly serrated leaves. The white flowers have a striking trumpetlike shape and are sometimes tinged violet on the inside. The flowers grow from axils on the branches and point slightly sideways or almost straight up. They blossom in the evening, exuding a sweet, delicate,

delicious scent. They wither during the course of the following day. The green fruits, which have only a few long thorns, are pendulous. They contain numerous black seeds (an important feature for identification). Apart from this, the plant is very similar to ***Datura innoxia***, although it is somewhat smaller in every respect.

Psychoactive Material

- Seeds
- Leaves
- Roots

Preparation and Dosage

A medicinal tea can be prepared from the dried, ground seeds of *Datura discolor*, cinnamon bark (*Cinnamomum verum*), the leaves of desert lavender (*Hyptis emoryi* Torr.), and sugar (Felger and Moser 1991, 320, 366*). Unfortunately, we have no information about dosages.

The dried leaves can be smoked alone, in **kinnikinnick**, or in other **smoking blends**. The fresh root can be chewed. Apart from this, the plant is used in the same manner as *Datura innoxia*.

Typically, preparations of *Datura discolor* must be dosed more carefully than those of ***Datura innoxia***, as the former contains higher concentrations of alkaloids.

Ritual Use

According to the mythology of the Serí Indians, *Datura discolor* was one of the first plants of creation; as a result, humans should avoid contact with the plant (Felger and Moser 1991, 366*). Because inappropriate use can be very dangerous, the plant is used only by shamans.

In the American Southwest, the ritual use of *Datura discolor* is similar to that of ***Datura innoxia*** (see there). *Datura discolor*, however, is used much more rarely.

Artifacts

See ***Datura innoxia***.

Medicinal Use

The Serí Indians of northern Mexico drink a tea made from the seeds to treat a swollen throat (Felger and Moser 1974, 428*).

The ethnomedical use of *Datura discolor* is similar to that of ***Datura innoxia***.

Constituents

The entire plant contains between 0.13 and 0.49% alkaloids (primarily **tropane alkaloids**), half of which is hyoscyne (= **scopolamine**). The alkaloid concentrations of the plant can vary considerably as it grows. The highest concentrations have been found to occur in the stems during the fruiting phase (Saber et al. 1970).

The dried herbage contains 0.17% alkaloids. The principal alkaloid is hyoscyne/**scopolamine** (0.08% by dry weight). Apohyoscyne, norhyoscyne, hyoscyamine, meteloidine, tropine, and c-tropine are also present.

The dried roots contain 0.31% alkaloids, chiefly hyoscyne/scopolamine, along with norhyoscyne, atropine, littorine, meteloidine, 3 α ,6 β -ditigloyloxytropine, 3 α ,6 β -ditigloyloxytropine-7 β -ol, cuscohygrine (the primary alkaloid in the roots), tropine, and c-tropine (Evans and Somanabandhu 1974).

Effects

See *Datura innoxia*.

Commercial Forms and Regulations

Datura discolor is found only rarely in nurseries. Both the plant and the seeds are available without restriction.

Literature

See also the entries for *Datura innoxia* and **tropane alkaloids**.

A pre-Hispanic Mexican representation of the toloache fruit (*Datura innoxia*). (From Camilla 1995)

History

Toloache is the most ethnopharmacologically significant of all thorn apple species in the New World. Archaeological studies of ritual rooms dating to 1200 to 1250 C.E. have demonstrated that the prehistoric Pueblo Indians of the Southwest used the seeds for ritual purposes (Litzinger 1981, 64; Yarnell 1959). Our present state of knowledge does not allow us to say with certainty how long this thorn apple has been used in Mexico, although such use certainly has its roots in the prehistoric period. Today, many Mexican Indians still frequently use *Datura innoxia* for ritual and medicinal as well as aphrodisiac purposes.

Distribution

The original range of *Datura innoxia* extended from the American Southwest and Mexico to Guatemala and Belize. From there, the species spread into the islands of the Caribbean. It was introduced into Asia at an early date. In India, it often occurs in association with ***Datura metel***. It also grows wild in Greece and Israel (Dafni and Yaniv 1994*).

Cultivation

For information on cultivation, see *Datura discolor*.

Datura innoxia is grown commercially in Central America, North Africa, Ethiopia, India, and England for pharmaceutical purposes (as a source of **scopolamine**) (Gerlach 1948).

Appearance

Datura innoxia is usually a 1- to 2-meter-tall annual plant; in the tropics, where it can grow to more than 3 meters in height, it can thrive as a perennial. The root can grow up to 60 cm long. The light to dull green plant is heavily branched and develops hairy leaves with serrated margins. The white, funnel-shaped flowers grow almost perpendicularly out of the axils. The flowers bloom at night, exuding a delicious scent, and begin to wither the following day. In central Europe, the plant flowers between June and September; in protected locations, the plant can produce flowers into November.

The fruits are pendulous and covered with numerous short thorns. The seeds have an ocher color with hints of orange. They are larger than the black seeds produced by *Datura discolor* and *Datura stramonium* and are easily mistaken for those of *Datura metel* and *Datura wrightii*.

Datura innoxia is very similar to the Asian *Datura metel* and is easily confused with this plant. It is in fact questionable whether the two species should be regarded as distinct. Recent phyto-chemical studies have shown that the two species are extremely similar (Mino 1994). It may be that they are actually subspecies or varieties of the same species. The two species (or forms) are most easily distinguished on the basis of their stalks. *Datura innoxia* has green stalks with soft hairs, while *Datura metel* has smooth stalks that are purple in color.

Datura innoxia is also easily confused with *Datura discolor* and *Datura wrightii*, although it occurs in a geographical area different from that of the latter two species.

Psychoactive Material

—Leaves (*daturae innoxiae herba*), fresh or dried

—Roots

—Flowers

—Seeds

Preparation and Dosage

The dried leaves and flowers can be smoked alone or in combination with other herbs and substances (cf. **smoking blends**).

Shamans of the Yucatec Maya (*hmenó'ob*, “the doers”) use the leaves of *Datura innoxia* and tobacco (*Nicotiana tabacum*, *Nicotiana undulata*; cf. *Nicotiana spp.*) to roll cigars known as *chamal*. They typically use one leaf of each plant per cigar. A shaman will smoke this cigar until he has attained the altered state of consciousness he desires (which can differ considerably from one individual to the next).

The seeds and leaves may be crushed and treated with a fermenting agent to produce an alcoholic drink (Havard 1896, 39*). The roots are often used as an inebriating additive to pulque (see *Agave spp.*), **beer**, or **chicha**. The Tarahumara add the seeds to the maize **beer**, known as *tesgüino*, they brew (Bye 1979b, 35*). Both the tribes that live along the Colorado River and the Paiute fortified their beer with the seeds and leaves of *Datura innoxia* (Havard 1896, 39*).

The Yaqui Indians make an ointment by adding crushed seeds and leaves to lard; they rub this onto their abdomens to induce visions.

Fresh roots may be crushed and applied externally, chewed, or dried and powdered. Unfortunately, the literature does not provide any precise information about the amounts of roots that should be

chewed or eaten.

For smoking, up to four leaves is regarded as an appropriate dosage for eliciting aphrodisiac effects. Consuming the plant in this manner effectively rules out the possibility of overdose. Teas made from the leaves must be dosed with care. As little as one large leaf can be sufficient to induce profound hallucinations. Because alkaloid concentrations can vary considerably (see “Constituents”), and because individuals react quite differently to **tropane alkaloids**, detailed information about dosages is rarely provided. Thirty to forty seeds is regarded as a potent visionary or hallucinogenic dosage. However, as few as ten seeds can lead to profound perceptual changes. For information about lethal dosages, see *Datura stramonium*.

In Pakistan, 150 g of leaves, fruits, or flowers is regarded as a lethal dose (Goodman and Ghafoor 1992, 40*). This amount appears to be quite high.

The typical upright, funnel-shaped flower of the Mexican thorn apple (*Datura innoxia*), also known as toloache

Ritual Use

In Aztec medical texts, toloache is cited numerous times as a remedy, especially for fever (Rätsch 1991a, 254ff.*):

Toloa. It is also a fever medicine. It is drunk in a weak infusion. And where gout is, it is applied to it, one is rubbed with it there. It soothes, dispels, wards off [pain]. It is not inhaled and it is not breathed in. (Sahagun, Florentine Codex 11:7*)

The written sources do not contain any clear indications that the plant was used as an inebriant. Since ritual and magical use occurs throughout modern Mexico, it can be assumed that the potent inebriating powers of *Datura innoxia* were also being utilized in pre-Hispanic times. It has even been suggested that victims destined for human sacrifice were given a *Datura* drink to prepare them for their death (Rätsch 1986a, 234*). The administration of *Datura* preparations for initiatory purposes also appears to have been known in Mesoamerica (cf. *Datura wrightii*).

The thorny fruit of *Datura innoxia* typically hangs straight down.

In the Yucatán (southern Mexico), *Datura innoxia*, which is known as *xtohk'ùh* (“in the direction of the gods”), is a rare plant. But it is frequently planted in house gardens as both an ornamental and a source of drugs. The *hmenó'ob* (shamans) use *Datura* not just as a medicine but first and foremost as a ritual drug. When divining with a quartz crystal (*ilmah sastun*), they either smoke cigars (*chamal*) rolled from datura leaves or eat datura seeds (Rätsch 1987*). They say of the cigars and the seeds *hach mà'lo' ta wòl*, “they are very good for your consciousness.” In the resulting inebriated state, the shaman is able to see things in the crystal that can provide insights into questions posed beforehand (e.g., pertaining to stolen or lost objects, the causes of illness, sorcery). Some modern Mayan shamans also use tarot cards¹¹³ (which were introduced into Mexico some one hundred years ago) when they perform divinations (Rätsch 1988b). Occasionally, they may smoke *Datura* before laying out the cards. Eating the seeds enables the *h-mèn* to travel to *yuntsil balam*, “the jaguar lord,” when a sick person has lost his *ah-kanul*, “protector spirits.” The aromatic flowers are also regarded as an excellent offering for the gods (Rätsch and Probst 1985, 1138). Among the Maya, use of the plant as an aphrodisiac (smoking the dried leaves) and a love magic (presenting the flowers to the desired person) is also common (Kennedy and Rätsch 1985; Rätsch and Probst 1985).

Jugo de toloache, a Mexican magical drink made from *Datura innoxia*, is used in love magic.

In urban *brujería*,¹¹⁴ toloache plays an important role in the preparation of magic powders (*verdadero polvo de toloache*), in the manufacture of aphrodisiac ointments and bath additives, and in love magic. In some parts of central Mexico, *Datura innoxia* is venerated in churches as a quasi-Catholic healer known as Santo Toloache, who is called upon to effect love magic.

Many Mexicans look upon the plant with respect, timidity, or disdain. It has an intimate connection to dark practices that may appear eerie to the ignorant (Madsen and Madsen 1972*). The plant has a reputation for causing insanity,¹¹⁵ of being toxic, and of being misused by the *brujos* (“sorcerers”) for harmful magic. According to many Mexican shamans, toloache is especially dangerous because it gives its users power. The Huichol regard it as a “bad plant of the gods” and usually associate it with sorcery (cf. *Solandra spp.*). Carlos Castaneda received the following explanation of the magical properties of the “devil’s weed” from his teacher, Don Juan:

The second portion of the devil’s weed is used to fly. . . . The unguent by itself is not enough. My benefactor said that it is the root that gives direction and wisdom, and it is the cause of flying. As you learn more, and take it often in order to fly, you will begin to see everything with great clarity. You can soar through the air for hundreds of miles to see what is happening at any place you want, or to deliver a fatal blow to your enemies far away. As you become familiar with the devil’s weed, she will teach you how to do such things. (Castaneda 1968, 92*)

Datura innoxia plays an important role in Indian divination. The Náhuatl-speaking peoples, and those who belong to the language family of the Maya, use the thorn apple as a prophetic and oracular plant. The Mixtec are said to ingest *Datura innoxia* as a traditional hallucinogen for divinatory purposes (Avila B. 1992*). Many tribes of the Southwest (the Colorado River and Paiute tribes and the Coahuilla) smoked the leaves and added them to drinks (**chicha**, pulque; cf. **Agave spp.**) to induce a prophetic delirium (Barrows 1967, 75*).

Datura innoxia is sacred to the Navajo, who view it with great respect and use it because of its great potency. The Navajo have many names for datura, including *ch'óhojilyééh*, “producing madness,” and *hoozhónee yilbéézh*, “Beautyway decoction” (Brugge 1982, 92). The Navajo collect the thorn apple, which is ritually addressed as “little white hair,” according to a specific ritual. They begin by sprinkling maize pollen over the plant and uttering the following prayer: “Little white hair, forgive me for taking you. I do not do this out of arrogance. I would like you to heal me. I will take only as much as I need” (Abel 1983, 193).

In many Navajo healing ceremonies, visions and dreams play a central role. The medicine men or shamans learn from the visions and attain powers they can then use for healing (Haile 1940). During the ceremony known in the literature as the Beautyway, preparations of *Datura* are ingested to produce such visions (Brugge 1982, 92). The Navajo medicine men also use the thorn apple to treat hallucinations.¹¹⁶ In secret ceremonies, the seeds are eaten as well.

The Navajo ingest small portions of *Datura* to protect themselves from the attacks of witches (Simmons 1980, 154). At the same time, the magical powers of the plant are also used for both positive and negative love magic (Hill 1938, 21), in which a person attempts to mix *Datura* into the food or smoking tobacco of the person he desires (Tierney 1974, 49).

The Navajo *ajilee* ceremony has been described in the ethnographic literature under the names Excess Way, Prostitution Way, and Frenzy Witchcraft. *Ajilee* is the name of a myth, a magical song, and a ritual in which the performer is transformed into a *Datura* spirit and is able to gain power over the women he desires as well as the game he wishes to hunt (Haile 1978; Luckert 1978). *Ajilee* is not one of the main healing rituals, and some Navajo (especially those who have been Christianized) regard it as witchcraft. Four magical plants, including *Datura innoxia* and probably also *Argemone mexicana* and the locoweeds (*Astragalus* spp.), play a central role in the *ajilee* myth and ritual. The ritual is intended to summon desired women (especially virgins from the Hopi and Pueblo Bonito) for sexual enjoyment. The same songs are also used to attract game. The ritual is also used to heal people who are suffering from sexual excesses as well as women who have been forced to prostitute themselves (Haile 1978). The person conducting the ritual is transformed into *Datura innoxia*, and the plant's aphrodisiac effects give him magical power over the woman he desires. As a result of the confusing and stupefying effects of *Datura*, the ritual performer also gains power over animals (Haile 1978, 26, 35ff.).

It is said that a few medicine men who perform *Datura* divinations, also known as criminal telepathy, live in the region to the east of the Lukachukai Mountains. They use the plant to detect thieves and locate lost objects (Simmons 1980, 154).

The Apaches use the powdered root in secret ceremonies as a ritual medicine. The Coahuilla utilize it to ceremonies as a ritual medicine. The Coahuilla utilize it to produce ritual delirium. The Costanoan smoke dried leaves as a hallucinogen. The seeds are mixed with tobacco (*Nicotiana tabacum*) to make a “love medicine” that is smoked during rituals of love magic. Hopi medicine men chew the root to induce a visionary state for diagnosing diseases (cf. *Mirabilis multiflora*). The Luiseño give their youths juice from the roots during their initiations (cf. *Datura wrightii*). The Shoshone brew a hallucinogenic tea for secret rites (Moerman 1986, 148f.*).

The Cultural Significance of *Datura innoxia* among the Navajo

(From Müller-Ebeling and Rätsch 1998)

- Agent for inducing visions
- Love magic
- Aphrodisiac
- Hunting magic

- Divination (criminal telepathy)
- Diagnosis (of disease causes)
- Medicine
- Magical protection
- Agent of pleasure

The plant was introduced into Baluchistan (Pakistan) from the Americas. Now growing wild, it is a well-known inebriant that is referred to by the Sanskrit name *dhatūra* (cf. ***Datura metel***). The people of the region smoke a few crushed seeds or a dried leaf mixed with tobacco (***Nicotiana tabacum***) (Goodman and Gharfoor 1992, 40*). In India, *Datura innoxia* is used in the same manner as ***Datura metel***.

Artifacts

Strangely, artifacts associated with toloache are relatively uncommon in Mexico. The Denver Museum has a postclassical Mayan ceramic that represents a three-dimensional head wearing ear ornaments that are clearly naturalistic representations of *datura*.

Numerous incense vessels have been found in western, central, and southern Mexico, the forms of which are reminiscent of the thorny fruits of *Datura innoxia* (Kan et al. 1989, 129, 201). In some Indian areas, e.g., among the Lacandon of Naha', this tradition of incense vessels still exists (Ma'ax and Rätsch 1994, 58*). Litzinger (1981) regards these vessels as true representations of the inebriating fruit. Today, *Datura* seeds are still burned for medicinal and ritual purposes. Incenses that include *Datura* seeds (copal, *pom*; cf. ***Bursera bipinnata***) are definitely capable of eliciting profound psychoactive effects (cf. **incense**).

Numerous ceramic vessels ("spiked vessels") have been found in the American Southwest and in northern Mexico. These appear to be representations of thorn apple fruits and were presumably used as vessels for burning incense (Camilla 1995, 106f.*; Litzinger 1981, 58ff.).

In a kiva (cosmological ritual room) at Kuaua, near Bernalillo, New Mexico, a Pueblo IV wall painting (1300–1550 C.E.) depicts a figure holding a *Datura* flower in its hand (Wellmann 1981, 92*).

The Hopi women of Moki traditionally twisted their hair into two round buns that they wore on the sides of their heads. Although the two buns were thought to represent squash blossoms and were known by that name, they actually represented the sacred *Datura innoxia* (Furst and Furst 1982, 56). Several petroglyphs at Moki resemble thorn apple flowers as viewed from above. In the literature, these also have been wrongly interpreted as squash blossoms (Patterson 1992, 189).

The Zuni use a head ornament in various ritual dances that is intended to recall the headpiece of A'neglakya, the personification of *Datura innoxia*. They wrap a dried fruit of *Martynia louisiana* Mill. with colored woolen ribbons and tie it to a leather headband. Early anthropologists interpreted this headpiece as a symbol of the squash flower. The Zuni themselves approved of this error, as it helped keep their sacred *Datura* secret (Müller-Ebeling and Rätsch 1998).

Navajo jewelry features a type of chain that is known both publicly and in the popular literature as the squash blossom necklace. However, these ornaments are representations not of squash flowers but of the flowers of a plant that had much greater cultic significance: the sacred thorn apple (*Datura innoxia*, ***Datura discolor***). The term *squash blossom* has come to be a widely used alias for *Datura*, which is used and venerated in secret (Müller-Ebeling and Rätsch 1998).

Some Shoshone petroglyphs depict visions that were obtained while under the influence of *Datura innoxia* (Camilla 1995, 109*).

The American artist Georgia O'Keeffe (1887– 1986) produced several paintings of luxuriously beautiful *Datura innoxia* flowers, e.g., the oil paintings *White Trumpet Flower* (1932) and *Jimson Weed* (ca. 1934). These paintings, which are regarded as typical of O'Keeffe's style and expression

(Castro 1985), have been reproduced on numerous calendars and postcards.

Medicinal Use

Datura innoxia plays a significant role in the ethnomedicine of the tribes of the Southwest (***Datura discolor*** is used in precisely the same manner, albeit much less frequently). The Apaches use juice freshly pressed from the flowers and roots to disinfect wounds. The Coahuilla rub plants crushed in water onto their horses' saddle sores. The Costanoan smear an ointment made from the leaves onto burns. They use dew drops that have collected in the flowers as an eyewash. Heated leaves are applied to the chest to relieve difficulties in breathing. The Mahuna use the plant to treat rattlesnake and tarantula bites. The Navajo use it to treat the castration wounds of their sheep. Fresh thorn apple leaves or aqueous extracts are applied to the skin to treat wounds. The root is chewed for severe pain. The Zuni used the root as an anesthetic when performing surgery (cf. **soporific sponge**). The Tubatulabal consume the plant to relieve constipation and use it to treat inflammations, wounds, and swelling (Brugge 1982, 92; Moerman 1986, 148f.*).

“How Datura came to be:

In olden times, there lived a boy and a girl (the name of the boy was A'neglakya and the name of the girl was A'neglakyatsi'tsa), brother and sister, in the inside of the earth. But they often came up to the earth and wandered about. They observed everything very closely and reported to their mother what they had seen and heard. This constant talking did not please the divinities (the twin sons of the sun father) at all. Once, when the divinities encountered the boy and the girl, they asked them: 'How are you?' The brother and the sister answered: 'We are happy!' (Sometimes A'neglakya and A'neglakyatsi'tsa appeared on the earth as people.) They told the divinities how they had caused a person to fall asleep and see spirits and could have someone wander around who could see where a theft had occurred. After this encounter, the divinities decided that A'neglakya and A'neglakyatsi'tsa knew too much and that they had to be banished from the world. And so the divinities caused the brother and the sister to vanish from the earth forever. But on the place where they disappeared, flowers grew—exactly those kinds of flowers that they had worn on their head when they had visited the earth. The divinities named the plants A'neglakya, after the boy. The first plant had many children who spread over the entire world. Some of the flowers are colored yellow, some blue, some red, some are entirely white—the colors of the four cardinal points.”

ZUNI MYTH

IN “ETHNOBOTANY OF THE ZUNI INDIANS”

(STEVENSON 1915)

Although it is known as a “squash blossom” necklace, this Navajo design actually symbolizes the sacred *Datura*.

The Aztecs utilized thorn apple leaves in the treatment of broken bones (e.g., skull fractures), abscesses, and swollen knees. They usually placed leaves that they had warmed in a steam bath directly onto the affected area. The Maya use the leaves to treat rheumatism (Pulido S. and Serralta P. 1993, 61*). Smoking the dried leaves to treat asthma, bronchitis, and coughs is a very common practice.

Toloache is one of the most important aphrodisiacs¹¹⁷ and sedatives of Mexican folk medicine. In rural areas, toloache brews are administered during childbirth to induce a twilight sleep and to mitigate the pains of childbirth (Heffern 1974, 98*). Ointments made with lard and extracts of *Datura innoxia* are often used to treat skin diseases as well as muscle and joint pain. Along with the plant, this use was introduced into Europe at an early date. John Gerard, in his sixteenth-century work *The Herball*, wrote:

The juice of Thornapple, boiled with hog’s grease, cureth all inflammations whatsoever, all manner of burnings and scaldings, as well of fire, water, boiling lead, gunpowder, as that which comes by lightning and that in very short time, as myself have found in daily practice, to my great credit and profit. (In Grieve 1982, 2:806*)

The plant finds use in the ethnomedicine of every region of the Old World into which it has spread. In Israeli folk medicine, a decoction of the leaves is drunk to treat diarrhea and a paste of the leaves is applied externally to treat pain (Dafni and Yaniv 1994, 13*). In Asia, this introduced species is used in the same manner as *Datura metel* and *Datura stramonium* (Shah and Joshi 1971, 420*; Singh et al. 1979, 188*).

Constituents

The entire plant is rich in **tropane alkaloids**. **Scopolamine** (the primary alkaloid) and hyoscyamine

predominate in the aboveground parts, while the flowers contain large amounts of tyramine and the stems large amounts of meteloidine.

The roots contain the following alkaloids: hyoscyamine, **scopolamine**, cuscohygrine, 3-tigloyloxytropine, 3-hydroxy-6-tigloyloxytropine, 6-hydroxyhyoscyamine, 6-tigloyloxyhyoscyamine, and tropine (Ionkova et al. 1989). A different analysis detected tigloidine, **atropine**, pseudotropine, 7-hydroxy-3,6-ditigloyloxytropine, 3 α ,6 β -di-tigloyloxytropine [428], hyoscyne, and meteloidine (Evans and Wellendorf 1959).

The seeds contain a total of 0.3% alkaloids (0.09% scopolamine, 0.21% hyoscyamine).

In addition to the alkaloids, the leaves also contain phenolic compounds (caffeic and hydroxycinnamic acid esters).

Some plants produce considerably more **scopolamine** than others (H  rouart et al. 1988). This fact helps explain some of the difficulties in determining dosages.

Effects

The effects of *Datura innoxia*—and in fact of all *Datura* species—are heavily dependent upon dosage and can vary greatly depending upon the method of application (Weil 1977). The Indian division into three stages has particular relevance here: A mild dosage produces medicinal and healing effects, a moderate dosage produces aphrodisiac effects, and high dosages are used for shamanic purposes.

The effects of four leaves smoked together by one couple appear to be typical for *Datura innoxia*:

The skin acquired an unimagined sensitivity. A simple, light caress became a tender, fulfilling experience. The blood collected in our lower abdomens so quickly that it demanded we join. The normal sexual functions were extremely heightened. Every form of erotic exchange and sexual activity had a special deliciousness. The time to orgasm was much longer, and the orgasm itself appeared to last for minutes. During the phase of sexual activity, we were both pleasantly free of thoughts, uninhibited, and very much focused on the moment. The effects lasted the entire night, so that there were many couplings. The next morning, after a short sleep with erotic dreams (!), we awoke with a clear consciousness, a very pleasurable warm sensation in the body, a still overly sensitive skin, and a dry throat. (R  tsch and Probst 1985, 1139)

Shamanic dosages induce profound visions, strong hallucinations, and delirium. As with those produced by *Brugmansia suaveolens*, the hallucinations can have a metaphysical character or can be quite banal.

Overdoses can begin with initial excitation, the urge to dance, frenzy, and fits of laughter before leading to acute hallucinosis and finally to death through respiratory paralysis (Siegel 1981*). In Mexico, peyote (*Lophophora williamsii*) is used as an antidote for toloache overdose (Nadler 1991, 95*).

“This person is going to drink you. Give him a good life.

Show him what he wants to know.”

PRAYER TO TOLOACHE

(FROM SCHULTES AND HOFMANN 1992:107*)

Commercial Forms and Regulations

In Mexico, various preparations allegedly made from toloache (such as magical juices and powders) are sold at the *brujer  a* markets. Chemical analysis of one *leg  timo polvo de toloache* (“legitimate

toloache powder”) revealed that the sample did not contain any alkaloids and therefore could not consist of *Datura* (Hasler 1996).

In Europe, potted plants and seeds are available at nurseries without restriction. Pharmaceutical preparations of *Datura* are made almost exclusively from *Datura stramonium* or *Datura metel* (see there.)

These Shoshone petroglyphs from Wyoming show the visions that are obtained under the influence of *Datura innoxia*. (From Camilla 1995)

These Indian incense vessels clearly resemble thorn apple fruits. (From Camilla 1995)

Datura metel Linnaeus

Indian Thorn Apple

This early illustration of the Indian thorn apple (*Datura metel*) is botanically quite accurate. (Woodcut from Garcia da Orta)

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Dutra Section

Forms and Subspecies

Because of the considerable variation within this *Datura* species, numerous forms, varieties, and subspecies have been described, and the taxonomy is confusing (Avery 1959). White-flowering varieties are now usually referred to as *Datura metel* var. *alba*, and violet-blooming varieties as *Datura metel* var. *fastuosa*. There also are a number of cultivars: *Datura metel* cv. *Fastuosa* (double violet flowers), cv. *Chlorantha* (yellow double trumpets), cv. *Coerulea* (blue flowers), cv. *Atrocarmina*, cv. *Lilacina*, cv. *Violace* (violet flowers), cv. *Alboplana*, cv. *Flavaplana*, et cetera. *Datura metel* L. f. *pleniflora* Degener has triple yellow flowers.

Stramonium fastuosa (L.) Moench

Folk Names

Arhi-aba-misang, bunjdeshtee (Persian), chosen-asagau (Japanese, “Korean morning beauty”), da dhu ra (Tibetan), datula, datur-a (Mongolian), datura (Sanskrit), datura engletrompet (Danish), datura indica, datura kachubong, devil’s trumpet flower of Ceylon, dhatra (Santali), dhattûra (Sanskrit), dhatura (Sanskrit, “heterogeneous”), dhatûrâ, dhatur-ma, dhaturu, dhétoora (Hindi), dhustura, dhustûra, dhutro (Bengali), dhutura (Bengali), dootura, dornäpfel, dotter (Dutch), doutro, doutry, dutra, dutro, dutroa, dutro banguini, engelstropete, engletrompet, ganga bang, gelber stechapfel, goozgiah (Persian), hearbe dutroa, Hindu datura, hummatoo, indischer stechapfel, insane herb, jous-mathel (Arabic), jowz massel, kachubong (Philippines), kala dahtoora, kala dhutura (Hindi, “black datura”), kalu antenna, kalu attana, karoo omatay (Tamil), kechu-bong, kechubong hitam (“black datura”), kechubong puteh (“white datura”), kechu-booh (Egyptian), kechubung (Malayan), kecubong (Bali), keppate jad, krishna dhattura, man-t’o-lo (Chinese),¹¹⁸ menj (Arabic/Yemen), metelapfel, metelnuß, mnanaha (Swahili), mondzo (Tsonga), nao-yang-hua (Chinese), neura, neurada, ñongué morado, nucem metellam arabum, nulla oomantie, nux metel, nux-methal, paracoculi, pig-ble, rauchapfel, rauchöpfel, rotecubung, shan-ch’iehêrh (Chinese), Shiva’s plant, stechöpfel, stramonium, talamponay, takbibug, tatorah (Arabic), thang-phrom dkar-po (Tibetan), thorn apple, umana, unmata (Sanskrit, “divine inebriation”), unmeta, violettblauer stechapfel, violettblaue engelstropete

History

The Indian thorn apple was first mentioned in Sanskrit literature (Vamana Purana, Garuda Purana). The Arabic physician Avicenna (Ali al-Husayn Abd Allah Ibn Sina, 980–1037) discussed its medicinal use and the importance of dosage among the Arabs, who classified the plant as one of the so-called *mokederrat*, the narcotics (Avery 1959, 3). This thorn apple also appears in very ancient Tibetan and Mongolian texts, the existence of which demonstrates that *Datura metel* was indigenous to Asia prior to the fifteenth century (Siklós 1993, 1996). It is not known when this thorn apple spread into Africa. Today, *Datura metel* is still a psychoactive plant of great ethnopharmacological significance, especially in India, Southeast Asia, and Africa.

Distribution

This species most likely originated in northern India but then spread quickly throughout Southeast Asia. It is now found in the Philippines, in Indonesia, and on the islands of the Indian Ocean (Seychelles, Mauritius, etc.). It presumably spread into Africa and the New World (Central and South

America, the Caribbean) through human activity.

Cultivation

Propagation is performed with seeds (cf. *Datura discolor*). It is best to soak the seeds overnight before sowing. The next morning, they should be pressed 1 to 2 cm deep into sandy, humus-rich seedling soil and lightly covered. Do not allow the soil to dry out. The time to germination is fourteen to thirty-five days. In central Europe, the seeds should be sown (in the open) between April and July, preferably in June. The plant is sensitive to frost but can be trimmed back in late fall and allowed to overwinter in the cellar. With a little luck, the plant will develop shoots again the following spring.

Datura metel is cultivated commercially as a source of alkaloids (**scopolamine**) chiefly in subtropical and tropical regions throughout the world (especially in India and Africa).

Appearance

Datura metel is an annual or biennial plant that has an herbaceous, bushy appearance. It can grow to more than 2 meters in height and develops numerous branches. The soft leaves are light to dull green in color and have a slightly serrated margin. The plant has smooth, violet or dark purple stalks. The funnel-shaped flowers, which can be white, violet, or yellow (depending on the variety, subspecies, or cultivar), point upward at an angle. They open in the evening, exude a pleasant scent during the night, and then wither over the course of the next day or two. *Datura metel* often produces filled double or triple flowers. The variety *fastuosa* frequently develops violet double flowers. In the tropics, the plant will blossom throughout the year. In central Europe, the flowering period is from June to October.

The fruit, which hangs upward at an angle, has a few short thorns that are often only roundish bumps. The kidney-shaped seeds are yellow ocher and almost identical to those of *Datura innoxia* and *Datura wrightii*.

Datura metel, especially the variety *alba*, is very easily confused with *Datura innoxia*. It is sometimes even mistaken for certain forms of *Datura stramonium*.

Psychoactive Material

- Leaves
- Seeds
- Roots
- Flowers (these are used in Chinese medicine, where they are known as *yang jin hua*; Lu 1986, 82*)

Because the alkaloid content of the entire plant increases until the plant reaches the end of its reproductive phase, the raw drug is best collected during or after the end of fruit development (Afsharypuor et al. 1995).

Preparation and Dosage

A narcotic or inebriating drink is prepared by adding equal parts of *Datura metel* seeds and/or leaves and hemp (*Cannabis sativa*) flowers to **wine** (Perry and Metzger 1980, 392*). In Asia, the leaves are often taken together with wine or **sake** (Penzer 1924, 160). Thorn apple seeds are used to fortify *rokshi* (barley spirits; see **alcohol**) in Darjeeling and Sikkim. The seeds are also used in **betel quids**.

A unique method for preparing the plant was discovered in East India. Here, women feed datura leaves to a certain type of beetle (the exact species is unfortunately unknown) for a period of time and collect the beetle's excrement. They then mix this into an unfaithful husband's food for revenge. Overall, there are a number of traditional preparations in India:

India has zones of datura use. For example, Bengal. The particularly passionate smoke *Cannabis indica*, ganjah, with two or three thorn apple seeds or a quantity of leaves as additives. In order to potentiate and alter the effects of alcoholic drinks upon the brain, they soften seeds in the drink, filter this, and mix it with palm wine. This is done, e.g., in Madras province. Or, as in Bombay, they allow the smoke of roasted seeds to come into contact with an alcoholic beverage for a night. It is certain that active components of the plant volatize in this way, and they can then be absorbed by the alcohol. (Lewin 1980 [orig. pub. 1929], 181*)

The flowers of the Asian *Datura metel* (= *Datura alba*) point upward.

Datura metel is recognized primarily by its fruits, which have few thorns and hang at an angle, and by its smooth, violet stems. (Photographed in Uttar Pradesh, India)

Datura metel var. *fastuosa*, common in northern India, has violet-tinged flower margins and smooth stems. (Photographed in Uttar Pradesh, India)

This cultivated form of *Datura metel* var. *fastuosa* produces double flowers.

Datura metel f. *pleniflora* develops filled yellow flowers (triple trumpet).

The dried leaves (or less often the flowers and seeds) are an important ingredient of tantric **smoking blends** (cf. *Aconitum ferox*). A mixture of equal parts of *Datura metel* leaves and hemp (*Cannabis indica*) flowers is particularly esteemed for its inebriating and aphrodisiac effects. The seeds are also added to magical or psychoactive **incenses**. In Malaysia, the seeds are mixed with aloe wood (*Aquilaria agallocha*), cat's eye resin (from *Balanocarpus maximus* King; Dipterocarpaceae), or leban resin (from *Vitex pubescens* Vahl.; Verbenaceae) and burned as an inebriating incense

(Gimlette 1981, 216*).

In Malaysia, a hallucinogenic paste is mixed from opium (cf. *Papaver somniferum*), *Datura* seeds, the green shoots of a wild yam species known as *gadong* (*Dioscorea triphylla* Lam.; cf. *Dioscorea composita*), and the green inner bark of *Glycosmis citrifolia* (Rutaceae) (Gimlette 1981, 220*).

The seeds are a main ingredient of **Oriental joy pills** and other similar aphrodisiacs. In Burma (Myanmar), the seeds are added to curries to increase their aphrodisiac effects (Perry and Metzger 1980, 391*). In Oceania, they are added to kava drinks to potentiate their inebriating effects (see *Piper methysticum*). On Java, the thorn apple is prepared as an inebriant in the following manner: Fully grown, ripe, but still unopened fruits are collected and opened. The seeds are dried in the sun and then ground. They then may be mixed with tobacco (Indonesian tobacco [*Nicotiana tabacum*] perfumed with clove oil) or rolled into a tobacco leaf and smoked. In Japan as well, dried leaves were once smoked together with tobacco (*Nicotiana tabacum*) (Lewin 1980 [orig. pub. 1929], 181*).

Datura metel var. *alba*, depicted in an early Japanese woodcut from Siinuma Yokusai

On Mactan Island (off the coast of Cebu, in the Philippines), young flowers that have not yet unfurled are plucked and dipped briefly in boiling water. They are then laid out in the sun to dry. The dried flowers are crumbled, rolled in a cigarette paper, and smoked. The effects are said to be similar to those of marijuana, but stronger.

The homeopathic mother tincture is produced from ripe seeds with 90% ethyl alcohol (medicinal content of the tincture 1/10).

In Malaysia, fifty seeds taken internally is regarded as a hallucinogenic or (when used for criminal purposes) deliriant dosage (Gimlette 1981, 214*). One hundred seeds (= 1 g) can produce dangerous states and toxic effects. In India, 125 seeds have been reported to be lethal (Gimlette 1981, 217*).

Ritual Use

According to the Vamana Purana, the thorn apple grew from the chest of the Hindu god Shiva, the lord of inebriants (cf. *Cannabis indica*). In the Garuda Purana, it is said that *Datura* flowers should be offered to the god Yogashwara (= Shiva) on the thirteenth day of the waxing moon in January (Mehra 1979, 63f.). In Nepal, where *Datura* is usually known as *dha-tur-ma*, the plant is considered to be sacred to Shiva. *Dhatur* is interpreted as another name for Shiva; *ma* means “plant.” Thorn apple flowers and fruits are among the most important offering gifts of the Newari of Nepal. At every

family *puja* (devotional service or offering ceremony), Shiva is first offered *Datura* fruits in order to please him. In Varanasi, Shiva's sacred city, metal fruits and rose flowers are made into sacrificial garlands (*malas*) for the god of inebriation and sold to pilgrims and devotees at the entryways to his temples. These *Datura* chains are then devoutly placed around the lingam, the deity's phallic-shaped image, as fresh flowers are tossed over it (cf. "Artifacts"). The lingam is normally placed in a yoni, the cosmic vulva. Fresh metal fruits are placed into it as offerings.

In Uttar Pradesh (northern India), it is common knowledge that *Datura metel* can be used for inebriating purposes. Smoking the plant is regarded as pleasurable and not dangerous, whereas eating or drinking it is considered dangerous and is generally avoided. Yogis and sadhus in particular smoke thorn apple leaves or seeds together with hemp (*Cannabis indica*) and other herbs (*Aconitum ferox*, *Nicotiana tabacum*).

In Tibet and Mongolia, this thorn apple is used as an **incense** in secret Vajramabhairava Tantra rituals intended to transform wealth into poverty and to dispel certain spirits or energies. The fruits or seeds are used to induce insanity (Siklós 1995, 252).

In China, the white-blossomed *Datura metel* var. *alba* was considered to be sacred because it was believed that shimmering dew drops had rained from the heavens onto its flowers while the Buddha was giving a sermon. The Chinese Buddhists called it *man-t'o-lo*, after a non-translatable passage from a sutra named *man t'o lo hua*. In ancient China, it apparently was popular to steep the aromatic flowers in **wine** or **sake** before consumption. In the sixteenth-century *Pen tsao kang mu*, Li Shih-chên wrote of the plant's properties:

Tradition has it that if someone laughs while the flowers are being plucked for use with wine, the wine will evoke laughter in all who drink it. If the flowers are picked while someone is dancing, the wine will induce dancing.

It is possible that this information may be referring to an ancient shamanic ritual.

The Igorot, a Malayan tribal people of Luzon (Philippines), boil the leaves to make an inebriating soup that is eaten communally in a ritual circle.

In Africa, *Datura metel* is used for criminal telepathy and in initiations. The seeds are also used to poison victims so they can be robbed. The toxic and hallucinogenic properties of the plant are well known in East Africa. Seeds are added to the locally brewed **beer** to potentiate its effects (Weiss 1979, 49).

In Tsongaland, which stretches from Mozambique to the Transvaal, *Datura metel* var. *fastuosa* is utilized as a hallucinogenic ritual drug (*mondzo*) in the initiation of girls into women (similar to the use of *Datura wrightii* in the initiation of boys). At their initiation, the girls are painted with red ocher (a symbol of menstrual blood). One after another, they are made to lie down in a fetal position on a mat made from palm fronds while the others dance around them holding on to their hips. Special songs are sung. Afterward, the initiates are tied to a tree (*Euphorbia cooperi* N.E. Br.). Others beat the tree with a stick until white latex (a symbol of spermatozoa) issues from its bark.

The next stage is a water ritual, through which the initiates are cleansed and are supposed to cast aside their childish past. Before they ingest the thorn apple, the girls are required to stretch an animal skin over a vessel of water. Older women perforate the skin with sticks and stir the water. Following this symbolic defloration, a "school-mother" covered entirely in *Datura* leaves, toad skins, and dog teeth bursts out from the bushes. The initiates are covered in blankets and laid onto palm mats as rhythmic drumming prepares them to receive the *Datura* drink. The schoolmother approaches the initiates, spits upon them, and tells them repeatedly that they will soon hear the voice of the fertility god. She then places cubes of clay, from which pieces of straw protrude, between the girls' legs (the

girls' pubic hair is shaved off prior to the ceremony). The clay cubes symbolize the fact that when the pubic hair regrows, it will belong to a woman, not a girl. Then the thorn apple drink is carried around in a ceremonial seashell. It is made by boiling the herbage in water and is said to contain human fat or powdered human bones as well. The schoolmother holds the drink in her hands and sings, "We dig up the medicinal plants that are known to all. Take the medicine, about which you have already heard so much!" Now the initiates drink and listen for the voice of the fertility god. They experience certain visions that are shaped and channeled by means of music and song. At the end of the initiation, the girls are freed from their coverings, dressed in new clothes, and adorned with ornaments. Finally, they dance and sing. The young women are now able to marry (Johnston 1972).

Artifacts

Datura metel flowers are sometimes depicted in Hindu/tantric art, usually in connection with images of Shiva in his various forms. One famous eighteenth-century painting shows a lingam-yoni statue (= the cosmic union of phallus and vulva) upon which a thorn apple flower has been placed in offering (Mookerjee 1971, 49). The plant is also represented on Tibetan medicine thangkas (Aris 1992, 67*). In the Kathmandu Valley, thangkas and statues show Unmata Bhairab, the "divinely inebriated thorn apple Bhairab" (a special tantric form of Shiva), standing straight up.

Hans Simon Holtzbecker, a flower painter from Hamburg, painted a masterful portrait of the plant for the Gottorfer Codex (ca. 1650) (de Cuveland 1989, table 50*).

Numerous Oriental fairy tales mention the inebriating and aphrodisiac properties of the plant (Penzer 1924, 158–62). E. T. A. Hoffmann (1776– 1822) wrote a story, "*Datura fastuosa* (Der schöne Stechapfel)" [The Beautiful Thorn Apple], in which he romantically describes the psychoactive effects of the plant's scent (Hoffmann 1967, 329–80).

In Tsongaland, special music as well as *Datura fastuosa* songs are used during initiations to control the visionary state (Johnston 1975). One techno-pop band, *Datura*, has even taken its name from the thorn apple.

"The [metel] seeds are a forbidden article among the Dutch, both in India and in Holland, inasmuch as the beer brewers use it to fortify their weak beer, and the brandy distillers do the same; but when they use a bit too much of it, it makes the people who drink of it senseless for a time, or it weakens their reason, so that they imagine some wondrous and almost laughable things, depending upon how their humors are inclined, as for example that one would be a great lord, king, or prince, or another that he wants to swim in the water, even though he is lying in a bed or is in the room, while another has foolish fantasies. Some misuse this datura to force the favors of the fairer sex, although with some this grave thing would not require such force, but when you drink a little warm milk, it is soon over, otherwise it is in 4 degrees of cold nature, it robs a person of sense and reason, and before this of the sense of feeling, because it induces a heavy sleep, blinds the vision, makes the head silly, as if drunken, so that he would pluck at his own clothes and limbs like a born idiot, and would make comical gestures like an Indian monkey when you spread *Urtica Indica* over his claws."

GEORG MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]

(1677, CH. 9, 31*)

"The smoke apples are also an exotic growth / recently come to us from the Oriental lands / it is now grown in many gardens / more for fun / than for usefulness or use / for it is beautiful and amusing to look upon / especially when it is flowering and bearing fruits."

PIERANDREA MATTHIOLUS *KRÄUTERBUCH* [HERBAL] (1627, 377*)

Traditional representation of *Datura metel* on a Tibetan medicine thangka (close-up)

“Not very far from the gate there bloomed a *Datura fastuosa* (beautiful thorn apple), with its wonderfully scented, large, funnel-shaped flowers in such splendid magnificence, that Eugenius thought with shame about the wretched appearance that the same plant displayed in his own garden. . . . There floated, as if borne by the evening airs, the sweet accords of an unknown instrument from the remote magical bushes, and the wondrous heavenly tones of a woman’s voice ascended luminously.—It was one of those melodies that can spring only from the deepest breast of the fires of love of the south; it was a Spanish romance that the hidden one sang.”

E. T. A. HOFFMANN

“*DATURA FASTUOSA* (DER SCHÖNE STECHAPFEL)” [THE BEUATIFUL THORN APPLE]
(1967, 358)

Medicinal Use

There is evidence that *Datura metel* seeds have been used in Indian folk medicine as well as Ayurveda since a very early date. In the Ayurvedic system, preparations of *Datura* are used to treat numerous illnesses and ailments: headaches, mumps, chicken pox, furuncles, wounds that will not heal, pains of all types, rheumatism, muscle tension, nervous disorders, spasms, convulsions, epilepsy, insanity, syphilis and other venereal diseases, asthma, bronchitis, and overdoses of opium (see *Papaver somniferum*). The seeds were even once used as a substitute for opium (see **morphine**).

In the Indian medical system known as Unani, which was shaped substantially by Avicenna and is still practiced today (Chishti 1988), *Datura metel* was and is used in similar or identical manners to its use in the Ayurvedic system.

In the Indian folk medicine of the Santal, thorn apple is administered as a remedy for a large number of illnesses: headaches, otitis, wounds, mumps, pain, dropsy, insanity, rheumatism, muscle tension, epilepsy, spasms, delirium febris, pimples, smallpox, syphilis, venereal diseases, and orchitis (Jain and Tarafder 1970, 251). In Karnataka, crushed fresh leaves are applied externally to treat mumps. An infusion is applied externally to treat scorpion stings. Thorn apple is mixed with the leaves of *Solanum nigrum* (see *Solanum spp.*) and *Erythrina variegata* L. (see *Erythrina spp.*) to make a tonic (Bhardary et al. 1995, 155f.*). In Uttar Pradesh (northern India), a paste obtained from the seeds is used to treat parasitic skin diseases (Siddiqui et al. 1989, 484*). Powdered seeds are ingested together with dried seedlings of *Cannabis sativa*, roots of *Laportea crenulata*, and roots of ginger (*Zingiber officinale*) and used as a remedy for pain and cramping (Jain and Borthakur 1986, 579*).

A woodcut depicting the thorn or metel apple. (From the herbal of Hieronymus Bock, 1577)

In Java, the seeds are placed onto teeth, inserted into cavities, or chewed lightly to relieve dental pain. *Datura metel* var. *alba* is also used for numerous purposes in traditional Chinese medicine. Mixed with wine (see *Vitis vinifera*) and hemp (see *Cannabis indica*), it is used as a narcotic. The flowers and seeds are used to treat skin eruptions and other skin diseases, colds, and nervous disorders.

Datura metel is used to treat asthma in all the regions of the world in which it occurs (Perry and Metzger 1980, 391*; Baker 1995*). In East Africa, dried leaves are either smoked in the form of cigars or burned in incense vessels and inhaled for this purpose (Weiss 1979, 49). In the Philippines, the fresh herbage is placed in an open fire so that asthmatics can inhale the resulting smoke (cf. **incense**). In Europe, this species of *Datura* quickly became known as a medicinal plant under the name *rauchapfel* (“smoking apple”) because its leaves can be smoked to treat asthma.

Constituents

All forms and varieties of *Datura metel* contain potently hallucinogenic **tropane alkaloids** (Afsharypuor et al. 1995). Of all the thorn apple species, *Datura metel* contains the highest concentrations of **scopolamine**. Also present are hyoscyamine, **atropine**, meteloidine, norscopolamine, norhyoscyamine, hydroxy-6-hyoscyamine, and datumetine. The entire plant also contains **with-anolides**: daturiline, withameteline, daturilinole, secowithameteline, and various daturametelines (Lindequist 1992, 1142*).

The leaves have been found to contain 0.5% alkaloids, the flowers 0.1 to 0.8%, the fruits 0.12%, the roots 0.1 to 0.2 %, and the seeds 0.2 to 0.5% (Lindequist 1992, 1142*).

Effects

The effects of *Datura metel* are essentially the same as those of *Datura innoxia* (see there). However, some of what is known indicates that the former can produce effects specific to the species. For example, **smoking blends** made with *Datura metel* seeds and tobacco (with clove oil) have cheering effects and produce a sleep with lively dreams.

In Tsongaland, the hallucinogenic effects are controlled by music, resulting in auditory hallucinations and synesthetic perceptions in which the music is perceived as colors and stereotypical patterns. The contents of these visions include blue-green patterns, green snakes or worms, whirlpools, and sandbanks. The snakes are interpreted as ancestral gods and the auditory hallucinations as the spoken messages of the fertility god (Johnston 1977).

Overdoses will usually result in a delirious state that sometimes can last for days, after which little or nothing can be recalled. Thieves, criminals, and bands of robbers (e.g., the Thuggs) make use of

this property when they wish to sedate their victims and rob or rape them without disturbance (Gimlette 1981, 204 ff.*).

In Southeast Asia, licorice (*Glycyrrhiza glabra* L.) is a recommended antidote for overly strong doses of *Datura metel* (Perry and Metzger 1980, 392*).

Commercial Forms and Regulations

The seeds and potted plants of all cultivars, forms, varieties, and subspecies are freely available. In Germany, preparations of the homeopathic mother tincture (*Datura metel* hom. *HAB34*) and various dilutions are available from pharmacies (Lindequist 1992, 1142*). The mother tincture as well as dilutions to D3 require a prescription (cf. *Datura stramonium*).

The South American thorn apple (*Datura stramonium* ssp. *ferox*) is usually called *chamico* or *miyaya*. (Photographed in Ecuador)

Datura stramonium Linnaeus

Common Thorn Apple

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Stramonium Section

Forms and Subspecies

This diverse species is now divided into four varieties:

The stigma of the common thorn apple (*Datura stramonium*), shown here enlarged and covered with pollen, resembles a phallus. Is this an indication of the aphrodisiac effects of the plant? (From Louis Figuier, *The Vegetable World*, London 1869)

Datura stramonium L. var. *godronii* Danert [syn. *Datura inermis*] has thornless fruits and light violet flowers.

Datura stramonium L. var. *inermis* (Juss. ex Jacq.) Timm. has smooth fruits, white flowers, and green stalks.

Datura stramonium L. var. *tatula* Torr. has thorny fruits, violet flowers, and violet-tinged shoots, leaf stalks, and leaf veins. The karyotype of *Datura stramonium* L. var. *tatula* Torr. is almost identical to that of ***Datura wrightii*** (Spurná et al. 1981).

Datura stramonium L. var. *stramonium* Off. has thorny fruits, white flowers, and green shoots.

The following varieties were described at an earlier date:

Datura stramonium L. var. β *canescens* Wallich in Roxburgh

Datura stramonium L. var. β *chalybea* Koch

The following subspecies are also accepted today:

Datura stramonium L. ssp. *ferox* (L.) Barclay (Franquemont et al. 1990, 99*), which is probably from South America and not from China

Datura stramonium L. ssp. *quercifolia* (H.B.K.) Bye

Datura stramonium L. ssp.[or var.] *villosa* (Fern.) Saff.

Stramonium vulgatum Gaertner

Folk Names

Ama:y mustak, ama:y'uhc (Mixe, “dangerous plant”), ñña panku (Quechua), apple of Peru, arhiaba, asthmakraut, atafaris, attana, azacapanyxhuatlazol-patli (Nahuatl), chamaka, chamico (Quechua), chasse-taupe, chililiceño tapat (corruption of *tlapatl*), cojón del diablo, common thorn apple, concombre à chien, concombre zombi (Caribic, “zombie cucumber”), devil’s apple, devil’s trumpet, dhatura, donnerkugel, doornappel (Dutch), dornapfel, dornkraut, dutry, el-rita (Morocco), endormeuse, estramonio, fêngch’ieh-êrh (Chinese), gemeiner stechapfel, héhe caroocot (Seri, “plant that makes crazy”), herbe aux sorciers (French, “sorcery plant”), herbe de taupes, hierba del diablo (“plant of the devil”), hierba hedionda (“stinking plant”),¹¹⁹ hierba inca (“Inca plant”), higuera loca (“crazy fig”), igelkolben, ix telez ku, Jamestown weed, jimsonweed, jimson weed, jouj macel (Arabic), khishqa khishqa (Quechua, “very thorny”), kieli-sa (Huichol, “bad *kieli*”), kratzkraut, manzana del diablo (“apple of the devil”), manzana espinosa (“thorny apple”), matul (Tzeltal), mehen xtohk’u’u (Mayan, “little plant in the direction of the gods”), menj (Arabic/Yemen), mezerbae, mezzettoni, miaia, miaya (Mapuche), mixitl, miyaya, moshobaton tahui (Shipibo), muranha (Swahili), niungué, noce puzza, noce spinosa, ñongué, ñongué morada, papa espinosa (Spanish, “thorny potato”), parbutteeya, patula (Turkish), patura, pomme de diable, pomme épineuse, rurutillo (from the Quechua *ruru*, “fruit”), santos noches, schlafkraut, schwarzkümmel, semilla de la virgen (“seeds of the virgin”), shinah azqhi, simpson weed, stachelnuß, stachelnüss, stink weed, stramoine, stramoine commune, stramonio, stramonio comune, stramonium, taac-amai’ujts (Mixe), ta:g’amih (Mixe, “grandmother”), tatula (Persian, “to prick”), tc’óxwotjilyáih (Navajo), teufelsapfel, thanab (Huastec), thanab thakni’ (“white thanab”), thangphrom dkar-po (Tibetan), thorn apple, tohk’u (Mayan, “the direction of the gods”), tollkraut,¹²⁰ toloache, tonco-onco, torescua (Tarascan), tukhmtâtûrâ (Persian), tztizintlapatl (Aztec, “thorny *tlapatl*”), weißer stechapfel, wysocan, xholo (Zapotec), yacu toé, yoshu chosen asago (Japanese, “exotic morning flower”), zigeunerapfel

History

The origins of this potentially hallucinogenic thorn apple species are unknown and have been the subject of considerable botanical debate (Symon 1991, 142*). Some authors have suggested that *Datura stramonium* is an Old World species from the region of the Caspian Sea, while others maintain that it originated in Mexico. It is less frequently assumed that the species is from the eastern coast of North America (Schultes and Hofmann 1995*). Still other authors believe that the plant is from Eurasia and did not arrive in Mexico until the colonial period (Berlin et al. 1974, 489*).

In the seventeenth century, the plant's use as an inebriant ("drunk in wine") was documented in Chile (Hoffmann et al. 1992, 145*). *Datura tatula* (= *Datura stramonium* L. var. *tatula*) has been interpreted as the "lost inebriant" of the Shawnee (Tyler 1992). In 1676, a troop of soldiers in Jamestown, Virginia, was served a salad made from thorn apple leaves by their cook. The soldiers fell into a state of delirium that got out of hand and acted like idiots (see "Effects"). As a result, the plant also became known by the name *Jamestown weed*, which eventually became *jimsonweed*. In Mexico, *Datura stramonium* is generally regarded as a "younger sister" of ***Datura innoxia***, and it is used in the same ways.

The interpretation that *Datura stramonium* is the plant that Theophrastus and Dioscorides referred to as *strychnós manikós* is quite uncertain (cf. Dieckhöfer et al. 1971, 432; Marzell 1922, 170*). It is more likely that these ancient descriptions refer to the poison nut (***Strychnos nuxvomica***). The trance-inducing smoke of Delphi (cf. ***Hyoscyamus albus***) has been attributed to an **incense** made with *Datura stramonium* (Lewin 1980 [orig. pub. 1929], 183*).

In the European literature, this and other species of thorn apple (***Datura innoxia***, ***Datura metel***) were described in all the herbals compiled by the fathers of botany. The first botanically precise illustrations of *Datura stramonium* are contained in the herbals of Hieronymus Bock and Pierandrea Matthioli. It is widely believed that Gypsies brought this thorn apple to Europe (Perger 1864, 183*). Matthioli wrote that *Tatula Strominio altera* was an Oriental plant.

The common thorn apple (*Datura stramonium*) produces small white flowers.

Distribution

Today, *Datura stramonium* is commonly found throughout North, Central, and South America; North Africa; central and southern Europe; the Near East; and the Himalayas. The plant is very common on the islands of the Caribbean (Concepción 1993, 554). In the Himalayas (Nepal), the violet-blooming *Datura stramonium* var. *tatula* is the most common form. The subspecies *ferox* grows primarily in Central and South America. In Germany and Switzerland, the common thorn apple has been growing wild (usually in rubbish dumps and on roadsides) since at least the sixteenth century (Lauber and

Wagner 1996, 802*). It has also spread into Israel and Greece (Dafni and Yaniv 1994*).

Cultivation

Cultivation occurs in the same manner as with *Datura discolor* (see there).

The common thorn apple is cultivated commercially for pharmaceutical purposes (as a source of raw drugs and of **scopolamine**). It has been determined that cultivated thorn apples produce considerably more scopolamine when exposed to intense light (Cosson et al. 1966). In contrast, nitrogenous fertilizers have no effect (Demeyer and Dejaegere 1991). It is likely that alkaloid production in the plant can be stimulated by the addition of sugar (saccharose) (Dupraz et al. 1993).

Appearance

This annual plant can grow to a height of about 1.2 meters. It produces many forked, bald branches. The margins of the rich green leaves are coarsely serrated. The funnel-shaped, five-pointed flowers grow from the axils and point straight up; in the common form, they are white. This species produces the smallest flowers (6 to 9 cm long) of the *Datura* species. The egg-shaped green fruits, which are densely covered with short, pointed thorns, are quadripartite and always grow straight up from the axils, a feature which makes it easy to distinguish this species (including all of its varieties and/or subspecies) from the other *Datura* species. The kidney-shaped, applanate seeds (up to 3.5 mm long) are usually black.

The subspecies *ferox*, which was previously thought to be a distinct species, bears leaves that are more clearly and more deeply serrated than those of the common form, while its fruits have longer and slightly curved thorns. The seeds are somewhat lighter in color; they can be brown or black (and may occur in different colors in the same fruit). The flowers are pure white.

The variety *tatula* produces smaller violet flowers. The variety *stramonium* has many short thorns; the subspecies *ferox* has only a few long, sometimes slightly curved thorns; the variety *quercifolia* has even fewer thorns that are somewhat shorter but thicker at the basis. The subspecies *villosa* (cf. *Datura spp.*) has very pileous (hairy) branches, stalks, and calyxes.

One of the first European illustrations of the common thorn apple (*Datura stramonium*), clearly showing the typically upright fruits. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The upright fruit of *Datura stramonium*

The fruits of the South American thorn apple (*Datura stramonium* ssp. *ferox*) are characterized by their especially long thorns. (Photographed in San Pedro de Atacama, northern Chile)

The fruits of *Datura stramonium* var. *godronii* are completely smooth.

Datura stramonium var. *tatula* is distinguished on the basis of its violet flowers. (Wild plant, photographed in northern California)

Datura stramonium can be confused with small forms of ***Datura discolor***, ***Datura innoxia***, and ***Datura metel***.

Pyschoactive Parts

- Leaves (stramonii folium, folia stramonii, stramonium leaves, thorn apple leaves)
- Seeds (stramonii semen, semen stramonii, thorn apple seeds, tollkörner,^{[121](#)} kachola^{[122](#)})
- Flowers
- Roots (radix stramonii, tollwurzel)

Preparation and Dosage

The herbage is harvested shortly after the flowering phase and hung in the shade to dry. It may be smoked alone or in **smoking blends** with other herbs:

The leaves of *Datura stramonium* are said to be smoked by the Utahs, the Indians of the Great Salt Lake, as well as the Pima and Maricopa, together with the leaves of *Arctostaphylos glauca* or alone. (Lewin 1980 [orig. pub. 1929], 183*)

Even into the twentieth century, the herbage was one of the primary ingredients in asthma cigarettes (cf. ***Cannabis indica***). One gram of leaves (alkaloid content = app. 0.25%) is regarded as a therapeutically efficacious dosage for smoking (Lindequist 1992, 1148*). As with all information concerning thorn apple dosages, however, this information should be used with care: “When the drug is administered through inhalation of smoking powders and ‘asthma cigarettes,’ the amount of applied alkaloids is incalculable” (Roth et al. 1994, 291*).

The Huastec, who live on the Gulf Coast of Mexico, make a magical medicine from thorn apple leaves, slaked lime, and chili pods (*Capsicum annuum* var. *annuum*; cf. ***Capsicum* spp.**) (Alcorn 1984, 93*). In South America, a paste of freshly ground leaves (of the subspecies *ferox*) and vinegar is prepared for external use (Schultes 1980, 115*). In the Andes region, *Datura stramonium* (usually the subspecies *ferox*) is used as an additive to San Pedro drinks (see ***Trichocereus pachanoi***). The thorn apple, which is also known as the zombie cucumber, is an active ingredient in **zombie poison**.

Four to 5 g of dried leaves contains enough alkaloids to produce fatal results (Lindequist 1992, 1149*), and as little as 0.3 g can be toxic (Roth et al. 1994, 291*). In Morocco, inhaling the smoke of forty seeds that have been strewn over glowing coals is regarded as a hallucinogenic dosage (Vries 1984*). For use in psychoactive **incense**, see ***Datura metel***.

In homeopathic medicine, thorn apple is also used in composite medicines, e.g., Stramonium Pentarkan, which consists of *Datura stramonium*, Ignatius beans (cf. ***Strychnos* spp.**), calcium phosphate, zinc, and passionflower (***Passiflora* spp.**).

Ritual Use

In Mexico and neighboring regions, the psycho-active use of *Datura stramonium* is similar to that of ***Datura innoxia*** (see there). Among the Huastec, it is said that *Datura stramonium* leaves can kill witches and sorcerers (*brujas* and *brujos*) (Alcorn 1984, 624*). The Yucatec Maya call this plant *mehen xtoh-k'uh* (“little plant in the direction of the gods”).

The Mixe of Oaxaca (Mexico) believe that *Datura stramonium* contains a plant spirit in the form of a very old woman. For this reason, one Mixe name for the plant is *ta:g'amih*, “grandmother” (cf. ***Datura wrightii***). When a portion of the plant is to be harvested, the people make a small offering of three pebbles or a couple of branches. They also speak a prayer:

Grandmother, do us a favor and cure the illness [name of person] is suffering from. Here we pay you, we carry [the plant] to see what illness [she or he] has. We are sure that you will remedy [the illness]. (Lipp 1991, 37*)

The seeds are then swallowed in a ritual context for divination (cf. ***Datura innoxia***)—following the same pattern as the mushroom ritual (see ***Psilocybe mexicana***—in the following dosages: Men take three times nine seeds (= twenty-seven), while women three times seven seeds (= twenty-one). In contrast to mushrooms and ololiuqui (***Turbina corymbosa***), however, *Datura* seeds can be ingested during the day (Lipp 1991, 190*).

Although preparations of *Datura stramonium* (cf. ***Datura innoxia***), e.g., *jugo de toloache* and *polvo de toloache*, are sold in Mexican herb stores, such transactions usually occur under the table, as the (Catholic) population believes that this plant was created by the devil (Bye and Linares 1983, 4*).

Chamico, the common South American name for the thorn apple (ssp. *ferox*), is derived from the Aymara word *chamakani*, “soothsayer” (Guevara 1972, 160). The plant apparently has had a long tradition as a prophetic and oracular plant (similar to ***Brugmansia sanguinea***). The Mapuche use a psychoactively effective brew made with seeds of *Datura stramonium* ssp. *ferox* (*miyaya*) to treat (mental) illnesses that are produced by the *wefukes* spirits and to educate their children¹²³ (Munizaga 1960).

In North America, the most significant use of *Datura stramonium* in ritual contexts is as an ingredient in **smoking blends** and **kinnikinnick**, which are used to aid in vision quests. If the interpretation of the term *wysoccan* as a common name for *Datura stramonium* is in fact correct, then the Algonquian used the plant as a ritual narcotic.

In Europe, the thorn apple was associated with witches' rituals and **witches' ointments** in the early

modern period. In Germany, Russia, and China, the seeds were added to **beer** to lend it potent narcotic properties (Marzell 1922, 172*). In Europe, the seeds served as an incense, a custom allegedly derived from the Gypsies:

The seeds are used in fumigations to chase away ghosts or to invoke spirits. All of the gypsies' arts are said to come primarily from a precise knowledge of the juices of the thorn apple. (Perger 1864, 183*)

The Gypsies used the thorn apple as an oracular plant in a ritual reminiscent of shamanism:

On Andrea's night (November 30), thorn apple seeds are placed outside in the open. The next morning, they are then thrown into the fire. If the seeds burn with a loud crackle, then the winter will be dry but very cold. . . . When the tent gypsies wish to find out if a sick person is going to become healthy or not, they ask the "magic drum." An animal skin is marked with lines, each one of which has a special meaning. Nine to twenty-one thorn apple seeds are strewn across the skin, and these are set in motion by hitting the skin with a small hammer a certain number of times (9 to 21). The position of the seeds on or between the lines then tells whether the sick person will recover or die. This same procedure is also performed for sick animals or to recover stolen objects. (Marzell 1922, 173, 174*)

Artifacts

Among the edifices fashioned from the bizarre, alchemically suggestive constructions of floral and artistic elements contained in his painting *The Garden of Desires*, the late Middle Ages painter Hieronymus Bosch (ca. 1450–1516) included several depictions of fruits that appear to be naturalistic depictions of thorn apples. The entire painting is filled with allusions to the abilities of strange fruits to alter consciousness (Beagle 1983). Perhaps some of the visions of Hieronymus Bosch were produced by *Datura stramonium* (cf. ***Claviceps purpurea***). If this interpretation is correct, then the thorn apple would have been indigenous to Europe prior to its first contact with the Americas (see "Distribution").

In her novel *The Clan of the Cave Bear*, bestselling American author Jean Auel describes how sorcerers of the prehistoric Neanderthal prepared an inebriating beverage from the thorn apple and ingested it during their tribal ceremonies and dances and to induce visions (Auel 1980).

The Scandinavian death-metal band Tiamat sang of *Datura stramonium* and its effects in their song "Whatever That Hurts" (*Wildhoney*, Magic Arts 1994; Gaia Century Media, 1994).

Medicinal Use

Aztec medical texts provide the following description of *Datura stramonium*:

Mixitl. It is of average size, round, green-leaved. It has seeds. The ground seeds are applied where there is gout. It is not edible, not drinkable. It paralyzes one, closes one's eyes, constricts one's throat, holds back the voice, makes one thirsty, deadens the testicles, splits the tongue.

It cannot be noticed when it has been drunk. Those whom it paralyzes—when that person's eyes are closed, he remains behind with closed eyes for all time. That which he looks at, he looks at forever. One becomes stiff, dumb. This can be relieved a little with wine [= pulque; cf. ***Agave* spp.**]. I take Mixitl. I give someone Mixitl. (Sahagun, Florentine Codex 11:7*)

The Yucatec Maya roast the leaves on a clay or metal disk (*comal*) and then place them on areas

affected by muscle pains and rheumatism (Pulido S. and Serralta P. 1993, 61*). Apart from this, the folk medical uses are the same as with ***Datura innoxia***.

“More serious however are the effects that religious fanatics, clairvoyants, miracle workers, magicians, priests, and deceivers induce in men by using datura, who inhale the smoke of the burning plant during cultic ceremonies or who are given it internally. The sorcerer’s or devil’s weed—*herbe aux sorciers*, *herbe au diable*—was used to produce fantastic hallucinations or illusions and the deceptions which result. In demonology, this plant in particular has a role whose significance outsiders of course can scarcely imagine.”

LOUIS LEWIN

PHANTASTIKA

(1980[ORIG. PUB. 1929], 180f.*)

“In magical beliefs, the thorn apple is used as an agent for producing ecstasy. For example, the priests of the sun temple in the Peruvian city of Sagomozzo would chew the seeds of this plant in order to achieve the inspiration that was the prerequisite for divination. Thorn apple extracts play an enormous role both in witches’ ointments and in narcotic magical incenses. It is generally known that the so-called asthma cigarettes have stramonium as an additive even today. Various people have told us that those in the know smoke these asthma cigarettes because they allegedly stimulate the sex drive.”

MAGNUS HIRSCHFELD AND RICHARD LINSERT

LIEBESMITTEL [APHRODISIACS]

(1930, 175*)

“Decoction of Jimsonweed

Slimy trailing plants distil Claustrophobia and blood mixed seed
Cursed downstairs against my will.”

TIAMAT

WILDHONEY

(1994)

“Among the Transylvanian Gypsies, when a newlywed couple returns to the camp, water is poured over them, after which a weasel skin filled with thorn apple seeds [from *Datura stramonium*] is rubbed over them. The weasel skin protects them from misfortune and the thorn apple seeds from the evil eye. . . .

“Before the nomadic Gypsies of Hungary move into their winter caves, they never forget to light a fire of dried thorn apple bushes in front of each dwelling and shake some alum into the embers. They also carry some of this fire into the caves, for it is an excellent agent against the evil eye.”

SIEGFRIED SELIGMAN

DIE MAGISCHEN HEIL- UND SCHUTZMITTEL AUS DER BELEBTE NATURE [THE MAGICAL HEALING AND
PROTECTIVE AGENTS FROM THE ANIMATED NATURE]

(1996, 257*)

In Peru and Chile, a tea made from the leaves is drunk to alleviate pain (Schultes 1980, 115*). In Peru, a tea made with *Datura stramonium* ssp. *ferox* is drunk for stomachaches (Franquemont et al. 1990, 40*). The Mapuche use a tea of the fresh herbage of *Datura stramonium* ssp. *ferox* as a narcotic and a *Datura* ointment for toothaches. The entire plant is administered in various preparations to treat pains, inflammations, cancer, and neuritis (Houghton and Manby 1985, 100*).

In Uttar Pradesh (India), juice pressed from the fruits is massaged into the scalp to treat dandruff (Siddiqui et al. 1989, 484*). In Southeast Asia, the roots are used to treat the bites of rabid dogs and insanity, while the leaves are smoked for asthma (Macmillan 1991, 423*).

Throughout the world, *Datura stramonium* is regarded as an aphrodisiac (Guevara 1972, 160) and as an agent for treating asthma (Baker 1995*; Dafni and Yaniv 1994, 13*; Mösbach 1992, 105*; vries 1984*; Wilson and Mariam 1979, 30*). When used for asthma, either the leaves are smoked or the seeds, burned as **incense**, are inhaled. In the Canary Islands, where this species is known as *santos*

noches (“holy nights”), the dried leaves are also smoked for asthma (Concepción 1993, 54).

During the early modern period, *Datura stramonium* was used to make love drinks, but it was also recommended for mental disorders and other diseases:

In some parts of France and Germany, both the herbage and the seeds of this narcotic poisonous plant are used as a home remedy for toothaches, wheezing, and other nervous afflictions of a chronic nature. The seeds are placed in the hollow, painful tooth, and a small pipe full of one part of the leaves and eight parts of tobacco [see *Nicotiana tabacum*] are smoked once daily or as often as the asthma attacks occur. Dried, it is also made into cigars that are smoked for the same purpose. In the hands of the physician, the Tinctura Semen Stramonii, five to fifteen drops two to three times daily, is a very effective agent against a pathologically increased sexual desire, nymphomania, and satyriasis, but should never be allowed to become a folk medicine. (Most 1843, 141*)

In Peru, *chamico* leaves (*Datura stramonium* ssp. *ferox*) are applied externally as a facial wash to treat headaches and migraines. An industrially manufactured perfume called Chamico is dabbed onto the face for the same purpose. This scent is also used to promote one’s own attractiveness, for love magic, and to increase male potency. It is unknown whether this perfume is made using *Datura*, but it is very unlikely. However, the enclosed instructions include a “prayer to the chamico perfume” that makes reference to its hypnotic effects.

In Europe, the plant has been widely used for medicinal purposes since the eighteenth century. In 1747, Elisabeth Blackwell wrote the following in her *Herbal*: “Some use the leaves as a cooling agent when a person has received a burn, and to fight inflammations. The seeds have a power to make one slack and sedated” (Heilmann 1984, 82*).

Cigarettes made from *Datura stramonium* were being smoked as a treatment for asthma and mental illnesses as late as the twentieth century (Hirschfeld and Linsert 1930, 174*).

In homeopathy, *Datura stramonium* hom. (usually in dilutions of D3 and greater) is used in accordance with the medical description to treat such ailments as whooping cough, asthma, neuralgia, and nervous excitement (Pahlow 1993, 304*). It is used especially for disturbances of the mind, for “the entire power of this agent appears to expend itself in the brain” (Boericke 1992, 720*).

Constituents

The entire plant contains **tropane alkaloids**. The alkaloid content can vary greatly and lies between 0.25 and 0.36% (with one recorded instance of 0.5%) in the leaves and between 0.18 and 0.22% in the roots. The flowers can contain as much as 0.61% alkaloids and the seeds up to 0.66%. The main alkaloids in all parts of the plants are L-hyoscyamine and L-**scopolamine**; also present are apoatropine, tropine, belladonnine, and hyoscyamine-*N*-oxide. Dried leaves and seeds contain 0.1 to 0.6% alkaloids. Apoatropine and tropanole arise only when the raw drug is stored in an inappropriate manner or for too long a time (Roth et al. 1994, 291*). Young plants contain chiefly **scopolamine** and older ones primarily hyoscyamine.

Datura stramonium L. var. *tatula* Torr. contains primarily hyoscyamine (Spurná et al. 1981). In addition to the alkaloids that are regarded as the primary active constituents, **withanolides**, lectines, peptides, and **coumarins** are also present.

The seeds of the Argentinean *Datura stramonium* ssp. *ferox* have been found to contain 3 α -tigloyloxytropine (= tigloyltropeine), 3-phenylacetoxy-6 β , 7 β -epoxytropine (= 3-phenylacetoxyscopine), aposcopolamine (= apohyoscine), 7 β -hydroxy-6 β -propenyloxy-3 α -tropoyloxytropane, traces of 7 β -hydroxy-6 β -isovaleroyloxy-3 α -tigloyloxytropine, the pyrrolidine

alkaloid hygrine, and the previously unknown 3-phenylacetoxy-6 β ,7 β -epoxytropane (= 3-phenylacetoxyscopine) and 7 β -hydroxy-6 β -propenyloxy-3 α -tropoyloxytropane (Vitale et al. 1995).

Effects

The profile of effects of *Datura stramonium* is essentially the same as that of *Datura innoxia* and *Datura metel*. Among the characteristic effects are dryness of the mouth, difficulty in swallowing, dilation of the pupils, restlessness, confusion, and hallucinations. The effects sometimes begin after only a half an hour but may occasionally appear after four hours, and they can persist for days (Gowdy 1972; Lindequist 1992, 1148*; Roth et al. 1994, 292*).

In his *History and Present State of Virginia*, Robert Beverly described the oft-quoted effects that occurred when English soldiers at Jamestown unknowingly or accidentally ate thorn apple leaves as a salad:

The James-Town Weed (which resembles the Thorny Apple of *Peru*, and I take it to be the Plant so call'd) is supposed to be one of the greatest Coolers in the World. This being an early Plant, was gather'd very young for a boil'd salad, by some of the Soldiers sent thither, to pacifie the troubles of *Bacon*; and some of them eat plentifully of it, the Effect of which was a very pleasant Comedy; for they turn'd natural Fools upon it for several Days: One would blow up a Feather in the Air; another wou'd dart Straws at himself, and another stark naked and grinning like a monkey, sitting in the corner, tried to mow the grass; a Fourth would fondly kiss, and paw his Companions, and sneer in the Faces, with a Countenance more antick, than any in a *Dutch Droll*. In this frantick condition they were confined, lest they should in their Folly destroy themselves; though it was observed, that all their Actions were full of Innocence and good nature. Indeed, they were not very cleanly; for they would have wallow'd in their own Excrements, if they had not been prevented. A Thousand such simple Tricks they play'd, and after Eleven Days, return'd themselves again, not remembering anything that had pass'd. (In Safford 1920, 557–58)

In the Canary Islands, thorn apple grows like a weed. Many young tourists have consumed teas made from the flowers, swallowed or smoked the seeds, or eaten the fresh leaves. The majority of the experiences they have reported have been unpleasant. One man smoked thorn apple seeds and became feverish for three days. Another man who drank a tea made with the flowers collected and ate his feces for three days. Others who had eaten the seeds went swimming and decided to swim to one of the neighboring islands. Some have felt themselves transported back in time, where they conversed with the Guancha, the indigenous inhabitants of the islands, who have been “extinct for 600 years” (cf. *Cytisus canariensis*). Many simply felt ill. Reports mention nausea, headache, and confusion. Positive experiences, which do also occur, are only rarely mentioned.

Occasionally, *Datura stramonium* intoxications can also prove fatal (MMWR 44 [3] 1995; Roth et al. 1996, 291f.*).

People who smoked asthma cigarettes often reported “undesired” side effects, namely, “dreams with sexual overtones” (Schenk 1954, 78*; Hirschfeld and Linsert 1930, 174f.*). The medical literature also contains accounts of such erotic effects (Dieckhöfer et al. 1971, 432).

Commercial Forms and Regulations

All commercially available pharmaceutical forms (herbage, extracts, tinctures, homeopathic preparations [*Datura stramonium* hom. *HAB1*]) can be obtained only in a pharmacy with a prescription from a physician. *Datura stramonium* is a proscribed substance under the Cosmetic Regulations (from 19 June 1985, appendix 1, 301). In contrast, both the seeds and potted plants are

freely available.

“In Kenya, I was able to learn from the British Secret Service—when I was reporting on the Mau Mau uprising for *Life* magazine—that the Mau Mau secret society had collected large amounts of thorn apple seeds and leaves (*Datura stramonium* and *Datura fastuosa* L. or *Datura alba* Nees). An informant told the English that it was planned to use the black cooks and servants to add a powder of this drug to the food on a certain evening, so that they would be helpless during the massacre that was planned for the night. A person who is under the influence of this drug will allow anything to happen. . . . Shortly after this incident, I heard that the English had been given the order to exterminate and burn all of the thorn apple plants. . . . During an extended drive, I was then able to determine that the blacks had simply disregarded the order.”

Datura stramonium, *D. metel*, *D. innoxia*

D. stramonium ssp. *ferox*, *D. wrightii*, *D. leichhardtii*. (From Festi 1995, 122 f.)

Datura wrightii Regel

Wright's Datura

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe, Dutra Section

Forms and Subspecies

The karyotype of this plant is almost identical to that of ***Datura stramonium*** L. var. *tatula* Torr. (see *Datura stramonium*). It is possible that *Datura wrightii* is only a local (California) variant of ***Datura innoxia*** (Hickman 1993, 1070).

Synonyms

Datura metel var.[?] *quinquecupida* Torr.

Datura meteloides Dunal in DC.

Datura wrightii Bye

Datura wrightii Hort.

Folk Names

Kalifornischer stechapfel, kiksawel (Cahuilla), kusi (Diegueno), malkapit, manai (Yokut), manet, manit (Gabrieliño), manitc (Serrano), mánoyu (Miwok), momoy (Chumash), mo'moy, monayu (Miwok), nakta mush (Luiseño), naktanuuc (Cupeño), smalikapita (Yuma), tanabi, tanábi (Mono), tanai, tañai, táñai, taña'nib (Mono), thornapple, toloache, Wright's datura, Wright's stechapfel

History

This Southern California species of thorn apple has apparently been used for ritual and medicinal purposes for more than five thousand years (Grant 1993; cf. Boyd and Dering 1996, 266 f.*). During the colonial period, shamanic use of the plant was extremely common among many tribes, much to the distress of Catholic missionaries. Although it is occasionally rumored that some contemporary Chumash youth have been using the plant in an attempt to explore their cultural roots, there is as yet no evidence to support this (cf. Baker 1994).

Distribution

This *Datura* is found only in Southern California and is especially common in the territories once occupied by the Chumash (Los Angeles and Ventura Counties).

Cultivation

See ***Datura discolor***.

Appearance

Datura wrightii is almost indistinguishable from ***Datura innoxia***, but it grows in a prostrate and creeping manner and produces pendulous fruits with many thin thorns. *Datura wrightii* is also easily confused with ***Datura discolor*** and less frequently with ***Datura metel***.

Psychoactive Material

—Roots, fresh or dried and powdered

—Leaves

Preparation and Dosage

The fresh root is crushed and extracted in water (Timbrook 1990, 252*). Unfortunately, the ethnographic sources provide little information about dosages (cf. *Datura innoxia*).

Datura wrightii, the predominant Southern California species, has a creeping pattern of growth. (Wild plant, photographed near Moorpark, in the former territory of the Chumash Indians)

Several Southern California tribes used the seeds or entire fruits to produce a beerlike drink (cf. **beer**). The fresh seeds (or fruits) were ground and then added to water. It is possible that the tribes added other fermentation agents, such as manzanita fruits (*Arctostaphylos manzanita* Parry). The vessel containing the liquid was set in the sun so that fermentation (by means of wild yeasts) would begin quickly. Fermentation was complete after one to two days. The drink, which was only mildly alcoholic, must have been extremely potent (Balls 1962, 67).

As with all other species of *Datura*, the seeds and dried leaves of this species are suitable as additives to smoking blends and incense.

Ritual Use

This *Datura* species played an especially important role in the initiation rites (*chungichnich* cult, *manet*, *kiksawel*) of the Indians who once lived in Southern California (Gayton 1928; Jacobs 1996).

The fruit of *Datura wrightii* hangs downward at an angle.

The Chumash regarded this *Datura* as a female spirit being, “the old woman Momoy” (*momoy* is the Chumash name for *Datura wrightii*; Baker 1994). They had shamans specializing in the use of *Datura*; such a shaman would be known as *alshukayayich* (“one who causes intoxication) or, in Spanish, *toloachero* (“datura giver”) (Applegate 1975, 10; Walker and Hudson 1993, 43). The thorn apple was regarded as a “dream helper” that shamans used frequently to induce prophetic dreams.

The most significant use of thorn apple occurred in conjunction with the initiation of boys into men. Before ingesting the drink, which would be prepared by the initiate’s grandmother, the initiate was required to fast and to avoid all consumption of meat. During the fast, he would smoke a great deal of tobacco (*Nicotiana attenuata*, *Nicotiana bigelovii*; cf. *Nicotiana* spp.) (Applegate 1975). Normally, the initiate was left alone, in a cave or a dwelling, after he received the drink and surrendered himself to the visions it induced. Any questions he had could be answered only by the *Datura* spirit, for it was said that “the *Datura* will teach you everything.” During the visionary state, finding a spirit ally in the form of an animal (coyote, hawk, etc.) was considered an especially fortunate occurrence. The initiate usually fell into a delirious state for some twenty-four hours, from which he only gradually awoke. Afterward, a *Datura* shaman would help him interpret the visions and develop them into a plan for the rest of his adult life (Applegate 1975).

The Chumash also used *Datura* in conjunction with sweat lodge rituals. Unfortunately, the precise manners of such use have not come down to us (Timbrook 1987, 174). It is possible that the seeds may have been used as a psychoactive incense that was strewn over the glowing rocks (cf. *Artemisia* spp.).

Many other California tribes (Coahuilla, Yokut, Gabrieliño, Luiseño, Diegueno, Dumna) also used a potent *Datura* tea to initiate their youths into the mysteries of life (Beau and Siva Saubel 1972, 61ff.). The visions and dreams they experienced were intended to be signposts for their future lives (Jacobs 1996).

Similar to the use of *Datura*, several California tribes used red ants for psychoactive purposes during their initiatory rites (Blackburn 1976*; Groark 1996; cf. *Nepeta cataria*).

The shamans of the Miwok ate the roots or drank a decoction of the fresh herbage in order to acquire supernatural powers and peer into the future (Barrett and Gifford 1933, 169). Shamans also used *Datura* for harmful purposes (Applegate 1975).

The Kawaiisu use *Datura wrightii* as a ritual medicine in the initiation of boys and to produce visions and prophetic dreams (Moerman 1986, 149*).

Artifacts

The initiatory use of *Datura* is well known from the American Southwest, e.g., among the Chumash (Timbrook 1987, 174 f.) The Chumash have a long tradition of creating ritual paintings on rocks and in caves. Some of these five-thousand-year-old paintings have been interpreted as evidence of a *Datura* cult (Grant 1993). They also incorporate what are clearly shamanic elements (Hedges 1992). *Datura* visions have apparently shaped all of the Chumash rock art. Many paintings provide symbolic representations of elements that were significant in the visions. In some ways, the painters translated their visions into the symbolic code of the Chumash culture (Hudson 1979; Wellmann 1981*).

“With this [*Datura*] they [the Chumash] intoxicate themselves. They take it in order to become strong, in order not to fear anyone, to prevent snakes from biting them and that darts and arrows may not pierce their bodies, etc.”

FRANCISCAN MISSIONARY IN “VIRTUOUS HERBS” (TIMBROOK 1987, 174)

“In California, the leaves of the stalk and sometimes also the root of the [*Datura wrightii*] plant were squeezed, softened in water, and drunk after being decocted. This drink called forth hallucinations—an Indian would speak of visions—as well as dreams which make it possible to look into the future and make supernatural beings visible. The drink also produced clairvoyance and revealed things that would not be revealed in the context of normal visions: events which had taken place hundreds of kilometers away or only in the future.”

SERGE BRAMLEY

IN *REICHE DES WAKAN* [IN THE REALM OF THE WAKAN]

(1977, 82 f.*)

Medicinal Use

The Chumash drank infusions or decoctions of the root to treat pain, especially in cases of broken bones and injuries. They also drank *Datura* for snakebites, apparently as a kind of sympathetic magic. It was said that snakes would bite into a thorn apple with their fangs in order to make their teeth poisonous before they would bite an animal or a person. In other words, the Chumash used the same toxin to combat the venom, in the manner of the basic principles of homeopathy. To treat asthma, they inhaled the smoke of the dried leaves as a medicinal **incense** (Timbrook 1987, 174).

The Kawaiisu administer the pressed root internally to alleviate strong pain and apply a paste of it externally to treat broken bones and swelling. A tea made with the roots is used as a medicinal bath for rheumatism and arthritis (Moerman 1986, 149*).

Constituents

See *Datura innoxia*.

Effects

See *Datura innoxia*.

Commercial Forms and Regulations

Datura wrightii is occasionally found in specialty nurseries in California. The plant is not subject to any regulations.

This Chumash Indian rock art image was allegedly inspired by the ritual use of *Datura wrightii*.

Datura spp.

Thorn Apple Species

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Datureae Tribe

Eleven species of *Datura* are usually accepted today (D'Arcy 1991, 78*). Some botanists have recently suggested that the genus *Datura* is indigenous only to the New World and did not spread into Asia (*D. metel*) and Australia (*D. leichhardtii*) until the past four hundred years. I cannot accept this purist view in any way (cf. *Datura metel*). These botanists do not appear to possess any detailed ethnohistorical knowledge and appear to have overlooked the fact that the very name of the genus is Sanskrit in origin (Symon and Haegi 1991).

Datura kymatocarpa A.S. Barclay

This species (if in fact it is a distinct species and not simply one of the many varieties of *Datura innoxia*) is found only in the tropical valley of the Río Balsa (Mexico). It is recognizable by its hairy fruits (Barclay 1959, 257). To date, no ethno-botanical use has been reported.

Datura lanosa Barclay ex Bye [syn. *Datura innoxia* ssp. *lanosa*]—rikuri, rikúi

Only recently described (Bye 1986), this thorn apple species occurs exclusively in northern Mexico and may simply be a local variety of *Datura innoxia*. The name the Tarahumara use to refer to the plant (*rikuri*) is derived from *rikú*, “drunken” (Bye et al. 1991, 34). The name is linguistically related to *kiéri*/*kíeri*, a word the Huichol use chiefly for *Solandra* spp.

Datura leichhardtii F. Muell. ex Benth. [syn. *Datura pruinosa* Greenman]—Leichhardt's datura, Australian thorn apple

This Australian species, which is very common on the continent and is almost the only species there, is also said to occur in very remote areas of Mexico and Guatemala (Symon and Haegi 1991). It has small, round, drooping fruits with numerous short thorns. Apart from this, the plant is very similar to *Datura stramonium*. In Australia, where it is used as a **pituri** substitute, the plant is also known as “killer of sheep” (Low 1990, 187*).

Datura pruinosa Greenman—pruinose thorn apple

This Mexican species is found only in Oaxaca at altitudes between 550 and 1,550 meters. It has very small flowers and finely haired leaves that look as though they have been affected by frost. The dried herbage contains 0.16% alkaloids (the primary alkaloid is **atropine**; also present are apoatropine, noratropine, hyoscyne [= **scopolamine**], norhyoscyne, apohyoscyne, littorine, tigloidine, 3 α -tigloyloxytropine, meteloidine, tropine, and X-tropine) (Evans and Treagust 1973). The chemical composition is practically identical to that of *Datura leichhardtii*. The name *Datura pruinosa* is now usually regarded as a synonym for *Datura leichhardtii* (Symon and Haegi 1991, 198).

Datura quercifolia H.B.K. [syn. *Datura stramonium* ssp. *quercifolia* (H.B.K.) Bye]—oak-leaf datura

This *Datura* is limited to Texas, Arizona, and northern Mexico. Its fruits have long thorns and its

leaves resemble those of an oak (hence the name). It is probably identical to *Datura stramonium* (Safford 1921, 177) and is now best regarded as a subspecies of *Datura stramonium* (Bye 1979b, 37*).

The Pima Indians of northern Mexico roast the fruits, which they call *toloache*, and then grind them and mix them with fat to produce an ointment they apply to open wounds. Together with the leaves of a *Physalis* species known as *coronilla* or *kokovuri*, the fruits are boiled to produce a decoction for treating coughs (Pennington 1973, 228*).

***Datura reburra* A.S. Barclay**

This species has been described for the Mexican state of Sinaloa. The plant is similar to *Datura discolor*, however, the thorns are longer and thinner (Barclay 1959, 259). It is likely only a variety of *Datura discolor*.

***Datura villosa* Fernald [syn. *Datura stramonium* ssp./var. *villosa* (Fern.) Saff.]—shaggy thorn apple**

This species occurs in Jalisco and San Luis Potosí (Mexico); it may be identical to *Datura stramonium* (Safford 1921, 177).

***Datura (Ceratocaulis) ceratocaula* Ortega [syn. *Datura macrocaulis* Roth, *Apemon crassicaule* Raf., *Datura sinuata* Sessé et Moc., *Ceratocaulus daturoides* Spach.]—tlapatl**

This species is found only in central Mexico (México, Querétaro, Oaxaca). It is a water plant that has the appearance of a vine instead of an herbaceous plant or bush. It has thick, forked stalks and thornless fruits that hang to the side. In Mexico, it is known as *tornaloco* (“maddening plant”), and it is apparently identical to the magical plant the Aztecs called *atlinan*, “his mother is water,”¹²⁴ or *tlapatl*. The Aztecs regarded it as the “Sister of Ololiuqui” (see *Turbina corymbosa*) (Schultes and Hofmann 1992, 41, 111*). An Aztec-language source provided the following description of the plant:

“The effects of all species are similar, since their constituents are so much alike. Physiological activity begins with a feeling of lassitude and progresses into a period of hallucinations followed by deep sleep and loss of consciousness. In excessive doses, death or permanent insanity may occur. So potent is the psychoactivity of all species of *Datura* that it is patently clear why peoples in primitive cultures around the world have classed them as plants of the gods.”

RICHARD EVANS SCHULTES AND ALBERT HOFMANN

PLANTS OF THE GODS

(1992, 111*)

This ancient Mexican representation of a flower in the process of opening can be interpreted as *Datura*.

The fruit of the rare Mexican *Datura quercifolia* resembles a weapon and protrudes horizontally.

It is small and round, blue, green-skinned, broad-leaved. And it blossoms white. Its fruit is smooth, its seeds black, foul-smelling. It causes one harm, takes away the appetite, makes one mad, inebriates one.

He who eats of it will not want any other food until he dies. And if he eats it regularly, he will always be confused, mad; he will always be possessed, never again calm. And where gout is present, it is applied thinly as an ointment in order to heal this. It is also said to be sniffed, for it will cause harm, it takes away a person's appetite. It causes harm, makes one mad, takes away the appetite. I take Tlapatl; I eat, I go around and eat Tlapatl.

This is what is said of him who goes around and is contemptuous, who goes around with arrogance, presumptuousness, who goes around and eats the Mixitl and Tlapatl herbs; he goes around and takes Mixitl and Tlapatl. (In Sahagun, Florentine Codex 11:7*)

An Aztec magical formula from the colonial period invoked the plant spirit of this *Datura* in the following manner:

I call to you, my mother, she who is of the beautiful water!

Who is the god, or who has the power to break and consume my magic?

Come here, sister of the green woman Ololiuqui, of she by means of which I go and leave the green pain, the brown pain, so that it hides itself.

Go and destroy with your hands the entrails of the possessed, so that you test his power and he falls in shame.

(Jacinto de la Serna, in *Documentos Ineditos para la Historia de Espawa* 104:159–60; cf. Safford 1921, 182; also Räscht 1988a, 142*)

This *Datura* is said to have very potent narcotic effects. Little is known about any modern use (Schultes and Hofmann 1992, 111*). In Mexico City, preparations of *Datura ceratocaula* are supposedly used as a drug of fashion in some circles. I have also heard that some Mexican psychiatrists administer combinations of ketamine and *Datura ceratocaula* to their patients for psychotherapeutic purposes.

***Datura velutinosa* Fuentes—silky thorn apple**

This species has recently been described for Cuba. However, the name is apparently a synonym for

***Datura innoxia*.**

As the species name suggests, the deeply emarginated leaf of *Datura quercifolia* resembles that of an oak.

Desfontainia spinosa Ruíz et Pavón

Latuy

Family

Desfontainiaceae (only one genus); occasionally, the genus is assigned to the family Loganiaceae (Brako and Zarucchi 1993, 618*).

Forms and Subspecies

The variety *Desfontainia spinosa* Ruíz et Pav. var. *hookeri* (Dun.) Voss ex Vilmorin occurs in Chile (Emboden 1979, 176*). A small-leaved (Andean) form has been described as *Desfontainia spinosa* var. *parvifolia* (D. Don) Hooker (Brako and Zarucchi 1993, 618*).

Synonyms

Desfontainia obovata Kraenzlin

Desfontainia parvifolia D. Don

Desfontainia spinosa var. *hookeri* (Dun.) Reiche

Folk Names

Borrachera de páramo (“inebriator of the swamps”), chapico (“chili water”), desfontainia, intoxicator, latuy, latuye, mëchai, michai, michai blanco, michay, michay blanco, muerdago, taique, trau-trau (Mapuche, “unique”), trautrau¹²⁵

History

Richard Evans Schultes discovered the psycho-active use of this beautiful plant in the Sibundoy Valley of Colombia in 1941 (Davis 1996, 173*). Unfortunately, the plant has been little studied or tested since that time.

Distribution

The bush occurs from Colombia (Sibundoy) to southern Chile (Chiloé), as well as in Ecuador and in the higher Andean regions of Argentina (Brako and Zarucchi 1993, 618*). In southern Chile, the bush is found from the Río Maule to Magallanes, most frequently south of Valdivia, and typically in the underwood of lenga and coigüe forests. It has also been observed in Costa Rica (Zander 1994, 230*).

Cultivation

In southern Chile, *Desfontainia* is a recommended garden ornamental (Donoso Zegers and Ramírez García 1994, 49*). Methods of cultivation are still unknown. It likely can be propagated from seed or, even more easily, from cuttings. The plant requires moist to very moist soil (swampy areas, marshes).

Appearance

Desfontainia spinosa is a small evergreen bush or shrublike tree that grows up to 2 to 3 meters in height. It has thick, thorny, mid- to dark green leaves and large, funnel-shaped flowers that are orange-red with yellow margins. The leaves resemble those of the English holly (*Ilex aquifolium* L.; cf. *Ilex cassine*). The flowers are similar to those on some nightshades, e.g., *Ichroma fuchsioides*.

The plant is easily confused with several species of the genus *Berberis*, especially *Berberis darwinii* Hook. In Chile, many species of *Berberis* (*B. actinacantha* Mart., *B. chilensis* Gill. ex Hook, *B. darwinii*, *B. serrata*, *B. dentata*) are known as *michay* (Mapuche, “yellow tree”; Mösbach 1992, 78*) and are used as sources of yellow dye (Donoso Zegers and Ramírez García 1994*). *Berberis* fruits are used to make **chicha**.

Psychoactive Material

—Leaves

—Fruits

Preparation and Dosage

The leaves can be brewed or decocted into a hallucinogenic tea. The fruits are considered to be more effective and presumably are prepared as a decoction. No information concerning dosages is available. The fruits may once have been used to prepare a potentially psychoactive **chicha**.

Ritual Use

The shamans of the Kamsá in the Sibundoy Valley of Colombia drink a tea made from the leaves when they “want do dream” or receive visions to diagnose diseases (Schultes 1977, 100).

The *machis* (shamans) of the Mapuche appear to use the plant in the same manner as they use *Latua pubiflora*. This use, however, requires further research.

Artifacts

The folklore of Chiloé (an island in southern Chile) speaks of a mythical figure named El Trauco who may originally have been a plant spirit of *Desfontainia*, known locally as *trau-trau*. El Trauco is a small, perverse man, a “satyr of the forest.” He has a stone ax that he uses to cut down trees, and he looks like a mushroom spirit. There is a large statue of El Trauco in Ancud (Chiloé), and small replicas carved from stone are sold as souvenirs.

The Mapuche of southern Chile use the leaves to obtain a yellow dye that they use to color wool and the material they use for their traditional garments (Mösbach 1992, 101*).

The evergreen herbage of the Chilean shamanic plant *Desfontainia spinosa*, shown in blossom

El Trauco, a satyrlike forest spirit, is a popular figure in the mythology of Chiloé. It is possible that he is a representation of the plant spirit of *Desfontainia spinosa*, which is also known as *trau-trau*. (Section of a statue in Ancud, Chiloé, southern Chile)

Medicinal Use

The leaves are used in Chile as a folk remedy for upset stomachs. One older Chilean book about medicinal plants surprisingly makes reference to *Desfontainia* but states that it has no medicinal use (Urquieta Santander 1953, 87).

Constituents

No constituents have been identified to date (McKenna 1995, 100*). A Dragendorff test for alkaloids yielded negative results (Schultes 1977, 100).

In southern Chile, the plant is regarded as poisonous (Mösbach 1992, 101*). However, no toxic component has yet been identified. Recently, Rob Montgomery and I collected information in Chiloé (May 1995) that indicates that the plant is well known among indigenous plant specialists, who regard it as nonpoisonous but hallucinogenic.

Effects

Smoking two dried leaves produced clear psychoactive effects with perceptual changes (flickering lights, feelings of being “high”).

Commercial Forms and Regulations

None

Diplopterys cabrerana (Cuatrecasas) B. Gates

Yahé Vine

“Like *Banisteriopsis caapi*, *Diplopterys cabrerana* grows in Amazonian lowlands, and the plant has been collected only in southern Colombia and Venezuela, eastern Ecuador, northern Perú and western Brazil. Like *B. caapi*, *D. cabrerana* rarely flowers, and is normally cultivated by shamans for use in *ayahuasca*. Both plants are commonly propagated by cuttings.”

JONATHAN OTT *AYAHUASCA ANALOGUES* (1994, 24)

Family

Malpighiaceae (Barbados Cherry Family)

Forms and Subspecies

None

Synonyms

Banisteria rusbyana Niedenzu

Banisteriopsis cabrerana Cuatrecasas

Banisteriopsis rusbyana (Niedenzu) Morton

Banisteriopsis rusbyana sensu ethnobotanical, non (Niedenzu) Morton

The literature also contains the spelling *Diplopteris*.

Folk Names

Biaxíi, chagropanga, chagropanga azul pisco, chagrupanga (Inga, “*chagru* leaf”), chakruna, kahee-ko (Karapaná), kahi (Tukano, “that which causes vomiting”), kamárampi (Campa, “vomit”), mené kahi ma, mené kahima, nyoko-buko guda hubea ma (Barasana), nyoko-buku guda hubea ma, oco-yagé (“water yagé”), oco yáge, yaco-ayahiasco (Quechua/Peru), yagé, yage-oco, yageúco, yagéúco, yahéliane, yahé ‘oko (Siona-Secoya, “*Banisteriopsis* water”), yahé-oko (Kofán), yahé vine, yajé, yajé oko, yaji, yají

History

This vine was first named *Banisteria rusbyana* in honor of Henry Hurd Rusby (1855–1940), one of the pioneers of ethnobotany (the name unfortunately fell victim to the synonym). Rusby was one of the first white people to witness an **ayahuasca** ceremony, which he actually filmed. He also was one of the first druggists and botanists to intensively investigate coca (*Erythroxylum coca*), guaraná (*Paullinia cupana*), and *Fabiana imbricata* (Rossi-Wilcox 1993*).

The confusion surrounding the botanical identity of the plant was not clarified until 1982 (Gates 1982, 214).

Distribution

This tropical vine is found only in the Amazon basin (Ecuador, Peru, Brazil, Colombia). It grows wild in the forests but is most often found in cultivation.

Cultivation

The plant is cultivated in house gardens using cuttings. A young shoot or the tip of a branch is allowed to sit in water until it develops roots; it can also be placed directly into the moist jungle soil.

Appearance

This very long vine has opposite leaves that are oblong-oval and retuse-attenuate in shape. The inflorescences, each of which bears four tiny flowers, grow from the petiolar axils. However, the plant only rarely develops flowers, and almost never under cultivation.

The closely related species *Mezia includens* (Nieden zu) Gates [syn. *Diplopterys involuta* (Turcz.) Nieden zu] is known in Peru as *ayahwasca negro*. It is possible that this species was once also used for psychoactive purposes (Schultes 1983b, 353*). The very similar species *Diplopterys mexicana* B. Gates is common in Mexico (Gates 1982, 215).

Diplopterys cabrerana is easily confused with ***Banisteriopsis caapi***. The two species are most easily distinguished on the basis of their leaves. Those of *Diplopterys* are distinctly wider and larger in size.

Psychoactive Material

—Fresh or dried leaves

Preparation and Dosage

The Desana, Barasana, and other Indians in the Colombian regions of the Amazon use the leaves of this vine (which is closely related to *Banisteriopsis*) to make **ayahwasca** (Bristol 1965, 211*; Reichel-Dolmatoff 1979a, 35*). In the Colombian Sibundoy, an inebriating beverage known as *biaxíi* is boiled from ***Banisteriopsis caapi*** and the leaves of *Diplopterys cabrerana* (see **ayahwasca**).

The Shuar use the leaves as an ayahwasca additive (Bennett 1992*), as do the Siona-Secoya (Vickers and Plowman 1984, 19*) and the Mocoa Indians of Colombia. Unfortunately, the sources do not provide any precise information about the quantities of leaves to use (cf. Bristol 1966).

Ritual Use

The Barasana of the lower Piraparaná use the stems to make a hallucinogenic drink that they call *yagé* and use in the same manner as **ayahwasca** (Schultes 1977b, 116*). Apart from this, the primary use of the leaves is as a source of **N,NDMT** as an ayahwasca additive (Der Marderosian et al. 1968; Gates 1982).

Artifacts

See **ayahwasca**.

Medicinal Use

None, except when used medicinally in **ayahwasca**.

Constituents

The leaves contain 0.17 to 1.75% **N,N-DMT** (Agurell et al. 1968; Der Marderosian et al. 1968; Poisson 1965). In addition to the main alkaloid, DMT, they also contain *N*-methyltryptamine, **5-MeO-DMT**, **bufotenine**, and *N*-methylnetetrahydro- β -carboline (cf. **β -carboline**). The main alkaloid in the stems is *N,N*-DMT; also present are 5-MeO-DMT and *N*-methylnetetrahydro- β -carboline (Pinkley 1973, 185*).

Effects

See *Psychotria viridis* and **ayahuasca**.

Commercial Forms and Regulations

In the Colombian Sibudoy region, Indians and shamans trade in finished preparations of the plant (Bristol 1966, 123). Apart from the fact that the legal situation regarding plants and products that contain DMT is unclear, the plant is not subject to any restrictions.

A South American ethnobotanist with the *Diplopterys cabrerana* vine. (Photograph: Bret Blosser)

“Amazingly, the spirit of the *Diplopterys cabrerana* plant spoke English. When I asked him about his nature, I was answered: *Power and Beauty*.”

Duboisia hopwoodii F. v. Mueller

Pituri Bush

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Anthocercideae/Salpiglossideae Tribe

Forms and Subspecies

None

Synonyms

Anthoceris hopwoodii

Duboisia piturie Bancroft

Folk Names

Bedgerie, bedgery, camel poison, emu plant, pedgery, petcherie, picherie, pitchery, pitchiri, pitjuri, pitschuri, pituri,¹²⁶ pituribaum, pituri-busch, pituri bush, pituristrauch, pizuri, poison bush

History

It is possible that the Aborigines have been using the psychoactive pituri bush for hedonistic and ritual purposes since the settlement of Australia. The plant and its dried, fermented leaves were a valuable article of trade and played an important role in the indigenous economy.

The plant was first described in 1878 by the great German/Australian botanist Ferdinand J. H. von Mueller (1825–1896), who also recognized it as the source of **pituri** (Hartwich 1911, 518*). In 1879, an alkaloid was isolated and was named piturine. Only in recent decades has the plant become the focus of more detailed studies.

Distribution

Duboisia hopwoodii is found primarily in the Australian interior. The plant is not found either in the Victoria Desert or in Tasmania (Barnard 1952, 5).

Cultivation

This and other *Duboisia* species are propagated by seeds or cuttings from the branch ends (Barnard 1952).

Appearance

This branched, evergreen shrub has a woody stem and can grow as tall as 2.5 to 3 meters. Its wood is yellow and has a noticeably vanilla-like scent. The green leaves are lineal/lanceolate (12 to 15 cm long, 8 mm wide), entire, and tapered at the petioles. The white, sometimes pink-spotted flowers are campanulate (up to 7 mm long) and occur in clusters at the branch ends. Flowering occurs between January and August. The fruit is a black berry (6 mm long) containing numerous tiny seeds.

Duboisia hopwoodii is easily confused with other

Duboisia species and also can be mistaken with

Anthoceris spp. (Solanaceae).

Psychoactive Material

—Leaves

Preparation and Dosage

The leaves are collected in August when the plant is flowering and are hung up to dry or roasted over a fire. They are either chewed as quids (cf. **pituri**) or rolled together with alkaline substances into cigars for smoking: “The Australian Aborigines sometimes smoke moistened pituri leaves mixed with plant potash” (Stark 1984, 98*).

The pituri quids consist of chopped *Duboisia hopwoodii* leaves mixed with acacia leaves (cf. **Acacia** spp.), “small, dried berries, and unopened flower buds in the form of a caper” (Maiden 1888, 370). *Duboisia hopwoodii* leaves also can be chewed by themselves, although the effects are not considered particularly strong. It is said that the addition of the plant ashes is what brings out the full stimulating effects.

Ritual Use

See **pituri**.

Artifacts

The rock art—paintings, spray paintings, and rock carvings—of the Aborigines can be traced back to the earliest times. Spiritlike *wondjinas*, Dreamtime animals, magical totems, “x-rays,” and visions of the Milky Way are all among the earliest works of Aboriginal art. The abstract paintings found on bark bast (in Arnhem Land) appear to be very old.

The semi-abstract art of the rain forest peoples in the region of Cairns (North Queensland) also has a long tradition. They used natural pigments to paint especially their war shields: “All of the images represented food for daily use and medicines or antidotes that are obtained from a wide variety of trees. Each one of these drawings is associated with a story with a certain meaning” (Hollingsworth 1993, 115). It is certain that pituri and corkwood (***Duboisia* spp.**) were depicted in this manner, for the rain forest peoples used them as inebriants, medicines, and fish poisons.

In the nineteenth century, some Aborigines adapted European painting techniques and began to orient themselves around European art. It was only in the mid-twentieth century that a contemporary Aboriginal style of its own developed, borrowing from the ritual sand paintings of the “outback” tribes. These contemporary Aboriginal paintings appear extremely psychedelic to the eyes of many Western observers. They usually portray Dreamings, and also often primordial beings associated with the clan of the painter or his family members. Many of these paintings tell the myths of the Dreamtime and show the Dream paths or “song lines” of the ancestors. They appear to show what the Dream soul of the painter sees as it flies over the Dream land. They are cartographies or topographies of the Dreamtime. The artist, e.g., Clifford Possum Tjapaltjarri (sometimes called “the Van Gogh of Aboriginal art”), sees himself as a “cartographer of the Dreaming” (Johnson 1994, 47). The Aboriginal art not only records the effects of the Dreamtime on our contemporary world but also creates them anew with every painting and every piece. The art is the reality of the Dreaming. Colin McCormick has said that some of the Aboriginal painters creating this type of art are inspired by pituri inebriation.

Sometimes Dreamings of particular plants are depicted. Some plants appear as totems or ancestor spirits, while others appear symbolically, often simply as individual points in the Dreamings. Theoretically, all plants, including pituri, are totems and can be represented. Clifford Possum has

produced a painting, *Corkwood Dreaming* (1982), that has a very psychedelic appearance (Johnson 1994, ill. 34, pp. 94, 95, 165). It is the Dream of his mother. Since the term *corkwood* can refer to many different plants, and not just to species of *Duboisia* (e.g., also *Hakea* spp.¹²⁷), it is uncertain whether this painting is a secret “pituri Dreaming.”

Plants are often simply suggested by lines, points, and dabs of color. In his autobiographical novel *Songlines*, Bruce Chatwin describes how an Aborigine painted “pitjuri” (“Pitjuri is a mild narcotic which Aborigines chew to suppress hunger”) as a “squiggle” in the center of a painting (Chatwin 1988, 260). It is only through the artist’s explanation that one can decipher the meaning of the squiggle.

The Australian pituri tree (*Duboisia hopwoodii*) in bloom. The tiny inflorescences are almost invisible. (Photographed in North Queensland)

“Pituri is an entryway to the Dreamtime.”

COLIN MCCORMICK (1994)

“In order to understand the Australian Aborigines, in order to recognize the illuminating power that radiates from the multidimensional depths of their paintings—which the Western observer usually regards as childlike and primitive—you must also know about *pituri* (*Duboisia hopwoodii*). With this nightshade, a person can find an entryway into the primordial ‘Dreamtime,’ the place of the totem animals, the original images that eternally exist.”

WOLF-DIETER STORL

VON HEILGÖTTERN UND PFLANZENGOTTHEITEN

[ON HEALING GODS AND PLANT DIVINITIES]

(1993, 341*)

Nicotine

Nornicotine

Medicinal Use

Pituri is now regarded as a bush medicine, a wild medicinal plant that “bushwalkers” use as an analgesic (Cherikoff 1993, 171*; Lassak and McCarthy 1992, 33*).

Constituents

Duboisia hopwoodii contains various potently stimulating as well as toxic alkaloids: piturine (possibly identical to nicotine), duboisin, D-nor-nicotine, and **nicotine** (Hicks and LeMessurier 1935). The presence of nicotine is contested but possible (Peterson 1979, 178*). D-nor-nicotine is regarded as the primary constituent (Barnard 1952, 12; Bottomley et al. 1945). Dried leaves can contain between 2.4 and 5% nicotine/nornicotine. Gas chromatography has also demonstrated the presence of myosmine, *N*-formylnornicotine, coti-nine, *N*-acetylnornicotine, anabasine, anatabine, anataline, and bipyridyl (Luanratana and Griffin 1982).

The root has been found to contain the hallucinogenic **tropane alkaloid** hyoscyamine (Kennedy 1971). Traces of **scopolamine**, **nicotine**, nornicotine, metanicotine, myosmine, and *N*-formylnornicotine have also been detected (Luanratana and Griffin 1982).

Effects

Carl Lumholz compared the effects of *Duboisia hopwoodii* to those of tobacco (*Nicotiana tabacum*) and opium (*Papaver somniferum*) (1889, 49). Carl Hartwich, who studied *Duboisia hopwoodii* intensively, wrote that the plant’s effects “are inebriating, it invokes passionate dreams. It also takes away . . . feelings of hunger and thirst” (Hartwich 1911, 834*). These effects reminded him of the effects of coca (*Eythroxyllum coca*).

When the leaves are smoked alone, they produce an effect similar to that of marijuana (see *Cannabis indica*). There have also been reports of “invigorating, mildly psychedelic and erotic properties of the plant” (Stark 1984, 98*).

Commercial Forms and Regulations

Duboisia spp. and Hybrids

Corkwood Trees

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Anthocercideae/Salpiglossideae Tribe

The genus *Duboisia* is composed of just three species (D'Arcy 1991, 78*), all of which are native to Australia and two of which are endemic (Haegi 1979). The genus is closely related to the genera *Anthoceris*, *Anthotroche* (both endemic to Australia), and *Brunfelsia* (cf. *Duboisia hopwoodii*). In Australian English, all of these are known by the name *corkwood* because of their corklike bark (Dowling and McKenzie 1993, 151f.*).

The constituents of *Duboisia* appear to be extremely variable with regard to the concentration, distribution, and mixture ratio, and this has produced considerable confusion in the phyto-chemical literature. The alkaloid content depends upon a number of factors: location of the plant, time of collection, and the existence of chemical races and hybrids (Dowling and McKenzie 1993, 153*). In addition to **nicotine** and nicotine derivatives, all species of *Duboisia* have been found to contain the following **tropane alkaloids**: hyoscine (= **scopolamine**), hyoscyamine, norhyoscyamine, tigloidine, valeroidine, poroidine, isoporoidine, butropine, valtropine, 3 α -tigloyloxytropane, 3 α -acetoxytropane, norhyoscine, apohyoscine, tropine (= tetramethylputrescine), 6-hydroxyhyoscyamine. Most of these tropanes also occur in the genus *Datura*. Today, corkwoods (*Duboisia* spp.) are used by the international pharmaceutical industry to manufacture agents for the treatment of travel sickness (Lewington 1990, 149*).

Various (?) *Duboisia* species are also found on Papua New Guinea. The Papuas smoke and even chew these along with both indigenous and introduced tobacco species (*Nicotiana suaveolens*, *N. fragrans*, *Nicotiana tabacum*, *Nicotiana* spp.). The Papuas discovered the *Duboisia* leaves and their effects partially on their own, while their use and even the plant material was introduced into New Guinea via trade relationships with the Torres Strait Islands.

Duboisia leichhardtii F. Muell.—Leichhardt's corkwood

This bushlike tree, which has a straight trunk and can grow as tall as 7.5 meters, is the least known of all *Duboisia* species. The 0.5 to 1.5 cm long flowers are the most distinct feature of this species; the petals are long, slender, and tapered at the ends. This corkwood species thrives only in clayey and sandy soils. Its natural range is restricted to central and western Queensland and western New South Wales (Dowling and McKenzie 1993, 152*; Morton 1977, 299*). The concentration of **tropane alkaloids** contained in the species is quite high and can be increased through breeding and hybridization (Luanratana and Griffin 1980a). The dried leaves contain approximately 1.4% alkaloids, primarily **scopolamine** (Morton 1977, 299*). It is not yet known whether this species was or is used by the Aborigines.

Duboisia myoporoides R. Br. [syn. *Natalaea ligustrina* Sib.]—corkwood, onungunabie, ngmoo

This evergreen, shrublike tree can grow as tall as 15 meters. It has lanceolate leaves 10 cm long and 3 cm wide. The small flowers are white and have five pinna. The fruits are 0.5 cm long, oval, and greenish yellow in color. They turn black when ripe. Both the flowers and the fruits develop in July (the winter or rainy period). Corkwood is a typical rain forest tree of the Australian east coast

(Pearson 1992, 95*). It grows in clayey and sandy soils, and sometimes even on sandy beaches near the coast (Dowling and McKenzie 1993, 152ff.*).

The leaves of this *Duboisia* species, which is also known as eye-plant or elm, are used as an alternative for *Duboisia hopwoodii* as **pituri** or as a pituri substitute. The Aborigines obtained a “stupefying drink” from corkwood (Cribb and Cribb 1984, 222*) and used the alkaloids in other ways as well (Pearson 1992, 95*; Stark 1984, 76*).

At the beginning of the twentieth century, the Australian raw drug was used as a substitute for *Atropa belladonna*. The preparation Duboisia (an essence of the fresh leaves of *D. myoporoides*) is an important homeopathic agent (Schneider 1974, II:44*). The Aborigines of New Caledonia use the fresh leaves as an antidote for ciguatera poisoning (Bourdy et al. 1992; Dufva et al. 1976; Ott 1993, 376*).

“The Australian Aborigines bored holes into the trunk of the corkwood tree, which they then poured water or another liquid into and allowed to stand overnight. The next morning, they drank the juice, which was so potent that it produced an inebriated state with noticeably erotic sensations.”

RAYMOND STARK

APHRODISIAKA [APHRODISIACS] (1984, 76*)

Botanical illustration of *Duboisia myoporoides*. (From Köhler's *Medizinalpflanzen*, 1887/89)

It has long been known that *Duboisia myoporoides* contains large amounts of scopolamine (Emboden 1979, 146*); in fact, this species is now grown commercially as a source of **scopolamine** for the pharmaceutical industry (Morton 1977, 294*). The alkaloids **nicotine**, nornicotine, **atro-pine**, and **scopolamine** have been detected in all parts of the plant. The main alkaloids in the leaves are scopolamine and hyoscyamine (Cougoul et al. 1979). Approximately two mouthfuls of leaves contains 50 mg of nicotine and 20 mg of scopolamine (Ott 1993, 376*). Also present are tropine, 3 α -acetoxytropine, α -alkylpiperidine alkaloids (e.g., pelletierine), and myrtine. The roots contain a quinolizidine alkaloid as well as β -**phenethylamine** derivatives (Bachmann et al. 1989). Providing root cultures or the plant with certain tropane precursors, e.g., putrescine, ornithine, arginine, and

tropine, has been found to substantially increase the biosynthesis of scopolamine (Yoshioka et al. 1989).

The Australian mistletoe (***Benthamia alyxifolia***), which lives as a parasite on *Duboisia myoporoides*, apparently accumulates scopolamine in its leaves as a result.

***Duboisia myoporoides* R. Br. x *Duboisia leichhardtii* F. Muell.—hybrid corkwood**

In Australia, the two treelike *Duboisia* species have been bred to produce a hybrid that is grown on large plantations as a source of alkaloids. This hybrid has been found to be especially rich in tropane alkaloids and therefore useful for commercial cultivation (Luanratana and Griffin 1980a, 1980b). The hybrid has the advantage of being almost devoid of nicotine and sometimes developing scopolamine concentrations as high as 3% (Morton 1977, 301*). Several methods for influencing and increasing the alkaloid content have been discovered and developed (Luanratana and Griffin 1982). The hybrid (presumably) plays no part in Aboriginal ethnobotany.

Because of the corklike bark of *Duboisia myoporoides*, this nightshade has been given the name *corkwood*. (Photographed in North Queensland)

Echinopsis spp.

Sea Urchin Cactus

According to Zander (1994, 249*), *Echinopsis* Zucc. is now the taxonomically valid genus name for ***Trichocereus* spp.** The genera *Chamaecereus*, *Lobivia*, *Setiechinopsis*, and *Soehrensia* were all incorporated into the genus *Echinopsis*. Yet because the traditionally accepted genus name *Trichocereus* is so widely used worldwide—in the botanical as well as the ethnobotanical and ethnopharmacological literature, and in academic botanical gardens—in this encyclopedia I will continue to use the established genus name *Trichocereus*. It is questionable whether the inclusion of *Trichocerus* in the genus *Echinopsis* can be botanically justified and is sensible. For example, the most recently revised edition of *Flora del Ecuador* lists the San Pedro cactus under the botanical name *Echinopsis (Trichocereus) pachanoi* (Patzelt 1996, 108).

History

This plant must already have been known in the Vedic or post-Vedic period, for it was used as a **soma** substitute (cf. also **haoma**). It was botanically described in the eighteenth century. The species name refers to John Gerard, the English herbal author, who published one of the earliest precise descriptions and illustrations of *Ephedra* under the name *Vua marina* (Gerard 1633, 1117).

Distribution

The species is found in the Himalayas (from Afghanistan to Bhutan) in altitudes between 2,400 and 5,600 meters (Navchoo and Buth 1989, 143*). It prefers drier Alpine regions and high mountain deserts (with less than 50 cm of precipitation annually). In Nepal, somalata is common in Langtang and the Mustang district. In Sikkim, the variety *sikkimensis* is most common.

In Nepal, this high mountain *Ephedra* species is most frequently encountered at altitudes between 3,000 and 4,000 meters, often in association with *Juniperus recurva* and *Rhododendron* spp. (Malla 1976, 34). In the high mountains, *Ephedra* herbage is an important source of nourishment for yaks and goats during the winter (Polunin and Stainton 1985, 384). It is likely that these animals also eat the plant as a stimulant.

In Nepal, *Ephedra gerardiana*, which thrives in the high mountain regions of the Himalayas, is still known by the name *somalata*, “soma/moon plant.” (Photographed at approximately 4,000 meters above sea level near Muktinath, Nepal)

The subspecies *Ephedra gerardiana* var. *sikkimensis* is prevalent in Sikkim.

“Today Ephedra is the vehicle of Ephedrine. Formerly it was the carrier of a large but fixed quantum of soul.”

S. MAHDIHASSAN

INDIAN ALCHEMY OR RASAYANA (1991, 100)

Cultivation

The plant can be grown from seed. It requires a humus-poor, rocky soil; it can survive with very little water and is able to grow in very dry locations. This robust plant even thrives in soils that contain salt, such as in the neighborhood of salt lakes (Hemsley and Rockhill 1973, 18).

Appearance

Somalata is a perennial herbaceous plant that has practically no leaves and consists solely of fibrous, segmented stalks (in older specimens, some fifteen segments). The small and inconspicuous yellow flowers grow directly from the stalks at the segments. The small, round red fruits (6 mm in diameter) ripen in autumn (August to September). The fruits are edible. The herbage typically does not grow

taller than 20 cm, although it can attain an overall height of 60 cm (Morton 1977, 33*).

As with all other species of *Ephedra*, this species is very easily confused with its relatives.

Psychoactive Material

—Dried stalks; these are collected during the monsoon season (July) when they are flowering, as the alkaloid content is greatest then (Manandhar 1980, 35*).

Preparation and Dosage

The dried herbage (stalks) is boiled in water for approximately ten minutes. Six grams of dried herbage is regarded as a medicinally efficacious individual dosage. Dosages as high as 20 g may be used for euphoriant purposes.

In the Himalayas, ashes of the plant are said to be used as **snuff** (von Reis and Lipp 1982, 6*).

Ritual Use

In the post-Vedic period, when the Aryans were no longer able to find the original psychedelic soma plant in the Indus Valley and the knowledge of the plant was being kept secret or lost, the sacred soma drink (which corresponds to the Persian **haoma**) was prepared with substitute plants, which included *Ephedra* sp. (cf. **soma**). It is for this reason that this Himalayan *Ephedra* species is still known by the name *somalata*, “plant of the moon” (Singh et al. 1979, 189*). While the effects of the plant are stimulating, they are not visionary. The closely related and very similar or synonymous Himalayan species *Ephedra saxatilis* Stapf is also known as *somalata*.

In contrast to the Tibetans, the Nepali Tamang cremate their dead. The cremations are carried out on small chortens (Lamaist shrines) that are erected outside of the villages specifically for this purpose. Dried bundles of *Ephedra* herbage are used as **incense** during the cremation ceremonies. The smoke has a surprisingly pleasant, fine, slightly spicy fragrance somewhat reminiscent of the scent of a forest fire.

Artifacts

A Pakistani Gandhara sculpture (first to sixth century C.E.) in the Archaeological Museum of Peshawar (India) depicts the Buddha as an herbalist. Farmers are shown offering him bundles of stalks which Mahdi Hassan (1963 and 1991) has interpreted as those of *Ephedra gerardiana*.

Medicinal Use

In Ayurvedic medicine, an *Ephedra* tea (6 g per dosage) is used to treat colds, coughs, wheezing, bronchitis, asthma, arthritis, and dropsy. To avoid undesirable side effects (such as tachycardia), licorice (*Glycyrrhiza glabra* L.) can be added to the *Ephedra* tea.

In Nepali folk medicine, the herbage is used as a tonic for asthma, hay fever, and diseases of the respiratory tract (Manandhar 1980, 35*; Singh et al. 1979, 189*). In Tibetan medicine, *Ephedra* is regarded as a rejuvenant. In Ladakh, the powdered plant is ingested along with water as an expectorant and to treat “blood diseases” (Navchoo and Buth 1989, 144*).

Constituents

The herbage contains 0.8 to 1.4% alkaloids, of which 50% is **ephedrine** and 50% is composed of other alkaloids, such as pseudoephedrine (Manandhar 1980, 35*; Morton 1977, 34*). Bitter and tanning agents are also present. Fertilizing the plant with amino acids increases the biosynthesis of ephedrine (Ramawat and Arya 1979).

Effects

A decoction of *Ephedra gerardiana* elevates blood pressure; constricts blood vessels; has diuretic, stimulating (natural stimulant), and euphoriant effects; and causes allergic symptoms (hay fever, asthma) to disappear. The effects last six to eight hours.

Commercial Forms and Regulations

Herbage of *Ephedra gerardiana* that is sold outside of the Himalayan region is subject to the same regulations as other *Ephedra* species (see ***Ephedra sinica***).

Ephedra sinica Stapf

Ma-huang

Family

Ephedraceae (Ephedra Family); Ephedra Section

Forms and Subspecies

None

Synonyms

None

Folk Names

Ask-for-trouble,¹²⁸ Chinese ephedra, Chinese joint fir, chinesisches meerträubel, mahuang, ma-huang, máhuáng, ts'ao ma-huang

History

Ma-huang is one of the oldest known medicinal plants of China. It has been estimated that its medicinal use may date back six thousand years (Bremness 1995, 102*; Morton 1977, 35*). Mahuang was first mentioned in the herbal text of the legendary Shen Nung, and it has occupied a firm place in the Chinese materia medica since that time. There are several ma-huang species in China that are used for medicinal purposes, but the most important of these is *Ephedra sinica*. China was the primary source of ephedrae herbae until 1925 (Morton 1977, 35*).

Distribution

Ephedra sinica is found in northern China from Xinjiang Uygur to Hebei Province and into Outer Mongolia. It is found only at an altitude of about 1,500 meters (Morton 1977, 33*) and chiefly on steep slopes in semiarid regions (Bremness 1995, 102*).

The other *Ephedra* species are clearly isolated geographically. *Ephedra shennungiana* is found only in Fujian (Zander 1994, 256*). *Ephedra equisetina* grows only at altitudes between 1,220 and 1,700 meters in Inner Mongolia (Morton 1977, 33*). Recently, it has been suggested that *E. shennungiana* is a synonym for *E. equisetina* (Hiller 1993, 48). *Ephedra intermedia* is found from Inner Mongolia to Pakistan, but it thrives only in lower altitudes.

The typical red fruits of mahuang, or Chinese ephedra (*Ephedra sinica*)

The herbage of *Ephedra sinica*, also known as ma-huang, as sold on the international herb market

Ma-huang buds

Cultivation

Cultivation occurs via seeds that are sown in light, sandy soil in the spring. The plant can also be propagated using pieces of the rootstock (Morton 1977, 34*). The seeds germinate best when they are extracted by hand from ripe fruits still attached to the stalks. The plant requires a dry, warm climate.

Species of *Ephedra* are also cultivated in Australia, Kenya, the United States (South Dakota), and England (Morton 1977, 33*).

Appearance

This perennial horsetail-type plant, which can grow as tall as 75 cm, develops leafless, segmented canes that are round in cross-section. The male flowers resemble catkins. The red fruits contain several black seeds and are attached to short stalks that develop from the stem segments. The fruits develop in late autumn.

The species *sinica* is almost impossible to distinguish from other *Ephedra* species on the basis of its external appearance. The most reliable method of identification is to consider the geographical distribution, the altitude (see under “Distribution”), and the height the plant can attain: *E. sinica* grows to between 45 and 75 cm in height, *E. equisetina* to between 60 and 180 cm, and *E. intermedia* only to 30 to 60 cm (Morton 1977, 33*).

Ma-huang species are easily confused with the species ***Ephedra gerardiana***, *Ephedra likiangensis* Florin, *Ephedra przewalskii* Stapf, and *Ephedra distachya* L. (the raw drug can be counterfeited with these species) (Paulus and Ding 1987, 124*).

Psychoactive Material

—Ma-huang: dried stems (ephedrae herba, herba ephedra)

Ephedrae herba is derived primarily from *Ephedra sinica* but is also available as a mixture of various species. The quality of the commercial drug can vary substantially (Liu et al. 1993, 377).

—Ma-huang gen: dried roots (*radix ephedrae*)

Dried roots should be stored away from light (Hiller 1993, 52).

Preparation and Dosage

A tea (made with 1 heaping teaspoon of *Ephedra* herbage boiled in 1/4 liter of water for five to ten minutes) can alleviate hay fever, bronchitis, asthma, or asthmatic complaints very well. The fresh or dried herbage can also be added to heavy wine or brandy. The astringent taste can be improved by the addition of cardamom, anise, and fennel. The daily dosage of ma-huang herbage is listed as 1.5 to 9 g by itself or in combination preparations (as a tea); the daily dosage of the root ranges from 3 to 9 g (Paulus and Ding 1987, 123*).

The Chinese preparation *mimahuang* is obtained from the chopped raw herbage and **honey** (10:2). The stems are roasted until the honey has been absorbed and they are no longer sticky (Hiller 1993, 53).

Ritual Use

Because traditional Chinese medicine is rooted in shamanism (Schneider 1993) and the use of mahuang certainly dates back at least five thousand years, it can be assumed that northern Chinese and Mongolian shamans used *Ephedra* for magical, medicinal, and ritual purposes. Unfortunately, we have not yet found any sources that can confirm this assumption. It is interesting that *Ephedra*'s name (*ma-huang*) places it in the same taxonomic category (*ma*) as ***Cannabis sativa*** (*ma-fen*). This may be due to the fact that both plants produce euphoriant and stimulating effects and would thus have been very useful to shamans.

Because ma-huang continues to be used as an ingredient in tonics and vitalizing aphrodisiacs, it can also be assumed that Taoist alchemists utilized the plant in their quest for long life and immortality and in their magical sexual rites.

Artifacts

None known

Ephedra intermedia, the middle ephedra, is also a source of mahuang.

In Asia, the species *Ephedra equisetina* is also known as mahuang and is used in the same manner as *Ephedra sinica*.

Ephedra intermedia Schrenk et Meyer

ma-huang

Ephedra shennungiana Tang

ma-huang

Ephedra sinica Stapf

ts'ao ma-huang

Medicinal Use

In traditional Chinese medicine, ma-huang has been used with success to treat asthma for more than five thousand years (Wee and Keng 1992, 77*). Generally, both the stems and the roots are used to treat diseases of the lungs and bladder. The stems are used especially in the treatment of fever, colds, headaches, bronchial asthma, and hay fever, while the root is administered for excessive perspiration (Paulus and Ding 1987, 123*).

Constituents

Air-dried herbage contains 1 to 2.5% alkaloids (sometimes as much as 3.3%!), primarily *l*-**ephedrine**, *d*-pseudoephedrine, and *l*-norephedrine. Also present are the analogs norpseudoephedrine, methylephedrine, and methylpseudoephedrine. The alkaloid content is greatest in material collected in autumn. Analyses of different commercial ma-huang preparations from Taiwan have shown that the herbage of *Ephedra sinica* consistently exhibited the highest alkaloid content (approximately 1.1 to 2.1%), followed by *Ephedra equisetina*. *Ephedra intermedia* had the lowest amounts (0.8 to 1.5%) (Liu et al. 1993). The roots and fruits are almost completely devoid of alkaloids (Hiller 1993; Morton 1977, 34*).

Ephedroxane, an anti-inflammatory principle, was also discovered in ma-huang drugs (Konno et

al. 1979). In addition to the alkaloids, which should be regarded as the primary active constituents, there are tanning agents, saponines, flavonoids (vicenine, lucenine, etc.), an **essential oil**, and dextrose (Paulus and Ding 1987, 124*).

Effects

Ephedra herbage has an arousing effect on the central nervous system that is similar to that of **ephedrine**: It stimulates, awakens, accelerates the pulse, and constricts the blood vessels. Extracts of the entire plant effect vasoconstriction, stimulate circulation, elevate blood pressure, arouse the central nervous system, are strongly diuretic, suppress the appetite, alleviate bronchial spasms, and relieve the symptoms of hay fever (for at least eight hours).

Both *Ephedra* extracts and ephedrine hydro-chloride are regarded as excellent aphrodisiacs, especially for women. Because of the potent vasoconstrictive effects, high dosages of *Ephedra* can produce temporary impotence in men in spite of erotic arousal!

People with elevated blood pressure and heart problems should avoid using *Ephedra*. The drug should not be used when heart arrhythmia or high blood pressure is present (Paulus and Ding 1987, 123*).

MAO inhibitors (*Peganum harmala*, harmaline and harmine) can potentiate the effects of *Ephedra* preparations considerably (Hiller 1993, 53).

Commercial Forms and Regulations

According to the *DAB10*, ma-huang is officinal under the name *ephedrae herba* (ephedra herbage). A tincture, Tinctura Ephedrae *EB6*, is prepared from powdered *Ephedra* herbage and diluted ethyl alcohol (1:5). The pharmacopoeia of Chinese medicine states that the alkaloid content may not be less than 0.8% (Hiller 1993, 51).

In Germany, *Ephedra* herbage and especially preparations made with it are available only with a prescription. The International Olympic Committee and the German Sport Federation have included medicaments containing ephedrine in their lists of doping agents as prohibited stimulants (Hiller 1993, 54).

In the United States, both the herbage and herbal tablets and tinctures were available without restriction prior to 2004, but an FDA ban on supplements containing Ephedra went into effect on April 12, 2004 (cf. Hirschhorn 1982).

“The roots of Chinese medicine lie in the shamanic tradition of the Shang and Zhou periods (between the sixteenth and first centuries B.C.E.), a tradition associated with magic and geomancy that is now regarded as superstition. During the course of time, and stimulated by the rational orientation of the state philosophy of Confucianism, this increasingly crystallized into the rational and empirical beginnings of a prescientific medicine.”

Ephedra spp.

Ephedra Species

Family

Ephedraceae (Ephedra Family)

Folk Names

Ephedra, ephedrakraut, joint fir, meerträubchen, meerträubel, meerträubelarten, meerträubl, uva maritima

Distribution

Ephedra species occur primarily in Eurasia and the Americas. Some three species are found in the Himalayan region (see ***Ephedra gerardiana***). There are also several species in China and central Asia (see ***Ephedra sinica***). *Ephedra* species also grow in Europe, chiefly in the eastern Mediterranean region (Greece, Turkey, Cyprus). These *Ephedra* bushes can be mistaken for an *Ephedra*-like broom (*Genista ephedroides* DC.) that is found throughout the Mediterranean.

There is some confusion regarding the taxonomy and nomenclature of the genus *Ephedra*. While as many as seventy-seven species were once described and accepted (Stapf 1889), a revision of the genus has resulted in only some forty-four well-defined species. Questions regarding synonyms, subspecies, and varieties continue to produce considerable confusion in the literature (cf. Zander 1994, 225f.*).

History

Ephedra is one of the oldest plants used by humans. The Neanderthals of Shanidar (modern Iraq) used the plant for ritual and apparently medicinal purposes. Plant remains (pollen) have been recovered from the caves of Shanidar, a Neanderthal burial site dating to approximately 30,000 B.P. (Solecki 1975). *Ephedra* herbage and other bioactive flowers (***Senecio** spp.*, *Achillea* sp., *Centaurea solstitialis* L., *Muscari* spp.) were placed with the deceased for his last journey. The species has been identified as *Ephedra altissima* Desf. (= *E. distachya* type, *E. fragilis* type) (Leroi-Gourhan 1975; Lietava 1992). But it is possible that it may in fact have been a different species, such as *Ephedra alata* Decne., *Ephedra foliata* Bois. et Kotschy, or *Ephedra fragilis* ssp. *campylopoda* (Solecki 1975, 881).

During archaeological excavations in the southeast of the Kara-kum Desert (Turkmenistan), a three-thousand-year-old temple site that looked exactly like a pre-Zoroastrian shrine was uncovered from under enormous walls of sand. Large clay vessels and basins in which great quantities of a presumably fermented ritual drink were obviously prepared were found on the well-preserved fire altar. Some of the remains of the brewing were able to be identified, with astonishing results: Drinks containing *Ephedra* were being brewed at the site. This temple may have been the home of Zoroaster (= Zarathustra), the founder of the religion that now bears his name. This find suggests that *Ephedra* was an ingredient in the inebriating **haoma** drink. Remains of ***Papaver somniferum*** were also found on associated objects (pestles, etc.) (Sarianidi 1988). Today, *Ephedra* species are still known as *hum*, *huma*, and *yahma* in the Harirud Valley (Baluchistan). The name appears to preserve a certain reminder of the ancient fire cult.

Constituents and Effects

Almost all *Ephedra* species contain the amphetamine-like **ephedrine** as well as the related alkaloids pseudoephedrine and norephedrine, along with tanning agents, saponines, flavonoids, and an **essential oil**. The Mediterranean species exhibit their highest concentrations of alkaloids in August, which is why they should be collected at that time. *Ephedra major* contains 0.69% alkaloids, *E. distachya* 0.35%, and *E. campylopoda* only 0.14% (Tanker et al. 1992). Extracts of the entire plant for all the species mentioned have the same effects as ***Ephedra gerardiana*** or ***Ephedra sinica***.

Woodcut of a small *Ephedra* species from the herbal of John Gerard (1633)

The winged ephedra (*Ephedra alata*), common in North Africa and southwest Asia, was already being used for ritual purposes during the Stone Age.

Ephedra andina, known in the Andes as *pingo-pingo*, is devoid of ephedrine.

***Ephedra* Species with the Greatest Ethnobotanical Significance**

Species with ethnobotanical and ethnopharmacological significance are found primarily in South America and Asia. The most important of these are discussed below.

***Ephedra americana* Humb. et Bonpl. ex Willd.—pinku-pinku**

Known as *pinku pinku*, *naranja naranja* (“orange”), and *refresco* (“refresher”), this shrub is found from Ecuador to Argentina and also occurs in the high mountains. In Peru, a tea prepared from the plant is drunk as a tonic (Franquemont et al. 1990, 40*). The related but more prostrate-growing species *Ephedra rupestris* Benth. is known in Quechuan as *pampa pinku pinku*, and it is drunk as a tea for lung ailments (Franquemont et al. 1990, 40 f.*).

***Ephedra andina* Poepp. ex C.A. Mey. [syn. *Ephedra americana* var. *andina* Stapf]—pingopingo**

This South American bush is called *pingo-pingo* (literally, “tubes”) and is also known as *canotu* (“joint” or “hashish cigarette”), *solupe*, and *transmontaga*. In Chilean folklore, this plant is a symbol for “he-men” and heartbreakers—perhaps because of its purported aphrodisiac effects. The plant is used in (folk) medicine to treat bronchitis, asthma, and whooping cough (Mösbach 1992, 60*). In contrast to the other species of the genus, *Ephedra andina* does not contain any ephedrine, although vicenine-I and -II as well as flavones and camphor oil have been demonstrated to be present (Gurni and Wagner 1982; Montes and Wilkomirsky 1987, 40*). Further research is needed to determine whether this plant is psychoactive. The very similar species *Ephedra multiflora* Phil. is also known as *pingo-pingo* (Aldunate et al. 1981, 209*).

***Ephedra breana* Phil.—pingo-pingo**

This species grows into a proper tree that develops a woody, thick trunk as large as 20 cm in diameter. It is found only in the extremely dry high desert of Atacama (northern Chile), where it is known as *pingo-pingo* or *tume*. The edible fruits are known as *granada*, “pomegranates” (Aldunate et al. 1981, 209*; 1983*). A decoction of the fresh or dried stems has very strong stimulating and mood-enhancing effects with pleasurable aphrodisiac sensations. In some ways, these effects are reminiscent of those of MDMA (cf. **herbal ecstasy**).

***Ephedra campylopoda* C.A. Mey [syn. *Ephedra fragilis* Desf. ssp. *campylopoda* (C.A. Mey) Aschers et Graebn., *E. fragilis* Desf. var. *campylopoda* (C.A. Mey) Stapf]—polik stap**

This species is found primarily on Cyprus and the Greek isles (Sfikas 1990, 94*). In ancient times, it

apparently was known as “food of Saturn.” Unfortunately, almost nothing is known about its early history. The modern Greeks consider the plant to be poisonous. Decoctions have only weakly stimulating, albeit very refreshing, effects.

***Ephedra distachya* L. [syn. *E. maxima* Saint-Lager, *E. vulgaris* L.C. Rich, *E. distachya* L. ssp. *distachya*]—sea grape, little sea grape**

This species, which can grow as tall as 50 cm, is indigenous to the Mediterranean region and is also found in flat areas from the Black Sea to Siberia. It is sometimes regarded as a synonym for ***Ephedra gerardiana***, which occurs only in high mountains. This species is primarily used in homeopathy (*Ephedra distachya* hom. *HAB1*, *Ephedra distachya* spag. Zimpel hom. *HAB1*, *Ephedra vulgaris* hom. *HPS88*). The herbage is nearly as rich in alkaloids as that of *Ephedra sinica*.

***Ephedra helvetica* C.A. Mey. [syn. *Ephedra distachya* L. ssp. *helvetica* (C.A. Mey.) Aschers]—Swiss ephedra**

This central European species has rather thin green stems and a creeping growth pattern, achieving a height of only 20 to 50 cm. It thrives chiefly in rocky areas. Swiss ephedra is found primarily in Ticino and Valais (Rhône Valley), where it may be collected from the wild (Lauber and Wagner 1996, 82*). Teas made from the plant have stimulating effects that are similar in potency to teas made from *Ephedra sinica*.

Ephedra breana, known locally as *pingo-pingo*, occurs primarily in the higher regions of the Atacama Desert (northern Chile), where it can grow into proper trees with very woody trunks. (Photographed in the Atacama Desert)

Andean ephedra (*Ephedra andina*) grows at very high altitudes.

Ephedra distachya, found in Greece, develops red berries with a sweet taste. (Photographed on Naxos, Greece)

Swiss ephedra, *Ephedra helvetica*, is found in the Alps. (Photographed in Switzerland)

Ephedra microsperma, a species from central Asia.

Dwarf ephedra (*Ephedra minima*) is found on the Tibetan Plateau.

Large ephedra (*Ephedra major*)

The subspecies *Ephedra major* ssp. *procera* (Fischer et C.A. Mey.) Markg. is found in southern Greece.

The stimulating Mormon tea (*Ephedra nevadensis*) is occasionally found growing in rocks. (Photographed in Black Canyon, Colorado)

***Ephedra intermedia* Schrenk et Mey.—narom**

Four geographically isolated varieties of this species are distinguished:

- var. *glauca* (Regel) Stapf (Transcaspian region, Pamir, Mongolia)
- var. *persica* Stapf (Iran, western Afghanistan)
- var. *schrenkii* Stapf (northwest Iran, Turkistan)
- var. *tibetica* Stapf (Afghanistan, Pakistan, India, Tibet)

In Baluchistan (Pakistan), the aboveground herbage of the variety *tibetica* is used for dyeing and

tanning (Goodman and Gharfoor 1992, 14*). A decoction of 25 g of the stems is drunk for back pain or as a general tonic (Goodman and Gharfoor 1992, 52*). In Pakistan, the herbage is burned to ashes and mixed with *Nicotiana tabacum* to produce a chewing tobacco (Morton 1977, 36*). In China, the variety *glauca* is one of the three ma-huang species (see *Ephedra sinica*). The Persian variety is known as *hôm*, *hum*, or *huma* and is regarded as a substitute for or ingredient in **haoma**.

***Ephedra major* Host [syn. *Ephedra equisetiformis* Webb. et Berth., *E. nebrodensis* Tineo ex Guss., *E. scoparia* Lange]—large ephedra**

There are two subspecies of large ephedra: *E. major* ssp. *major* and *E. major* ssp. *procera* (Fisch. et C.A. Mey.) Markg. [syn. *E. procera* Fisch. et C.A. Mey.]. The subspecies *major* is found in Spain and along the Mediterranean Sea as far as western Asia. The subspecies *procera* is indigenous to Dalmatia, Greece, southwest Asia, and the Caucasus (Zander 1994, 256*). This rather rare and fairly tall plant contains more than 2.5% alkaloids, 75% of which is ephedrine (Morton 1977, 34*). It is thus a very good source of ephedrine.

***Ephedra monosperma* C.A. Mey—Tibetan ephedra**

This high mountain species is found almost exclusively in Tibet, where it is known by the name *mtshesdum*. It has been a part of the Tibetan pharmacopoeia since ancient times and was mentioned in the Blue Beryl Treatise of Sangye Gyamtso (1653–1705). The herbage is used to treat “liver fever” and bleeding, but it is particularly renowned for its refreshing and rejuvenating properties (Aris 1992, 1:69, 2:225*).

***Ephedra nevadensis* Wats—Mormon tea**

This species, which can attain a height of approximately 90 cm, predominates in the American Southwest. Analyses of coprolites (fossilized feces) have demonstrated that prehistoric Indians of the Caldwell Cave Culture (1200–1450) used this species for ritual or medicinal purposes (to treat diarrhea) (Sobolik 1996, 8; Sobolik and Gerick 1992). The Coahuilla Indians of Southern California call the plant *tú-tut*. They make an infusion of the plant for use as a stimulating tea (Barrows 1967, 73f.*). Because of the aphrodisiac effects of the plant and the teas made from it, it is also known as “whorehouse tea” (Morton 1977, 36*). It is one of the favorite drinks of the Mormons, who are otherwise avowedly “anti-drug.”

***Ephedra torreyana* S. Wats—Torrey joint fir**

The Navajo call this species, which grows to a height of only 60 cm, *tl’oh azihii libáhígíí* (“gray rasp grass”). They use its stems as a diuretic to treat kidney ailments and venereal diseases and to alleviate postpartum pain. They roast the stems before brewing in order to remove their bitter taste (Mayes and Lacy 1989, 54*).

***Ephedra trifurca* Torr.—tlanchalahua**

This Mexican species has been used medicinally since the pre-Columbian period. Teas (infusions, decoctions) made from it are used in folk medicine to achieve weight loss and to suppress the appetite (Martínez 1994, 304*). Such uses reflect the high alkaloid content of the plant.

Erythrina americana Miller

American Coral Tree

Family

Leguminosae (Legume Family); Subfamily Papilionoideae

Forms and Subspecies

None

Synonyms

Corallodendron americanum Kuntze

Corallodendron triphyllum nom. nud.

Erythrina carnea Ait.

Erythrina enneandra DC.

Erythrina fulgens Loisel.

Folk Names

American coral tree, amerikanischer korallenbaum, bolita grande, cehst (Mixe), chakmolche' (Mayan, "the tree of the red puma"), chak-moolché', chocolín, chotza, colorín, cosquelite, demti (Otomí), equimite, hutukuu' (Huastec), iquemite, iquimite, jiquimiti, k'ante' (Mayan, "yellow tree"), korallenstrauch, lakatilá (Totonac), lakatili, lakatilo, lak'tanga, li-pashcua (Chontal), madre alcaparra, madre brava, madre cacao, madre chontal, ma-ja-nú (Chinantec), palo de coral, pali de pite, parencsuni, patol, pat-olli, pichoco, pito, pito pichoco, puregue, purenhecua (Tarascan), purgne, quemite, quimiti, sompantle, sompantli, sumpantle, te'batai (Otomí), tlalni, tsejch (Mixe), tsizch, tu saba (Mixtec), tzinacancuáhuatl, tzite (Quiché), tzompancuahuatl (Aztec "tzompantli tree"),¹²⁹ tzompantli, tzompomitl (modern Nahuatl), tzon të kichilo, uhkum, xk'olok'max (Yucatec Mayan), xoyo' (Mayan), zompantli, zompantlibaum, zompantlibohne, zumpantle

The edible red flowers are known in Veracruz as *gasparitos* and in Nahuatl as *cozquelite*.

History

The red seeds have been found in prehistoric strata. The tree and its hieroglyph appear in pre-Columbian Mayan manuscripts (Codex Dresdensis) under the name *k'ante'*, "yellow tree" (Rätsch 1986, 223*). The tree is also mentioned in Aztec sources, as well as sources in other languages, from the early and late colonial period. The genus and many of its species were first described by Linnaeus.

Because of the paralyzing effects of the extract, this agent was once misused for vivisections (Roth et al. 1994, 327*).

In Veracruz, the flowers are cooked and eaten as a vegetable. They are regarded as an aphrodisiac food (Reko 1938, 127*; Ott 1993, 423*). The seeds were once used in a kind of dice game (*patol*) (Krukoff 1939, 210).

The luminous red flower of the American coral tree (*Erythrina americana*). (Photographed in Teotihuacán, Mexico)

This Aztec relief from the Templo Mayor of Tenochtitlán (Mexico City) depicts a tzompantli, a rack for holding skulls from human sacrifices that was made from wood.

Distribution

The tree occurs from northern Mexico to Guatemala. It prefers a dry and warm climate. Its range is concentrated around central Mexico (Morelos, Puebla, Veracruz, Colima, Guerrero, Oaxaca) (Krukoff 1939, 299).

Cultivation

Cultivation is performed simply by planting pre-germinated seeds in the soil. The seeds should be watered well, but not too much. In Mexico, the tree has been planted as a living fence since pre-Columbian times (Krukoff 1939, 210).

Appearance

The American coral tree can grow to a height of some 6 to 8 meters. It has large, wide, and attenuate leaves that are attached to the stalks in clusters of three. The luminously red flowers can grow as long as 10 cm and are arranged in upright clusters. The tree loses its foliage in the winter. The flowers begin developing while the tree is still bare (January to March). The slightly constricted pods then ripen as the leaves emerge. The pods contain two to five bright red, bean-shaped seeds.

The tree is easily confused with the very similar species *Erythrina mexicana* Kruk. (whose seeds,

like those of *E. americana*, are known as *equimitl* in Aztec) as well as with other *Erythrina* species. It is almost identical to *Erythrina standleyana* Kruk. and can be distinguished from the latter species only on the basis of its geographical distribution (Krukoff 1939, 300 f.).

Psychoactive Material

—Seeds (*colorines*, *equimitl*, *tzite*)

Preparation and Dosage

When intended for internal use, the seeds must be ground. The effective dosage is given as no more than half of a seed. But this guideline should be used with great care, as no dependable information is available!

Ritual Use

The pre-Columbian Maya associated this tree with the direction south, whose symbolic color is yellow. The Mayan name *k'ante'*, “yellow tree,” refers not to the color of the red flowers or the red seeds but to the yellow dye that is obtained from the root cortex (Krukoff 1939, 210). The tree is invoked in magical formulae uttered to treat possession (*tancasil*). In the prophetic texts of the shamanic jaguar priest (*chilam balam*), the plant is mentioned in an anthropomorphized form as a divine being known as *ah kantenal*, “he of the yellow tree” (Rätsch 1986, 223*). There are only a few vague indications that contemporary Yucatec Mayan shamans use the seeds for healing rituals and divinations (Garza 1990, 188*).

The Huastec still use the wood to make ritual masks (Alcorn 1984, 640*).

The traditional divinatory priests of the Kanjobal (Guatemala) still use the ancient Indian 260-day calendar for their divinations. They use the seeds of the coral tree to count the days. This calendar divination has been maintained into the present time and has an important function for the Kanjobal in solving personal problems and social conflicts (Hinz 1984).

In the Aztec culture, the coral tree was closely related to human sacrifice. Before the victims were disemboweled and butchered for sale at the great market of Tenochtitlán (present-day Mexico City), their heads were removed. The skulls were placed on a rack of vertical poles. They were speared onto the wooden stakes, so that the growing numbers of skulls were placed one on top of the other. In Aztec, this rack was known as a *tzompantli* (“skull frame”), and it was always located in close proximity to the main temple (Krickeberg 1975, 239). Several pre-Hispanic stone sculptures depicting the *tzompantli* have been preserved. Since it is known by the name *tzompantli tree*, the coral tree was directly or symbolically associated with this practice. Unfortunately, the sources do not provide us with any insights into the actual nature of this relationship. It is possible that the seeds were administered to the selected victims to sedate them (cf. *Datura innoxia*, *Bursera bipinnata*). The wood the frame was made from was definitely not that of the coral tree, for coral tree wood is very soft and would not have provided sufficient support for the many skulls.

One of the earliest European illustrations of a botanically correct branch of the American coral tree. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

“Tzompanquauitl

It is a tree of average size; its round leaves are of average size. The name of its leaves, its foliage, its flowers is *equimixochitl*. [The flowers] are chili red, very chili red. They have no scent; they are useless, without any use, not necessary. This *tzompanquauitl* is honey-like, sweet; still it is somewhat hard of taste. It produces a bean. The name of this bean is *equimiltl*; it is chili red like *ayecotli*. It is multiplied in the following way: the seed is planted; and the branch is only broken, cut in order to transport it, as with *uexotl*.”

BERNARDINO DE SAHAGUN FLORENTINE CODEX (BOOK 11)

Artifacts

The wood was and still is used to manufacture ritual objects, including masks and figures of gods (Aguilera 1985, 128f.*). In central Mexico, small ithyphallic images of gods were still being carved from the wood in the twentieth century; these were placed in the kitchen as a magical protection against food spoilage (Reko 1938, 127f.*).

A statue of the god Maximón made from the wood of a closely related species is still cultically venerated in the Guatemalan highlands, among the Tzutujil of Lago Atitlán. The fly agaric mushroom (*Amanita muscaria*) is associated with this sacred wooden figure of Maximón, who is said to have risen from a coral tree (*Erythrina rubrinervia*) when it was struck by lightning. According to legend, the tree had been standing in the midst of a group of fly agaric mushrooms when it was hit by the lightning bolt. A man is said to have eaten a piece of these mushrooms and become young again (Lowy 1980).

In Mexico, the red seeds are frequently used in the manufacture of amulets and necklaces:

It is also said that the seeds can incite love. According to folk belief, when a girl is wearing a chain of such seeds around her neck, she will soon become so incapable of resisting a man's wishes that she will simply give herself to him.—Because of this tradition, it is probable that certain ladies who belong to the category of those who do not die as long as they love still like to decorate themselves with these ominous necklaces today so that they can tell the world of the living about the magic which affects them. (Reko 1938, 127*)

A beautiful portrait of the plant by the flower painter Georg Dionys Ehret (1708–1770) was published in 1750 in the *Plantae selectae* of Christoph Jakob Trew (Trew 1981, table 8*).

Medicinal Use

The modern Huastec use the leaves as a medicine for sleeplessness, restlessness, and “crying out at night” (Alcorn 1984, 640*). In Mexican folk medicine, a decoction of the flowers is ingested for chest pains. The juice tapped from the trunk is used for scorpion stings. The bark is drunk as a diuretic and purgative (Krukoff 1939, 210).

Constituents

The seeds and, to a lesser extent, the flowers and other parts of the plant contain erythrina alkaloids (erythrane, erythroidine, coralline, coralloidine, and erythro-coralloidine). The seeds have been found to contain 1.61% alkaloids (erysopine, erysovine, erybidine, erysodine, and erythartine) (Lara Ochoa and Marquez Alonso 1996, 39*; Martínez 1994, 78*). The flowers contain 0.11% alkaloids (α -erythroidine and β -erythroidine) (Aguilar et al. 1981).

The raw drug is known as Mexican curare (Krukoff 1939, 205; Roth et al. 1994, 327*).

Effects

The seeds are said to produce a so-called women’s inebriation, i.e., nymphomaniac/ecstatic states with a strong desire for sex:

The first such intoxication is described in a report from the year 1719. An Indian woman prepared a dish from the red beans, which appeared to her to be edible, and gave this to other women. All who ate of it began to laugh without reason, babbled all kinds of nonsensical things, and talked shamelessly. Later, they reeled like drunkards and finally fell into a deep sleep, so that they had to be carried home.

In September 1738, an honorable young girl accidentally ate some of the red zompantli beans and shortly thereafter lost her mind. She ran through the streets with her skirt raised, laughing horribly, much to the dismay of the women and the derision of the men. Neighbors brought her back home, where she fell into a hot fever, ripped apart all of her bedding, and died on the third day thereafter. . . . In all of these cases, the ingestion of the red beans initially produced immoderate gaiety, then confused speech, wobbling as if drunk, and a heightened libido. The intoxicated persons then fell into a deep sleep, from which they usually did not reawaken. (V. Reko 1938, 129 ff.*)

These and similar reports describe the alleged effects of the red seeds. It is difficult to determine whether these are in fact authentic or belong to the domain of legend. In any case, these reports have had such an effect that since that time no one else has attempted to try the seeds himself.

In Mexico, the boiled flowers are eaten as a vegetable and produce mild hypnotic effects (Aguilar et al. 1981).

Botanical illustration of the American coral tree (*Erythrina americana*). (Colored copperplate engraving from Trew 1750.)

Commercial Forms and Regulations

In Mexico, *colorines* are available in the markets and in stores selling devotional articles. Indians often sell chains of the seeds near ruins and other tourist attractions.

The rain god Chac, with his tapir nose (= God B), is shown sitting on the *k'ante'*, the “yellow tree” of the south (*Erythrina americana*). (Codex Dresdensis, 31c)

Erythrina berteroana Urban

Pito Coral Tree

Family

Leguminosae (Legume Family); Subfamily Papilionoideae

Forms and Subspecies

None

Synonyms

None

Folk Names

Aposhí, aposí, chilicote, colorín, coral bean, coralina, k'änte' (Lacandon, “yellow tree”), peonía, pioneo, pito coral tree, pito-korallenbaum, tzinacancuáhuítl (Aztec), tzompantli

History

For the history of the coral trees, see *Erythrina americana*.

In Guatemala and El Salvador, the young flowers of this species of coral tree are eaten as a vegetable (fresh or frozen). When a large amount is consumed, the meal has sedative effects and induces a long and deep sleep. The tree is frequently cultivated in Central America (as a living fence). In former times, crushed branches were used as a fish poison (Morton 1994).

Distribution

This species is found primarily in Guatemala, El Salvador, and southern Mexico. It also occurs in central Mexico and in rare cases in northern Mexico.

Cultivation

The tree is difficult to grow from pregerminated seeds. In contrast, it is easily propagated from cuttings (of trunks or branches that have already become woody). It does not place any particular demands upon the soil. It should be watered well but not overly much. It does not tolerate any cold or frost (Grubber 1991, 26*).

Appearance

This shrublike tree, which can grow as tall as 9 meters, develops thorny branches. The 6 to 9 cm long leaves are arranged on the stems in groups of three. The red flowers (3 to 6 cm long) develop in loose, many-flowered clusters. The brilliant red, bean-shaped seeds are enclosed within the seed-pods (two or three per pod).

This tree is easily confused with the closely related species *Erythrina flabelliformis* (see *Erythrina* spp.).

Psychoactive Material

—Seeds (*colorines*)

Preparation and Dosage

One quarter or one half of a seed is chewed thoroughly and swallowed (Gottlieb 1973, 9*). Otherwise, see *Erythrina americana*.

Botanical illustration of the pitto coral tree (*Erythrina berteroana*). (Colored copperplate engraving from Trew, 1750)

Erythratine-*N*-oxide

The large flower of the coral tree known as pito (*Erythrina berteroana*) is edible. (Photographed in Naha', Chiapas, Mexico)

A traditional string of red seeds of *Erythrina berteroana*, as produced by the Lacandon

“Almost all of the Indian women of this region (Nayarit) know about the colorines or zompantli beans which, when ingested, induce hot dreams and cause them to concern themselves with thoughts of fleshly desire. They say that one can eat only a very little of these, as too much will produce fever, pains in the breasts and lower abdomen, and a daze akin to drunkenness. They keep this custom a secret from the men. But in confession, some of them ask whether this agent is Christian or abominable, and to justify it they cite the advantage that those who use it never defile themselves with a man. I regard the bean as diabolic, for it clearly incites lewd behavior and probably also leads to infertility. It will therefore be no great wrong if its use is forbidden at every opportunity, in particular in conversations during

confession.”

FATHER SALAMIELLA

FROM A LETTER IN THE ARCHIVE OF TEPIC

IN *MAGISCHE GIFTE* [MAGICAL POISONS]

(V. REKO 1938, 131 f.*)

Ritual Use

See *Erythrina americana*.

Artifacts

The seeds have been used to make necklaces since ancient times. They also are a component of amulets.

A botanically accurate portrait of the plant by the flower painter Georg Dionys Ehret (1708–1770) was published in 1760 in the *Plantae selectae* of Christoph Jakob Trew (Trew 1981, table 58*).

Medicinal Use

A tea made from the flowers is occasionally drunk as a “sleeping pill” (Morton 1994).

Constituents

The seeds contain erythrina alkaloids (erysodine, erysopine, erysothiopine, erysothiovine, α - and β erythroidine, and hypaphorine), which are also present in the flowers in lesser amounts. These alkaloids are responsible for the sedative effects.

The new alkaloid erythratine-*N*-oxide was isolated from this species (Soto-Hernandez and Jackson 1994).

Effects

The psychoactive effects of the seeds have been characterized as narcotic, sedative, and mildly inebriating, and purportedly also as aphrodisiac (cf. *Erythrina americana*).

Commercial Forms and Regulations

In southern and central Mexico, the red seeds can be obtained in Indian markets and shops that sell devotional articles. Indian women sometimes offer strings of seeds for sale in tourist areas (e.g., Palenque).

Literature

Erythrina spp.

Coral Tree Species

Family

Leguminosae (Legume Family); Subfamily Papilionoideae

Coral trees are found primarily in the tropical zones of the New and Old Worlds (Standley 1919), although there are also species in Australia. The genus is composed of some one hundred species (Bärtels 1993, 142*). The seeds contain chiefly cytisine or other erythrina and curare-like alkaloids (El-Olemy et al. 1978; Wandji et al. 1994). It is for this reason that they generally are regarded as poisonous. Only the seeds of the Andean species *Erythrina edulis* Triana [syn. *Erythrina esculenta* Sprague, *E. edulis* Posada-Arango, *E. lorenoi* F. Maehr., *E. megistophylla* Diels] can be eaten (Bärtels 1993, 68*). They are often sold as “beans” at Indian markets. The seeds of some species contain lectins (Peña et al. 1988).

***Erythrina corallodendron* L. [syn. *Erythrina corallodendron* var. *occidentalis* L., *E. spinosa* Mill., *E. inermis* Mill., *E. corallifera* Salisb., *Corallodendron occidentale* Kuntze]—madre del cacao**

This tree is indigenous to Central America, where it is found both in cultivation and in the wild. It is an important shade tree in the tropical cacao plantations (cf. *Theobroma cacao*). Its red seeds, known as *colorines*, are strung together to make bracelets and necklaces. They allegedly contain “hallucinogenic substances” (Bärtels 1993, 68*).

***Erythrina falcata* Benth.—seibo**

This beautiful blooming tree is known in Peru as *pisonay*. It also occurs in Bolivia, Brazil, and Paraguay, as well as in northwestern Argentina, where it is known by the folk names *seibo*, *ceibo*, *seibo del noroeste*, *seibo de jujuy*, *seibo de salta*, *seibo de Tucuman*, *seibo de la selva*, *seibo rosado*, *seiba*, and *suiñandi* (Santos Biloni 1990, 21*). According to a physician in Tartagal (pers. comm.), it may also be called *seibo silvestre*, and it is said to be the source of a hallucinogenic **snuff**. The national tree of Argentina, *Erythrina crista-galli* L., is also known as *seibo*. It plays a role in numerous legends; it is said that an ugly Guaraní maiden named Anahí was transformed into the beautiful flower (Santos Biloni 1990, 171*).

***Erythrina flabelliformis* Kearney [syn. *Erythrina purpusi* Brand.]—fan-shaped coral bush**

The shamans of the Tarahumara formerly used the seeds in rituals, although we do not know how (Bye 1979b, 38*). The seeds probably also were added to the *tesgüino* beer that was brewed from agaves (*Agave* spp.) or maize (*Zea mays*) to potentiate the effects (Bye 1979b, 38*). The seeds are or were strung into necklaces by northern Mexican Indians (Bye 1979b, 37*). They are used as an alternative to mescal beans (*Sophora secundiflora*). The Serí Indians of northern Mexico boil the seeds to produce a decoction that they drink to treat diarrhea (Felger and Moser 1974, 425*). The Pima Indians grind the seeds and mix them with lard to produce an ointment that is applied to treat inflammations. Partially ground seeds—which are regarded as poisonous—are swallowed as a purgative (Pennington 1973, 222*). The Tarahumara used the seeds to treat toothaches and lower abdominal ailments. The Indians of the Barranca de Batopilas region applied a kind of ointment made

from ground seeds to their eyelids to improve their vision (Bye 1979b, 37*).

The seeds contain numerous erythrina alkaloids, including 14% erysotrine, 45% erysodine, 40% erysovine, and approximately 1% eryspine (Bye 1979b, 38*). The Tarahumara say that this plant produces erotic dreams. The extract has effects like those of curare (Díaz 1979, 87*). To date, there is no evidence that the plant produces psychoactive effects (Schultes and Hofmann 1980, 338*).

***Erythrina fusca* Lour.**

This coral tree, known as *amasisa* or *gachica*, is found in Amazonia, where it is used as an **ayahuasca** additive. It has been found to contain the alkaloids erythraline, erythramine, and erythratine.

Erythrina glauca* Willdenow—*amasisa

The “blue” coral tree is found in the Amazon basin. It is known as *amasisa* in Colombia and as *assacú-rana* in Brazil. The Tikuna Indians boil the bark to wash out wounds. In Brazil, a tea made from the roots is drunk to treat rheumatic complaints and liver ailments, while higher dosages are used as a purgative. Very strong concentrations of the root tea are said to produce narcotic effects. The chemistry of this species is unknown (Schultes and Raffauf 1990, 241*). Parts of the plant are used as **ayahuasca** additives (Ott 1993, 217*).

Erythrina indica* Lamarck [syn. *Erythrina variegata* L.]—*mandara

This tree is sacred in India and Nepal, where it is associated both with the production of *amrita*, the drink of immortality (cf. **soma**), and with Shiva’s paradise. According to Vedic mythology, the tree arose when the milk of the primordial ocean was churned to make the drink of the gods. Indra saw the tree rise up from the depths and planted it in his pleasure garden. It is regarded as one of the five heavenly trees and is venerated for its abilities to fulfill wishes (*kalpavriksha*). Krishna stole the tree from Indra’s garden and brought it to humans. The wood of the mandara tree is sacred and is burned as a sacrificial offering on the fire altar known as *homa*. The bright red flowers are offered to Shiva, and the tree is generally closely associated with the god. The three leaves on each stalk symbolize the trinity of Hindu gods: Brahma, Vishnu, and Shiva (Gupta 1991, 39 f.*).

The enchanting flower of a Brazilian species of coral bush, *Erythrina crista-galli*

“The consumption of just a small amount of ‘colorines’ produces an extraordinary increase in blood pressure. For this reason, the Indians in the Sierra of Tlaltizepam (Michoacan) use this in the form of an extract for acts of revenge, when they wish that a person be struck by a ‘blow.’ ”

LUTZ ROTH, MAX DAUNDERER, AND KURT KORMANN *GIFTPIANZEN—Pflanzengifte* [POISONOUS PLANTS—PLANT POISONS]
(1994, 327*)

The seeds and bark of the species found in the Himalayas were or are used as a fish poison. It is quite possible that the tree was once used as a hallucinogen. In Sri Lanka, the trees are cultivated as a support for the cubeb pepper vine (*Piper cubeba*; cf. ***Piper* spp.**) to climb (Macmillan 1991, 415*). A tonic is prepared from the plant together with the leaves of *Solanum nigrum* L. (see ***Solanum* spp.**) and the seeds of ***Datura metel*** (Bhandary et al. 1995, 155 f.*).

***Erythrina mulungu* Mart.—mulungu**

The bark of this Brazilian species was once used medicinally as a narcotic in the form of a Galenic preparation. It “contains a narcotic with opium-like effects” (Schneider 1974, 2:66*).

The Indian coral bush (*Erythrina indica*) in full bloom. This tree is venerated as sacred. (Photographed in the Arum Valley, Nepal)

The characteristically colored leaves of the cultivated *Erythrina indica* var. *variegata* cv.

This traditional necklace of the Aborigines of northeastern Australia incorporates *Erythrina* seeds in its design.

As the jaguar indicates, the Argentinean coral tree (*Erythrina falcata*), known locally as *seibo*, is clearly a shamanic tree that was or secretly still is used as a hallucinogen. (From Pedro de Montenegro, *Materia médica misionera*, seventeenth century)

Colorines

Many Mexican markets have stands that offer fresh and dried herbs, images of saints, amulets, and candles and incense. Often they sell *Erythrina* seeds under the name *colorines* as “magical seeds” or “magic beans” (Bye and Linares 1983, 6*). However, the seeds of other plants are also sold under this name and attributed with identical or similar magical significance (Martínez 1987*).

Name of the Stock Plant	Description of the Seeds
<i>Abrus precatorius</i> L.	red-black seeds (small, roundish)
<i>Capparis indica</i> (L.) Fawc. et Rendl.	red berries
<i>Erythrina americana</i> Mill.	red seeds (bean shaped)
<i>Erythrina berterioana</i> Urb.	red seeds (bean shaped)
<i>Erythrina breviflora</i> DC.	dark brown seeds (bean shaped)
<i>Erythrina corallodendron</i> L.	red seeds (bean shaped)
<i>Erythrina coralloides</i> DC.	scarlet red seeds with a black line
<i>Erythrina flabelliformis</i> Kearn.	red to yellow seeds (bean shaped)
<i>Erythrina herbacea</i> L.	red seeds (bean shaped)
<i>Erythrina lanata</i> Rose	red seeds (bean shaped)
<i>Erythrina lepthoriza</i> DC.	black seeds (bean shaped)
<i>Erythrina occidentalis</i> Standl.	red seeds (bean shaped)
<i>Erythrina phaseloides</i> DC.	red seeds (bean shaped)
<i>Erythrina</i> spp.	red seeds (bean shaped)
<i>Hamelia xerullensis</i> H.B.K.	?
<i>Ormosia istmensis</i> Standl. ¹²⁸	red seeds (round, humped)
<i>Ormosia macrocalyx</i> Ducke	red seeds (round, humped)
<i>Ormosia toledana</i> Standl.	red seeds (bean shaped)
<i>Ormosia</i> spp.	red-orange seeds (round, humped)
<i>Ormosia</i> spp.	red-black seeds (round, humped)
<i>Piscidia americana</i> Moc. et Sess.	?
<i>Rhynchosia pyramidalis</i> (Lam.) Urb.	red-black seeds (small, round)
<i>Rivina humilis</i> L.	red seeds
<i>Sophora conzatti</i> Standl.	red seeds (bean shaped)
<i>Sophora purpusii</i> T.S.	red seeds (bean shaped)
<i>Sophora secundiflora</i> (Ort.) Lag.	red to yellow seeds (bean shaped)
<i>Sophora tomentosa</i> L.	red or yellow seeds (bean shaped)

Erythrina poeppigiana (Walpers) Cook

Parts of this coral tree, which is native to the Amazon basin, are used as **ayahuasca** additives (Ott 1993, 217, 270*). In Latin America, the flowers of this species are eaten as a vegetable or salad.

Erythrina standleyana Krukoff—chakmolche’, pito del monte

In Yucatán (Mexico), the seeds are believed to offer magical protection against “evil winds” (*k’ak’as ik’o’*). The Maya place them on the altar for the rain ceremony *ch’a’chak* (cf. **balche’**) (Barrera M. et al. 1976, 303*). It is not known whether the seeds were or are used for psychoactive purposes. It is possible that this species is actually only a variety of *Erythrina americana*.

Erythrina vespertilio Benth.—batswing coral tree

This small tree is found in tropical eastern Australia, where the local Aborigines make the red, beanlike seeds into chains and (magical) ornaments. They also make shields from the wood of the tree (Pearson 1992, 106*). Whether the seeds were used for psychoactive purposes is unknown. The plant is rich in alkaloids (Collins et al. 1990, 40*).

Erythrina spp.

The seeds of many species of *Erythrina* are known as *colorines* and are used for magical as well as ethnopharmacological purposes (see the table at left). The ethnographic literature makes frequent mention of species that certainly were not compared to herbarium specimens and whose botanically identity may thus be incorrect. For this reason, it is not possible to provide a precise classification.

In Venezuela, the ashes of the wood of several *Erythrina* species known as *bucare* (also *anauco*,

ceibo, immortelle) are used as additives in the tobacco mixture known as *chimó* (see *Nicotiana tabacum*).

In Mexico, the red seeds of the rain forest tree *Ormosia* are also known as *colorines* and are used to make necklaces.

The red-black seeds of an *Ormosia* species from the southern Mexican rain forest are also known as *colorines*.

A typical Mexican amulet, in the center of which is an *Erythrina* seed

In Mexico, the small black-red seeds known as rosary peas (*Abrus precatorius*) are also called *colorines*

These red mescal beans (*Sophora secundiflora*) are easily mistaken for the red seeds of the other tree legumes.

The red seeds of this southern Mexican *Erythrina* species are also known as *colorines*.

Erythroxylum coca Lamarck

Coca Bush

Family

Erythroxylaceae (Coca Family)

Forms and Subspecies

The genus *Erythroxylum* (previously *Erythroxylon*) encompasses some three hundred species. Apart from *Erythroxylum coca* and ***Erythroxylum novogranatense***, however, none of these contains any significant amount of cocaine. The most commonly cultivated species is *Erythroxylum coca*, which is subdivided into two varieties that are distinguished on the basis of morphological, geographical, and ecological characteristics (Plowman 1982):

Erythroxylum coca Lam. var. *coca*—huanuco, Bolivian coca (humid mountain regions from Ecuador to Bolivia)

Erythroxylum coca var. *ipadú* Plowman—ipadú, Amazonian coca (tropical lowlands, Amazonia)

Synonyms

Erythroxylon coca Lam.^{[131](#)}

Erythroxylon peruvianum Prescott (= *E. coca* var. *coca*)

Erythroxylum bolivianum Burck (= *E. coca* var. *coca*)

Erythroxylum peruvianum Prescott (= *E. coca* var. *coca*)

Folk Names

Erythroxylum coca var. *coca*:

Bolivian coca, bolivianische coca, botô, ceja de montaña coca, Ceylon huanuco, coca, coca bush, coca del Perú, cocaine plant, cocaine tree, cocamama, cocastrauch, cocca, cochua, coco, cuca, divine plant of the Incas, gran remedio, huanacoblatt, huánuco coca, koka, khoka (Aymara, “tree”), kuka (Quechua), la’wolé (Mataco), mamacoca, Peruvian coca, spadie

***Erythroxylum coca* var. *ipadú*:**

Batú, botô (Makú), coca, coca-á (Siona), daallímü, ebee, hibi, hibia, hibio, huangana-coca (Bora), igatúa (Karijona), ipadó, ipadu (*língua-geral*), ipadú, ipatú (Yucuna), ípi (Bora), jibína (Witoto), kaheé (Makuna), majarra coca, pató (Tatuyo), patoó (Kubeo), pelejo coca, tsi-paa, ypadu, ypadú

The word *coca* is from the Aymara language and means simply “tree” (Weil 1995). This is an expression of the great cultural significance of the plant.

History

The coca bush is originally from the rain forests of the Andean foothills. For millennia, it has been cultivated and used in South America for a multitude of purposes. The oldest archaeological evidence of coca chewing has been dated to approximately 3000 B.C.E. In the dry lowlands of Peru, numerous pre-Columbian graves have yielded remains of coca leaves (cf. ***Erythroxylum novogranatense***), lime, and artifacts associated with coca use (Hasdorf 1987; Martin 1969; Towle 1961, 58ff.*).

Archaeological finds of coca leaves are extremely rare in the Andean highlands, primarily because of the poor state of preservation of botanical materials and the clumsy excavation methods of past decades. Recently, *Erythroxylum coca* var. *coca* was identified in a prehistoric settlement in the Upper Mantaro Valley (Peru) (1000–1460; Late Intermediate and Late Horizon periods) (Hastorf 1987). Hairs taken from mummies found in northern Chile have been tested for cocaine and its most significant meta-bolite (benzylecgonine). Trace amounts were detected in almost all of the samples. The oldest of the mummies dates to some four thousand years ago (Cartmell et al. 1991).

Coca had an extremely important function in many pre-Columbian cultures as an article of economic exchange, a medicine, an aphrodisiac, a remedy, and a ritual inebriant. Without coca, the civilizations of the Andes would have been inconceivable (Mortimer 1974). The Spanish first encountered the widespread use of coca when they moved into South America to subdue and suppress the indigenous cultures. They understood this custom as little as they understood other aspects of Indian culture. The government of New Spain quickly forbade coca use in the years between 1560 and 1569, using a dubious line of reasoning that is quite reminiscent of many modern arguments in support of some drug laws: “The coca plant is nothing more than idolatry and witchcraft which only appears to strengthen evil by deceit, possesses no true virtues, but probably takes the lives of a number of Indians who in the best case only escape from the forests with damaged health” (cited in Voigt 1982, 36). In the seventeenth century, the Inquisition viewed the veneration of coca as a sign of witchcraft and magic but found it a difficult custom to overcome. For the Indians, who regarded the coca bush as sacred and not diabolic, life in the oxygen-poor high mountains was inconceivable without coca. For this reason, they held firm to their tradition and disregarded the laws of New Spain and the Catholic Church. When the separation from the Spanish motherland occurred, the use of coca was normalized and, ultimately, legalized in Peru and Bolivia. Today, the use of coca is associated with Indian identity; coca is, so to speak, the expression of the Indian way of life and of indigenous culture (Instituto Indigenista Interamericano 1986, 1989; Lobb 1974).

Mama Coca presents the coca bush, her sacred plant, to the Spanish invaders. (Engraving by Robida, from the French edition of Mortimer, ca. 1904)

In 1565, the Spanish physician Nicolas Monardes wrote that the Indians chewed coca together with tobacco. Monardes brought the first coca plant to Europe in 1569 (other sources say 1580) (Morton 1977, 180*). The first botanical illustration of the plant was made by Clusius in 1605 (Lloyd and Lloyd 1911, 3). The main constituent, **cocaine**, was first isolated from the leaves in 1859 by the German chemist Albert Niemann.

At the end of the nineteenth century, cigars and cigarettes made of coca leaves were being smoked in Philadelphia. It appears that the leaves were also smoked in England, where they were known as Peruvian tobacco (Lindequist 1993, 90).

Henry Hurd Rusby worked on behalf of the Parke and Davis Company to have coca leaves incorporated into the American pharmacopoeia (Rossi-Willcox 1993*). In 1863, the Corsican chemist Angelo Mariani created his Vin Mariani, a coca extract in sweet wine. Fans of the preparation included Queen Victoria, Pope Leo XIII (who served from 1878 to 1903), Mozaffer-et-Dine (the shah of Persia), Thomas Edison (who invented the motion picture and numerous other devices), and a great number of artists and intellectuals (Andrews and Solomon 1975, 243–46; Voigt 1982, 22).

The most important botanical and ethno-botanical studies of the past century were conducted by Timothy Plowman (1944–1989), who produced forty-six publications about coca and *Erythroxylum* (Davis 1989, 98).

In recent years, the governments of Bolivia and Peru have been working to have coca products legalized around the world. The discussions, however, continue to make a moral dichotomy between “good coca” and “bad cocaine” (Cabieses 1985; Henman 1990).

Distribution

The coca bush (*coca* variety) is originally from the rain forests on the mountain slopes of Peru and Bolivia, the so-called *yungas* (Schröder 1991, 112*). It is found at altitudes of up to 2,000 meters, although it is most often cultivated between 500 and 1,500 meters. As a result of cultivation, the coca bush is now found in many regions of the world (Indonesia, Seychelles, East Africa, India) (Potratz 1985); Ceylon huanuco, which was successfully cultivated in Sri Lanka, is now quite well known (Macmillan 1991, 415*). Amazonian coca (*ipadú* variety) is found only in tropical lowlands (Amazon basin) (Plowman 1979b, 46).

Cultivation

The seeds of *Erythroxylum coca* var. *coca* are sown naturally by birds that eat the ripe drupes from the bush and excrete the seeds undigested. In the Andes, this variety is propagated almost exclusively from seeds (Plowman 1979b, 46). Coca seeds become infertile when they dry (normally after three days). The seeds are pressed into shaded seedbeds for germination. The seedlings are transplanted when they have grown about as large as a person’s hand. The plants are placed into the ground at a distance of about 1.5 meters from one another. In South America, transplanting is carried out during the rainy season. The large fields and plantations of coca in the Andes are known as *cocal* (singular) or *cocales*.

The bush does not place any great demands upon the soil. It prefers loose, humus-rich soil, which should be fertilized often with plant compost. It thrives well in loamy soil formed from weathered slate. Chalky soils are not suitable (Bühler and Buess 1958, 3047). This skiophilous plant requires high humidity and ample precipitation (at least 2,000 mm per year) and does not tolerate frost.

From the time of planting, a period of some eighteenth months is necessary before the first leaves can be harvested. A bush produces for twenty to thirty years. During the rainy season, the bushes can be harvested every fifty to sixty days. During the dry season, harvesting can be performed only every three or four months. The plant is not disturbed by the removal of almost all of its leaves. If the leaves

are not harvested, the bush will grow into a proper tree.¹³² The leaves of these coca trees are almost devoid of effects.

In the Amazon region, coca growing is almost exclusively a male activity. In contrast, the planting of food crops is usually done by women. The Amazonian coca bush is pruned to a height of about 1.5 meters. Such bushes are known as *ilyimera*, “little birds.” Amazonian coca is propagated solely through cuttings, as this variety does not produce viable seeds (Plowman 1979b, 46 f.).

Appearance

The coca plant usually grows as a bush. The elliptical foliage leaves, whose length varies by subspecies, are arranged spirally. The bark of young plants is reddish in color. The scaly leaves that appear at the base of young branches are a characteristic feature of the plant. The tiny, monoclinous white flowers develop from the axes of these scaly leaves. The flowers are radially symmetrical and have ten stamens that are joined at their bases. As they ripen, the small oval fruits (drupes) initially turn yellow and then luminously red.

An engraving of an herbarium specimen of *Erythroxylum coca*. The two “transparent” leaves clearly show the vein pattern typical of the variety *coca*, in which two lines run parallel to the central vein. (From Mariani, *La Coca et la Cocaïne*, 1885)

Erythroxylum coca var. *coca* usually grows to only 3 to 5 meters in height, although it can grow taller. *Erythroxylum coca* var. *ipadú* grows to a height of only about 3 meters and can be recognized by its long and very thin branches. The leaves are larger, somewhat rounder, and more elliptical than those of *coca* variety, and they do not taper at the end (Plowman 1979b, 46). In Amazonia, coca bushes are often covered completely with lichens.

The coca bush is very easily confused with other species of the genus *Erythroxylum*, as many of these have a similar appearance. The most certain method of botanical identification is to chew the dried leaves together with an alkaline substance. If the mucous membranes of the mouth become numb, then the plant can only be one of the two species that contain cocaine (*Erythroxylum coca* and *Erythroxylum novogranatense*) or their varieties.

It appears that the scientific literature continues to confuse some of the species of the genus

Erythroxylum with *E. coca* or subsume them within this species. Because of the many local varieties of the coca plant, even botanists can have difficulty identifying the species in question (Plowman et al. 1978).

Psychoactive Material

—Dried leaves (cocae folium)

The leaves must be dried (roasted) before use or they will not produce the intended effects. Freshly picked leaves can be either lightly roasted or made into a tea. The freshly harvested leaves are dried in such a manner that they retain their green color while also remaining supple and elastic. Drying can occur in the sun or by artificial means. If the leaves are dried in an oven or similar manner, the temperature should not exceed 40°C (= 104°F) lest the cocaine content be adversely affected (Schröder 1991, 114*). The taste of the dried leaves of huanuco (*coca* variety) is strongly reminiscent of that of green Chinese tea (*Camellia sinensis*). In contrast, Amazonian coca (variety *ipadú*) is somewhat bitter in taste (Koch-Grünberg 1921, 175*).

Preparation and Dosage

Coca leaves can be chewed, smoked or otherwise burned and inhaled, or ingested in the form of an extract (tea, decoction, tincture, etc.).

By far the most common method of ingestion is chewing or, more precisely, sucking the leaves. In the Andes, coca quids are usually known as *acullico*, and coca chewing is known as *acullicar*. At the beginning of the Incan period, coca leaves were chewed together with tobacco leaves (see *Nicotiana tabacum*), a practice that was also observed during the colonial period but now appears to have largely disappeared. The Swiss naturalist Johann Jacob von Tschudi (1818–1889), who also was the first to observe and report the use of angel's trumpet (see *Brugmansia san-guinea*), provided a very thorough description of the Andean use of coca that still applies today:

At least three times, but normally four times per day, the Indians rest from their work so that they may chew coca. For this purpose, they carefully remove the individual leaves from the *Huallqui* (bag), remove the veins, place the divided leaf into their mouth, and chew this for as long as it takes for a proper ball to form under their molars, they then take a thin, moistened little stick of wood and dip this into slaked lime and then place this together with the adhering powder into the ball of coca in their mouths; they repeat this a couple of times until it has the proper spice; some of the copious amounts of saliva, which mixes with the green juice of the leaves, is spit out, but most of this is swallowed. When the ball no longer produces enough juice, they throw it away and begin with another. I have often watched how a father would pass an almost juiceless ball to his little boy, who eagerly took it into his mouth and chewed on it for a long while. (In Bühl and Buess 1958, 3052 f.)

A branch tip of the coca bush *Erythroxylum coca* var. *coca*

The tiny flowers of the coca bush *Erythroxylum coca* var. *coca*

The leaves of the coca bush *Erythroxylum coca* retain their elasticity when dried.

“I myself used coca over a period of eight years during my work with the Indians of the Amazon, and I have never found it harmful, not to mention addictive.”

RICHARD EVANS SCHULTES

“COCA IN THE NORTHWEST AMAZON” (1980, 53)

The coca leaves must be mixed with an alkaline substance (known as “sweetening” the coca quid) for the **cocaine** to be released so that it can be absorbed through the mucous membranes of the mouth (Cruz Sánchez and Guillén 1948; Rivier 1981; Wiedemann 1979, 280). In South America, either plant ash or burned/slaked lime from various sources is used for this purpose (Gantzer et al. 1975, 10).

In the Andes, coca is chewed together with what is known as *llipta* (Quechuan), scrapings from a cake of ash. *Llipta*—also known as *chile*, *llucta*, *llinta*, *lliptu*, and *tocra*—is made from the ashes of various plants (see the table on pages 247–48). The ashes are produced not by burning the plants but by roasting them thoroughly. To do this, the plant pieces are placed in a metal or ceramic pot. The pot is kept over a fire until the plant pieces break down into an ashlike powder. The ashes are then moistened with lemon juice, boiling water, **chicha** (maize beer), sugarcane schnapps (**alcohol**), sweetened tea (*Camellia sinensis*, *Ilex paraguariensis*), salt water, or even urine and kneaded together with a carrier substance such as potato flour or starch. The mixture is formed into large disks, small pyramids, snakes, etc., and allowed to dry in the air for a day (Bühler and Buess 1958, 3054; Franquemont et al. 1990, 66 f.*). When dried, the *llipta* is as hard as a rock. Pieces are broken off and added to the coca quids.

In Bolivia and northwestern Argentina, coca leaves are now chewed with sodium bicarbonate (*bicarbonato de sodio*, *bica*, *yuspe*), which is sold in plastic bags weighing 20 g. The Mataco (Wichi, “people of the place”) chew coca in the style of the Andes, whereby they “eat” the entire leaf. They stuff their mouths so full that their faces have an enormous bulge. They then simply toss some *llipta* (sodium bicarbonate) into their open mouths.

A variety of substances may be added to coca quids in order to modify their psychoactive or medicinal effects or to make the effects more specific. In the triangle of countries formed by Bolivia, Argentina, and Chile, coca quids may be chewed together with the ashes of the flowers and fruits (without seeds) of a large columnar cactus (*Trichocereus pasacana*) that is frequently confused with the San Pedro cactus (cf. *Trichocereus pachanoi*) (C. M. Torres, pers. comm.). It is possible that the (main) alkaloid of the cactus, candicine,¹³³ alters the effects of the coca. The Argentinean Mataco

obtained their *yista* (= *llipta*) from the ashes of the cactus flesh of a *Trichocereus* species (*tso'nahlak*). This was said to potentiate the effects of the coca (cf. *Trichocereus* spp.).

There are also a number of substances used to aromatize coca quids and improve their taste. Leaves of the rosary pea (*Abrus precatorius* L.; cf. *Rhynchosia pyramidalis*), known in northern Peru as *misquina*, which are roasted beforehand so that they will not produce any toxic effects, impart a licorice-like taste to coca quids. The leaves of *Tagetes pusilla* H.B.K.¹³⁴ (cf. *Tagetes* spp.), known in southern Peru as *pampa anis* ("prairie anise"), are also used to lend the coca quids an aromatic taste (Plowman 1980, 254).

The Peruvian Campa Indians like to add the bark of the *chamairo* vine (*Mussatia hyacinthina* [Standl.] Sandw.; Bignoniaceae), which is also used for medicinal purposes, to their coca. This practice can also be observed in other parts of Peru; the bark is sold in markets for precisely this purpose (Plowman 1980, 255 f.).

The Amazonian preparation is very different from the Andean and is identical among all the tribes except one. The leaves of the Amazonian coca (*E. coca* var. *ipadú*) are plucked fresh daily from the bush and immediately roasted on a cassava baking tin. This roasting must be done gently and carefully so that the leaves do not carbonize. The men then pound the roasted leaves in large mortars made from hollowed-out trunks of the hardwood trees *Tabebuia* spp., mahogany (*Swietenia mahagoni* [L.] Jacq.), or chontaduro palm (*Guilielma speciosa* Martius). While they are pounding, the leaves of other plants are turned into ashes over a charcoal fire. The gray ash is mixed with the green coca powder in more or less equal amounts and is then ready for consumption. A person typically takes a spoonful, which he or she carefully moistens with saliva and then pushes between the cheek and the teeth with the tongue. There, the mixture slowly dissolves over a period of thirty to forty-five minutes and is gradually swallowed.

Of all the Amazonian coca additives, by far the most popular are the ashes of the large, fresh leaves of *Cecropia sciadophylla*, known variously as *pêtuy'*, *göra-ñá*, *guarumo*, or *setico* (Schultes and Raffauf 1990, 313*). Other species from the genus *Cecropia* as well as *Pourouma cecropiaefolia* are also utilized (Plowman 1979b, 47). Occasionally, other plant substances may be used as well. The Witoto sometimes add some powdered root of *Chelonanthus alatus* to the coca/ash mixture to lend it a "bitter taste" (Schultes 1980, 57) or mix it with dried and powdered leaves of *Tachia guianensis* Aublet (Gentianaceae) to improve the taste (Schultes and Raffauf 1986, 276*).

A typical cake of ash (*llipta*) from the southern Andes, scrapings of which are added to the coca leaves

In northwestern Argentina, industrially manufactured baking powder (sodium bicarbonate) is usually used as an alkaline coca additive.

“Coca enhances performance and suppresses both hunger and tiredness. But its primary effect is to induce the latent power of those visions which lead one closer to the ‘reality of dreams.’ ”

WOLFGANG MÜLLER

DIE INDIANER AMAZONIENS [THE INDIANS OF AMAZONIA]

(1995, 197*)

An unusual method of preparing coca was discovered among a small group of the Tanimuka (on the Río Apaporis, Colombia). They aromatize the ashes of *Cecropia* leaves with **incense**. To do this, they make incisions in the bark of *Protium heptaphyllum* March and tap the resin, which they then allow to age for three to four months. The resin,¹³⁵ which is known in Amazonia under the names *o-mo-tá*, *hee-ta-ma-ká*, *brea*, *pergamín*, *tacamahaca*, and *breuzinho*, is broken into small pieces and rolled into a semidried leaf of an *Ischnosiphon* species to make a kind of cigarette. The men who are involved in the preparation of this coca will put this cigarette in their mouths and light it, but they will not inhale. Instead, they blow through the resin-filled tube so that the aromatic smoke flows out of the other end. When the cigarette is burning well, they place its tip into the *Cecropia* ashes for a couple of minutes to fumigate it. The scent is absorbed by the plant ash, thereby giving the finished mixture of coca and ash a resinous, incenselike aroma (Schultes 1957; Schultes and Raffauf 1990, 117*; Uscátegui M. 1959, 297*).

The Makú Indians use their coca (*ipadu*, *botô*) in a manner different from that of all the other Amazonian tribes. The leaves are roasted, mixed with the ashes of fresh green banana leaves (*Musa* spp.), and finely crushed in a ritual context. This powder is then mixed with flour (cassava, farina, tapioca) and made into bread. The bread is prepared fresh every evening and is regarded as food; it is not just chewed but properly eaten (Prance 1972a, 19*).

The coca/ash powder is also sniffed (cf. **snuffs**) in some regions of Colombia, although such use

has been little documented (Schultes 1980, 53).

Coca can be combined with almost any other psychoactive substance. Coca will sometimes even potentiate the effects of another substance, e.g., *Anadenanthera colubrina*. Coca leaves are also suitable for use as a stimulating ingredient in **incense** and **smoking blends** and are especially well suited for smoking together with *Cannabis sativa*.

When chewing coca, one should avoid drinking maté (*Ilex paraguariensis*) entirely, not because the two substances produce a negative synergy, but because the anaesthetized mucous membranes of the mouth are unable to detect the temperature of the maté and can be scalded very easily without notice. Chronic coca chewing will occasionally result in mild inflammations of the mucous membranes. A tea made of the leaves and bark of *Pagamea macrophylla* Spruce ex Benth. may be drunk to counteract such problems (Schultes 1980, 57).

The usual dosage for a medicinal tea is given as 5 g of dried coca leaves (Morton 1977, 180*). Much larger amounts are consumed, however, when the coca is chewed. With an average use of 60 g of good leaves per day, it can be assumed that 100 to 200 mg of **cocaine** are being absorbed. In some Amazon tribes (e.g., the Yucuna), it is not unusual to observe men consuming up to 1 pound of coca/ash powder daily (Schultes 1980, 51). When smoked, even small amounts (0.1 g or more) of the roasted leaves will produce stimulating effects. The Omagua smoke leaves as they chew them (Bühler and Buess 1958, 3054).

Ritual Use

The ritual uses of coca are manifold. The leaves are used as parts of offerings and for oracles, socially integrative forms of interaction, shamanic healings, initiations, and tribal festivals. The ritual use of coca is probably as old as the use of the leaves in general, at least five thousand years. Unfortunately, little is known about the use of coca in pre-Hispanic times. Grave goods clearly indicate that coca was given to the dead for their journey to the other world. The representations of coca chewing contained on pre-Columbian artifacts also point to a very ancient ritual use.

The ethnohistorical evidence from the colonial period is rather limited and was obviously filtered through the “devil’s glasses” of the Catholic Spanish. In *The Naturall and Moral Historie of the West Indies* (ca. 1570), José de Acosta provides an amazingly unprejudiced account: “The Ingua [= Inca] are said to have used coca as an exquisite and regal thing which they most often used in their offerings by burning it in honor of their gods.”

The significance of coca in the kingdom of the Incas has been summarized as follows:

In ancient Peru, where coca was venerated as a gift of the gods of the sun, there were few ceremonies which did not require the drug. At great festivities, coca leaves were burned as fumigants, and priests adorned with coca wreaths would use the smoke to divine. Only with a quid of coca in his mouth could one dare to approach the gods, and coca was one of the gifts offered to the priests. The coca offering had a special significance. (Bühler and Buess 1958, 3061)

Coca is sacred to the Indians because it makes possible the connection between humans and the gods (Allen 1988, 132; Lloyd and Lloyd 1911) and also deepens the contact between people, e.g., as a love magic and an aphrodisiac¹⁴¹ (Mortimer 1974, 429).

A branch of the coca bush (*Erythroxylum coca* var. *coca*) from the highlands of Bolivia. (From Mariani, *La Coca et la Cocaïne*, 1885)

In northern Chile, the herbage of an *Amaranthus* species is added to coca quids. (Photographed in San Pedro de Atacama)

Various species of the genus *Chenopodium* are traditionally used as coca additives.

In Amazonia, the leaves of *Cecropia peltata* are one of the primary sources of the ashes used as an alkaline additive to finely ground Amazonian coca (*Erythroxylum coca* var. *ipadú*).

The flower petals of the American sunflower (*Helianthus annuus*) not only are used as a coca additive but also are regarded as an aphrodisiac in Indian medicine.

Whenever the Indians of the Andes come together, they offer, exchange, and chew coca with one another. People invite one another to chew coca as a way of initiating a social exchange. Although the practice is essentially the same throughout the region, the actual form of the exchange varies from place to place (Allen 1988, 126 ff.). Before the leaves are placed in the mouth to be moistened, three of them are placed together like a fan and held before the brow. The person then turns to face the highest of the neighboring mountains and consecrates the leaves with the words *poporo apú*.

In the Andes, coca leaves still number among the most important of all ritual offerings. A pile of offerings known as an *apacheta* can be found at the highest location of a mountain pass. This typically consists of a pile of hand-size stones, over which coca leaves are strewn as “payment” for a safe crossing of the pass. Chewed coca quids, bottles of **beer**, *aguardiente*, and pure **alcohol** may also be placed there. The coca leaves are a gift to Pachamama, the Mother Goddess. The offering of coca leaves at sacred places gives the Andean Indians a deep connection with their world (Allen 1988, 130). The offerings also have a medicinal importance:

Coca, along with other aromatic plants, is either burned as a smoke offering or offered in the natural state in the form of especially attractive leaves. The simplest type of offering consists of six beautifully shaped coca leaves, over which some distilled spirits and llama fat are dripped. More extensive offerings are composed of one hundred and forty-four *aita* (each consisting of six coca leaves) in rows of twelve. The *curandero*—medicine man—does this when he celebrates his mass for the ill. He asks that the relatives of the ill person bring offerings of aromatic herbs, llama fat, mussels, a rosary, sweets, and a woven cloth with coca leaves (*inkuña*). The sweets are offered in the beginning, during the “sweet” mass. This is followed by the “Apostles’ mass,” which is named after the twelve rows of coca leaves that are offered. Only then can the healer make a diagnosis. After this, he burns the offerings to appease the gods. (Wiedemann 1992, 7)

In the Andes region, coca leaves are an absolutely indispensable part of magical and religious healing rituals. The roots of many illnesses lie in the spirit world: *puquio*, a sleeplessness that afflicts a person who has not shown respect to the sacred springs; *huari*, a disease that is produced by the spirits that reside in ancient ruins; *japipo*, a sickness caused by spirits who steal parts of the soul; *tinco* or *tasko*, which occurs when a person encounters an aggressive soul; *susto*, “fright,” which is

induced by great emotional burdens. To heal these peculiar afflictions, which do not fit into the Western view of symptom-oriented diagnosis, the traditional healer must locate and visit the place where the spirits live or at which the encounter with them occurred. When he has found the correct location, he will continue to offer the appropriate beings as many coca leaves as needed until they permit themselves to be asked to remove the illness from his patient (Hoffman et al. 1992, 75*).

Specialized diviners use coca leaves for casting oracles (*coca qhaway*). These oracles are consulted by people suffering from illnesses and other types of problems (Allen 1988, 133 ff.; Franquemont et al. 1990, 67*; Quijada Jara 1982, 39 ff.). This ancient technique of coca oracles is still practiced today:

The contemporary oracular use of coca leaves is but a pale reflection of such renowned state oracles of the Incan period as Pachamama (“lord of the earth”) near Lima. There, in the Lurin Valley, lies one of the oldest cult centers in South America, the settlement of which began 10,000 years ago. Pilgrims came from the jungle regions and even from Central America to listen to the words of the oracle after a prolonged period of fasting. (Andritsky 1987, 52)

Through his art, the coca oracle played an important function in structuring the community (Allen 1988, 133 ff.) and therefore had enormous social responsibility. A person had to undergo a long period of training to become a coca oracle and needed a great ability to empathize with his clients. Lest the clients become suspicious of the diviner’s intent, the ritual had to be carried out precisely:

Through the ritual acts of the oracle, the spiritual principle of the coca leaves, “coca mama,” acquires a new quality together with the “wamanis” [local mountain spirits]: because of his abilities to mediate, and in an altered state of consciousness, the diviner enters into a dialogue with these spirit powers. His role is that of interpreter, who lays out the structure of the coca leaves and their pattern on the oracular cloth according to specific rules. . . . Because many coca diviners are also healers, diagnosing with coca leaves is an important activity. (Andritsky 1987, 52)

Sometimes, other objects such as ergot-infected grains (cf. *Claviceps purpurea*) may also be thrown and read with the coca leaves.

Peruvian shamans inhale copious amounts of coca smoke so that they can enter an ecstatic state in which they are able to travel to the world beyond. In doing so, they cross over a “bridge of coca smoke” and enter a different reality, the shamanic universe, in which they are able to heal (Martin 1969).

Most tribes in the Amazon basin use coca as a stimulant and agent of pleasure, chewing it almost daily. Besides manioc (*Manihot esculenta*), the main source of food, the ipadú bush is the most important cultigen. But it also has a ritual significance. The Tukano Indians believe that the first coca plant arose from a finger joint of a daughter of the lord of the animals. Because the *Banisteriopsis caapi* vine arose from the finger joint of another of his daughters, *ayahuasca* and coca are regarded as “siblings” (Schultes and Raffauf 1990, 167*). Among the Tukano tribe of the Yebámasa, ipadú has both a ritual and a hedonistic significance:

Every adult male spends some three hours a day preparing the coca powder from the roasted leaves of the coca bush. The men consume this powder throughout the day almost without interruption. It makes them more able to be productive, prevents tiredness, and suppresses their hunger. But the Yebámasa do not eat it for these reasons alone. When they ingest coca, they also

partake of the magical power that lies within, which has invigorating effects upon them and thus protects their body and spirit. In addition, the coca powder has an important social function: the reciprocal offering of coca powder is a gesture of contact and friendship. (Deltgen 1979, 23*)

A pre-Columbian lime or *llipta* pouch from Peru

A pre-Columbian lime container of wood with mother-of-pearl and shell inlay, for use with coca. (Peru, Inca period)

“When the divine son of the sun, Manco Capac, climbed down from the rocks of Lake Titicaca, he gave humans light, knowledge of the gods, and knowledge of the arts and of coca, a divine plant which satiates the hungry, gives new strength to the tired and exhausted, and helps the unhappy to forget their cares.”

GARCILASO DE LA VEGA (1539–1616)

Artifacts

Numerous artifacts are associated with the coca bush. These include the paraphernalia for consuming the leaves, depictions of the plant and the goddess that dwells within, and many cultural products that have been inspired by its stimulating effects.

Both the Andean and the Amazonian Indians manufacture special containers for storing and transporting (carrying along) coca leaves. In the Andes, coca purses (*chuspa*, *pisca*, *mochila*, *guambis*) are used for storage. Over the centuries or even millennia, the production of these purses has become a great art. The woven bags are usually decorated with abstract patterns and images of symbolically important animals and gods. For example, the highest god, Viracocha (literally “father of the sun”; also spelled Huiracocha and Virakocha), is represented by a small duck (Wiedemann 1992, 17).

In the Amazonian regions, the coca and ash powder is usually stored in coca bottles (*cuya*) made from *jicaras* (fruit coats of tree gourds or calabash trees, *Crescentia cujete* L.) or coca bags (*tuturî*) produced with paper made from the bark of a *Ficus* sp. or an *Eschweilera* sp. The lime containers (*checo*, *iscupuru*, *calero mombero*) are usually made from smaller gourds. The Amazonian coca spoons were once made chiefly from jaguar bones (Schultes 1980, 51). Today, Western-style spoons are also used.

In Europe, coca has influenced or inspired numerous poets, writers, and artists. The first European poem—a hymn—that appears to have been dedicated to coca was penned by the English physician and diplomat Abraham Crowley (1618–1667).

In the late nineteenth century, a potent coca wine known as Vin Mariani played an especially significant role in stimulating, inspiring, and supporting the creative efforts of numerous artists, intellectuals, and politicians. The writers Alexandre Dumas, Henrik Ibsen, Octave Mirbeau, Sully-Prudhomme, and particularly Jules Verne and H. G. Wells all “lived” on Mariani wine and wrote their best works while under its influence. The French composers Charles Gounod (1818–1893) and Jules Massenet (1842–1912) were passionate enthusiasts of the “wondrous coca wine” and praised this “beneficent creator.”

Modern music contains numerous references to cocaine but only rarely makes mention of coca. Merrell Fankhauser dedicated a hymn to the plant (“Treasure of the Inca”) on his CD *Jungle Lo Lo Band* (Legend Music LM 9015, 1994).

Medicinal Use

We know with certainty that coca leaves were an important medicine in pre-Hispanic times. Unfortunately, the paucity of sources from the period means that we do not have any specific information concerning the ways in which they were utilized. For more on the use of coca in pre-Columbian trepanations, see *Erythroxylum novogranatense*.

Today, the folk medicinal uses of coca are so manifold that it has been called the “aspirin of the Andes.” Coca is used for pains of all types, neuralgia, rheumatism, colds, flu, digestive problems, constipation, colic, upset stomachs, altitude sickness, exhaustion, and states of weakness and to ease labor (Quijada Jara 1982, 35 ff.). Coca leaves are burned or smoked to treat bronchitis, asthma, and coughs (Morton 1977, 180*). In the nineteenth century, the popular *Encyclopädie der medizinisch-pharmazeutischen Naturalien- und Rohwarenkunde* of Eduard Martiny (1854) listed coca smoke as a treatment for asthma. Coca leaves appear to have been smoked for this purpose quite often in England, where they were imported under the name *Peruvian tobacco*.

A brewed coca tea (*mate de coca*) is recommended in cases of diabetes and to suppress the appetite of people who are overweight, as a stomach tonic, as an aid in digestion, and to treat diarrhea, states of exhaustion, and especially altitude and travel sickness. The tea is effective both therapeutically and

as a preventative for *soroche* or *la puna*, the altitude sickness that is common on the Altiplano, the high plateau of the Andes (Europeans are especially fond of the tea) (Sarpa and Aimi 1985; Schneider 1993, 19*).

In Peru, a tea made with coca leaves and *cedrón* (*Lippia citriformis* [Ort. ex Pers.] H.B.K. [syn. *Aloysia triphylla* (L'Hérit.) Britt.]; cf. **marari**) is drunk to treat stomach pains and other indispositions.

The usage information provided for an extract of *E. coca* var. *coca* produced in Bolivia and known as *Jarabe de coca* states that the product will improve physical beauty, sexual functioning, digestion, and mental activity; stimulate the appetite and the circulation; strengthen the bones; and promote liver activity.

The wandering Callawaya healers of the Andes use a mixture of coca leaves and other herbs (see *Cytisus* spp., *Mikania cordata*) to treat rheumatism (Bastien 1987, 131*).

Today, many star athletes (soccer, football, baseball, etc.) utilize pure **cocaine** as a doping agent. Such use has its roots in the use of coca by the runners who carried messages throughout the Incan empire. These “postal runners” traversed great distances in the high mountains to take the messages contained in knotted strings from one corner of the empire to another. Without coca, this pre-Hispanic postal service would certainly have collapsed.

In the Atacama Desert of northern Chile, the dried leaves of the sow-thistle or hare's lettuce (*Sonchus oleraceus* L.) are chewed together with an alkaline substance as a coca substitute. The Atacameños call the wild plant, which is originally from Eurasia, *wirikocha*. This name is a reference to Viracocha, one of the most important deities of the Andes, who was regarded as the highest god in the Incan religion. This ancient Andean god of the heavens would select his priests and shamans with a lightning bolt. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

The Kofán do not (or only rarely) chew coca for hedonistic purposes but cultivate the bush solely for use as a medicine. They and other Amazonian tribes drink a tea made from ipadú leaves to treat pains in the region of the heart. In the Vaupés region of Colombia, consumption of a tea brewed from leaves of coca and *Vochysia laxiflora* Stafleu¹⁴² is recommended when a person is unable to urinate (Schultes 1977b, 117*; 1980, 57).

Although once officinal, coca leaves are no longer used in European medicine. The only modern

use occurs in homeopathic medicine, where the agent *Erythroxylon coca hom.* HPUS88 is produced by macerating fresh or dried leaves (Lindequist 1993, 96).

Constituents

Depending upon their source, coca leaves can have an alkaloid content of 0.5 to 2.5%. The primary alkaloids are **cocaine** and cuscohygrine. Among the most important secondary alkaloids are cinnamoylcocaine, α -truxilline, and β -truxilline. Peruvian and Bolivian coca leaves contain the highest amounts of cocaine, which makes up some 75% of the total alkaloid content (Morton 1977, 178*). In a dried state, these may contain as much as 2% cocaine!

The fresh leaves in particular contain an **essential oil** as well as flavonoids (rutin, quercitrin, isoquercitrin), tanning agents, vitamins (A, B, C), protein, fat, and large amounts of minerals, especially calcium and iron. Approximately 100 g of coca leaves suffice to provide the recommended daily dose of all important minerals and vitamins (Duke et al. 1975). Both fresh as well as dried leaves possess good nutritional value (305 calories per 100 g)—which is why the Indians regard coca as a food.

The essential oil of *E. coca* var. *coca*, which has a scent reminiscent of that of grass, consists of 38% α -dihydrobenzaldehyde, 16.1% *cis*-3-hexen-1-ol, 13.6% methyl salicylate, 10.4% *trans*-2-hexanal, some *N*-methylpyrrole, 1-hexanol, and *N,N*-dimethylbenzylamine,¹⁴³ and several as yet unidentified substances (Novák and Salemink 1987).

The leaves and the bark contain the **tropane alkaloids** cuscohygrine and hygrine. The seeds and the bark also contain some cocaine (Bühler and Buess 1958, 3046; Morton 1977, 178*).

Effects

The Indians classify coca as a food and emphasize the nutritional value of the leaves (Hanna 1974). The Andean Indians say that when coca is chewed properly and with respect, it can soak up sadness and pain and protect the chewer like a mother (Allen 1988, 135). Coca chewing has a regulating effect upon blood sugar levels. Apparently, chewing coca will raise a blood sugar level that is too low and lower a blood sugar level that is too high. In other words, coca use helps maintain blood sugar concentrations at a level that the body requires (Burchard 1975). Coca chewing counteracts the stresses associated with high altitudes and appears to improve oxygen absorption in the thin mountain air (Bittmann 1983; Bolton 1979; Bray and Dollery 1983). The nutritional value of coca leaves is higher in the forms in which Amazonian coca is prepared and typically ingested in the region (where everything is swallowed) (Schultes 1980, 52). In addition to its nutritional value, coca deadens the stomach nerves, thereby suppressing sensations of hunger. In general, chewing coca has stimulating and animating effects that can range from a general improvement in mood to aphrodisiac sensations and even euphoria. One quid of coca to which *chamairo* bark has been added is said to induce a “sensation of well-being and calm” (Plowman 1980, 256). When mixed with ***Trichocereus* spp.**, coca quids can apparently have profoundly stimulating, perhaps even mildly psychedelic, effects (Fernandez Distel 1984).

The cocaine that is released from the leaves by chewing remains in the body for some seven hours in the form of its metabolite, ecgonine, albeit only in very low concentrations. The active amount is present in the blood for one to two hours. It is this that is responsible for the stimulating effects of the coca quid (Holmstedt et al. 1978). For information on pharmacology, see **cocaine**.

When a quid of coca is placed in the mouth, moistened well with saliva, and mixed with an alkaline substance, it takes a few minutes for the cocaine to dissolve out of the leaves and spread throughout the entire mouth, mixed with the copious amounts of saliva that are also produced. The surface of the mucous membranes immediately become numb. The quality of the coca can be recognized by the

rapidity with which this numbing effect takes place. After an additional five to ten minutes, the stimulating effects of the cocaine become clearly noticeable. This effect slowly increases during the following minutes, persists for about 45 minutes, and then quickly dissipates.

It has often been claimed that cocaine can destroy the nasal septum. However, the effects of *coca y bica* (“coca leaves and bicarbonate of soda”) upon the mucous membranes of the cheeks are much more destructive. Longtime *coqueros* (“coca users”) must develop a kind of leathery surface in their mouths. In my own experience, the effects of a coca quid upon the mouth’s mucous membranes are considerably more damaging than those that cocaine produces on the mucous membranes of the nose.

“Coca has a bitter taste and a somewhat astringent effect upon the mouth, but one soon becomes accustomed to this. The effects are stimulating. For this reason, coca is used with enthusiasm especially at dance festivals and while traveling, for it dispels tiredness and feelings of hunger and stimulates the body and mind to greater performance. On these occasions, the Indians keep the coca powder in beautifully polished, round calabashes which they wear over their left shoulder on a woven band or in small, plain bags made of strong red bast with a cord for hanging. For sucking, they use a hollow heron’s bone which is tied to the carrying string and is always present in the container for immediate use. When used in excess, coca can be harmful to the nerves.”

THEODOR KOCH-GRÜNBERG

ZWEI JAHRE BEI DEN INDIANERN NORDWEST-BRASIL [TWO YEARS AMONG THE INDIANS OF NORTHWEST BRAZIL]

(1921, 175*)

Cocaine

Cuscohygrine

The leaves of hare's lettuce (*Sonchus oleraceus*), a plant introduced from Europe, are used as a coca substitute.

When coca is in short supply, the inhabitants of the oases in the Atacama Desert will chew the leaves of a plant introduced from Europe, the quince (*Cydonia oblonga* = *Cydonia vulgaris*).

Coca chewing can indeed lead to various problems in the oral cavity. In the Vaupés region of Colombia, the bark of *Tachigalia cavipes* (Spruce ex Benth.) Macbride is powdered and strewn over the ulcerous wounds that are said to result from immoderate coca chewing (Schultes 1978a, 184*).

Commercial Forms and Regulations

The cultivation, trade, and use of coca leaves is permitted in Peru, Bolivia, and northwestern Argentina (Gran Chaco). Both the dried leaves and *llipta* and other alkaline substances (sodium bicarbonate) are sold at markets, herb shops, newspaper stands, and other small shops, usually under the name *coca y bica*. Three qualities are usually available: *regular* (“normal”), *seleccionada*

(“select”), and *super seleccionada* (“super select”) or *sele desfolillada*. While the use of coca is forbidden in northern Chile, it is tolerated. The Aymara Indians and the Aborigines of the Atacama coast are permitted to use coca.

Coca leaves are also processed into tea bags for brewing tea (so-called *maté de coca*) and are even sold in supermarkets. In Peru, various flavors and combinations are available, including some containing spices, chamomile (*Matricaria recutita*), *hierba luisa* (“Louisa’s herb” [?]), anise (*Pimpinella anisum* L. or *Tagetes pusilla* H.B.K.; cf. *Tagetes* spp.), mint (*Mentha* spp.), *canelo* (“caneel”; probably imported cinnamon, and most likely originally *Canella winterana* [L.] Gaertn.), and *muun* (*Minthostachys andina* [Britt.] Epling, *Satureja* spp., or *Mentha virides* L.; cf. Bastien 1987, 133).

For years, the governments of Peru and Bolivia have been making efforts to have coca leaves legalized so that they can be exported throughout the world. The legalization of coca would have profoundly positive effects upon the economic situation in both countries (Weil 1995).

In Europe, coca preparations (the leaves) are regarded as obsolete, although theoretically they are available through pharmacies, as no prescription is required (Lindequist 1993, 96). However, because they contain cocaine, they are subject to various drug laws (Körner 1994, 96*). In Germany, they are listed as trafficable substances in List II of the drug laws (Körner 1994, 57*).

<i>Werneria dactylophylla</i> Sch. Bip.	leaves ¹⁴⁴	High Andes

“See how densely it is set with leaves,
every leaf is fruit, and such substantial fare,
that no fruit will dare to compete with it.
Moved by his land’s coming fate (whose soil must be exposed to plunder because of its treasures),
our Varikocha first sent coca,
furnished with leaves of wondrous nutritional power,
whose juice is sucked in and passed to the stomach,
and allows hunger and work to be endured for long periods;
And which gives more help to our weak and tired bodies
and refreshes our tired spirit more than
your Bacchus and your Ceres are capable of together.

A supply of three leaves suffices for a march of six days.
With this supply, the Quitoita can traverse
the mighty, cloud-covered Andes,
the terrible Andes, between the abundance of wind, rain, and snow of winter
and that more modest earth
which brings forth the small but powerful coca bush,
this warrior who provides cheer to the warlike Venus.”

ABRAHAM CROWLEY (1618–1667)

BOOK OF PLANTS

The tiny flowers of the coca bush (*Erythroxylum coca* var. *coca*), shown in various views. (Copperplate engraving, nineteenth century)

“Among the persons to whom I gave coca, three reported profound sexual excitation which they unhesitatingly attributed to the coca. A young writer, who was able to take up his work after a long silence because of coca, renounced the use of coca because he found this side effect undesirable.”

SIGMUND FREUD

“UEBER COCA” [ON COCA] (1884, 314)

Erythroxylum novogranatense (Morris) Hieronymus

Colombian Coca Bush

Family

Erythroxylaceae (Coca Family)

Forms and Subspecies; Synonyms

There are two regionally distinct cultivated varieties of the Colombian coca bush:

—*E. novogranatense* Morris var. *novogranatense* [syn. *Erythroxylum coca* var. *novogranatense* Morris]: Colombian coca (dry/hot regions of northern South America)

—*E. novogranatense* var. *truxillense* (Rusby) Plowman [syn. *Erythroxylum truxillense* Rusby, *Erythroxylum hardinii* E. Machado, *Erythroxylum coca* Lam. var. *spruceanum*]: Trujillo coca (coastal zone of northern Peru)

Folk Names

—var. *novogranatense*:

Coca, Colombian coca, hahio, hayo, hayu, koka, kolumbianischer kokastrauch

—var. *truxillense*:

Coca, coca de trujillo, Trujillo coca, trujillo-kokastrauch, tupa (“kingly” or “noble”), small-leaved coca, Peruvian coca, Java coca

History

Within its range, this coca species has been used for as long as has *Erythroxylum coca*. During excavations of the ancient Valdivia culture (Ecuador), lime containers were found that have been dated to 2100 B.C.E. All of the coca leaves that have been recovered from archaeological excavations in the coastal region of Peru are Trujillo coca (Cohen 1978; Griffiths 1930; Plowman 1979, 55). The plant has been in use for at least three thousand years, primarily in the pre-Hispanic Moche and Nazca cultures.

Typical leaves of the four types of coca: *Erythroxylum novogranatense* var. *truxillense*; *Erythroxylum coca* var. *coca*; *Erythroxylum coca* var. *ipadú*; *Erythroxylum novogranatense* var. *novogranatense*. (From Burck, 1892)

The first European source to describe the use of coca (from *E. novogranatense* var. *novogranatense*) is the report of Amerigo Vespucci (after whom America is named) from 1499:

We spied an island in the sea, which lay some 15 miles from the coast, and decided to go there and see if it was inhabited. We encountered the most corrupt and hideous people that we had ever seen: their faces and their expression were very hideous, and all of them had their cheeks filled with a green herb which they chewed upon the entire time like animals, so that they could hardly speak; and each of them carried two gourds around their neck, one of which was filled with the herb that they had in their mouths, and the other with a white powder that looked like ground plaster, and from time to time they dipped a stick into the powder after they had moistened it in their mouths, and placed it deep into each side of the mouth, to bring the powder to the herb which they chewed; they did this with great frequency. We were very amazed about this and could not understand their secret or why they did this.

During the early colonial period, the Spanish chronicler Pedro de Cieza de León provided a very precise description of the use of *Erythroxylum novogranatense* in Colombia and the northern Peruvian coast and of several coca substitutes that unfortunately were not identified:

Everywhere that I have traveled in the West Indies, I have noticed that the natives take great pleasure in keeping roots, twigs, or plants in their mouths. In the area around the city of Antiocha (Antigua in Colombia), some of them chewed small coca leaves and in the province of Arma other plants, and in Quimbaya and Acerma they cut strips from a kind of small tree that has soft wood and is evergreen, and they kept this between their teeth the entire time. Among most tribes that are subject to the cities of Cali and Popayan, they keep the leaves of the small coca of which I have spoken in the mouth and dip a mixture that they prepare from small gourd bottles that they carry and place this into their mouths, and chew it all together; they do the same with a kind of

earth that is like chalk. In all of Peru, it was and is custom to have this coca in the mouth, and they keep it there without removing it from the morning until they go to sleep. When I asked some of the Indians why they always have this plant in their mouths (which they do not eat, but merely keep between their teeth), they said that because of it they feel no hunger and that it gives them great power and strength. I believe that it apparently exerts some type of effect of this nature, although I find it a disgusting practice that was to be expected of such people as these Indians. (In von Hagen 1979, 101 f.)

Neither in Colombia nor in Peru were the Spanish able to exterminate the coca use that they were so unable to comprehend. During the colonial period, the Indians put up with many things—too many things—but one thing they would not tolerate: the end of their coca use. In these areas, the situation has changed little into the present day.

The name Trujillo comes from that of a city in northwestern Peru; the plant is cultivated in a desert zone near Trujillo (Plowman 1979, 52). Trujillo coca is the type that is used even today as the source of aroma and taste for the production of Coca-Cola. During the early 1860s, before the beginning of Prohibition, Dr. John S. Pemberton (1831–1888) successfully introduced Coca-Cola, which was inspired by Vin Mariani, to the market. In addition to extracts of Trujillo coca and the West African cola nut (***Cola spp.***), the drink contained Mediterranean sweet wine and damiana extract (***Turnera diffusa***) and thus was a rather potent, psychoactive, and probably also aphrodisiac drink (Pendergrast 1996, 40). Although there has been no **cocaine** in Coca-Cola since 1903, the drink has acquired a mythological significance and has become one of the most popular soft drinks in history. Today, Coca-Cola often is regarded as a symbol of American cultural imperialism.

In Colombia, *Erythroxylum novogranatense* var. *novogranatense* increasingly is cultivated for the (illegal) production of cocaine.

Distribution

The two varieties of this coca species generally occur at lower altitudes than ***Erythroxylum coca*** (Towle 1961, 60*). The species prefers generally warmer climates. The variety *novogranatense* is indigenous chiefly to northern Colombia, both in the foothills of the Andes and in the Sierra Madre, and has been cultivated there by numerous Indian tribes since ancient times.

Adapted to a desert climate, Trujillo coca now has a very small range and area of cultivation that lies in the northern Peruvian coastal strip near the town of Trujillo (= Truxillo) (Plowman 1979, 52). Its range was probably much larger in pre-Columbian times, extending throughout the entire coastal strip (Rostworowski 1973). Smaller populations that are grown primarily in home gardens as medicinal plants have been found in northwestern Ecuador and neighboring Colombia (Plowman 1979, 56).

COCA

Praeparate.

Gegen die Krankheiten des Halses, der Lunge, Störungen des Nervensystems und Magenleiden empfehlen sich als vorzüglichstes, sicher und radikal wirkendes Heilmittel die Dr. Alvarez'schen Coca-Präparate der Adler-Apotheke in Paderborn, welche nach den Originalrezepten dieses Arztes echt und unverfälscht hergestellt werden. Die verschiedenen Coca-Pillen, Coca-Spiritus und Coca-Liqueur (Pillen Nr. I bei Hals- und Lungenleiden, Nr. II bei Magenleiden, Nr. III bei Nerven anomalies und Schwächezuständen, Nr. IV bei Hämorrhoiden, der Coca-Spiritus und Liqueur als Unterstützungskur) kosten pr. Schacht. od. Flasche 3 Mark u. sind zu beziehen i. d. meisten Apotheken; in **Stuttgart** bei **Lotterer & Speidel**, Rothebühlstr. 42 b. 944 Die Gebrauchsanweisung besagt das Nähere.

In the early twentieth century, coca preparations were a standard part of the home medicine cabinet; they were used as tonics and for hedonistic purposes and also as remedies. (Advertisement from a German magazine, ca. 1915)

Branch tip with leaves and fruits of the Colombian coca bush *Erythroxylum novogranatense*.

During the colonial period, the Dutch introduced *Erythroxylum novogranatense* var. *truxillense* into their colonies on Java and Sumatra. The English brought the plant to Ceylon (Schröder 1991, 113*).

Cultivation

In principle, this coca species is propagated in the same manner as ***Erythroxylum coca***. This coca bush is usually trimmed back to remain small. The bush, which is pruned to a height of about 1 meter, is called a *pajarito*, “little bird.”

Cultivation is occasionally subject to ritual rules. In the Sierra Madre de Santa Marta, for example, new coca fields (which are regarded as sacred) can be planted only after consultation with medicine men or priest shamans (*mames*) (Baumgartner 1994; Bühler 1958, 3059).

Because it could hardly survive otherwise, Trujillo coca planted in the desert of northern Peru is artificially irrigated (Plowman 1979, 51).

Appearance

For nonspecialized botanists, *Erythroxylum novogranatense* is difficult to distinguish from *Erythroxylum coca*. The most characteristic features are probably the size and the structure of the leaves. The leaves of the variety *novogranatense* are not as wide as those of *Erythroxylum coca* and often have a slightly yellowish tinge.

Trujillo coca can grow as tall as 3 meters and is most easily recognized by its smaller, relatively narrow, lanceolate, tapered leaves. The leaves have a characteristic scent reminiscent of that of Coca-Cola (which is how the leaves can be distinguished from those of the other types even when dry). In addition, the flowers are arranged in small clusters and are attached to longer stalks (Plowman 1979).

Psychoactive Material

—Leaves

Erythroxylum novogranatense has an aromatic taste. As a result, many users prefer it to ***Erythroxylum coca***, even though it contains less **cocaine**.

Preparation and Dosage

Erythroxylum novogranatense is prepared in a fashion somewhat similar to ***Erythroxylum coca***. The variety *novogranatense* is often prepared and used in precisely the same manner as *E. coca* var. *ipadú*, and the variety *truxillense* in the same manner as *E. coca* var. *coca*. In order to be able to manifest their effects, the leaves of *Erythroxylum novogranatense*, like those of *E. coca*, must be mixed with an alkaline substance (see the table on pages 247–48).

In Colombia, lime from shells, limestone mineral deposits, or plant ashes is usually used as an alkaline additive. There, the ash cakes are known as *mambe* or (in Spanish) *lejia*. The Indians of the Sierra Madre de Santa Marta (Kogi, Arhuaco, Ika), as well as their pre-Columbian and colonial-period ancestors, the Tairona, chewed or chew coca leaves with slaked lime (*yotinwe*) from seashells and saltwater snails (Nicholl 1990, 389; Reichel-Dolmatoff 1955).

The Kogi prepare their coca in the following manner: Fresh coca leaves are dried or toasted and ground. The lime additive is obtained from the shells of snails and shells (*Melongena melongena* L., *Venus* spp., *Strombus* spp., and others) from the Caribbean coast (Reichel-Dolmatoff 1955). From time to time, the Kogi make a pilgrimage to the coast to acquire new supplies of shells, which are then burned in fires of grass piled up in the shape of pyramids. The lime they obtain in this manner is transformed into slaked lime by the addition of water or through the humidity of the air, and it is

stored in special gourds (*Cucurbita pepo* L.).

Among the Arhuaco Indians, the processes of harvesting and drying are quite elaborate:

To dry, [the leaves] are spread onto large stone plates near the houses. When the conditions are right, then the early morning's harvest is completely dry in the evening. Quick drying seals the stimulating alkaloids into the leaf, and the *coca del dia* ["coca of the day"] is the leaf that fetches the highest price. When first dried, the leaves are brittle and easily broken. After drying, they are piled up and allowed to sit for two to three days. This causes the leaves to perspire, which gives them back some of their suppleness and moisture. Afterward, they are very quickly dried in the sun once more and then packaged. Every one of the steps in this process is a delicate affair. If the first drying stage lasts too long, then the leaves will turn brown and become damp. If the leaves are allowed to perspire for too long a time, then they will turn gray and musty, look moldy, and have . . . a *caspa*, which means scales. To store, the coca leaves are first pressed with wooden weights, then folded in banana leaves, and finally wrapped in sackcloth or coarse woolen fabric. If the coca leaves have been dried and packaged properly and are then stored in a cool and dry place, they will retain their power for an entire year, and the *coquero* will be supplied until the next harvest. (Nicholl 1990, 395f.)

The shells of Caribbean snails of the genus *Strombus* provide the Indians of northern Colombia (Kogi, Ika, etc.) with a source of lime for chewing coca.

Engraving of a pressed herbarium specimen of *Erythroxylum novogranatense*. (From Mariani, *La Coca et la Cocaïne*, 1885)

“In ancient times, it is said, the coca tree was an exceptionally beautiful woman. But because she misused her body, she was killed and cut into two halves. From one of the two pieces grew a tree. And this tree was given the name *Mamacoca* or *Cocamama*. Since this event it has been used as an agent of pleasure.”

RAFAEL LARCO HOYLE

ARS ET AMOR: PERU [ART AND LOVE: PERU]
(1979, 22)

“When you chew coca, it is not as though you are ‘high.’ You don’t have any ‘drug experience,’ but rather the feeling that you have been freed of a burden.”

CHARLIE NICHOLL

TREFFPUNKT CAFÉ “FRUCHTPALAST” [MEETING PLACE CAFÉ “FRUIT PALACE”]
(1990, 397)

“What kind of meaning did life have for the trephined? A ‘normal’ way of life was no longer possible. They constantly found themselves in an exceptional mental and physical state. How did they bear this? Their extraordinary experiences, inebriation, hallucinations, pains, self-denials, placed them outside of the community. They represented something like their own social status. Did they perhaps comprise an order that was obligated to perform quite specific psychological and spiritual tasks?”

INGE VON WEDEMEYER

“ ‘CULTURA CEFÁLICA’ IN ALT-PERU” (1969, 309)

In Colombia, it is or was common to mix coca powder with a paste of ground fresh tobacco leaves (*Nicotiana tabacum*) or dried and powdered tobacco leaves for chewing (as well as smoking?). It appears that powdered coca leaves are also used as “sniffing tobacco” in Colombia (cf. **snuffs**).

Ritual Use

Archaeological finds as well as the few available ethnohistorical sources clearly demonstrate that the cultures of the Peruvian desert (Nazca, Mochica) have always used coca, more specifically the variety *truxillense*. For example, coca leaves were placed in the mouths of the dead so that they would be sufficiently stimulated for their “last journey” (Bühler 1958).

The Mochica used coca as an aphrodisiac and in erotic rituals that have been immortalized on ceramic grave goods. Unfortunately, little is known about these erotic rites, although the ceramics do provide a clear picture. The goal of the erotic activities was not reproduction (95% of the erotic images depict heterosexual anal intercourse)¹⁴⁷ but the production of altered states of consciousness that in turn were utilized to obtain insights into the normally invisible world (Larco Hoyle 1979, 145).

Trepanation, the act of making openings in the skulls of living people, also was widely practiced in these cultures. Such large numbers of finds have been made that it is improbable that all of these operations were carried out with the intention of removing brain tumors. It is likely that the numerous trepanations (as many as 45% of the skulls found in Paracas were trephined; von Wedemeyer 1969, 302) were carried out for ritual and religious rather than medical reasons. It appears “as if the trepanations were also intended to induce personality changes and increases. In modern medicine, the remarkable observation has been made that peculiar euphoric states often occur after serious head injuries. The sensation of weight is suspended, people think they are floating, they have a kind of ‘experience of traveling to heaven’ ” (von Wedemeyer 1969, 307). It may be that trepanation was an important shamanic method for producing ecstatic states of consciousness.

The chewing of coca (of the variety *novogranatense*) was widespread throughout Colombia during pre-Hispanic times (Uscátegui M. 1954). Numerous gold objects from the time of the Tairona make reference to the use of coca. As with the later Kogi and Ika, the use of coca among the Tairona was associated with divination and the shamanic priesthood:

According to Castelanos (1601, II, Santa Marta 1, Str. 16), women were also involved in divination, which allows us to assume that there was a distinctive group of religious specialists (shamans?), for the priesthood in the more narrow sense was restricted to the men. Priestly qualifications were earned during a 16- to 20-year fast in isolation and visionary experiences under the influence of aromatic woods that were marked solely for the temple fires, augmented by the use of coca. (Bischof 1986, 25)

The descendants of the Tairona have preserved both these rituals and the restrictions concerning coca use:

Almost everywhere [in northern Colombia], the use of coca is limited to the men and strictly forbidden to the women. The extent to which coca chewing is considered a prerogative of the men can be seen in a report . . . about the Ijca [= Ika]. At the beginning of a lunar eclipse, these Indians attempt to influence the astronomical events by exchanging the roles of man and woman, i.e., the men sit down upon the floor and begin to spin, while the women watch, chewing coca as they do. (Bühler 1958, 3059)

Among the Arhuaco, only married men are allowed to chew coca. When a young man wishes to marry, he is instructed in many things by the *mame*, the shaman priest, and initiated into the mysteries of adult life. At the wedding, the newlywed then receives his own lime bottle, called a *poporo* (from *Lagenaria* spp.), and from that time on, he may chew coca—as much as he wants to or can. The lime bottle is the symbol of his initiation and is regarded as an amulet (Nichol 1990, 394 f.).

Both the use of coca and the associated symbolism are very similar among the Kogi (Baumgartner 1994; Ereira 1993; Müller-Ebeling 1995). At his initiation into manhood, each young boy receives his own lime gourd (*poporo*), which he will carry with him without interruption for the rest of his life. The initiate is told that the gourd bottle symbolizes a woman whom he will ritually wed during his initiation ceremony. When the initiate introduces the wooden stick (lime spoon) into the gourd bottle

for the first time during this ritual, he is said to “deflower” his “partner,” thereby winning her for his “bride.” The stick that is introduced is understood to be the phallus, the rubbing of the stick represents coitus, and the gourd bottle is the vulva. The Kogi men are supposed to suppress all sexual activities and experience their erotic life solely through the constant use of coca (Reichel-Dolmatoff 1985, 1:87–90*; Uscátegui M. 1959, 282*; Ochiai 1978):

The little figure-eight-shaped gourd [*poporo*] used as a lime container is an image of the cosmos, and the stick that is inserted into it is its axis. It follows, by Kogi logic, that the gourd is a womb, the stick is a phallus, the coca leaves to be chewed are female, and the powdered lime is semen. (Reichel-Dolmatoff 1987, 78)

Artifacts

Many archaeological objects associated with coca and its use are known from both the northern Peruvian desert and northern Colombia.

The spectacular gold artwork of the Tairona and related peoples contains numerous representations of people using coca. There are also gold lime containers in the form of gourd bottles as well as other shapes. The small gold lime bottles shaped like a coca-chewing Indian holding coca bags in his hands are especially impressive. The opening to the bottles is located at the crown of the head (Bray 1979a, cat. no. 143a). A number of richly decorated gold lime spoons have also been discovered (Bray 1979b).

The ritual chewing of coca is a frequent theme in the paintings and the ceramics of the Moche and the Nazca cultures (Kutscher 1977*; Naranjo 1974, 610; Towle 1961, 58 f.*). The Mochican ceramics include numerous anthropomorphic vessels depicting people using coca (Dietschy 1938, 1999). Some authors have attempted to associate the erotic art of the Mochica (Larco Hoyle 1979), which they consider “perverse,” with the use of coca. They regard this art as an expression of sexual pathology resulting from a “cocaine psychosis”(cf. Kaufmann-Doig 1978, 22). I mention this hypothesis only to point out the “perversions” of some would-be scholars.

The ceramics also show the use of coca in (ritual) trephinations:

There is a Peruvian clay sculpture which shows a surgeon holding the patient’s head between his knees, chewing coca, and spitting this into the wound as a local anesthetic. The saliva is attributed with magical as well as therapeutic effects. It has, for example, a distinctive function in confession. A person would spit out his sins onto a bundle of grass that would then be thrown into the river; this is a special way to make a cathartic statement. (von Wedemeyer 1969, 306)

Artifacts were even made from the bush itself. The wood of older plants was and still is carved into images of the gods (*idolos*). Some beautiful examples of these can be seen in the Ethnology Museum in Basel (Switzerland). They are used primarily as altar objects in shamanic healing seances.

Today, the Indians still use bags for the leaves, gourds for the lime, and lime sticks. Among the Indians of the Colombian Sierra Madre, the coca bags are known as *mochilas*, *tutu*, or *kuetand diaja*. The lime gourds are called *poporo*, *yoburo*, or *kuetand-tuky*, and the lime spoons *sokane*.

In some ways, Trujillo coca also left its mark upon the early products of Coca-Cola. The ads produced around the turn of the twentieth century in particular feature young, rosy, healthy-looking women who are well dressed and are usually shown together with bouquets of roses. It almost seems as though the spirit of Mama Coca is still present in these illustrations.

Medicinal Use

The Mochica used coca for medicinal purposes; unfortunately, no documents about actual applications have come down to us (von Hagen 1979, 156 f.). In pre-Columbian times, coca apparently was commonly used as a local anesthetic for trephinations and other surgical procedures (Dietschy 1938).

The contemporary folk medical uses of *Erythroxylum novogranatense* are more or less identical to the uses of *Erythroxylum coca*.

Constituents

The constituents of the two varieties are essentially the same as those in *Erythroxylum coca*, with some slight exceptions. The greatest difference is in the concentration of **cocaine**. Both varieties contain less than 1% cocaine and other alkaloids. The leaves and the bark contain the **tropane alkaloids** cuscohygrine and hygrine.

Representation of a caterpillar (?) with the typical leaves of the coca bush. (After a painting on a jar from Nazca, Peru, fifth to tenth century)

Coca-chewing shamans beneath a starry sky. The lime container, from which lime is removed with a spoon and placed in the mouth, is clearly visible. (Painting on a Moche jar, Chimú, ca. 500 C.E.)

A shaman with all of the coca paraphernalia (bag for leaves, gourd for lime) beneath a starry sky that is spanned by a double-headed snake (rainbow, a ladder of coca). (Painting on a Moche jar, Chimu, ca. 500 C.E.)

Of the four types of coca, the variety *truxillense* contains the highest concentration of **essential oil** and other pleasant flavor agents (Plowman 1979, 52).

Effects

The effects correspond to those of *Erythroxylum coca*, although they are somewhat milder as a result of the lower amounts of cocaine.

Commercial Forms and Regulations

The Indian use of coca is tolerated in Colombia. In Peru, the cultivation and use of Trujillo coca is legal.

Some years ago, a *maté de coca* made with Trujillo coca (in tea bags) was exported to the United States. Sales were quickly suspended, however, as the tea was found to contain small amounts of **cocaine** (Siegel et al. 1986).

The legal situation (laws regulating drugs and medicines) is identical to that pertaining to *Erythroxylum coca*.

The Trujillo coca bush (*Erythroxylum novogranatense* var. *truxillense*), which is cultivated in the desert of northern Peru, is most readily recognized by its small leaves and long branches. (From Mariani, nineteenth century)

Eschscholzia californica Chamisso

Golden Poppy, California Poppy

Family

Papaveraceae (Poppy Family); Subfamily Papa-veroideae, Eschscholzieae Tribe

Forms and Subspecies

Numerous forms (over thirty) have been cultivated for ornamental purposes, especially white-and red-blooming cultivars, including some with double flowers (Grey-Wilson 1995, 55*). Several varieties or subspecies of the wild plant have been described (Kreis 1993, 111):

Eschscholzia californica Cham. var. *alba*

Eschscholzia californica Cham. var. *crocea* (Benth.) Jepson

Eschscholzia californica Cham. f. *dentata* (deeply incised leaves)

Eschscholzia californica Cham. var. *douglasii* (Benth.) Gray

Eschscholzia californica Cham. var. *maritima* (Greene) Jepson (perennial)

Eschscholzia californica Cham. ssp. *Mexicana* (Greene) C. Clarke

Eschscholzia californica Cham. ssp. [or var.] *peninsularis* (Greene) Munz (Southern California, Baja California)

Synonyms

Chryseis californica Torr. et Gray

Eschscholtzia californica Cham.

Eschscholtzia douglasii Benth.

Eschscholtzia douglasii (Hook. et Arn.) Walp.

Eschscholtzia maritima Greene

Eschscholtzia mexicana Greene

Folk Names

Amapola amarilla, amapola de California, amapola de los indios (“opium of the Indians”), amapolla, California poppy, Californian poppy, copa de oro (Spanish, “cup of gold”),¹⁴⁸ cululuk (Rumsen), globe du soleil, golden poppy, goldmohn, indianischer mohn, kalifornischer mohn, knipmutsje (Dutch), pavot de californie, schlafmützchen, slapmutshe, yellow poppy

History

The Indians of California have used the golden poppy for medicinal and/or psychoactive purposes since prehistoric times.

The genus is named after the surgeon Dr. J. F. Eschscholtz (1793–1831), who served as naturalist in the 1816 and 1824 Russian expeditions to the coast of the Pacific Northwest (Grey-Wilson 1995, 55*).

The golden or California poppy is the official state flower of California (Bremness 1995, 250*).

The plant has been cultivated in European gardens since 1790 (Grey-Wilson 1995, 55*).

Since the 1960s, the California poppy has been regarded as a “legal high” and as a marijuana

substitute (cf. *Cannabis indica*) (Kreis 1993, 113).

Distribution

The plant is indigenous to western North America (California, Oregon). It thrives at altitudes of up to 2,000 meters above sea level and requires moderately dry soil and much sun. It occurs as far south as Baja California and northern Mexico (ssp. *mexicana*).

Cultivation

Propagation occurs through the seeds. These are pressed into the ground to a depth of 0.5 to 1 cm and watered. At temperatures between 10 to 22°C, they germinate within eight to fifteen days. The young plants must be transplanted so that their later growth is not disturbed. In central Europe, it is advisable to raise the plants indoors and transplant them into a garden or planter box at the end of April.

California poppy seeds germinate so effectively that only a few seeds are needed. The plant can tolerate various soil types.

Cultivation for pharmaceutical purposes occurs primarily in southern France (Kreis 1993, 112).

Appearance

The California poppy is an annual that can grow as tall as 40 cm. The multipinnate leaves are opposite and are blue-green or even grayish in color. The silky flowers are luminously orange-yellow and sit at the end of long, slender stalks. The wild plant blossoms from June to August. The fruits are long, thin, tapered pods that point straight up and contain numerous tiny seeds.

The genus *Eschscholzia* is composed of some ten species that occur in the wild only in North America, especially California. *Eschscholzia californica* is easily confused with *Eschscholzia caespitosa* Benth. [syn. *E. tenuifolia* Benth.], a species found in the Sierra Nevada of California, and with *Eschscholzia lemmonii* Greene (Grey-Wilson 1995, 60f.*).

One of the many cultivated sorts of golden poppy (*Eschscholzia californica*).

The flower and fruit of the golden poppy (*Eschscholzia californica*). (Wild plant, photographed in northern California)

Psychoactive Material

- Leaves/herbage (eschscolziae herba, herba eschscholtziae, herba eschscholziae, eschscholzienkraut)
- Flowers
- Fruits

Preparation and Dosage

The leaves, flowers, and fruits can be dried and smoked, either alone or mixed with other herbs (cf. **smoking blends**). The effects are very mild. The maximum dosage appears to be rather open (Gottlieb 1973, 9*).

To make a tea with sedative effects, add one to two heaping teaspoons of dried herbage to one cup of boiling water and allow to steep for thirteen minutes.

The fresh fruits (and the fresh herbage) can be chewed if desired. Tinctures and extracts at first should be dosed according to the instructions on the packaging material. Dosages can then be increased as desired for experimentation.

Ritual Use

It is possible that the California Indians may have used the plant for ritual purposes in prehistoric times.

Artifacts

Because of its beauty, the golden poppy is often depicted in paintings of California and on postcards and posters (e.g., The Panama-Pacific International Exposition, 1915).

Medicinal Use

The California Indians use the flowers, stalks, and leaves primarily as a sedative for toothaches (Bremness 1995, 250*). They usually chew the fresh leaves. A decoction of the flowers is used to treat head lice. Two flowers may be placed under a child's pillow to aid in sleep. Indian women avoid the golden poppy while pregnant (Kreis 1993, 113).

In northern Mexico, the golden poppy is used in folk medicine in the same manner as opium (cf. *Papaver somniferum*) (Martínez 1994, 36*). In pediatric medicine, it is also popular in place of opium as a mild sedative and analgesic (Sturm et al. 1993). Tinctures made from material collected during the flowering period are preferred (Columbo and Tomé 1993). In homeopathic medicine, preparations of the fresh flowering plant (*Eschscholtzia californica* hom. *PFX*, *Eschscholtzia californica* hom. *HPUS88*) are used in accordance with the medical description to treat such ailments as sleep disturbances (Kreis 1993, 114).

Constituents

The entire plant contains alkaloids. The concentrations are highest during the flowering period. Material collected at this time can contain as much as 1.1% alkaloids by dry weight. The root contains up to 2.7% alkaloids, including 0.014% magnoflorine (= escholine; an aporphine alkaloid), 0.013% (–)- α -canadinmethohydroxide, 0.05% norargemonine, and 0.08% bisnorargemonine; these substances are present in the herbage in only trace amounts. The primary alkaloid in the root is allocryptopine (approximately 1.8%). The seeds contain protopine (= macleyine; = fumarine; = biflorine), allocryptopine, chelerythrine, and other substances (Kreis 1993, 111). The herbage contains magnoflorine as well as californidine, protopine, allocryptopine, sanguinarine (= pseudochelerythrine), coptisine,¹⁴⁹ chelerythrine (= toddaline), escholtzine (= eschscholtzine; = californine), *N*-methyllaurotetanine (= lauroscholtzine), corydine, isocorydine, chelirubin, macarpine, chelilutine, and *O*-methylcariachine (Kreis 1993, 112). The alkaloids in the aboveground parts of the plant increase dramatically when the plant is grown under strong light (Colombo and Tomé 1991).

Effects

The psychoactive effects of the golden poppy are very subtle: “*Eschscholtzia* elevates the body's oxygen supply and promotes the absorption of vitamin A. . . . When smoked, the leaves and flowers induce a mild state of euphoria—side effects are unknown!” (Bremness 1994, 250*).

In animal experiments (mice), the extract has exhibited clear sedative and anxiolytic effects. In other words, the pharmacological behavior is that of a tranquilizer (Rolland et al. 1991). The extract extends the effects of barbiturates (Kreis 1993, 113).

The two alkaloids chelerythrine and sanguinarine bind to vasopressin (V_1) receptors, a neurochemical behavior that may explain the golden poppy's psychoactivity (Granger et al. 1992).

Commercial Forms and Regulations

The seeds may be purchased in most nurseries (usually a variety of cultivars are offered). Health food stores in the United States sell liquid extracts of California poppy (fresh roots, leaves, and flowers) from guaranteed organic sources. All products are available without restriction.

“The plant promotes sleep and alleviates pain. It should be able to substitute for opium for children.”

Fabiana imbricata Ruíz et Pavón

Fabiana Bush, Pichi-Pichi

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Nicotianeae Tribe

Forms and Subspecies

It is possible that one subspecies characterized by a treelike pattern of growth may exist in southern Chile.

Synonyms

None

Folk Names

Coa, fabiana bush, fabianastrauch, fabiane, fabiane imbriquée, k’oa,^{[150](#)} k’oa santiago, monte derecho (Spanish, “right mountain”), monte negro (Spanish, “black mountain”), Peru false heath, peta, piche, picheng, pichi,^{[151](#)} pichi-picheng, pichipichi, pichi-romero,^{[152](#)} pichirromero, romero,^{[153](#)} romero pichi, tola^{[154](#)}

History

The plant was brought to Europe during the early colonial period and was propagated in the botanical garden of Madrid, which was constructed specifically for the cultivation and distribution of plants from the New World. Strangely, the literature from the colonial period makes no mention of *Fabiana* (Hoffmann et al. 1992, 184*). The plant, which has enjoyed great success in folk medical contexts, did not attract the attention of the medical community until the nineteenth century. Henry Hurd Rusby was one of the first researchers and druggists to investigate *Fabiana* in more detail (Rusby 1885; Rossi-Wilcox 1993, 5*). Because of his work, the plant was introduced into the United States as a medicine under the name *pichi-pichi* (Rusby 1890). Around the turn of the century, it was also accepted into European pharmacopoeias as a diuretic (Schneider 1974, 2:86*).

The genus is named for Francisco Fabiano y Fuero (1719–1801), the archbishop of Valencia, who was a supporter of the botanical sciences (Genaust 1996, 243*).

Distribution

The fabiana bush is indigenous to Chile, where it occurs primarily in the south between Coquimbo and Magallanes. It also is found in Patagonia, including the Argentinean portion (Hoffmann et al. 1992, 184*), and in Bolivia, Peru, and several areas of Brazil.

There are some twenty-one species in the genus *Fabiana* (D’Arcy 1991, 78*), most of which are little known ethnobotanically. It is possible that the inhabitants of the Andes use the name *pichipichi* for many species. In Chile, several *Fabiana* species are known as *tola*^{[155](#)} (Mösbach 1992, 105*):

Fabiana barriosii Phil.

Fabiana denudata Miers.

Fabiana ericoides Dun.

Pichi-pichi is sometimes confused or counterfeited with the related species *Fabiana bryoides* Phil. and *Fabiana friesii* Dammer. These two species occur only in the high mountains (Atacama, northern Chile).

Cultivation

Propagation occurs via the tiny seeds, which like those of all nightshades should be pregerminated and potted when they are seedlings. The bush thrives best in rocky and poor soils. In southern Chile, it is grown in nurseries for use in gardens and as an ornamental (Hoffmann et al. 1992, 184*). In Europe, the plant can be grown in a cold house and in areas that are largely free of frost (Spain, Ireland).

Appearance

This bushy shrub can grow as tall as 3 meters and usually has a large number of branches at the ends of its stems. Tiny, almost rod- or needle-shaped leaves arranged like scales sit on the straight stems. The small, white or violet (the color is variable), trumpet-shaped flowers grow from the tips of the branches. The fruits develop into oval capsules 5 to 6 mm in length. The flowering period is usually from November to January in South America and from May to June in Europe.

Psychoactive Material

—Herbage (herba fabianae imbricatae, summitates fabianae, pichi, pichi-pichi-kraut)

—Wood (lignum fabianae, lignum pichi-pichi)

Preparation and Dosage

For psychoactive use, the tips of the branches are dried and, if necessary, chopped into small pieces. The dried herbage can then be burned as **incense** or strewn over glowing charcoal. When burned, the aromatic twig ends give off a resinous smoke that is easy to inhale and has a sweet/acrid scent somewhat reminiscent of that of pine or fir. No information is available concerning the dosage of this type of preparation. Overdoses from breathing in such smoke do not appear to be known. *Fabiana* and *Latua pubiflora* are combined as components of a psychoactive incense.

The fresh or dried herbage as well as the bark may be used when the intended use is medicinal in nature. A decoction of the bark is a potent diuretic. A tea made by steeping a tablespoon of the fresh or dried herbage is drunk as a tonic (Hoffmann et al. 1992, 186*).

Ritual Use

Fabiana herbage is a sacred **incense** that is burned at all traditional, originally Indian ceremonies (Aldunate et al. 1983). The Aymara of northern Chile keep bundles of the dried herbage, which they light when needed. The glowing herbage gives off copious amounts of smoke. The Indians of this region use *Fabiana* as an incense at all religious ceremonies and festivals and especially at the traditional ceremonies in which they make offerings to Pachamama. Patients and rooms are fumigated with the plant to treat illness. The smoke is said to banish spirits and ward off demons. In the Atacama Desert, the burning of incense is regarded as a “payment” for the dead and for general purification. The spirits of the dead are tamed and dispelled by the smoke (Aldunate et al. 1981, 210*). Other *Fabiana* species are used in a similar manner (see the table on page 265).

Artifacts

None

Medicinal Use

In Chilean folk medicine, an infusion of the fresh herbage has been used since ancient times to treat kidney ailments and urinary tract problems and as a diuretic (Donoso Zegers and Ramírez García 1994, 55, 104*; Houghton and Manby 1985, 100*; San Martín A. 1983). The tea is also used to promote digestion (Razmilic et al. 1994). In Peru and Chile, it is believed that the plant has strong anthelmintic effects upon sheep and goats (Schultes 1980, 115 f.*).

The use of the plant as a diuretic and a treatment for venereal diseases has become generally accepted in the folk medicine of South America. The herbage also was listed as a diuretic in international pharmacopeias. A mother tincture (*fabiana imbricata*) occasionally finds use in homeopathic medicine (Boericke 1992, 329*).

Constituents

The aboveground parts of *Fabiana imbricata* contain an **essential oil**, resin (fabiana resin), a bitter principle, an alkaloid of rather simple structure known as fabianine, various sugars (D-manoheptulose, D-arabitol, D-mannitol, D-galactose, D-xylose, primaverose), a glycoside (fabiana-glycotannoid), various alkanes, fatty acids, erythroglaucin, physcion, and acetovanillone (Hoffmann et al. 1992, 186*; Knapp et al. 1972; Roth et al. 1994, 347*). Various murolanes and amorphane sesquiterpenes¹⁵⁶ (3,11-amorphadiene) have been found in the leaves and herbage (Brown 1994; Brown and Shill 1994). The herbage also contains the flavonoids and glycosides quercetin (cf. *Artemisia absinthium*, *Psidium guajava*, *Vaccinium uliginosum*, **kinnikinnick**), camphor oil, and quercetin-3-O-rhamnoglucoside (= rutin) (Hörhammer et al. 1973). The herbage (especially the twigs) also contains the **coumarin scopoletin**, although the concentrations can vary considerably (Knapp et al. 1972, 3092; Razmilic et al. 1994; Roth et al. 1994; 347*), as well as a substance known as fabiatriina (Montes and Wilkomirsky 1987, 166*).

To the extent that they have been chemically investigated, other species of *Fabiana* (e.g., *Fabiana denudata* and *Fabiana squamata*) appear to have similar constituents (Knapp et al. 1972).

Effects

An extract of the herbage has potent diuretic effects and is thus very successful in the treatment of kidney and urinary tract ailments (Montes and Wilkomirsky 1987, 166*). An aqueous-alcohol extract of the herbage inhibits the enzyme β glucuronidase (Razmilic et al. 1994) and has antiseptic effects (Hoffmann et al. 1992, 184*). Teas made from the herbage have general tonic effects (Hoffmann et al. 1992, 186*). The smoke, when inhaled deeply, has euphoric and inebriating effects that are sometimes rather subtle but also can be quite pronounced in some individuals. Quercetin may be responsible for the narcotic effects (cf. *Psidium guajava*).

The pichi-pichi plant (*Fabiana imbricata*) is from southern Chile.

“The South American inebriant ‘pichi-pichi’ is dried shoot apexes.”

LUTZ ROTH, MAX DAUNDERER, AND KURT KORMANN *GIFTpflANZEN—PflANZENGIFTE* [POISONOUS PLANTS —PLANT POISONS]
(1994, 347*)

Fabianine

The aromatic and resinous smoke of *Fabiana denudata* is easily inhaled and has mild stimulating effects. The yellowish, intense smoke of *Fabiana bryoides* has a lemony, fragrant, and yet strange aroma, is not so easily inhaled, and does not produce the same stimulating effects.

Commercial Forms and Regulations

In Europe, the tips of fabiana herbage (fabiana herba, herba pichi-pichi, or summitates fabianae) are difficult to obtain. In pharmacies, fabiana usually is available only as a homeopathic mother tincture (under the name *Fabiana imbricata* or *pichi-pichi*). The living plant occasionally is sold in nurseries (as a cold-house plant; Roth et al. 1994, 347*).

Other *Fabiana* Species Used as Incense

(From Aldunate et al. 1981, 209 f.*)

Species	Folk Names
<i>Fabiana bryoides</i> Phil.	k'oa, k'oa santiago, pata de loro ("parrot's claw"), pata de perdíz ("partridge's claw")
<i>Fabiana densa</i> Remy var. <i>ramulosa</i> Wedd.	tara ("dyer's bush"), tara macho ("male dyer's bush")
<i>Fabiana denudata</i> Miers.	alma tola ("soul dyer's bush"), leña de alma ("firewood of the soul"), tara hembra ("female dyer's bush"), tolilla ("little dyer's bush")
<i>Fabiana squamata</i> Phil.	k'oa pulika

Fabiana bryoides, found in the Atacama Desert, is the most important ritual fumigant of the oasis inhabitants.

The naked fabiana (*Fabiana denudata*), which is adapted to the extreme desert climate, is used as incense during shamanic healing ceremonies. (Wild plant—still living!—photographed in San Pedro de Atacama, northern Chile)

Heimia salicifolia (H.B.K.) Link et Otto

Sinicuiche

Family

Lythraceae (Loosestrife Family)

Forms and Subspecies

One variety has been described for Mexico: *Heimia salicifolia* var. *mexicana* Link

Synonyms

Heimia salicifolia (Kunth) Link

Heimia syphillitica DC.

Nesaea salicifolia H.B.K.

Nesaea syphilitica Steud.

Folk Names

Abre-o-sol (Portuguese, “sun opener”), anchinol, anchinoli, chapuzina, cuauxihuitl (Nahuatl, “meadow fire”),¹⁵⁷ escoba colorada (Spanish, “colorful broom”), escoba de arroyo (Spanish, “broom of the creek”), escobilla del río, flor de San Francisco, garañona, granadilla,¹⁵⁸ granadillo, grandadillo, hachinal, hanchinal, hanchinol, hanchinoli, hauchinal, hauchinol, hauchinoli, heimia, herva de la vida (Portuguese, “herb of life”), herva de vida, hierba de San Francisco (Spanish, “herb of St. Francis”), hierba jonequil, huachinal, huauchinolli (Nahuatl, “the burning of the wood”), jara, jara negra, jarilla, jarrila,¹⁵⁹ ko’ßi la’wo, maajaji lop’om, maan witsiil (Huastec, “yellow are its flowers”), penaganaq’te, quiebra arado, quiebra yugo, rosilla de Puebla (Spanish, “little rose of Puebla”), sinicuiche, sinicuichi, sinicuil, sinicuilche, sinicuitl, to: la’-gaik, witlat lek’e, xonecuili, xonecuite, xoneculli, xoneguilchi, xonochilli, xonocuili (Nahuatl, “twisted foot”), yerba de las ánimas (Spanish, “herb of the spirits”)¹⁶⁰

History

No information is available concerning the prehistoric use of *Heimia salicifolia*. It is possible that the plant was associated with the cult of Xochipilli, the Aztec god of spring and desire (Wasson 1974*). During the nineteenth century, the plant was a recommended treatment for syphilis (Argueta V. et al. 1994, 851*).

It often has been (incorrectly) assumed that the plant was named for the renowned Alsatian mycologist Roger Heim (cf. *Psilocybe mexicana*). However, the genus *Heimia*, which consists of just three species, was actually named for Ernst Ludwig Heim (1747–1834), a physician from Berlin who introduced Alexander von Humboldt to botany (Genaust 1996, 281*).

The name *sinicuiche* is used both for the plant and for the drink that is prepared from it. The Mexican names *sinicuiche* and the derivatives *sinicuilche* and *sinicuil* are also used for other inebriating, psychoactive, or poisonous plants: *Abrus precatorius* L., *Rhynchosia* spp., *Piscidia* spp. (cf. *Lonchocarpus violaceus*), and *Erythrina* spp. (D. McKenna 1995, 102*; Reko 1938, 145 f.*; Schultes 1970, 35*).

“I drank some 25 g of a *Heimia salicifolia* tincture from OTJ, and the effects were wonderful. It brought me to a state which at the time I could only describe as ‘perfection.’ Perhaps the people do not drink all of the little bottle and for that reason do not feel the euphoria, the wisdom. Or perhaps I became inebriated solely as a result of the alcohol it contained; but if this was the case, then that was some strong alcohol!”

SOMA BABA

“*HEIMIA SALICIFOLIA* EXTRACT” (*ENTHEOGENE* 5 [1995]: 36)

The flower of *Heimia salicifolia*. (From Wasson)

Calderón (1896) was the first to describe *Heimia salicifolia* as the source of a psychoactive preparation. He noted the optical effects (yellow vision) and the acoustical phenomena that occur following ingestion of the leaves. However, he did not experience any of these effects in self-experiments using 5, 10, and 15 g of leaves (Malone and Rother 1994, 141). Calderón appears to have produced a morphogenetic field that still exerts itself and continues to develop today. Victor Reko contributed greatly to this reputation with his dramatic description of a “magical drink causing oblivion” (Reko 1938, 140–47*).

Distribution

The bush occurs primarily in the highlands of Mexico but is also found in Baja California (Martínez 1994, 293*). It is found throughout South America as far south as Argentina.

Cultivation

Propagation occurs through cuttings as well as the tiny seeds. The seeds are sown in seedbeds or pots. The soil must be of a fine consistency and should be pressed down with a tile and smoothed. The seeds are broadcast onto the soil and pressed in gently with a flat object. The seeds should then be only moistened with a water sprayer, and not watered by pouring. The soil should be kept slightly moist until the seeds have germinated. The seedlings do not tolerate any direct sunlight. Only when they have developed their first true leaves can they be placed in the sun and watered thoroughly. The soil should be allowed to dry out between waterings. When transplanting, be aware that even very young plants develop a large root system (Grubber 1991, 61 f.*).

The plant prefers loose soils that dry quickly after watering. It thrives best in warm, dry zones and does not tolerate frost. In central Europe, it can be kept only as a houseplant.

Appearance

The perennial, herbaceous shrub can grow to a height of over 3 meters. It has many wooden branches and narrow, willowlike leaves 2 to 9 cm in length. The yellow flowers (2 cm in diameter) have six petals and are usually arranged in pairs on the leaf axils. The tiny seeds are contained in ribbed fruits that are chalicelike capsules (5 mm in length).

The two other *Heimia* species are almost identical in appearance and are difficult even for experts to distinguish: *Heimia myrtifolia* Cham. et Schl. (indigenous to southwest Brazil)¹⁶¹ and *Heimia montana* (Griseb.) Lillo (found throughout Bolivia and Argentina) (Malone and Rother 1994, 136; Rother 1990). *Heimia myrtifolia* grows to a height of only about 1 meter and looks like a dwarf form of *Heimia salicifolia*.

Psychoactive Material

—Leaves

—Herbage/branch tips

Preparation and Dosage

Sinicuiche, the Mexican “magical drink causing oblivion,” is made from the leaves:

The preparation of the drink involves laying the slightly wilted leaves in water for a day and then pressing these thoroughly the following day. The juice obtained in this manner is allowed to ferment. In this way, one obtains a peculiar, not unpleasant-tasting drink whose effects, however, are certainly not due to the only low quantities of alcohol that are present but are derived from other substances that are produced during fermentation. (Reko 1938, 142*)

A more modern recipe calls for adding one handful of freshly crushed wilted leaves per person to water and allowing this to sit in the sun for a couple of days, whereupon the liquid will begin to ferment slightly. One cup of this is said to induce yellowish vision and mild euphoria (D. McKenna 1995, 102*). The cold-water extract of the leaves is sticky. Even with dosages as high as 15 g of dried leaves, no psychoactive effects could be observed (Martínez 1994, 295*).

The fresh or dried leaves can be brewed into a tea, both alone and in combination with other herbs.

The fresh herbage can be added to 60 to 80% ethanol to produce an alcoholic extract (tincture). Twenty to 25 g of this tincture is said to be an effective psychoactive dosage.

Ritual Use

To date, no traditional ritual use of *Heimia salicifolia* is known.

Artifacts

A floral element on the famous Aztec statue of Xochipilli appears to be a naturalistic representation of the *sinicuiche* flower (Wasson 1974).

The occult writer Hanns Heinz Ewers (1871–1943) immortalized the “magical drink causing oblivion” in his novel *Die blauen Indianer* [The Blue Indians] (Reko 1938, 141*).

Medicinal Use

In Mexican folk medicine, *sinicuiche* is regarded as a narcotic, inebriant, diuretic, and febrifuge (Díaz 1979, 77*; Jiu 1966, 254*). The Huastec use the bush as a medicinal bath additive (Alcorn 1984, 665*). In Mexican folk medicine, a tea made from the leaves is thought to promote digestion (Martínez 1994, 294*). The herbage is also used in the treatment of rabies and to counteract the “evil eye” (Argueta V. et al. 1994, 851*). The plant is widely used to treat syphilis (Malone and Rother

1994, 136).

In Mexico, *Heimia salicifolia* is used primarily for ethnogynecological purposes. Infertile women are said to be helped by a bath prepared from sinicuiche, *pericón* (*Tagetes lucida*; cf. ***Tagetes* spp.**), rosemary (*Rosmarinus officinalis* L.¹⁶²; cf. **incense, essential oils**), and lavender (*Lavandula angustifolia* Mill. [syn. *Lavandula officinalis* Chaix]).¹⁶³ To promote conception, women are advised to drink a tea made from sinicuiche twigs, *dormilona* (*Mimosa pudica*; cf. ***Mimosa* spp.**), *gobernadora* (*Larrea tridentata* [DC.] Cav.), and *raíz de la fuerza* (“root of power”; unidentified) or *raíz hijera* (?) daily. If a woman remains childless, she should consume a tea brewed from sinicuiche twigs together with *cuatecomate* (*Crescentia alata* H.B.K.), *pericón* (*Tagetes lucida*), and maize cobs (***Zea mays***). To increase fertility or treat sexual weakness and frigidity, ovarian inflammations, and uterine ailments, the vagina should be exposed to the steam from a tea of rosemary and sinicuiche. After giving birth, and to treat the symptoms of a potential miscarriage, a drink made of sinicuiche, cinnamon (*Cinnamomum verum*), pulque (cf. ***Agave* spp.**), and *piloncillo* (?) should be drunk (Argueta V. et al. 1994, 851*).

The Maká Indians of Chaco, in Paraguay, use fresh *Heimia* leaves as an extracting plant paste for treating wounds caused by thorns that have remained in the body. The leaves are said to simplify the removal of the thorn and also appear to promote the healing of the wound (Arenas 1987, 290*). The Pilagá of the Argentinean Chaco place fresh leaves onto sores, drink a decoction of the root for stomachaches, and bathe in the decoction for scabies (Filipov 1994, 188*).

Constituents

The bush contains the quinolizidine alkaloids lythrine, cryogenine (= vertine), heimine, sinicuichine, anelisine, heimidine, lyfoline, dehydrodecodine, abresoline, demethylasubine-I and -II, epidemethoxyabresoline, sinine, lythridine, vesolidine, and cryofoline. Cryogenine, the main alkaloid, has anticholinergic and antispasmodic effects (Malone and Rother 1994, 137; Scholz and Eigner 1983, 75*). The four Lythraceae alkaloids that have been best studied are vertine (= cryogenine), lyfoline, lythrine, and nesodine (Malone and Rother 1994). The biological precursor of vertine is phenylalanine (Rother and Schwarting 1972).

The sinicuiche bush (*Heimia salicifolia*), with ripe fruits.

Heimia salicifolia in bloom.

The raw drug that can be obtained in Mexico from *Heimia salicifolia* consists primarily of the thin branches.

“The farmers in certain parts of Mexico use the word *sinicuichi* for a drink that is produced from a plant that bears the same name. When taken over an extended period of time, gross forgetfulness occurs. The sinicuichi drinkers usually have no clear and correct orientation concerning space and time. They forget things that took place only a few hours ago, and they tell you things as great news that they told you just minutes earlier without being aware that they are repeating themselves. In contrast, ideas and memories from years ago, which have more or less engraved themselves into their memories, are correctly reproduced. Some babble that they are able to precisely recall occurrences that took place during the first days of their lives, and others that they can even recall events that took place before they came into the world, things that their grandfathers may have experienced and that they describe as if they were their own memories from a time before they were born.”

VIKTOR A. REKO

MAGISCHE GIFTE [MAGICAL POISONS]

(1938, 140 f.*)

The leaves contain 15% tannins, 9% bitter agents, and 14% resins (Martínez 1994, 294*). The roots and seeds are devoid of alkaloids (Dobberstein et al. 1975; Malone and Rother 1994, 139).

Effects

The drink brewed from *Heimia salicifolia* produces only mild psychoactive effects:

Sinicuiche has a weak intoxicating effect. It induces a pleasant, slightly euphoric dizziness and numbness, and the surroundings are perceived as being darker. Auditory hallucinations occur as the inebriated person hears indistinct sounds from a great distance. The world around one shrinks. No unpleasant aftereffects are known. (Scholz and Eigner 1983, 75*)

There have been repeated reports of yellowish vision and mild auditory hallucinations, tunnel effects, and tunnel vision (D. McKenna 1995, 102*; Rob Montgomery, pers. comm.). Chills and shivering have also been reported (Bob Wallace, pers. comm.).

Animal experiments have demonstrated that the alkaloids have anticholinergic and anti-spasmodic effects (D. McKenna 1995, 102*). The pharmacology of vertine (= cryogenine) is said to be identical to that of the whole extract (Kaplan and Malone 1966). Self-experiments with the alkaloids vertine, lythrine (310 mg, corresponding to 36 to 156 g of dried branch tips), and acetylsalicylic acid did not result in any detectable psychoactivity (Malone and Rother 1994, 142).

Commercial Forms and Regulations

The seeds are occasionally available from ethnobotanical specialty sources. The plant is not subject to any restrictions.

Cryogenine

Humulus lupulus Linnaeus

Hops

Family

Cannabaceae (Cannabinaceae; Hemp Family); sometimes placed in the Moraceae Family (cf. Zander 1994, 315*)

Forms and Subspecies

There is only one species,¹⁶⁴ a wild form with different varieties, but numerous cultivars (Edwardson 1952; Small 1978). The cultivars were formerly described as unique species (see “Synonyms”); they are now regarded as varieties. Today, morphological differences are the basis for recognizing five varieties: *Humulus lupulus* var. *cordifolius* (Miq.) Maxim in Franch. et Sav., *Humulus lupulus* var. *lupuloides* E. Small, *Humulus lupulus* var. *lupulus* L., *Humulus lupulus* var. *neomexicanus* Nelson et Cockerell, and *Humulus lupulus* var. *pubescens* E. Small. The most famous of the cultivated sorts are Saazer hops (Chechnya, Bohemia), Nittelfrüh hops (Bavaria), Tettnanger hops (Switzerland), Fuggles hops (England), Goldings hops (England), and Cascade hops (United States).

Synonyms

Cannabis lupulus (L.) Scopoli

Humulus americanus Nutt. (= *Humulus lupulus* var. *lupuloides* E. Small)

Humulus cordifolius Miq. (= *Humulus lupulus* var. *cordifolius* [Miq.] Maxim in Franch. et Sav.)

Humulus lupulus var. *brachystachyus* Zapalowicz

Humulus neomexicanus (Nelson et Cockerell) Rydberg (= *Humulus lupulus* var. *neomexicanus* Nelson et Cockerell) *Humulus volubilis* Salisb.

Humulus vulgaris Gilib.

Humulus yunnanensis Hu (may be a distinct species)

Lupulus communis Gaertn.

Lupulus humulus Mill.

Lupulus scandens Lam.

Folk Names

Bierhopfen, gemeiner hopfen, hop, hopf, hopfen, hoppen, hoppo, hops, houblon, hupfen, lupolo, luppolo, lupulo, vigne du nord

History

Pliny appears to have been the first to mention hops; Dioscorides was not yet aware of the plant. It is first referred to by name in medieval manuscripts, which also make mention of *homularien*, “hops gardens,” a reference not to cultivated fields but to large wild occurrences of the plant (DeLyser and Kasper 1994, 166). Hildegard von Bingen was the first to more precisely describe the plant’s psychoactive effects and its use as a preservative (in **beer**). Hops also appears in the works of all of the fathers of botany and was botanically described by Linnaeus.

Because no fossil precursors have been found, the phylogeny of the plant is entirely unknown. Hops is the closest relative of hemp (*Cannabis indica*, *Cannabis sativa*).

Today, hops is the most commonly used beer additive. This use was invented toward the end of the Middle Ages by Christian monks, who had a great interest in the anaphrodisiac qualities of hops flowers. Abbé Adalhard, in the *Statutae abbatiae corbej* (822 C.E.), was the first to document the use of hops in beer. However, the use of hops as a beer additive did not become commonplace until the sixteenth century, when the Bavarian Purity Law—the first German drug law—was promulgated (DeLyser and Kasper 1994, 168; Wilson 1975).

Distribution

Hops appears to have originated in northern Eurasia. Beer-loving humans spread the plant, which is now found throughout the world. Its presence in central Europe has been documented to as early as the eighth century. Today, hops is cultivated in all of the world's temperate zones. One of the most important areas of commercial cultivation is in Tasmania (Pearce 1976), which has the best air in the world, copious rainfall, and now—unfortunately—an overabundance of UV radiation (harmful to humans).

In central Europe, wild hops can be found growing in lowland forests and fens, on the sides of paths, and in hedges.

Cultivation

Female plants only are grown vegetatively, i.e., through clones and cuttings (Gross 1900).

Appearance

Hops is a 6- to 8-meter-long (in cultivation, it can grow up to 12 meters), perennial, dextrorotatory, twisting climber with three to five lobed, opposite leaves.

The plant is dioecious; the male flower is panicleate, the female a so-called strobile that becomes the fruit cone (hop cone or achene). The flowering period is between July and August, and the fruit cones ripen from September to October (in Australia and Tasmania, the ripening period is from April to May).

The stems are a source of fiber (similar to that of hemp, but not as durable). In former times, the fiber was made into linen cloth (DeLyser and Kasper 1994).

Today, the primary use of the sedative hops plant is as an additive to beer. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Psychoactive Material

—Female inflorescences (strobiles), also known as hops flowers (stroboli lupuli, lupuli stroboli) or hop glands (lupuli glandula)

Because the active constituents in the dried plant material are continuously broken down by oxidation, flowers that are more than one year old should not be used. The flowers must be harvested before they lose their glandular leaves.

Preparation and Dosage

A calming hops tea can be brewed with two heaping teaspoons of hops flowers and 1/4 liter of boiling water. To increase the sedative effects, valerian (*Valeriana officinalis* L.) may be added. Many breweries produce heavily hopped beer (pilseners), most of which have a very bitter taste and also are useful as soporific drinks.

Ritual Use

Hops—the “soul of Christian beer”—was first ingested “ritually” by monks to suppress their natural urges. These chaste men drank huge quantities of beer so that they could resist the temptations of the devil, i.e., their own desires.

However, hops has never played any particular role as a true ritual plant. In recent centuries, hops flowers have occasionally found use as an **incense** or an ingredient in incense blends. The plant was assigned to the planet Mars (Culpeper) and the element water.

The Omaha Indian tribe had a society of buffalo doctors (*te’ithaethe*) composed of men and women to whom the buffalo had appeared in a dream. The members of this society were specialized in the treatment of wounds. Their most important medicine consisted of wild hops, the root of the

nightshade *Physalis heterophylla* Nees., and American sweet cicely, *Osmorhiza longistylis* (Torr.) DC. They chewed these three ingredients and then spat them with some water onto the wounded region (Kindscher 1992, 269*).

Artifacts

Hops and the harvesting of hops are the subjects of many paintings and illustrations from the nineteenth and early twentieth centuries (e.g., *The Hops Harvest*, by William Henry Pyne, and *The Hops Pluckers*, by H. Stelzer).

Medicinal Use

Hops and hops extracts are used as sedatives in both folk medicine and biological medicine. The German Federal Health Office has recommended the use of hops tea as a sedative for unease, anxiety, and sleep disorders.

Hops pillows are used in aromatherapy to promote calm and to relieve difficulty in sleeping. These pillows have been known since at least the eighteenth century and were used in cases in which “opium had already failed” (DeLyser and Kasper 1994, 167).

In homeopathy, the agent *Humulus lupulus* is used primarily as a sedative.

Constituents

Hop flowers contain 15 to 30% resin, the bitter acids humulone and lupulone (and their auto-oxidation products), and an essential oil with mono- and sesquiterpenes (2-methyl-3-buten-2-ol, β -caryophyllene, **farnesene**, humulene, 2-methylisobutyrate, methyl-*n*-octylketone, myrcene, posthumulene-1, posthumulene-2), along with minerals, flavonoids, chalcones, polyphenoles, and catechines.

The yellow hops granules, which contain the bitter substance lupulone, are found in hops flowers. Lupulone, which has antibiotic properties, gives beer its characteristic bitterness. It has calming effects on humans and inhibits premature ejaculation. Also present are enzyme-inhibiting polyphenoles (Williams and Menary 1988).

Numerous chemical races (chemocultivars, chemovarieties) have been described for hops. These vary both quantitatively and qualitatively in their concentrations of bitter substances and essential oils (Wohlfart 1993, 448).

The leaves contain camphor oil, quercetin and quercetin glycosides (rutin; cf. *Psidium guajava*), proanthocyanidins (procyanidin, prodelphinidin), ascorbic acid, and quebrachitol (Wohlfart 1993, 448).

Because hops is very closely related to hemp (***Cannabis sativa***), attempts have been made to find cannabinoids (**THC**) in the former. To date, none has been detected.

Hops produces a yellow coloring agent that was once used in dyeing

Effects

Hops is a sedative and also has been characterized as a “mild hypnotic” (Roth et al. 1994, 406*; Lee et al. 1993). It has pronounced sedative effects, especially when used in combination with valerian (***Valeriana officinalis***), and is effective in treating sleep disorders and withdrawal from **diazepam** addiction (Brattström 1996).

The bitter substances have antibacterial, antimycotic, spasmolytic, and estrogenic effects. Because of the estrogenic properties of hops, chronic beer consumption can result in a feminization of the male body. This can be expressed in morphological changes, e.g., the development of what are known as “beer breasts.” The effects of hops are not affected by **alcohol** (Brattström 1996). Some of the

narcotic effects of the plant may be due to the presence of quercetin (cf. *Psidium guajava*).

A female hops plant (*Humulus lupulus*) with its characteristic flowers (hops cones).

Lupulone

“Of Hops:

The hop is warm and dry, and it has some moisture, and it is not very suitable for the use of man, for it causes melancholy to increase in man, and it makes the mind of man sorrowful, and it burdens his intestines. But with its bitterness, it keeps certain corruptions away from the beverages to which it is added, so that they are that much more imperishable.”

HILDEGARD VON BINGEN

PHYSICA 1.61

Fresh hops cones may irritate the skin (i.e., provoke allergic reactions) and produce a dermatitis known as hops pluckers’ disease. Hops eye, a kind of conjunctivitis, can also occur (Wohlfart 1993, 453 ff.)

Side effects (apart from the allergic reactions) and interactions are unknown.

Commercial Forms and Regulations

All hops drugs and preparations, including homeopathic preparations (*Humulus lupulus* hom. *HAB1*, *Humulus lupulus* hom. *PFX*, *Lupulus*, *Lupulinum* hom. *HPUS88*), are available without restriction.

The Japanese hops (*Humulus japonicus*) is not suited for use as a beer additive, although it may have psychoactive properties. (Photographed in Songlisan, South Korea)

Hyoscyamus albus Linnaeus

Yellow Henbane

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Hyoscyameae Tribe, Hyoscyaminae Subtribe

Forms and Subspecies

Three varieties are usually distinguished: *Hyoscyamus albus* L. var. *desertorum* *Hyoscyamus albus* L. var. *canariensis* *Hyoscyamus albus* L. var. *albus*

Synonyms

Hyoscyamus luteus nom. nud.

Folk Names

Altersum, apollinaris, bíly blín (Bohemia), diskí-amos (modern Greek), dontochorton (Cyprus), gelbes bilsenkraut, helles bilsenkraut, hyoskyamos, obecny (Bohemia), Russian henbane, sikran (Morocco), weiß bülsen, weiß bülsenkraut, weißes bilsenkraut, yellow henbane, zam bülsenkraut¹⁶⁵

A botanically accurate illustration of white henbane (= yellow henbane). (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

History

Hyoscamus albus was the most commonly used magical and medicinal plant of European antiquity (Schneider 1974, 2:184*). Though it is commonly referred to as yellow henbane today, it was more commonly known as white henbane in the seventeenth and eighteenth centuries. Much earlier it was described in detail by Dioscorides (4.69), who characterized it as the species with the greatest medicinal value. Pliny had similar things to say in his *Natural History* (first century):

The plant that is known to us as *apollinarus* and by some as *altercum*, and among the Greeks as *hyoskyamos*, is also ascribed to Hercules. There are several species of this: one [***Hyoscyamus niger***] has a black seed and almost purple-red flowers, is thorny at the calyx, and grows in Galatia; while the common species [***Hyoscyamus muticus*** (?)] is whiter, bushier, and taller than the poppy; the seeds of the third are similar to those of the wild radish; all three species produce frenzy [*insania*] and dizziness. The fourth species is soft, woolly, and fatter than the other species, has a white seed, and thrives in coastal areas. This [*Hyoscyamus albus*] is used by physicians, as is the one with the reddish seeds. But sometimes the white seed also becomes red when it is not yet ripe, and this is discarded. In general, the plant is not collected anywhere until it has become dry. It has the property of wine, which is why it unnerves the senses and the head. The seeds are used both by themselves and pressed as juice. This juice is pressed separately, as is that of the stems and leaves. The root is also made use of; but this, in my opinion, is a hazardous medicine. It is known that the leaves as well confuse the mind when more than four are taken in a drink; but according to the opinion of the elderly, in wine they will dispel fever. From the seeds is produced . . . an oil that will confuse the reason even if dripped into the ear, and it is remarkable that those who have drunk of it are given medicines as if for a poison, and yet it itself is used as a medicine. (Pliny 25.17, 35–37)

In England, the tobacco (***Nicotiana rustica***, ***Nicotiana tabacum***) imported from the New World was identified as a species of henbane (*Hyoscyamus peruvianus*). In the seventeenth century, the word *tobacco* was a kind of synonym for herbs that could be smoked. The so-called little yellow henbane (*Hyoscyamus luteus*) that was grown in many English gardens and appears to sow itself was known as English tobacco (Gerard 1633, 356*). This is a clear indication that henbane, a European native, was once numbered among the smoking herbs and may have been used for ritual purposes (cf. Golowin 1982*).

Today, yellow henbane has only a negligible pharmaceutical significance in the production of **tropane alkaloids** (Sauerwein and Shimomura 1991).

Distribution

Yellow henbane is found primarily in southern Europe (Spain, Italy, Greece) and in the Near East. It is very common in the Golan Heights of Israel (Dafni and Yaniv 1994, 12*). It prefers sunny locations close to the sea.

Cultivation

Hyoscyamus albus lives from one to three years and is the most easily grown of all henbane species. The seeds need only be loosely broadcast over sandy, clayey, or even poor soil. Water occasionally at first, but never overwater. This heat-resistant plant also thrives in crevices of old walls and between rocks. In the Mediterranean region, the plant flowers from April to May, while in central Europe (where it is grown as a cultivar), it flowers from June to September. The entire plant is harvested while still in bloom and hung by the roots in a well-aired location. Drying requires from three to six weeks.

Appearance

The plant grows to a height of 40 to 50 cm. Although the stems are vertical, the plant often takes on a bushy appearance. The light green stems and serrated leaves are very pileous, as are the calyxes and the fruits. On Cyprus and in Greece, the plant flowers from January to July. The flowers have a light

yellow color but often are dark violet on the inside. The seeds are whitish, ocher, or, less frequently, gray in color.

Psychoactive Material

- Leaves
- Herbage
- Seeds

Preparation and Dosage

The dried herbage can be smoked as a treatment for asthma, bronchitis, and coughs (in an amount equal to that contained in one cigarette). An aphrodisiac **smoking blend** can be produced by combining equal parts of the plant, hemp flowers (*Cannabis indica*, *Cannabis sativa*), and dried fly agaric mushrooms (*Amanita muscaria*). A “prophetic delirium” can be produced by inhaling the smoke of burning henbane seeds. The fresh or dried herbage can be added to wine and used as a remedy for pains and cramps. For information about dosages, see *Hyoscyamus muticus* and *Hyoscyamus niger*. In Morocco, it is said that twice the amount that can be taken up by the fingertips is sufficient to produce hallucinogenic effects (Vries 1984*).

Yellow henbane (*Hyoscyamus albus*) is a southern European plant.

Ritual Use

Henbane, and in particular this species, was certainly the most important ancient means for producing a trance state and clearly was ingested by many oracles and soothsayers (sibyls, Pythias). It was the “dragon plant” of the ancient earth oracle of Gaia, the “madness-inducing” plant of the Colchic oracle of the witch goddess Hecate, the “Zeus bean” of the oracle of Zeus-Ammon of late ancient times and the Roman Jupiter, and the “Apollo’s plant” of Delphi and other oracles of the god of “prophetic madness”¹⁶⁶ (Rätsch 1987).

The seeds, both alone and in combination with other substances, were usually burned as a ritual **incense** and inhaled, or the leaves were added to **wine** and drunk. When the soothsayers and prophetesses inhaled the smoke or drank the wine after their ritual ablutions, they called to the oracular deity, usually Apollo. When they had been possessed by the god, they would lose their human consciousness and proclaim the messages of Apollo through their mouths. Priests then “translated” (i.e., interpreted and proclaimed as the words of the oracle) their often unintelligible babbling, sighing, and groaning (Kerényi 1983; Maas 1993; Parke 1985, 1988; Roberts 1984).

In Morocco, the herbage or the seeds of *sikram*, “inebriant,” as the plant is known (cf. *Hyoscyamus*

muticus), are still burned for psychoactive purposes or used as an ingredient in psychoactive incenses, usually in combination with the seeds of ***Peganum harmala*** (Vries 1994*).

Artifacts

Curiously, there are no objects from ancient times that can be interpreted as representations of yellow henbane.

Medicinal Use

The legendary physician Hippocrates (ca. 460–370 B.C.E.) praised the medicinal use of henbane. His students, the Hippocratics, administered the seeds with wine to treat fever, tetanus, and gynecological ailments. Donkey’s milk was listed as an antidote for overdoses.

Yellow henbane was one of the most important analgesics of antiquity. According to Galen (ca. 130–199 C.E.), it was the main ingredient in a soporific and sedative agent known as *philonion*, which consisted of five parts saffron (***Crocus sativus***), one part each of *Pyrethrum*, *Euphorbium*, and *Spica nardi*, twenty parts each of white pepper (*Piper album* = *Piper nigrum*) and henbane, and ten parts opium (cf. **soporific sponge**).

On Cyprus, crushed leaves are still used as an analgesic plaster. The dried leaves are smoked together with tobacco (***Nicotiana tabacum***) as a remedy for asthma (Georgiades 1987, 2:56*). In the Golan Heights (Israel), various preparations of the leaves (decoctions, pastes) are used externally to treat skin diseases, open wounds, headaches, rheumatism, inflammations of the eye, and insect stings (Dafni and Yaniv 1994, 13*).

Constituents

The entire plant contains the **tropane alkaloids** hyoscyamine and **scopolamine**, along with aposcopolamine, norscopolamine, littorine, tropine, cuscohygrine, tigloidine, and tigloyloxytropine, in concentrations similar to those found in ***Hyoscyamus niger***.

Effects

The psychoactive effects of henbane were well known in ancient times and were characterized as *mania*, or madness. It should be noted, however, that the Greeks used the term *madness* to characterize not a pathological state but, rather, a dramatic alteration of consciousness:

Madness (*mania*): in kind there is but one madness, but in form it appears in a thousand ways. Its nature is a chronic condition of being out-of-oneself. . . . Even the inebriation of wine can heat one to insanity; even edible things produce frenzy, such as the mandrake [***Mandragora officinarum***] or henbane. But all of this does not fall under the name of madness; for it passes as quickly as it arrived. (Aretaeus, *De causis et signis morborum chronicorum* 1:6)

This “madness” was regarded as a “divine alteration of the normal, orderly condition”:

[W]e divided the divine kind of madness into four parts, each with its own deity. We attributed prophetic inspiration to Apollo, mystical inspiration to Dionysus, poetic inspiration to the Muses, and the fourth kind to Aphrodite and to Love. We said that the madness of love was the best kind. (Socrates in Plato, *Phaidros* 265)

Because henbane sedates the externally oriented consciousness, humans are opened up to the divine: “If the divine madness of prophetic enthusiasm is to come over humans, then the sun of

consciousness within them must set; the human light must disappear within the divine light” (Philos of Alexandria). In the same way, the “divining madness,” a kind of prophetic and clairvoyant state of consciousness (or a form of trance), was induced by the sacred “plant of Apollo” (cf. Pliny 26.140). Apart from this, the effects of this species of henbane are similar or identical to the effects produced by the other species.

This early modern illustration of white henbane (= yellow henbane) shows the characteristic flowers and fruit capsules. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“Now the effects of henbane, which were well known in ancient times, correspond to that which we know about Dionysian possession. Henbane causes states of delirium that are filled with visions and hallucinations and can develop into violent attacks of insanity; after this comes an irresistible need for sleep, which leads to very deep slumber.”

Hyoscyamus muticus Linnaeus

Egyptian Henbane

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Hyoscyameae Tribe, Hyoscyaminae Subtribe

Forms and Subspecies

One subspecies occurs in Morocco (Vries 1984*; 1989, 39*): *Hyoscyamus muticus* L. ssp. *falezles* (Saharan henbane).

Synonyms

Hyoscyamus betaefolius Am.

Hyoscyamus datura nom. nud.

Hyoscyamus insanus Stocks *Scopolia datora* Dun.

Scopolia mutica Dun.

Folk Names

Ägyptisches bilsenkraut, bhang, Cyprus henbane, Egyptian henbane, giusquiamo egiziano, Indian henbane, jusquiame d’Egypt, kohi-bhang, kohibung, mountain hemp, pitonionca (Greek, “dragon plant”), sakra, sakran, sekaran (Arabic, “the inebriating”), sikrane (Morocco), sikran sahra, ssakarân, traumkraut

History

Ancient Egyptians knew the henbane that grew among them as *sakran*, “the drunken one,” using a word borrowed from Aramaic (Kottek 1994, 129*). It is mentioned as a medicinal plant in a papyrus from the first century that was written in Greek. From that time until the present, the plant has been in use in Egypt as a medicinal and inebriating plant (Germer 1985, 169*).

In Arabia, the plant was used for criminal purposes. The powdered herbage, mixed with puréed dates (*Phoenix dactylifera*) or milk, was given to the intended victims, who then fell into a delirious state and were easily robbed (Morton 1977, 309*).

Today, Egyptian henbane is the most important of all *Hyoscyamus* species for pharmaceutical and economic purposes.

“Among the plant remains discovered in the animal necropolis at Saqqâra, which unfortunately could not be dated, were also parts of

H. [Hyoscyamus] muticus. It can be assumed that this poisonous plant as well was already part of the flora of ancient Egypt. Unfortunately, the medicinal texts from Pharaonic times do not contain any plant names that can be definitely construed as inebriants. Egyptian henbane was first mentioned as a medicinal plant in a papyrus written in Greek from the 1st century C.E. . . .

Today, this plant continues to be used as a medicine and inebriant in Egypt.”

RENATE GERMER

FLORA DES PHARAONISCHEN ÄGYPTEN [FLORA OF PHARAONIC EGYPT]

(1985, 169*)

Distribution

The plant prefers desert regions and occurs from Egypt to as far south as Sudan, and also in Syria, Afghanistan, Pakistan, and northern India.

Cultivation

The plant thrives in dry, rocky soils and a desert climate. The seeds (when they can be obtained) are scattered over sandy clay soil and pressed down lightly. The seeds should be well watered; later, the plant often can tolerate short dry periods. Even when the leaves appear wilted because of a shortage of water, a few drops of water will quickly restore them. After it is harvested, the herbage should be hung by the roots in a shady, airy location to dry (the plant may require up to six weeks to dry thoroughly).

The plant is cultivated for pharmaceutical purposes in Egypt, the former Yugoslavia, Greece, Pakistan, and India.

Appearance

The annual to biennial plant can grow as tall as 90 cm. The almost square stem is an important characteristic. Apart from this, it is quite similar to *Hyoscyamus albus* and *Hyoscyamus niger* (see there).

Psychoactive Material

—Leaves/herbage (folia hyoscyami mutici, hyoscyami mutici herba)

—Seeds

Preparation and Dosage

Either the fresh leaves are used as a poultice or the dried herbage and seeds are used internally. When taken internally, a single dosage should not exceed 0.25 g; the total daily dosage should not exceed 1.5 g. Because reactions to **tropane alkaloids** can vary significantly from one individual to another, it is difficult to provide dosage guidelines that apply to everyone. Anyone who wishes to experiment with Egyptian henbane for therapeutic or psychoactive purposes should exercise great care and begin with a very small dosage, which then can be slowly increased.

The dried leaves and seeds are suitable for use as ingredients in **incense** and **smoking blends**. The herbage also can be used to brew **beer** (see recipe under *Hyoscyamus niger*).

In Morocco, twenty seeds from the subspecies *falezles* are taken orally in a date (cf. **palm wine**), chewed thoroughly, and swallowed to induce hallucinations. They also are used as an ingredient in *majun* (see **Oriental joy pills**) (Vries 1984*; 1989, 39*).

Ritual Use

It has been suggested that the magical Homeric **nepenthes** was Egyptian henbane (Millsbaugh 1974, 488*). The ancient Assyrians sometimes brewed beer with henbane (Thompson 1949, 230*). According to Aelia (ca. 170–240 C.E.), when digging up this henbane, great care had to be exercised, similar to that taken with the mandrake (see *Mandragora officinarum*). Instead of using a dog to pull out the plant, however, a bird was tied to the plant (2:251).

It is very likely that Egyptian henbane was used as a ritual inebriant in ancient Egypt. Unfortunately, very little is known about this plant from late ancient times. It appears to have played a role in the cult of the dead; remnants recovered from the animal necropolis at Saqqâra have been definitely identified

as henbane (Germer 1986, 169*; Manniche 1989, 20*). However, it has not yet been possible to equate the plant with a particular hieroglyphic name. For this reason, the use of Egyptian henbane is known only from the Greek literature. A Greek papyrus from the Egyptian city of Arsinoites (third century B.C.E.) contains a quite interesting recipe, although it does not state what it was used for:

Other [recipe]: for the plaster he mixed three parts of white gum, one part of [copper] oxide, one-half part burnt copper, as much henbane juice as copper. Stir these [things] until smooth, dissolve in water, use.

A recipe with which one “can put a person to sleep for two days” (presumably to induce prophetic dreams) has come down to us in the late ancient Leiden magical papyrus:

Mandrake root [*Mandragora officinarum*], one ounce, licorice, one ounce, henbane, one ounce, ivy [*Hedera helix*], one ounce, you pound these together. . . . If you want to do this with skill, for every portion give the fourfold amount of wine [see *Vitis vinifera*], you moisten everything from morning until evening, you pour it off, you allow it to be drunk; very good. (Griffith and Thompson 1974, 149 f.*)

The Arabs liked to spice their coffee (see *Coffea arabica*) with crushed henbane seeds. It is possible that the plant also played a role in the secret rites of the dervishes or Sufis. In the twentieth century, the Towara Bedouins of the Sinai Peninsula were still smoking the leaves to produce “an inebriation with delirium” (Lewin 1981, 177*).

In India, *Hyoscyamus muticus* (the effects of which are more pronounced than those of *Hyoscyamus niger*) is used in place of opium (see *Papaver somniferum*) as an inebriant (Macmillan 1991, 421*). In the Punjab and in Baluchistan, the leaves are smoked together with *Cannabis indica* (Lewin 1981, 178*).

Egyptian henbane (*Hyoscyamus muticus*) in bloom.

A stem of *Hyoscyamus muticus*, showing the ripe seed capsules.

“I say to you, sacred plant, tomorrow I will call you into the house of Phileas, so that you may check the flow of the hands and feet [= rheumatism] of this man or this woman. I implore you with the great names of Jaoth, Sabaoth, who is god, who holds the earth fast and can make the sea stand still in spite of the number of rivers that flow into it, who dried the wife of Lot and transformed her into a pillar of salt. Take into yourself the spirit of the earth, your mother, and her power, and dry the flow of the feet or the hands of this man or this woman!”

HENBANE CONJURATION, LATE ANCIENT TIMES
(FROM ALEXANDER, SIXTH CENTURY)

Today, Egyptian henbane is known in some counterculture circles as “dream herb” (Lindequist 1993, 463) and is smoked by itself or in combination with other substances (**smoking blends**).

Artifacts

The magical henbane has been a plant of the gods since early times. According to Josephus Flavius, the turban (*mitra*) of the highest priest of the Hebrews was adorned with a branch of henbane (Kottek 1994, 129*). Apart from this, no artifacts are known.

Medicinal Use

In Nigeria, the herbage is used as an antispasmodic, to treat asthma, and for seasickness. In Iran, the smoke produced by burning the seeds is used to treat toothaches (Morton 1977, 308*). Moroccans use the seeds of the subspecies *falezles* for the same purpose (Vries 1984*).

Constituents

Egyptian henbane has the highest alkaloid content of any species of *Hyoscyamus*. The alkaloid content can be as much as 2% dry weight. Moreover, numerous methods have been discovered for increasing alkaloid concentrations in plants that are cultivated for pharmaceutical purposes (Misra et al. 1992; Oksman-Caldentey et al. 1991; Sevón et al. 1992; Sevón et al. 1993; Vanhala et al. 1992). The plant

forms chiefly hyoscyamine with only traces of hyoscyne (= **scopolamine**) and **atropine** (Misra et al. 1992). Also present are the **tropane alkaloids** scopolamine, aposcopolamine, norscopolamine, littorine, tropine, cuscohygrine, tigloidine, and tigloyloxytropene (Lindequist 1993). Amazingly, the flowers contain the highest concentration of alkaloids (2%), followed by the leaves (1.4 to 1.7%) and the seeds (0.9 to 1.3%). The lowest concentrations are in the stems (0.5 to 0.6%) (Morton 1977, 308*).

Effects

Of all the *Hyoscyamus* species, Egyptian henbane has the most profound inebriating effects. In India, some users are said to have developed feeble-mindedness, tarantism, and exhibitionism (Morton 1977, 308*). Other symptoms of higher dosages include hallucinations as well as possible unpleasant side effects (mydriasis, dry mouth, disturbances of coordination, flight of ideas, delirium) (cf. *Hyoscyamus niger*).

Commercial Forms and Regulations

According to *Hagers Handbuch der pharmazeutischen Praxis*, the herbage (*hyoscyami mutici herba*) can be obtained from a pharmacy without a prescription (in Germany) (Lindequist 1993, 464). Egypt does not permit the export of viable seeds (Morton 1977, 308*).

Hyoscyamus niger Linnaeus

Black Henbane

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Hyoscyameae Tribe, Hyoscyaminae Subtribe

Forms and Subspecies

The species can be divided into a number of varieties (cf. Strauss 1989):

Hyoscyamus niger L. var. α *agrestis* Kit.—flowers usually pale yellow

Hyoscyamus niger L. var. *annuus* Sims—annual, most commonly planted variety

Hyoscyamus niger L. var. *chinensis* Makino—Chinese variety

Hyoscyamus niger L. var. *niger*—wild form

Hyoscyamus niger L. var. *pallidus* (Wadst. et Kit.) Koch [= *H. niger* L. var. β *pallidus* Kit.)—biennial

Synonyms

Hyoscarpus niger (L.) Dulac

Hyoscyamus agrestis Kit.

Hyoscyamus auriculatus Ten.

Hyoscyamus bohemicus Schmidt (cf. ***Hyoscyamus* spp.**)

Hyoscyamus lethalis Salisb.

Hyoscyamus officinalis Cr.

Hyoscyamus pallidus Waldst. et Kit. ex Willd.

Hyoscyamus persicus Boiss. et Buhse

Hyoscyamus pictus Roth

Hyoscyamus sinensis Makino

Hyoscyamus syspirensis Koch

Hyoscyamus verviensis Lej.

Hyoscyamus vulgaris Neck

History

The ethnobotanist Wolf-Dieter Storl has conjectured that henbane was already in use in Eurasia for ritual and shamanic purposes in the Paleolithic period. When the Paleoindians migrated from Asia into the Americas via the Bering Strait, they brought their knowledge of the use of the plant with them. But because they were unable to find the plant they knew on the American continent, they substituted the similar and related tobacco (*Nicotiana tabacum*).

Henbane was used as a ritual plant by the pre-Indo-European peoples of central Europe. In Austria, two handfuls of henbane seeds were discovered in a kind of urn along with bones and snail shells; the find dates from the early Bronze Age (Graichen 1988, 69).

Ancient authors (Dioscorides, Pliny) were familiar with black henbane (see *Hyoscyamus albus*). It has been suggested that henbane was the magical Homeric **nepenthes** (Hocking 1947, 313). Carl Ruck believes that henbane, under the name *hyoskyamos*, was sacred to the goddess Deo-Demeter-Persephone, for her sacred animal was the sow, the “mother swine” (Ruck 1995, 141*)—perhaps being a “lucky swine” was a sign that a person had been allowed to ingest the plant.

In the Celtic regions, the plant was known by the name *belinuntia*, “plant of the sun god Bel.” The Gauls poisoned their javelins with a decoction of henbane. The healing properties of the plant were mentioned in medieval Anglo-Saxon pharmacopoeias. The plant’s name is derived from the Indo-European **bhelena* and is said to have meant “crazy plant” (Hoops 1973, 284). In Proto-Germanic, *bil* appears to have meant “vision, hallucination” or “magical power, miraculous ability” (vries 1993). There was even a goddess (Asin) known as Bil, a name interpreted as “moment” or “exhaustion.” She is understood to be the image in the moon or one of the moon’s phases. She may have been a henbane “fairy” or the goddess of henbane and may even have been a goddess of the rainbow: *Bil-röst* is the name of the rainbow bridge that leads to Asgard. *Bil* would then also be the original word for “heaven’s bridge” (Simek 1984, 48 f.).

秦州莨菪

Illustration of *lang-tang*, or Chinese henbane (*Hyoscyamus niger* var. *chinensis* Makino), from an ancient Chinese herbal (*Chêng-lei pên-ts'ao*, 1249 C.E.).

In the fourteenth century, Guy de Chauliac described a narcotic inhalation of henbane for medicinal purposes. A similar fumigation was mentioned in *The Thousand and One Nights* (Hocking 1947, 313, 314). But the plant was often used as a fumigant for magical purposes. Albertus Magnus, in his work *De Vegetabilibus* (ca. 1250; 6.362 f.), reported that necromancers (conjurers of the dead) used henbane to invoke the souls of the dead as well as demons.

In the infamous bathhouses of the late Middle Ages, henbane seeds were strewn over glowing coals in order to heat up the erotic atmosphere. The smoke, mixed with steam, appears to have induced strong aphrodisiac effects (Rätsch 1990, 148*).

Henbane was already being demonized during the Middle Ages and associated with alleged witchcraft (Müller-Ebeling 1991): “The witches drank the decoction of henbane and had those dreams for which they were tortured and executed. It was also used for witches’ ointments and was used for making weather and conjuring spirits. If there was a great drought, then a stalk of henbane would be dipped into a spring and the sun-baked sand would be sprinkled with this” (Perger 1864, 181*). In a Pomeranian witchcraft trial in 1538, “a witch confessed” that she had given a man henbane seeds so that he would run around “crazy” (= sexually aroused). In a file from an Inquisition trial, it was noted that “a witch admits” having once strewn henbane between two lovers and uttering the following formula: “Here I sow wild seed, and the devil advised that they would hate and avoid one another until these seeds had been separated” (Marzell 1922, 169*).

Henbane was also renowned as a **beer** additive with potent effects (Marzell 1922, 170*). This use was forbidden by the Bavarian Purity Law of 1516, the first German drug law (Kotschenreuther 1978, 83*).

The ancient use of henbane has been preserved into the present day, especially on Cyprus and in North Africa, primarily in Morocco and Egypt. There, henbane, often mixed with Spanish fly (cantharis; *Lytta vesicatoria*), is used to treat diseases of the female sex organs and as an analgesic, aphrodisiac, and inebriant (when mixed with hashish; cf. *Cannabis sativa*) (Venzlaff 1977*).

Distribution

Black henbane is the most widely distributed of all henbane species. It is found from Europe to Asia (Lauber and Wagner 1996, 804*) and grows wild from the Iberian Peninsula to Scandinavia (Morton

1977, 303*). It is common in North Africa (especially Morocco). In the Himalayas (Uttar Pradesh), it thrives at altitudes of up to 3,600 meters (Jain and Borthakur 1986, 579*). It has become naturalized in North America and Australia.

Cultivation

Propagation occurs via seeds that need only be pressed into sandy and clayey soil (in March and April). However, the likelihood of germination is greater when the seeds are allowed to germinate in seedling soil and then transplanted. Henbane also sows itself. Because the plant requires a nitrogen-rich soil, a pure nitrogen or calcium cyanamide fertilizer should be used. Do not overwater. The plant must be protected from potato beetles and henbane fleas (*Psylloides hyoscyami*) (Morton 1977, 304*).

Black henbane is grown for pharmaceutical purposes in central and eastern Europe (Romania, Bulgaria, Albania) and in India, although not as frequently as *Hyoscyamus muticus*. The plant material is collected or harvested during the middle of the flowering phase (June to August). The herbage dries very slowly.

The annual black henbane *Hyoscyamus niger* var. *annuus*, cultivated in northern Germany.

The ripe fruit panicle of black henbane (*Hyoscyamus niger*).

This flower, deep violet inside with fine violet veins outside, and otherwise yellow, is typical of black henbane (*Hyoscyamus niger* var. *niger*).

This bright yellow flower is typical of one variety of black henbane (*Hyoscyamus niger* var. α *agrestis*).

Appearance

Depending upon location and climate, black henbane can be an annual or a biennial; the former is more common. This upright plant can grow as tall as 80 cm and possesses undivided, serrated, very pungent leaves.¹⁶⁹ The alternate, quinquelobate flowers are in thick panicles. This *Hyoscyamus* species has the largest flowers of all the species in the genus. They are typically pale yellow with violet veins, but there is a unusual variety that has lemon or bright yellow corollas without veins. The black seeds are very small, and many remain in the fruit. In central Europe, the flowering period is from June to October. In the Mediterranean region, it begins in May and is usually over by July or August.

Black henbane is easily confused with ***Hyoscyamus muticus***, although the latter has smaller flowers that lack the violet veins and is more pilose. Black henbane is most similar to the species *Hyoscyamus reticulatus*, which has corollas that are purple-violet with reticulate veins. Also similar is yellow henbane (***Hyoscyamus albus***), which can be distinguished by its smaller, pure yellow flowers and the smaller, almost round leaves with few serrations.

The Asian variety known as *lang-tang* was first described as *Scopolia japonica* L. or *Scopolia sinensis* Hemsl. (see ***Scopolia carniolica***) and is still confused with these nightshades today (Li 1978, 19*).

Psychoactive Material

- Leaves (hyoscyami folium, DAB10 [Eur.], ÖAB, Helv. VII)
- Herbage without the roots (herba hyoscyami, hyoscyami herba)
- Seeds (hyoscyami semen); the seeds are listed in Chinese herbals under the name *tian xian zi* (Lu 1986, 80*)
- Henbane oil (hyoscyamus oil)

Preparation and Dosage

The chopped, dried herbage can be used as an ingredient in **incense** and **smoking blends**, for brewing **beer**, to spice **wine**, and as a tea (infusion, decoction). The seeds are most appropriate for use in incense recipes.

Dosages must be assessed carefully no matter what type of preparation is being considered. According to *Hagers Handbuch der pharmazeutischen Praxis*, the therapeutic individual dosage of prepared *Hyoscyamus* (with a standardized alkaloid content of 0.05%) is 0.5 g, and the daily dosage

1.5 g (maximum 3 g) (Lindequist 1993, 469). Apart from this, see the guidelines given for *Hyoscyamus muticus*.

Recipe for Henbane Beer

40 g dried, chopped henbane herbage (*herbae hyoscyamus niger conc.*)

5 g bayberry or another *Myrica* species (this aromatic ingredient is optional)

approx. 23 liters of water

1 liter (approx. 1.2 kg) brewing malt (barley malt)

900 g honey (e.g., spruce or pine honey) approx. 5 g dried top-fermenting yeast brown sugar

Boil the henbane and bayberry (if desired) in 1 liter of water (to ensure the necessary sterility). Leave the henbane in the water until it has cooled.

Sterilize the brewing vessel (plastic bucket) with boiling water. Then add the liquid malt to the bucket along with 2 liters of hot water and the honey. Stir until the ingredients are thoroughly dissolved. Add the henbane water together with the herbage and the bayberry. Stir thoroughly. Add cold water to make a total of approx. 25 liters of liquid. Pitch the yeast into the mixture and cover.

In order for the top-fermenting yeast to be effective, the wort should be allowed to stand in a warm location (20° to 25°C.). Fermentation will begin slowly because the tropane alkaloids will initially inhibit the yeast. The main fermentation will be over in four to five days, and the after-fermentation will then begin. The yeast will slowly settle and form a layer at the bottom of the bucket.

The beer can now be poured into bottles. A heaping teaspoon of brown sugar can be added to each (0.7 liter) bottle to promote an additional after-fermentation. Henbane beer tastes best when stored before use in a cool place for two to three months.

Oleum hyoscyamin infusum (henbane oil) is obtained by boiling the leaves in oil. It can be used externally for therapeutic or erotic massage.

Ritual Use

The Assyrians called henbane by the name *sakiru*. They used the plant for medicinal purposes, as an inebriating additive to **beer**, and as an **incense** (in combination with sulfur) to protect against magic (Thompson 1949, 230*).

In ancient Persia, henbane was known as *bangha*, a name that was subsequently applied to hemp (***Cannabis sativa***) and other psychoactive plants. Like the still uncertainly unidentified **haoma**, henbane had a religious significance as a ritual drug. Many Persian sources describe journeys to other worlds and visions that were evoked by various henbane preparations. Prince Vishtasp, who has gone down in history as the protector of Zoroaster (= Zarathustra), drank *mang*, a preparation of henbane and **wine**. After doing so, he fell into a deathlike sleep that lasted for three days and three nights. During this time, his soul journeyed to the Upper Paradise. According to a later source, he drank a mixture of *hom* (= haoma) and henbane in wine. Another Persian visionary named Viraz also made a three-day journey into other worlds with the aid of a mixture of henbane and wine. At the end of the third night, “the soul of the righteous [= Viraz] had the feeling of being in the midst of plants and inhaling scents. It sensed an intensely scented wind that blew from the south. The soul of the righteous inhaled this wind through its nose” (Couliani 1995, 141*).

Beer brewed with henbane acquires a red color and recalls the witches' beers (always described as red) that were consumed during the nocturnal Sabbats.

Botanical illustration of black henbane. (Engraving from Pereira, *De Beginselen der Materia Medica en der Therapie*, 1849)

“Sleeping within my orchard,
My custom always of the afternoon,
Upon my secure hour thy uncle stole,
With juice of cursed hebenon in a vial,
And in the porches of my ears did pour
The leperous distilment; whose effect
Holds such an enmity with blood of man
That swift as quicksilver it courses through
The natural gates and alleys of the body,
And with a sudden vigour doth posset
And curd, like eager droppings into milk,
The thin and wholesome blood.”

WILLIAM SHAKESPEARE *HAMLET* (1.5)

“But those who were best able to drink were aware that they should make themselves great; finally they all pranced around as if they

had eaten henbane seeds.”

GRIMMELSHAUSEN

SIMPLICISSIMUS (1.32)

The Celts knew black henbane as *beleno* and consecrated it to Belenus, the god of oracles and the sun. It was burned as a fumigant in his honor. Druids and bards who inhaled the smoke were taken to the “other world,” where they could communicate with fairies and other beings.

Henbane also appears to have been one of the most important ritual plants of the Vikings. Iron Age Viking graves have yielded hundreds of henbane seeds. The grave of a woman on Fyrkat (Denmark) is widely known. The most important grave good worn by the woman was a leather bag filled with countless henbane seeds (Robinson 1994, 544, 547*).

The oldest ethnohistorical evidence of the Germanic use of henbane as a magical plant is contained in the nineteenth book of the collection of church decrees (*Deutsche Bußbuch* [German Book of Atonement]) of the Bishop Burchard von Worms (died 1025). In one confessional question, the following ritual was described in astonishing detail:

Did you do as certain women are wont? If they need rain and have none, they gather several girls and select from these a small maiden as a kind of leader. They disrobe her and take her outside of the settlement to a place where they find hyoscyamus, which is known as *bilse* in German. They have her pull out this plant using the little finger of the right hand and tie the uprooted plant to the small toe of the right foot with any kind of string. Then the girls, each of whom is holding a rod in her hands, lead the aforementioned maiden to the next river, pulling the plant behind her. The girls then use the rods to sprinkle the young maiden with river water, and in this way they hope to cause rain through their magic. Then they take the young maiden, as naked as she is, who puts down her feet and moves herself in the manner of a crab, by the hands and lead her from the river back to the settlement. If you have done this or have agreed to do this . . . (in Hasenfratz 1992, 87*)¹⁷⁰

Such activities bring henbane into association with Donar, the Germanic god of thunder, weather, and storms. The Romans associated the plant with their god Jupiter, whom they equated with the Germanic god of thunder. In Switzerland, the folk name *jupitersbon*, “Jupiter’s bean,” is still used today.¹⁷¹ Of all the Germanic gods, Donar was the most enthusiastic drinker and the most able to hold his drink. Because of this, the strongly inebriating bock beers were consecrated to him. The **beer** of the thunder god was brewed with henbane, his plant. Because of the great demand for henbane, which is quite rare in Germany and northern Europe, ancient Germans planted henbane gardens specifically for the purpose of brewing beer. These fields of cultivated henbane stood under the protection of Wotan/Odin, Donar’s father, and were considered sacred. This history of many of the sites where these gardens once stood lives on in their names, such as Bilsensee (Henbane Lake), Billendorf (Henbane Village), Bilsengarten (Henbane Garden), and especially the Bohemian Plzeň (= Pilsen = henbane) (Römpf 1950, 271*).¹⁷²

During the Middle Ages and the early modern period of Europe, henbane was generally associated with witchcraft and magic, and especially with oracles and love magic. Lonicerus noted, “The old women use this plant to make magic, they say that anyone who carries the root around with them will remain invulnerable.”

It was also believed that henbane smoke could make one invisible, and the leaves were smoked in a pipe for this purpose (Hinrichsen 1994, 107). If any plant was in fact a true ingredient in **witches’ ointments**, it was henbane (cf. Marzell 1922, 168*):

Henbane poison acts quickly, for it is absorbed by the skin. And something else. It works especially quickly and intensively when taken up through the mucous membranes. But since henbane was also smeared on the broomsticks that men and women rode upon nude, the effects were profound. Among the women, the effects were considerably stronger and were felt more rapidly, as the mucous membranes of the anus and vagina came into contact with the broomstick during wild movements and the effects were immediate. (Hug 1993, 140)

In modern occultism, henbane seeds were used as fumigants to conjure spirits, especially for necromancy, or the conjuration of the dead. The following recipe was used to mix a powder for use as a fumigant (cf. **incense**):

1 part fennel root/seeds (*Foeniculum vulgare*)
1 part olibanum (*Boswellia sacra*)
4 parts henbane (*Hyoscyamus niger*)
1 part coriander seeds (*Coriandrum sativum* L.)
1 part cassia bark (*Cinnamomum cassia* Presl)

It was said that one should take this incense into a ghostly, dark forest and light a black candle and the incense vessel on a tree stump. The powder was to be burned until the candle suddenly went out. Then one would see the spirits of the night appear in the darkness from out of the smoke. To dispel the spirits, a mixture of equal parts of asafetida (“devil’s dirt”) and olibanum should be burned (Hyslop and Ratcliffe 1989, 15*).

Henbane was and still is used for psychoactive purposes in Asia. The *Pên-ts’ao Ching*, a very ancient Chinese herbal, contains the following information about the subspecies known as *lang-tang*:

[The seeds], when [properly prepared] and ingested over a long period of time, make it possible for one to go for a very long way, are useful for the mind, and increase power. . . . Moreover, through them one can communicate with spirits and see devils. If they are taken in excess, they will make one stupid. (Li 1978, 19*)

The seeds appear to have been used together with those of *Caesalpinia decapetala* as a psychoactive **incense** (Li 1978, 20 f.*).

In southern Kashmir (on the border of the Himalayas), the leaves, mixed with tobacco (*Nicotiana tabacum*), are smoked as a hallucinogen (Shah 1982, 297*). Unfortunately, nothing is known about the ritual or hedonistic context of this use.

Artifacts

Although henbane is an unmistakable member of the plant kingdom and has played a significant role in European culture and pharmaceutical history, no artifacts are known (cf. *Hyoscyamus muticus*). Similarly, the plant does not appear in depictions of witches from the early modern period. Henbane does occasionally appear as a floral element in the utilitarian art of the art nouveau movement. It is depicted on medicine thangkas used to illustrate Tibetan medicine.

Medicinal Use

The use of henbane smoke to treat toothaches (Rowell 1978, 263*) and asthma is widespread. In Darjeeling and Sikkim, henbane is used for these purposes and to treat nervous diseases (Biswas 1956, 71). In Uttar Pradesh, the plant is used to heal bones (Jain and Borthakur 1986, 579*). In Nepal,

the leaves are smoked to treat asthma and used as a sedative and narcotic (Singh 1979, 190*). In traditional Chinese medicine, the smoke of the seeds of Chinese henbane (*lang-dang-zi*) is inhaled in treatments for coughs, bronchial asthma, rheumatism, and stomach pains.

In Europe, preparations of henbane have been used for medicinal purposes since ancient times as analgesics and antispasmodics (cf. **soporific sponge**) to treat stomach cramps, whooping cough, toothaches, lower abdominal inflammations, neuralgia, and, in the form of cigarettes, asthma (Rätsch 1995a, 114–21*). Such use continued into the twentieth century.

Hildegard von Bingen recommended the psychoactive herbage as an antidote for alcohol inebriation: “But so that a drunken person will return to himself, he should lay henbane in cold water, and moisten his forehead, temples, and throat (with this), and he will fare better” (*Physica* 1.110).

A modern German folk medicinal recipe for treating fungal diseases (such as that caused by *Candida albicans*) instructs, “[P]our boiling hot meat broth over a third part stinging nettles [*Urtica dioica* L., *U. urens* L.], a sixth part henbane, a sixth part ground nutmeg [see *Myristica fragrans*], a pinch of saffron [see *Crocus sativus*], a third part balm [*Melissa officinalis* L.], and allow to steep in the refrigerator for four hours, then drink daily of this for four weeks” (*Natur*, June 1996, 60).

In homeopathy, the agent *Hyoscyamus niger* is used in accordance with the medical description to treat such ailments as unease, agitated states, sleep disturbances, and spasmodic digestive disorders (Lindequist 1993, 472).

Pharmaceutical adhesive bandages containing henbane extracts have been developed to treat travel sickness. They are adhered behind the ear (a traveler who is wearing such a henbane bandage is always on a trip . . .).

Constituents

The leaves and the herbage contain 0.03 to 0.28% **tropane alkaloids**. The principal alkaloids S-(–)-hyoscyamine (which is transformed into **atropine** by drying) and S-(–)-**scopolamine** are present in ratios of 2:1 to 1:1. Trace amounts of aposcopolamine, norscopolamine, littorine, tropine, cuscohygrine, tigloidine, and tigloyloxytropine are also present, as well are flavonoids (rutin) and **coumarin** derivatives (Lindequist 1993, 467).

The homeopathic mother tincture contains a minimum of 0.007 and a maximum of 0.01% alkaloids, calculated as hyoscyamine.

Effects

The parasympatholytic effects of the drugs and of preparations of black henbane are due to the principal alkaloids hyoscyamine (or **atropine**) and **scopolamine**. Peripheral inhibition with simultaneous central stimulation is characteristic. The primary effects last for three to four hours. Hallucinogenic aftereffects may persist for as long as three days. The alkaloids can cross via the blood into the placenta and have also been detected in breast milk (Lindequist 1993, 469).

Illustration of Chinese henbane (*Hyoscyamus niger* var. *chinensis*) on a Tibetan medical thangka (detail).

“Henbane is the treasure flower of the Underworld.”

MARGRET MADEJSKY (SEPTEMBER 1997)

Hyoscyamine

Scopolamine

Among the unpleasant side effects are severe dryness of the mouth, locomotor disturbances, and farsightedness. Overdoses can lead to delirium, coma, respiratory paralysis, and death. However, only a very few instances of lethality are reported in the toxicological literature (Lindequist 1993, 470). For this reason, the actual lethal dosage is not known precisely. The plant is also toxic to grazing cattle, deer, fish, and many species of birds. Pigs appear to be immune to the effects of the toxins (Morton 1977, 305*) and actually appear to enjoy the inebriating effects. This may be the source of the ancient name *hog's bean*.

Low dosages (0.5 to 1 liter) of beer brewed with henbane have inebriating effects, while higher dosages (1 to 1.5 liters) are aphrodisiac (henbane beer is the only beverage that makes one thirstier the more one drinks!). Very high dosages (more than 2 to 3 liters) can induce delirious and “inane” states, confusion, memory disturbances,¹⁷³ and “crazy” behaviors.

“In Prussia, [the black henbane] is placed under the roof or in the posts of the stall on the evening of Midsummer’s Day to protect against the witches. . . . In Mecklenburg, a cow that has been hexed is fumigated with henbane (duldill), which is plucked on Midsummer’s Day between 11:00 and 12:00 o’clock.”

SIEGFRIED SELIGMANN

DIE MAGISCHEN HEIL- UND SCHUTZMITTEL AUS DER BELEBTEN NATUR [THE MAGICAL HEALING AND PROTECTIVE AGENTS FROM THE ANIMATED NATURE]

(1996, 71*)

Commercial Forms and Regulations

The plant enjoys protected status and is included on the World Conservation Union’s Red List of endangered plants. The herbage requires a prescription and may be purchased only in a pharmacy. Henbane oil is available without restriction and may be purchased in shops other than pharmacies. Homeopathic preparations are subject to varying regulations (Lindequist 1993, 471).

“Horrible, stinking smoke of burned henbane swirls from a pan and lays itself upon the senses, as heavy as the hands of torment.”

GUSTAV MEYRINK

Hyoscyamus spp.

Henbane Species

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Hyoscyameae Tribe, Hyoscyaminae Subtribe

The genus *Hyoscyamus* Tourn. contains some twenty recognized species, all of which are indigenous only to Eurasia (D'Arcy 1991, 78*; Symon 1991, 141*). Some of these species are very rare and therefore do not play any significant ethnobotanical role. The species are similar, some very similar, in appearance, and thus sometimes can be difficult to identify (Lu and Zhang 1986, 67). All species contain the **tropane alkaloids** hyoscyamine and **scopolamine**, along with aposcopolamine, norscopolamine, littorine, tropine, cuscohygrine, tigloidine, and tigloyloxytropane (Lindequist 1993, 461).

Hyoscyamus aureus L.—golden henbane, gold henbane

In the Bible, this henbane species (the most common of the five species that occur in Israel) is mentioned by the name *shikrona* (Zohary 1986, 187*). Today, it is quite common in the Golan Heights (Dafni and Yaniv 1994, 12*). In Israeli folk medicine, the seeds and leaves are burned and the rising smoke is inhaled to treat toothaches and tooth decay. A decoction of the leaves is used in the form of eyedrops to treat eye inflammations; the crushed fresh leaves are mixed with olive oil and applied to open wounds. The steam produced by boiling the leaves or the smoke of burning leaves is inhaled as a treatment for asthma and other diseases of the respiratory tract. A poultice made of crushed leaves mixed with flour is applied externally to treat headaches (Dafni and Yaniv 1994, 13 f.*).

Hyoscyamus bohemicus F.W. Schmidt

This “Bohemian” species is found from northern China through central Asia and into the Near East. In traditional Chinese medicine, the seeds are used in a manner similar to those of *lang-tang* (*Hyoscyamus niger* var. *chinensis*) (Lu 1986, 80*; Lu and Zhang 1986, 71). To date, we know of no ethnic psychoactive use of this species. However, it is quite possible that in central Asia the species may be smoked in place of *Hyoscyamus niger*. This species also is regarded as a synonym or variety of *Hyoscyamus niger* (Lindequist 1993, 464).

Hyoscyamus boveanus (Dun. in DC.) Asch. ex Schweinfurth

This species is found in the eastern desert of Egypt. The Bedouins call it *saykaraan*, a word borrowed from Arabic that means “to become inebriated” (see *Hyoscyamus muticus*). In former times, the leaves and flowers of this little-known henbane species were smoked as an inebriant by the Bedouins and Nubians (some of whom still continue the practice), sometimes mixed with tobacco (*Nicotiana tabacum*) or other herbs (presumably *Cannabis sativa*). The plant is still sold in herb stands in the markets of the Nile Valley (Goodman and Hobbs 1988, 84 f.). This species is apparently synonymous with *Hyoscyamus niger*.

Hyoscyamus desertorum Boiss. (= *H. albus* var. *desertorum*)—desert henbane

The inhabitants of the Negev Desert and the northern Sinai smoke the dried leaves and seeds of this

plant as a treatment for toothaches, chest pains, coughs, asthma, and hysteria (Dafni and Yaniv 1994, 14*).

Hyoscyamus* x *györffy

This is a hybrid of ***Hyoscyamus niger*** and ***Hyoscyamus albus*** (Ionkova et al. 1994). It has no ethnopharmacological significance, although it does contain high concentrations of tropane alkaloids.

***Hyoscyamus pallidus* Kitaib.**

The Assyrians appear to have used this Near East species of henbane to treat toothaches and as an inebriant (Thompson 1949, 216*).

***Hyoscyamus physaloides* L.**

The Tungus roasted the seeds of this central and East Asian henbane species and brewed them into a drink. They drank this special “coffee” after eating, presumably for its inebriating effects (Rowell 1978, 263*). In Siberia, the entire plant, including the root, is used as an inebriant and opium substitute (see ***Papaver somniferum***). The root apparently also was used there as a potently inebriating, hallucinogenic **beer** additive (Hartwich 1911, 522*).

***Hyoscyamus pusillus* L.**

This species is found from northern China through central Asia and into the Near East, just as ***Hyoscyamus bohemicus*** is (Lu and Zhang 1986, 71). Likewise, its seeds are used in traditional Chinese medicine (Lu 1986, 80*). To date, we know of no psychoactive use of this species in any Asian culture. However, in central Asia it is quite possible that this species is used as an inebriant in place of ***Hyoscyamus niger***. The ancient Assyrians appear to have used this henbane species as an analgesic and inebriant (Thompson 1949, 216*). In Arabic, the plant is known as *sufairâ*.

“Today, the inhabitants of Siberia at Jenissei still use the plant [*Hyoscyamus physaloides*] as an agent of pleasure. They chop the leaves and the root into small pieces and add this to fermenting or already finished beer. One glass of this beer produces an utter confusion. The drinker begins to speak without knowing what. His senses are dulled, and he loses any sense of proportion. When he walks, he imagines that he is encountering insurmountable obstacles. Every moment, he sees his close and unavoidable death before him.”

CARL HARTWICH

DIE MENSCHLICHEN GENUßMITTEL [THE HUMAN AGENTS OF PLEASURE] (1911, 522*)

A strange and botanically unrecognizable species of Cretan henbane. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

***Hyoscyamus reticulatus* L.**

Like *Hyoscyamus desertorum*, this species is found only in the Negev Desert, where the Bedouins use it for folk medicinal purposes (Dafni and Yaniv 1994, 17*). The inhabitants of the Negev smoke the dried leaves to treat toothaches, as a sedative, and as an inebriant (Dafni and Yaniv 1994, 14*). In Syria and Iran, the plant is known as *bazr-i-banj*, *kohi bang*, *banj barri*, and *benj*. Physicians there use the seeds like opium (cf. *Papaver somniferum*) (Hooper 1937, 128*).

Folk Names

Black drink plant, cassena,¹⁷⁵ cassiana, cassina, cassinabaum, cassina tree, cassine, dahoon, dahoon holly, dahoon-holly, dahoon plant, holly-ilex, southern yaupon, yaupon, yupon

The fruits of the cassina tree (*Ilex cassine*), a native of the southern region of North America, are red berries. (Photographed in Florida)

The *Ilex* species that are used in North America to prepare the “black drink” are often confused with the closely related holly (*Ilex aquifolium*).

“The ‘black drink,’ or cassina, has a stimulating effect as a result of its high caffeine content. The drink was made and used in large areas of the Southeast and beyond as far as Texas. The use occurred in a strict ritual framework and was limited to high-ranking males. Its

emetic effects, which the literature often treats as a curiosity, were understood as an inner cleansing and preparation for contact with the spiritual world.”

ANDREA BLÄTTER

“DROGEN IN PRÄKOLUMBISCHEN NORDAMERIKA” [“DRUGS IN PRE-COLUMBIAN NORTH AMERICA”]
(1996A, 174*)

History

This plant was sacred to the Indians of Florida and the East Coast of North America and was used in the same manner as *Ilex vomitoria* to produce the “black drink” (Galle 1997, 165; Millspaugh 1974, 416*). The leaves were traded over long distances (Havard 1896, 40*).

Ilex cassine and *Ilex vomitoria* are still confused with one another today. Yet both can be easily distinguished from one another on the basis of their morphology and geographical distribution. The two species have sometimes been regarded as synonymous, which is inaccurate. Of course, the confusion has only been increased by the fact that Indians used the two plants in an almost identical manner, so that ethnographers did not make a distinction between the two.

Distribution

This North American *Ilex* species is indigenous to the margins of swamps and waterways. It usually is found near the coast and occurs in Virginia, Florida, and the Gulf Coast as far as the Colorado River (Texas). The variety *mexicana* is found in Mexico.

Cultivation

Unknown; presumably from seed

Appearance

This heavily branched tree can grow as tall as 8 meters and develops a projecting crown. The leaves are 6 to 10 cm long, lanceolate, tapered at the ends, and shiny on the upper surface. They are considerably longer and more narrow than the leaves of *Ilex vomitoria*. The fruits of *Ilex cassine* are luminously red and are more solitary than those of *Ilex vomitoria*, which are borne in thick clusters on the branches.

Cassina is often confused with holly (*Ilex aquifolium* L.,¹⁷⁶ which occurs in many varieties), especially in the ethnological literature.

Psychoactive Material

—Leaves

Preparation and Dosage

The fresh leaves are boiled in water (for at least ten minutes) until a black decoction has been produced. This tea is known as the “black drink” (cf. *Ilex vomitoria*).

A more potent preparation requires additional time: The leaves are first roasted and then boiled in water for at least half an hour. The decoction should be stirred well and/or poured into a different vessel repeatedly until it becomes foamy (Havard 1896, 40*). The taste of the black drink is slightly reminiscent of that of oolong tea (see *Camellia sinensis*).

Particularly potent versions of the drink were made for rituals and festivals, and various herbs and roots were added to potentiate and/or alter its effects. For example, plants that would induce vomiting—button snakeroot (*Eryngium aquaticum* L.), *Iris versicolor* L., and lobelia (*Lobelia inflata*)—were added. The participants in these rituals would often vomit violently, an act that was regarded as a

ritual purification (Havard 1896, 41*).

Sometimes fermenting agents were added to the black drink. In such cases, the drink had inebriating as well as potent stimulant effects (Havard 1896, 41f.*). Tobacco (*Nicotiana tabacum*, *Nicotiana spp.*) was a less common additive (Waldman 1985, 63*).

Ritual Use

The tribes of the coastal areas from the Carolinas to Florida and Texas, as well as inland tribes on both sides of the Mississippi, used cassina in the form of the black drink in such important annual ceremonies as the Green Corn Festival (also known as the Busk Ritual). The focus of this festival was the renewal of the world during the continually recurring passage of the year (Waldman 1985, 63*). Participants drank great quantities of the drink as part of this ritual's events. Sometimes only the men were allowed to partake of the black drink (Millsbaugh 1974, 416*).

“The leaves of the *Ilex cassine* tree were the primary ingredient of the renowned ‘black drink’ of the Indians of the Southeast. This drink induced immediate vomiting. It was generally used in the context of purification rituals, especially those that took place prior to war parties. The Creek used this emetic in almost all of their religious ceremonies.”

SERGE BRAMLEY

IM REICHE DES WAKAN [IN THE REALM OF THE WAKAN]

(1977, 84*)

At the tribal festivals of the Apalachicola tribe, copious amounts of black drink were offered in and consumed from large snail shells (*Busycon spp.*). Participants also smoked enormous amounts of tobacco (*Nicotiana rustica*).

For more on ritual uses, see *Ilex vomitoria*, the use of which was very similar to that of *Ilex cassine*.

Artifacts

In Florida and elsewhere, the large, sinistrorse shells of the sea snail *Busycon contrarium* Conrad were used as drinking vessels for the cassina drink (cf. Moore 1921). Some of these shells were engraved with markings representing mythical or shamanic beings.

Medicinal Use

The decoction was used primarily as an emetic (Millsbaugh 1974, 416*). The Cherokee, Alabama, Creek, and Natchez tribes used a decoction of the leaves and young shoots to induce vomiting, for urinary problems (gravel), as a sudorific, for dropsy, and for purification (including “moral”) (Moerman 1986, 232*).

Constituents

The leaves contain 0.27 to 0.32% **caffeine** (Havard 1896, 40*), along with a tanning agent and perhaps other substances. More recent data indicate that the leaves contain not caffeine but, more likely, **theobromine** (an important active principle in *Theobroma cacao*). Cyanidin-3-xylosylglucoside is present in the fruits (Alikaridis 1987, 126).

Effects

Because of its caffeine content, the black drink has both stimulating and strongly diuretic effects (Havard 1896, 41*). Higher dosages (to which individuals have varying responses) can induce vomiting. When additional substances were added to the drink to promote fermentation, the primary effects were certainly alcoholic, although it is likely that a person would not fall asleep as quickly as

with other alcoholic beverages. The addition of lobelia (cf. *Lobelia inflata*) or tobacco (cf. *Nicotiana* spp.) substantially increased the psycho-active and emetic effects.

Native Americans used the large shell of the sea snail *Busycon contrarium* as a drinking vessel for consuming the cassina drink. (From Moore, “Notes on Shell Implements from Florida,” 1921)

***Ilex* Species Used in the Production of Stimulating Drinks**

The genus *Ilex* consists of some four hundred to six hundred species that are found throughout the world, although they are concentrated in South America and Asia. Caffeoylequinic acid has been found in fifteen species. Purines occur in nineteen species. Many species contain **caffeine** and are or were used to produce stimulating beverages (Hartwich 1911, 452*).

Ilex guayusa Loesener

Guayusa

Family

Aquifoliaceae (Holly Family); Iliceae Tribe

Forms and Subspecies

Native Americans make a distinction between a wild form and the cultivated plant. Apart from this, no varieties or other forms have been described to date. It has been suggested that *Ilex guayusa* is a cultivated form of *Ilex paraguariensis* (Shemluck 1979, 156).

Synonyms

Ilex guayusa Loesener emend. Shemluck *Ilex guayusa* var. *utilis* Moldenke

Folk Names

Aguayusa, guañusa, guayupa, guayusa,¹⁷⁷ guayúsa, guayusa holly, guayyusa, huayusa, kopíniak (Záparo), rainforest holly, wais (Shuar), wayus (Achuar), wayusa, weisa (Jíbaro)

In Peru, the pepper plant *Piper callosum* Ruíz et Pav., which continues to enjoy great ethno-medicinal significance, is known in the local language as *huayusa*.

History

The ritual use of guayusa (whose name is a Quechuan word) in South America is very ancient. In Niño Korin (Bolivia), carefully wrapped leaves that had served as grave goods and were radiocarbon-dated to 355 C.E. were discovered. Chemical analyses revealed that the leaves still contained **caffeine**. The guayusa leaves were found together with paraphernalia for using snuff powder and devices for administering enemas. It is uncertain, however, whether the leaves were used in the making of stimulating **snuffs** or psycho-active **enemas** (Schultes 1972, 115 f.; Wassén 1972, 29). As early as the seventeenth and eighteenth centuries, Jesuits and other missionaries were suggesting that the plant was used for psychoactive and medicinal purposes (Schultes 1972, 126 ff.) It is possible that the use of guayusa was much more widespread in pre-Columbian America than it is today. It appears as though the great demand for the plant led to its large-scale cultivation (Schultes 1979, 144 f.).

The English botanist Richard Spruce (1817– 1893) made a precise record of the use of guayusa but surprisingly neglected to collect any botanical material (Schultes 1972, 120). The plant was first described in the early twentieth century (Loesener 1901). Even today, little is known about it, and much ethnopharmacological research remains to be done.

“The jungle Indians, for example, ingested guayusa as an emetic. The pot of guayusa, in which the leaves and water were transformed into a greenish brew, was always simmering. The drink caused anyone who partook of it to vomit out all of the food that had not been digested during the night. In this manner, they practiced medicine according to a primitive Hippocratic principle.”

VICTOR W. VON HAGEN

DIE WÜSTENKÖNIGREICHE PERUS [THE DESERT KINGDOMS OF PERU] (1979*)

Distribution

Guayusa occurs only in the tropical rain forests of the western Amazon region, chiefly in Ecuador, but also in northeastern Peru and southwestern Colombia (Schultes 1979, 144).

Cultivation

Propagation occurs only with cuttings that are grown in house gardens or in small plantations.

Appearance

This evergreen tree grows to a height of some 15 meters and is able to develop a very thick trunk (Patiño 1968, 314). The oval leaves are alternate and attenuate and grow to a length of 2.5 to 4.5 cm. The flowers grow in clusters from the leaf stalk axils (Shemluck 1979). Cultivated plants never produce flowers. After the initial description by Richard Spruce, more than one hundred years passed before a botanist, Homer Pinkley, was able to actually observe a guayusa flower. He reported that the flowers grow directly out of the trunk of the tree, are smaller than 3 cm in size, resemble a small bowl, and are pale yellow in color (Schultes 1972, 120 f.).

Ilex guayusa is very easily confused with *Ilex paraguariensis* as well as with other *Ilex* species (Shemluck 1979, 158).

Psychoactive Material

—Leaves

A report from the colonial period describes how the Indians would drink preparations of *tripiliponi*, a similar plant with somewhat larger leaves and less stimulating effects, together with lime or orange juice as a substitute for guayusa. Unfortunately, it has not yet been possible to determine the botanical identity of the *tripiliponi* plant (Patiño 1968, 311).

Preparation and Dosage

The plucked leaves are threaded onto a string and hung to dry either in the sun or in the house. The dried leaves are then boiled over low heat for at least ten minutes but preferably for half or even an entire hour.

Five leaves is often given as the dosage for one cup of tea (Schultes 1972, 132). A chemical analysis of a guayusa drink prepared by the Jíbaro (Achuar) revealed that it contained 3.3% **caffeine**. Each morning the men consume an average of 2.2 liters of the beverage. Most of them vomit half of this after some forty-five minutes. As a result, they ingest approximately 690 mg of caffeine, the equivalent of about eight cups of coffee (*Coffea arabica*) (Lewis et al. 1991, 25).

The Jíbaro often boil the leaves for hours or even overnight (Schultes 1972, 129). Although only the men of the Jíbaro are allowed to make guayusa (they call the tea *wayus*), the women and children also drink the decoction. The Jíbaro even give their dogs some of the tea before they go hunting so that they may better “see.”

These *Ilex guayusa* leaves from Ecuador are rich in caffeine.

Ritual Use

Because there is almost no evidence apart from that which has been found in graves, we can only conjecture about the pre-Columbian use of guayusa leaves in South America. However, a find of leaves in the grave of a shaman of the Tiahuanaco culture in Bolivia demonstrates that the leaves were both known and desired; they were held in high esteem and seen as a valuable grave good (Schultes 1972; Wassén 1972).

In 1682, the Spanish Jesuit Juan Lorenzo Lucero sent a letter to the viceroy of Peru, Melchor Navarra y Rocafull, in which he described guayusa:

They [the Jíbaro] mix together all of these diabolic herbs [*Banisteriopsis caapi*, *Brugmansia*, *Datura*, or similar plants] with *guañusa* and tobacco [*Nicotiana tabacum*], which was also invented by the devil, and allow this to boil until only a little liquid remains, the quintessence of evil, and the faith of those who drink this has been twisted by the devil through the fruit of enchantment and always to the disadvantage of all.” (In Patiño 1968, 311)

Guayusa has a long tradition as a love magic. In Ecuador, it is said that when a person gives guayusa to a lover, he or she will always return, no matter how far away the journey has taken him or her. The Indians of the eastern borders of the Andes drink guayusa tea as a tonic, as a ritual emetic, and to have “hunting dreams” (Müller 1995, 196*). The shamans or medicine men of the Kamsá Indians (Colombia) also use guayusa leaves, although we do not know how (Schultes 1979, 144).

The best-known example of guayusa use is the daily ritual use among the Jíbaro (Shuar, Achuar). Every morning, over a period of about one hour, and often in the company of one another, the men of the tribe drink some 2.2 liters of a guayusa decoction that has been boiled for at least one hour. They then stick their finger down their throat or tickle their throat with a feather so that they will vomit (Patiño 1968, 312). This causes them to regurgitate about half of the liquid they have consumed. The drink wakes up the men and gives them strength; also, they say that they will not need to eat anything all day (an important effect for a hunter) because of it. The vomiting that follows the consumption of these large quantities of guayusa does not appear to be caused by any substances contained in the drink but is instead a learned and trained body practice (Lewis et al. 1991). The vomiting is said to expel the undigested food from the previous day that burdens the stomach and also helps prevent an

overdose.

“The *wayus* ritual was approaching its inevitable end. The properties of this morning infusion are not merely social in nature: it is primarily an emetic. Small amounts of *wayus* have no particular effects. But here it is poured down without interruption, just like the manioc beer, until the large, black pot has been drunk to the bottom. Then a persistent nausea will begin if one does not expel the great quantities of liquid from the stomach as quickly as possible. . . . [They are devoted] to the daily habit of vomiting. Without this energetic purging which gives back to the organism the innocence of an empty stomach, the men would be unable to begin the day. The Achuar see the cleansing spewing of the physiological remnants as a good way to cast off the past and to experience their return to the world each morning with an entirely new bodily feeling.”

PHILIPPE DESCOLA

LEBEN UND STERBEN IN AMAZONIEN [LIFE AND DEATH IN AMAZONIA] (1996, 61*)

Large amounts of guayusa are also consumed before the most important tribal ceremonies, such as the women’s tobacco ritual, the victory celebration (*tsantsa*), and the (no longer practiced) manufacture of shrunken heads (Schultes 1972, 130 f.).

The Jíbaro say that guayusa can have narcotic or hypnotic properties, as a result of which they may obtain “little dreams” in which they can see whether a hunting expedition will be successful. Seeing heavily boiling guayusa in a dream is regarded as a good omen (Karsten 1935; Patiño 1968, 312 f.; Schultes 1972, 131).

The Shuar use the leaves as an **ayahuasca** additive (Bennett 1992, 492*). They also drink guayusa tea before, during, or after ingesting **ayahuasca** “to wipe out the bitter taste” and “to prevent a hangover”; moreover, “it gives power and strength in the use of ayahuasca” (Schultes and Raffauf 1990, 80*; Shemluck 1979, 157).

In addition to the Jíbaro, the following tribes are known to use guayusa: Omagua, Kokama, Pánobo, Kaschibo, Koto, Pioché, Lamisto, Kichos, Canelo, Mocoa, Aguano, Kandoschi, Sabela, Chívaro, Mayoruna, Tschayahuita, Tschamikuro, Chebero, Omurana, Yagua, Auischiri, Ssimaku, Ikito, Záparo, Yameo, and Pintsche (Patiño 1968, 312).

Artifacts

The Indians of Ecuador and northeastern Peru produce special guayusa drinking bowls or vessels known as *guayuceros* (Schultes 1972, 126 f.)

Medicinal Use

In the Amazon, it is believed that guayusa tea is good for calming the nerves and also for pregnant women. The tea is drunk for stomach problems and as an aphrodisiac (Shemluck 1979, 157). The Mocoa Indians use guayusa to treat liver pains, malaria, syphilis, and stomachaches and to regulate menstruation (Schultes and Raffauf 1990, 80*). The ashes of guayusa leaves, mixed with **honey** and barley, are said to provide a remedy for amenorrhea (absence of menstruation). Guayusa leaves, boiled together with the bark of *Paullinia yoco*, are drunk as a treatment for dysentery and stomach pains (Patiño 1968, 314). It is sometimes claimed that guayusa is useful for treating venereal diseases, chills, and infertility (Schultes 1972, 128).

The Jíbaro and other Indians drink guayusa as a “health tonic” (Schultes 1972, 120). It is said that a woman may become fertile if she drinks guayusa sweetened with **honey**. A woman who drinks a decoction of guayusa that has been sweetened with honey from a type of bee known as *apaté* will “immediately” become pregnant (Patiño 1968, 313). In Ecuador, the leaves are sold in herb markets as an “antispasmodic agent” (Schultes 1972, 135).

Constituents

The leaves typically contain 1.7 to 1.8% **caffeine**, and less frequently 3 to 4%. One wild plant actually

contained 7.6% caffeine—a world record for a plant's caffeine concentration. Also present are low amounts of theobromine (0.003 to 0.12%) and traces of other dimethylxanthines. Emetine and other substances with emetic effects (such as those found in ipecacuanha and similar plants; cf. *Psychotria* spp.) have not yet been detected (Lewis et al. 1991, 25, 27, 28).

The caffeine contained in guayusa leaves maintains its quality for a long period of time. Samples dating to over one thousand years ago have been found to contain more than half of the concentration (1.0%) of more recent leaves (1.8%) (Holmsted and Lindgren 1972).

It is possible that triterpenes and chlorogenic acid are also present, as both are well represented in the genus *Ilex* (Schultes and Raffauf 1990, 79*).

Effects

Guayusa tea has potent stimulating effects that will wake up those who ingest it and keep them awake. The emetic (inducing vomiting) effects that have been so often described are actually culturally learned and do not have any pharmacological basis (Lewis 1991, 27). The Jíbaro do not like to use wild plants with high caffeine concentrations, as they are not interested in a caffeine overdose. Instead, their intention is to produce a very specific kind of stimulation that they do not want to exceed. The Achuar report that the typical symptoms of an overdose include severe headache, bloodshot eyes, and disturbing hallucinations (pseudohallucinations, delusions, illusions) (Lewis et al. 1991, 27).

Commercial Forms and Regulations

Living guayusa plants are sometimes available through ethnobotanical specialty sources. The dried leaves are normally available only in Ecuador. The plant is not subject to any legal restrictions.

Ilex paraguariensis Saint-Hilaire

Maté Bush

Family

Aquifoliaceae (Holly Family); Iliceae Tribe

Forms and Subspecies

This variable species is difficult to separate into varieties, forms, and subspecies (Hölzl and Ohem 1993, 508). Occasionally, wild maté is described as *Ilex paraguariensis* var. *genuina*. Three varieties are distinguished along the Rio Grande do Sul (Brazil): var. *talo roxo* (“red stem”), var. *talo branco* (“white stem”), and var. *piriquita*. Botanically, the species is divided into three varieties:

Ilex paraguariensis St.-Hil. var. *paraguariensis*

Ilex paraguariensis St.-Hil. var. *sincorensis* Loes.

Ilex paraguariensis St.-Hil. var. *vestita* (Reiss.) Loes.

One of the earliest European illustrations of the Paraguayan and Argentinean maté tree, together with the leaf that is the source of the stimulating tea. (From Pedro de Montenegro, *Materia médica misionera*, seventeenth century)

History

In South America, maté appears to have been used as an agent of pleasure and a ritual drug for millennia. Pre-Columbian graves in the Andes region of Peru have yielded maté leaves. In northern Argentina, Indian graves containing silver maté drinking utensils have been discovered. The Guaraní Indians used maté for shamanic purposes as well.

During the early colonial period, attempts were made to enslave the Indians. The Spanish kings, however, quickly forbade this practice, whereupon the Jesuits forced the Indians onto reservations and compelled them to establish maté plantations so that they could become a part of the cash economy. In commemoration of this “great achievement” of Christian charity, maté was first known by the name *Jesuit tea* (Schröder 1991, 102*).

In Argentina and Paraguay, non-Indians have also been cultivating maté trees since 1606 (Santos Biloni 1990, 196*). In Brazil, maté has been proclaimed the symbolic tree of Rio Grande do Sul.

The physician and botanist Aimé Bonpland (1773–1858), one of Alexander von Humboldt’s traveling companions, described the plant that was the source of maté in 1821. The plant received its valid botanical name the following year.

Distribution

The true maté bush is found only between the twentieth and thirtieth parallels of South America. Its range extends over parts of Paraguay, northern Argentina, Uruguay, Brazil, and Bolivia (Hölzl and Ohem 1993, 508).

Cultivation

Maté was originally an underwood plant in the extensive araucaria forests. Today, maté plants often stand alone, because the large forests have been cut down. In Argentina, maté is grown on large plantations (*yerbatales*). The main source of maté, however, is Brazil. When grown on plantations, the bush is maintained at heights between 2 and 5 meters. The harvest takes place between May and September of every second year.

Propagation occurs via the seeds but is rather complicated, as it entails a six-month stratification:

The distribution is performed by birds (pheasant species). They peck up the seeds, and as these pass through the stomach and intestinal tract, the seed's hard outer shell is destroyed to such an extent that it can germinate after being eliminated. If the seeds are placed in the soil without any preparation, then the seed is unable to break through the shell and it will rot in the ground. The Jesuits solved the problem in their own way: they mixed the seeds into chicken feed! (Schröder 1991, 104*)

The maté tree prefers alluvial soils and does not tolerate clayey or calcareous soils. The young trees grow rapidly, and the first harvest occurs when they are three to six years old. During the harvest, up to 95% of the leaves (including branches) may be removed from the trees. Trees remain productive for fifty to sixty years.

The leaves of the maté bush (*Ilex paraguariensis*) are quite large.

Appearance

This evergreen tree typically has a light-colored bark. It can attain heights of 15 to 20 meters and has an oblong-oval crown. The alternate leaves, which can grow from 6 to 20 cm in length, have a serrate-crenate margin and a leathery upper surface. They are dark green on the upper side and light green below. The closely clustered axillary inflorescences have forty to fifty flowers with tetraphyllous or pentaphyllous calyxes. The reddish stone fruit is round and contains four to eight seeds. The trees blossom in the (South American) spring, i.e., from October to November. Although most plants are male, there are also female and even dioecious flowers (Schröder 1991, 103*).

Maté is sometimes confused with *Ilex aquifolium* L., as both species display considerable variation and can thus exhibit an astonishing degree of similarity. *Ilex aquifolium*, however, does not contain any **caffeine** and is therefore unsuitable for use as a maté substitute (Hölzl and Ohem 1993).

The very similar *palo de yerba* (*Ilex argentina* Lillo [syn. *Ilex tucumanensis* Speg.]) occurs in Argentina. The leaves of this plant were once used as a maté substitute (Santos Biloni 1990, 37*). In Chile, one plant (*Citronella mucronata* [R. et P.] D. Don) from the Family Icacinaceae is known as *yerba mate de Chile* (Mösbach 1992, 90*).

Psychoactive Material

—Leaves (mate folium, folia mate, mate)

The tea that is made from the leaves is known variously as maté tea, Jesuit tea, mission tea, Paraguay tea, parana tea, St. Bartholomew's tea, maté, thé du Paraguay, chimarrão, erva maté, and yerba maté.

In South America, the following species are used as substitutes for or additives to the true maté: *Ilex brevicuspis* Reiss., *Ilex conocarpa* Reiss., *Ilex dumosa* Reiss., *Ilex microdonta* Reiss., *Ilex pseudobuxus* Reiss., and *Ilex theezans* Mart. (Hölzl and Ohem 1993, 508). In Bolivia, *Coussarea hydrangeaefolia* Benth. et Hook. (Rubiaceae) is regarded as the true maté (Hartwich 1911, 452*).

Botanical illustration of *Ilex paraguariensis*. (From Köhler's *Medizinalpflanzen*, 1887/89)

“Maté is an agent of pleasure for invigorating one's powers and to increase the sense of well-being. It is the national drink of southern Brazil, northern Argentina, Paraguay, Uruguay, and Chile. The use of maté is part of the sociocultural environment; the guest is greeted with the drink; it is seen as the equivalent of the North American peace pipe. Maté is derived from the Guaraní word *mati*, which originally referred to the drinking vessel; the term was applied to the drink, the drug, and the plant.”

JOSEF HÖLZL AND NORBERT OHM “ILEX”
(1993, 511)

“Yari's slender body transformed itself into a tree trunk and the dainty arms and delicate fingers became the small yerba leaves. ‘The seeds of your blue fruits will open only if a bird has eaten and then eliminated them. You will give yourself to all and be desired by all, you shall calm, console, enliven.’ . . . Since that time there has been yerba, whose tea calms, consoles, enlivens. It is also called maté. Every year, the indios travel to Mbaracuyurú to harvest its leaves. Yet every year the bravest of them are torn apart there by jaguars and strangled by Sucuriús. Meanwhile, a gentle boy died of confusion. Caa Yari will also make jokes and caress, and she lives with the

glowing love of a woman who must wait for a year. The young man who experiences such a thing will not want to eat again. Crazy with love, he will wander confused in the forest until he dies.”

A GUARANÍ TALE

IN *DSCHUNGELMÄRCHEN* [JUNGLE FAIRY TALES]

(MELZER 1987, 57f.)

Preparation and Dosage

The freshly harvested leaves and twigs are quickly heated at a high temperature so that they will retain their green color (if dried slowly, they turn black). They are then dried, slowly burned, or roasted over a wood fire or reheated in a metal cylinder (a process known as toasting). Today, a variety of industrial processing techniques are used. The dried, roasted leaves are powdered or finely chopped and sold commercially. In Europe, a distinction is made between green and brown maté (also known as toasted maté leaves or *mate folium tostum*).

Maté has an acrid, smoky, mildly astringent taste. The normal individual dosage is 2 g of dried leaves to one cup of water. Hot, but not vigorously boiling, water is poured over the leaves, and the mixture is allowed to steep for five to ten minutes. The effects of infusions that are allowed to steep for only a short period are more stimulating, but even cold-water infusions are pleasant tasting and stimulating (Schröder 1991, 103*).

In South America, maté almost always is drunk through a straw (*bombilla*) from gourd containers or bottles known as *cuias*. The maté powder (*chimarrón*) is placed in a bottle and hot water is then added. After the liquid has been sucked out, new water is poured over the used leaves. This process can be repeated several times and has led to a ritualized use of maté. Maté is usually consumed unsweetened. Sometimes, lime or lemon juice may be added.

In Paraguay, maté was typically sweetened before drinking. The Guaraní Indians sweetened the tea with the dried, crumbled leaves of the sweet-tasting *Stevia rebaudiana* (Bertoni) Hemsl. (Compositae), which contains not sugar but, rather, sweet-tasting **diterpenes** (König and Goez 1994, 791; Soejarto et al. 1983, 9). The Guaraní call the *Stevia* plant *kaá hêê*, “sweet herb.” *Kaá* is also their name for the maté tree (Schröder 1991, 102*).

Ritual Use

Many Indian legends portray the tree as one of the most important plants made by the god of creation. During the colonial period, the Spanish were of the opinion that Santo Tomé (Saint Thomas) had brought the tree and the drink to the Indians. The Guaraní and Caingang venerated maté as a magical plant that enabled them to establish contact with the supernatural world. They believe(d) that a spirit named Ka’a Yary lives in the maté tree and protects good, industrious workers but punishes those who do not believe in plant souls (Cadogan 1950; Schaden 1948).

The stimulating effects of maté were discovered by Indian shamans in southern South America. They drank potent decoctions for stimulation and to produce the wakefulness they needed for their nocturnal rituals. The Indians developed their ritual consumption of maté in the pre-Columbian period. They sat together in circles and passed around a vessel filled with maté leaves and hot water. The stimulation was enjoyed communally and was used for telling one another stories.

Today, just as England has its five o’clock tea (cf. *Camellia sinensis*) and Yemen its afternoon khat chewing (cf. *Catha edulis*), the communal drinking of maté is a part of the daily life of all social circles in contemporary southern Brazil, Paraguay, and northern Argentina (Chaco).

Artifacts

Almost all of the artifacts associated with maté are objects used in its consumption, especially the *cuias*

(gourd bottle) and the *bombilla* (sucking straw). Nowadays, *cuias* are often made of pure silver, although they are still often made in the shape of a bottle gourd. The sucking tubes are usually simple in appearance, and the best are also made of silver.

Medicinal Use

Among the Indians of Argentina, it is customary to ingest almost all of their medicinal herbs in maté tea (Filipov 1994, 182*). In the countries in which it is produced, maté is generally thought to strengthen the stomach and is used to treat rheumatism and fever and as a plaster for sores (Hölzl and Ohem 1993, 511).

The men of the Maká Indians (Chaco, Paraguay) produce an aphrodisiac by pouring hot water over maté and the penis bone of a coati (*Nasua nasua* [Procyonidae]) (Arenas 1987, 285 f.*).¹⁷⁸ When made as a cold-water extract, the drink is known as *tereré*. To treat stomach ailments, they make a tea of maté and the bark of *Tabebuia caraiba* (Mart.) Bur. (293).¹⁷⁹

Homeopathic medicine uses an essence of the bark of the closely related species *Ilex verticillata* (L.) A. Gray under the name *Prinos verticillatus* (Schneider 1974, 2:193*). Maté hom. *HAB34* or *Ilex paraguariensis* hom. *HPUS88* is used in accordance with the medical description to treat digestive weakness and other problems (Hölzl and Ohem 1993, 511).

In Europe, maté is used primarily as an aid to dieting and fasting. Because of its stimulating effects and relatively high vitamin content, it is an ideal beverage for use during fasts.

Constituents

The leaves contain 0.4 to 1.6% **caffeine**, 0.3 to 0.45% theobromine, and traces of theophylline (cf. *Theobroma cacao*). In addition to these purines, the leaves also contain vitamin C, 0.01 to 0.78% **essential oil**, an enzymatic substance, caffeoylquinic acid (chlorogenic acids 3,5-, 4,5-, and 3,4-dicaffeoylquinic acid, neochlorogenic acid, cryptochlorogenic acid), flavonoids (isoquercetin, camphor oil glycosides, rutoside), saponines, menisdaurine, and several phenols (Hölzl and Ohem 1993).

Effects

Maté has a stimulating and invigorating effect that refreshes both the body and the mind. High dosages can produce euphoric feelings with clear wakefulness. The appetite is usually suppressed. Because these effects are induced by at least three different substances (caffeine, theobromine, and chlorogenic acid), the effects of maté are not identical to those of caffeine alone. Side effects or unwanted effects are unknown (Hölzl and Ohem 1993, 511).

According to reports from Guaraní shamans, the consumption of large quantities of maté enables them to enter clairvoyant trance states.

Commercial Forms and Regulations

Maté is available throughout the world without restriction. The form typically sold in Argentina (*la hoja elaborada con palo*) consists of crushed leaves together with pieces of stems. In Germany, maté is also sold in tea bags. This material usually consists of toasted maté to which aromatic substances have been added. Recently, tea bags containing both maté and guaraná (*Paullinia cupana*) have appeared on the market.

According to the *DAB86*, maté leaves should have a caffeine content of no less than 0.6% (Hölzl and Ohem 1993, 510). Commercially available maté tea is occasionally adulterated with material from related species (*Ilex brevicuspis* Reiss., *Ilex dumosa* Reiss. var. *guaranina* Loes.) (Santos Bilonio 1990, 196*).

Ilex vomitoria [Solander in] Aiton

Yaupon

Family

Aquifoliaceae (Holly Family); Iliceae Tribe

Forms and Subspecies

Two subspecies and one form are now botanically accepted:

Ilex vomitoria Ait. ssp. *vomitoria*

Ilex vomitoria Ait. ssp. *chiapensis* (Sharp) E. Murr.

Ilex vomitoria Ait. f. *pendula* Foret et Solymosy

A variety with pileous leaves and longer hairs on the branches has been described for Mexico (Chiapas) (Sharp 1950): *Ilex vomitoria* [Soland. in] Aiton var. *chiapensis* A.J. Sharp. Another variety has become known under the name *Ilex vomitoria* [Soland. in] Aiton var. *yawkeyii* Tarbox (Schultes 1950, 99).

Ilex vomitoria, also known as yaupon, has relatively small, round leaves.

History

We do not know with certainty how long *Ilex vomitoria* has been used in southeastern North America. It was certainly already known in prehistoric times, for it was described in the first sources from the colonial period (cf. ***Ilex cassine***).

Perhaps the earliest description of the yaupon plant in the botanical literature is contained in Bauhin and Cherler’s great encyclopedia, *Historia plantarum universalis* [Universal History of the Plant World] (1651). In contrast, the “black drink” (and its stimulating and appetite-suppressing effects) had already been described in 1542 by Nuñez Cabeça de Vaca in his *Relación y comentarios*.

During the American Civil War, toasted yaupon leaves were used as a substitute for tea (***Camellia sinensis***) and coffee (***Coffea arabica***). Because of its low **caffeine** concentration, the plant is only rarely used today, as many other sources of caffeine are now widely available. Yaupon was once

thought to be the source of maté (Schneider 1974, 2:192*; cf. *Ilex paraguariensis*).

The Cherokee are said to have used a “southern yaupon” form as a “hallucinogen” to “evoke ecstasies” (Moerman 1986, 232*). Unfortunately, we have no pertinent recipes or other information about special additives that may have been used to make the mildly caffeinated black drink into such a potent beverage.

Distribution

The tree is indigenous to the southeastern regions of North America and to areas in the proximity of the North American Caribbean coast. One variety or subspecies occurs in Mexico (Chiapas) (Sharp 1950).

Cultivation

The tree requires moist to moderately dry soil. The plant presumably is propagated from seeds. Because the Indians collected only wild material, they did not develop any methods of cultivation.

Appearance

This evergreen tree can grow to a height of 6 meters. It has multiple stems and many branches and produces white flowers and scarlet berries. The shiny, emarginated leaves are alternate and are similar in appearance to those of *Ilex para-guariensis*, although they are usually smaller. The more rounded leaves on the upper branches are some 4 cm in length and are distinctly smaller than those of *Ilex cassine*. The fruits ripen in October.

Psychoactive Material

—Leaves

—Fruits

Preparation and Dosage

Hartwich mentioned three methods for making the “black drink” or “yaupon holly tea”: “1. by decocting the fresh leaves, 2. the dried leaves, 3. a decoction which must ferment and which is then said to be inebriating” (Hartwich 1911, 468*). Unfortunately, we have no information about the potential fermenting agent for this drink. Saw palmetto fruits may have been used as an additive (cf. **palm wine, wine**).

The Mikasuki Indians, who now live in the Florida Everglades (to where they were deported), still use a ceremonial drink called black drink at certain tribal rituals. It is obtained or fermented from one or more Everglades plants. It is possible that it is made not from an *Ilex* species but from the fruits of the saw palmetto (*Serenoa repens* [Bartr.] Small [syn. *Serenoa serrulata* (Michx.) Nichols]; cf. **palm wine**). Neither the drink nor its associated ritual has been studied to date.

Ritual Use

The Indians of the southern coastal region of North America generally believed that *Ilex vomitoria* and the black drink prepared from it enabled them to attain a state of ceremonial purity, by means of which they were ideally prepared for all rituals and ceremonies (Moerman 1986, 232*). Among the Cherokee, only those warriors who had already proved their courage were allowed to partake of the black drink. It is said to have induced ecstatic states (Hamel and Chiltoskey 1975, 62).

In Oklahoma, the black drink was consumed by socially high-ranking or important personages to cleanse themselves for their public duties. Otherwise, the drink brewed from *Ilex vomitoria* was used in precisely the same manner as that prepared from *Ilex cassine*.

Artifacts

In Oklahoma, the large shells of the sea snail *Busycon contrarium* Conrad or *Busycon perversum* L.¹⁸⁰ were decorated and used for drinking yaupon ritually; they resemble Mesoamerican objects (cf. *Ilex cassine*).

Mark Catesby's comprehensive work *The Natural History of Carolina, Florida and the Bahama Islands* (1754) contains an illustration (fig. 25) of a yaupon branch with fruits, around which a snake is coiled. It is possible that the artist's intent was to express the medicinal or sacred quality of the plant.

Medicinal Use

The primary ethnomedicinal use of the plant was as an emetic, an agent for inducing vomiting (Schultes 1950). The Cherokee used yaupon in the same manner as *Ilex cassine*, i.e., to treat dropsy and gravel (Hamel and Chiltoskey 1975, 62).

Constituents

The leaves contain relatively low amounts of **caffeine**, typically between 0.27 and 0.32%, but approximately 7% tanning agents (Hartwich 1911, 468*; Power and Chestnut 1919). More recent studies (Stone County, Mississippi) found only 0.09% caffeine, along with 0.04% theobromine and no theophylline. Substances with actual emetic effects have not yet been reported (cf. *Ilex guayusa*). The fruits contain cyanidin-3-xylosylglucoside.

Effects

The black drink appears to have produced only mild stimulating effects. In the literature, it is occasionally claimed that a more potent decoction is able to “induce hallucinations” (Turner and Szczawinski 1992, 156*). The emetic effects are also questionable. The “vomiting rituals” of the Indians that were previously described presumably entailed ritual methods (e.g., putting one's finger in one's throat; cf. *Ilex guayusa*) that did not depend upon any pharmacological effects.

Commercial Forms and Regulations

None

“[Yaupon] is highly regarded by the Indians and used for many purposes, which gives it an even greater character. They say that the virtues of the shrub have been known since the earliest times and that for their use, it has always been prepared in the same manner as today. After drying or roasting the leaves in a pot over the fire, they are stored for use. From these they make their favorite beverage by preparing a potent decoction which they drink in great quantities, both for their health and also with great desire and good pleasure, without any kind of sugar or other additives. They drink great amounts of this, and time and again, and thus swallow many quarts. They have an annual custom in the spring in which the drinking takes place in a ceremony. The inhabitants of the village gather in the communal house after they have cleaned their own houses by burning all of their furniture and replacing this anew. The king is first served the drink in a great bowl or snail shell which has never been used before. After this, the other eminent personages receive the drink according to their rank. The women and the children are the last to receive the brew. They say that it makes lost appetites return, that it strengthens the stomach, and that it gives them power and courage for war.”

Iochroma fuchsioides (Bentham) Miers

Yas

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solaneae Tribe

Forms and Subspecies

Twelve to fifteen species are currently accepted in the genus *Iochroma* (D’Arcy 1991, 79*; Schultes and Raffauf 1991, 37*). To date, no subspecies or varieties have been described for the species *Iochroma fuchsioides*.

“How delicious is the scent of the long, bell-shaped flowers of the yas plant, when one inhales it in the afternoon and follows the country roads.

“But the tree has a spirit in the form of an eagle which has been seen as it flew through the air and then disappeared. It disappears completely in the leaves, between the branches, between the flowers.”

FRANCISCO TIMUÑA PILLIMUE IN “A NATIVE DRAWING OF AN HALLUCINOGENIC PLANT FROM COLOMBIA” (SCHULTES AND BRIGHT 1977, 155)

Synonyms

Iochroma fuchsioides (Humb. et Bonpl.) Miers *Lycium fuchsioides* H.B.K.

Folk Names

Árbol de campanilla, borrachera, borrachera andoke,^{[181](#)} borrachero, campanitas (Spanish, “little bell”), dotajuanseshe (Kamsá), flor de quinde (Spanish, “flower of the hummingbird”),^{[182](#)} gua tillo, hacadero, hummingbird’s flower, iochroma, isug yas gyeta, paguando, paguano, tatujansuche, tetajuanse, totubjansush, totubjansushe, totufjansush, totujanshve, yas

The Kamsá Indians (Colombia) also call the closely related species *Iochroma gesnerioides* (H.B.K.) Miers *borrachera*. It is not known whether this plant has psychoactive effects or was ever used for such purposes (Schultes and Raffauf 1991, 38*). *Iochroma umbrosa* Miers has been listed as an inebriating plant, but this information appears to be incorrect (Bristol 1965:290 f.*).

History

To date, we know of no pre-Columbian use of the yas bush. Richard Evans Schultes discovered the psychoactive use of this beautiful and rare plant in 1941 in the Sibundoy Valley of Colombia (Davis 1996, 173*). Detailed ethnobotanical and ethnopharmacological studies are lacking.

Distribution

The yas bush is found in the high Andes mountains of Colombia and Ecuador at altitudes around 2,200 meters.

Cultivation

Propagation occurs with seeds or cuttings. The cuttings are best taken in February or early March and placed in water. They require considerable time to develop roots (Grubber 1991, 41*).

In subtropical regions, yas is cultivated as an ornamental (Bristol 1965, 290*). The plant has been successfully grown in northern California,¹⁸³ e.g., in the botanical gardens of Berkeley and San Francisco (Strybing Arboretum). The plant does not tolerate any frost.

Appearance

This perennial bush can attain a height of 3 to 4 meters. It has woody stems and reddish brown branches and develops lanceolate, light green leaves that are up to 10 cm in length. The deep red, trumpet-shaped flowers are 2.5 to 4 cm long and hang in umbelliform clusters. The berries are fruits with a diameter of approximately 2 cm that remain partially enclosed by the wilted calyxes.

Yas is very similar to the Colombian species *Iochroma cyaneum* (Lindl.) M.L. Green [syn. *Iochroma lanceolatum* (Miers) Miers, *Iochroma tubulosum* Benth.], which is commonly cultivated as an ornamental in tropical and subtropical regions. The bush is also easily confused with the related Central American species *Iochroma coccineum* Scheid. (Bärtels 1993, 155*). In addition, the plant is astonishingly similar to the Mexican *Fuchsia fulgens* Moç. et Sessé ex DC. (Onagraceae).

The red-flowered yas bush, *Iochroma fuchsioides*.

The Ecuadoran species *Iochroma grandiflorum* bears large flowers.

Ichroma grandiflorum, photographed in Salala near Las Huaringas, in northern Peru.

Psychoactive Material

- Leaves
- Flowers

Preparation and Dosage

The leaves can be harvested and dried at any time of the year except the winter months. The flowers are collected as soon as they exhibit the first signs of wilting (Grubber 1991, 41*). The dried leaves are smoked or brewed into a tea. No precise information concerning dosages is available (Gottlieb 1973, 21*). It is likely that the leaves and flowers can be used in **smoking blends**, in combination with other plants.

In Colombia, the (fresh) leaves are drunk in the form of an infusion or a decoction.

The lush inflorescence of the blue *Ichroma cyaneum*.

An unidentified *Ichroma* species.

Fuchsia fulgens is astonishingly similar to the redflowered yas bush (*Ichroma fuchsioides*).

Ritual Use

The shamans of the Colombian Kamsá Indians ingest preparations of this nightshade when confronted with cases that are difficult to diagnose.

Ichroma fuchsioides is also used as an **ayahuasca** additive.

Artifacts

Despite what has been previously published, an old Indian drawing (A woman under a borrachero tree) by Francisco Tumiña Pillimue of Colombia portrays not ***Brugmansia sanguinea*** ssp.

vulcanicola but, rather, *Iochroma fuchsioides* (Schultes and Raffauf 1977; Schultes and Raffauf 1991, 38*). Above the bush is a bird, most likely a transformed shaman or the vision-bringing spirit of the plant (Hernández de Alba 1949). The drawing, however, is much more reminiscent of the larger-flowered *Iochroma grandiflorum* Benth., which occurs in the Ecuadoran and Peruvian Andes.

Medicinal Use

Iochroma fuchsioides is used ethnomedicinally as a narcotic for difficult births and digestive disorders (Schultes and Hofmann 1995, 46*).

The folk healers (*curanderos*) of northern Peru use an *Iochroma* species known as *contrahechizo* (“anti-magic”) as an additive to the San Pedro drink (cf. *Trichocereus pachanoi*) and as a purgative remedy for treating diseases caused by harmful magic. The plant is said to induce vomiting and diarrhea, thereby cleansing the body of all poisons and negative influences (cf. Giese 1989, 229, 250*).

In northern Peru, *Iochroma grandiflorum* is regarded as a typical medicinal plant from the region of Las Huaringas. The *curanderos* believe that the plant is especially powerful in this area because it absorbs the water of the sacred lake. It is known in the area as *campanitas* (“little bells”) ¹⁸⁴ or *yerba para mal hechizo* (“herb against bad magic”). It is used primarily as a bath additive for removing magic. It is sometimes combined with *Fuchsia* spp. for this purpose. It is possible that the *curanderos* may also use the plant for psychoactive purposes.

Constituents

To date, no alkaloids have been detected in *Iochroma fuchsioides*, although **withanolides** have been found (Raffauf et al. 1991).

The closely related *Iochroma coccineum* Scheid. has also been found to contain **withanolides** (Alfonso and Bernardinelli 1991; Alfonso et al. 1992).

The “inebriating” nightshade *Iochroma fuchsioides* is shown on this old Indian drawing (A woman under a borrachero tree) from Colombia. The bird shown hovering above the tree is likely a transformed shaman or the vision-inducing spirit of the plant.

(FROM GREGORIO HERNÁNDEZ DE ALBA, *NUESTRA GENTE—NAMUY MISAG*, 1949)

Effects

The inebriation produced by this plant is said to last for days or have aftereffects. No reports of self-

experiments are available.

Commercial Forms and Regulations

None.

Ipomoea violacea Linnaeus

Morning Glory Vine

Family

Convolvulaceae (Morning Glory Family); Sub-family Convolvuloideae, Ipomoeae Tribe

Forms and Subspecies

At least two varieties have been described:

Ipomoea violacea var. *rubrocaerulea* Hook.

Ipomoea violacea var. *tricolor* Cav.¹⁸⁵

The following sorts (cultivars), which are grown throughout the world as ornamentals, are known under their own names: ‘Blaustern’ ‘Blue morning glory’, ‘Crimson rambler’, ‘Darling’, ‘Heavenly Blue’ (= ‘Kaiserwinde’, ‘Blaue Trichterwinde’), ‘Klimmende blauwe winde’, (Dutch) ‘Morning glory’, ‘Pearly Gates’, ‘Summer Skies’, ‘Blue Star’, ‘Flying Saucers’, and ‘Wedding Bells’.

The purple- or violet-flowered vine known in Aztec as *mecapatli*, “cord medicine,” can be interpreted as *Ipomoea violacea* L. or *Ipomoea purpurea* (L.) Lam. (From Hernández, 1942/46 [Orig. pub. 1615]*)

Synonyms

Ipomoea tricolor Cav.

Ipomoea rubrocaerulea Hook.

Ipomoea violacea Lunan et auct. mult., non L.

Pharbitis rubrocaerulea (Hook.) Planch.

Folk Names

Badoh negro (Zapotec, “black badoh”), badolngás (“black badoh”), badungás (“black badoh”), bejucillo (Spanish, “little tendril”), blaue trichterwinde, coatlxoxouhqui, dreifarbigе prunkwinde, ipoméе, kaiserwinde, la’aja shnash (Zapotec, “seeds of the Virgin”), mantos de cielo (“coat of heaven”), ma:sung pahk (Mixe, “bones of the children”), mehen tu’xikin (Lacandon, “little stink ear”), michdoh, morning glory, morning glory vine, pih pu’ucte:sh (Mixe, “flower of the broken plates”), pihyupu’ctesy (Mixe, “flower of the broken plate”), prachtwinde, prunkwinde, purpurwinde, quiebraplato (Mexico, “breaker of plates”), tlitliltzin (Aztec, “black divine”), trichterwinde, xha’il (Mayan, “that from the water”), ya’axhe’bil, yaxce’lil

The seeds, which are used primarily in ritual contexts, are known among the Chinantec and Mazatec as *piule*, the same name given to the seeds of *Turbina corymbosa*. The Zapotec call them *badoh negro*, the same name they give to the plant itself (cf. *Rhynchosia pyramidalis*). The Aztecs are said to have called them *tlililtzin* or *tlitliltzin*, “the very black” (Schultes and Hoffmann 1992, 46*). In both the pharmaceutical and the ethnobotanical literature, and in other sources, the seeds of *Ipomoea violacea* are confusingly referred to by the name *ololiuqui*.

History

It has not yet been possible to confirm with certainty whether *Ipomoea violacea* is identical to the Aztecentheogenic plant known as *tlitliltzin*, but it is very likely. The psychoactive use of this plant in divinations and healing rituals has been documented since the late colonial period.

This vine was first botanically described by Linnaeus. Since his time, it has been repeatedly described anew under other names. At the same time, this beautiful plant has been changed through cultivation and breeding to such an extent that many of the new sorts must sometimes appear to be new, previously undescribed species. Closet shamans, gardeners, and breeders often confuse this plant with ololiuqui (*Turbina corymbosa*).

Distribution

The plant is originally from the tropical regions of Mexico but is now found as a garden ornamental (with numerous sorts) in tropical and subtropical areas around the world. In temperate zones, the plant occurs only as an ornamental annual.

Cultivation

This fast-growing *Ipomoea* species does well in topsoil, although it prefers slightly alkaline soils. It can be grown in protected locations in the open, e.g., in a flower box on a balcony facing south. It requires copious amounts of water but can survive for several days without watering. Even plants that appear to have dried out can recover if they are watered well.

To grow the plant, place four or five seeds in a flowerpot during March or April. If the seeds are kept at a temperature between 18 and 20°C, germination will take place in ten to twenty days (or sooner). The plant can be placed in the open or transplanted after mid-May.

Appearance

This vine branches early and can grow as long as 3 meters. The leaves are cordate. The first two leaves that develop from the young shoots exhibit a characteristic fissuring (a sure way to identify the seedlings).

In the Mexican tropics, *Ipomoea* can flower throughout the year. It is very frequently seen in full bloom in February and March. In temperate zones, where it grows only as an annual, the flowering period is between June and October (depending upon the cultivar or sort). The flowers of the wild

form are usually up to 8 cm wide and luminously violet; the flowers of the cultivated sorts can grow as large as 10 cm and may have a blue, pink, or white color. The flowers unfurl in the morning and close before the onset of twilight (often around four o'clock in the afternoon). The stigma is mono- to tricephalous. The seeds are black, elongate-triangular, some 7 to 8 mm long, and approximately 4 mm wide.

Ipomoea violacea is very frequently confused with *Ipomoea purpurea* (even in the specialized literature) as well as with other *Ipomoea* species.

Psychoactive Material

—Seeds (semen ipomoeae violaceae, ipomoeae violaceae semen)

Preparation and Dosage

Among the Mixe, a dosage consists of twenty-six seeds. The seeds should be ground by a ten- to fifteen-year-old virgin and mixed with water; otherwise, the seeds will not “speak” (Lipp 1991, 190*). The methods of preparing and administering the seeds are more or less the same for all the peoples of Oaxaca.

According to Schuldes, a low dosage consists of 20 to 50 seeds, a moderate dosage of 50 to 150, and a high dosage of 300 seeds or more; only with moderate to high dosages was he able to observe LSD-like effects (Schuldes 1993, 86 f.*). Other sources suggest chewing and swallowing 5 to 19 g of seeds or grinding them and allowing them to sit in water for thirty minutes (Gottlieb 1973, 37*).

A cold-water extract of three hundred crushed or ground seeds is said to correspond to approximately 200 to 300 µg of LSD (Rob Montgomery, pers. comm.; Veit 1993, 548). The LD₅₀ of the isolated alkaloids is said to lie between 164 and 214 mg/kg in rats and between 1 and 2 g for humans.

Ritual Use

It is very likely that the Nahuatl-speaking peoples (e.g., the Aztecs) were ritually using the seeds of *Ipomoea violacea* during pre-Hispanic times. Evidence of the ritual use of *tlitliltzin* in the colonial period is contained in the report of Pedro Ponce (*Breve Relación de los Dioses y Ritos de la Gentilidad*, par. 46):

On the ways in which one finds lost objects and other things that people want to know: They drink *ololiuhque* [sic; cf. *Turbina corymbosa*], peyote [cf. *Lophophora williamsii*], and a seed which they call *tlitliltzin*. These are so strong that they sedate the senses [of the natives] and that—so they say—little black men appear before them which tell them what they want to know about. Others say that Our Lord appears to them, while still others [say] that it is angels. And when they do this, they enter a room, close themselves in, and have someone watch so that they can hear what they say. And it is not allowed for people to speak to them before they have reawakened from their delirium, lest they go insane. And then they ask what they have said, and that is so. (Cf. Andrews and Hassig 1984, 218*)

The Zapotec use *Ipomoea* seeds in the same manner as *Turbina* seeds (MacDougall 1960). The black *Ipomoea* seeds are often referred to as *macho*, “male,” while the light-colored *Turbina* seeds are *hembra*, “female” (Wasson 1971, 340). The Mixe regard *Turbina corymbosa* and *Ipomoea violacea* as siblings. Mixe shamans, however, consider *Ipomoea* to be more effective as well as more powerful (Lipp 1991, 187*). And indeed, the alkaloid content of *Ipomoea* seeds is considerably higher than that of *Turbina* seeds (Hofmann 1971, 354).

The wild form of the morning glory (*Ipomoea violacea*) is indigenous to tropical Mexico. (Photographed in Naha', Chiapas, Mexico)

The most commonly sold cultivar: *Ipomoea violacea* cv. Heavenly Blue.

The species *Ipomoea violacea* is rather easily identified by its first set of leaves. The Indians equate these with snake tongues.

Mexican shamans ingest the seeds of *Ipomoea violacea*, known as *badoh negro*, during healing rituals.

The *mamas* (shaman priests) of the Kogi of the Colombian Sierra Madre are said to use *Ipomoea violacea* in ritual contexts (Baumgartner 1994; Reichel-Dolmatoff 1987):

“In the name of God and the holy Virgin,
be merciful and grant the remedy,
and tell us, beloved Virgin,
what ails the afflicted person!”

ZAPOTEC PRAYER TO BADOH NEGRO IN *SUMMA ANTROPOLOGICA EN HOMENAJE A ROBERTO J. WEITLANER* (WASSON 1966, 346)

All this astronomical imagery is related to certain present-day rituals in which a high-ranking priest, wearing a jaguar mask impersonating Sun, cohabits in the main temple with his sister-wife who wears a mask made from the wide gaping maw of a black jaguar, impersonating Moon. The ritual takes place during the dark of the moon, and under the influence of a hallucinogen, probably Morning Glory (*Ipomea violacea*).¹⁸⁶ Black jaguars (*nébbi abáxsë*) are said to be fairly frequent in Colombia and can interbreed with normally colored jaguars; both jaguars, also the black one, have dark pelt markings which, in Kogi terms, are sun-spots and moon-spots and which, according to the priests, are the marks of incest. We would call them *maculae*. The gaping gullet of Moon’s mask might be interpreted as another representation of the devouring womb of the Great Mother. . . . In any event, the ritual here described is one of recreation, as stated clearly by the Kogi; it is the conquest of darkness. . . .

The principal mythical jaguar priest was *Kasindúkua*, a lord or *máma* with very ambivalent attributes. He was an expert curer of human illness, and his principal power objects were a jaguar mask and a bluish pebble or seed called *nebbis kwái*/jaguar’s testicle; the Great Mother herself had given him these objects, and from a number of texts it appears that they suggest the use of hallucinogenic drugs. But putting on the mask and, simultaneously, swallowing the “testicle,” ordinary reality began to change; illnesses became visible to the eye in the form of black beetles and thus could be destroyed; women turned into luscious pineapples, and maize stalks were transformed into armed men. (Reichel-Dolmatoff 1987, 101, 105)

The plant in question may be *Ipomoea carnea* Jacq. (see ***Ipomoea* spp.**). The plant is not described in any more detail in another source:

The Kogi compare the brilliant reflection on the water with certain luminous sensations a person might perceive under the influence of a drug. A priest or any other devout believer who tries to

establish contact with the supernatural sphere by fasting, meditation, and the use of hallucinogenic drugs such as morning glory (Convolvulaceae) will sometimes perceive quite suddenly a brilliant light which he believes to be a direct manifestation of a divine being. Since these trance states are often accompanied by horrifying visions, these sudden flashes of light are greatly feared by the common people who will associate them with a ghostly and dangerous dimension. (Reichel-Dolmatoff 1978, 24–25)

Artifacts

A watercolor of a morning glory appeared in *Types of Floral Mechanism*, by Arthur Harry Church (1865–1937). Flowering vines also appear as floral elements in American art deco windows (cf. *Turbina corymbosa*).

Medicinal Use

The Lacandon know *Ipomoea violacea* as *äh tu'xikin*, literally “the feces/rot of the ear.”¹⁸⁷ In the Selva Lacandona, this violet-blooming vine thrives along paths, in clearings, and around ancient ruins and overgrown milpas (*pakche'kol*). The Lacandon view it as a relative of *äh mehen tu'xikin*, “little feces/rot of the ear” (*Aristolochia foetida* H.B.K.; Aristolochiaceae), and of *nukuch tu'xikin*, “big feces/rot of the ear” (*Aristolochia grandiflora* Swartz [syn. *Aristolochia gigas*]). This *Ipomoea* is a remedy for a disease that the plant itself causes: “If you play with the flowers of the purple vine, you get earaches, your ear rots. The purple vine has a disease. If you pick the flower or play with the purple vine, your ear rots. But I mean that it is a different ear [scrotum, genital labia]. It is the same whether women or men play with it, their ear will rot.” According to information provided by several of the Lacandon, this “ear disease” can be healed by roasting an *Ipomoea* flower and placing it (for how long?) into the diseased “ear” (Rätsch 1994c, 77*). I believe that this Lacandon statement is a rudiment from the time in which the psychedelic use of the vine was restricted to religious specialists. The warnings not to play with the flowers, i.e., not to be careless with them or not respect them, is evidence of a protective attitude toward the plant.¹⁸⁸

Constituents

The leaves contain the **ergot alkaloids** (ergoline derivatives) ergometrine, isolysergic acid amide, and lysergic acid amide (LSA). The biosynthesis of these **indole alkaloids** occurs in the leaves, while the subsequent translocalization leads to an accumulation of the alkaloids in the seeds. The seeds contain a variety of lysergic acid derivatives: (+)-lysergic acid amide, (+)-isolysergic acid amide, lysergic acid hydroxyethylamide, chanoclavine, elymoclavine, and ergometrine. The concentrations of these active compounds can vary considerably, depending upon the location of the plant and the sort (Gröger 1963a; Roth et al. 1994, 428*¹⁸⁹). In young seeds, the chanoclavine content is very high, but it declines as they mature and the lysergic acid amide levels increase (Gröger 1963b).

The Lacandon regard one *Aristolochia* species as a “sibling” of the morning glory (*Ipomoea violacea*). Whether this plant is psychoactive is a subject for future research. (Photographed in the Yucatán, Mexico)

The cultivars ‘Heavenly Blue’, ‘Pearly Gates’, ‘Summer Skies’, ‘Blue Star’, ‘Flying Saucers’, and ‘Wedding Bells’ all contain psychoactive alkaloids (Der Marderosian and Youngken 1966).

Effects

Eating the seeds can induce profound side effects (nausea, vomiting, indisposition, lassitude), which probably result from non-water-soluble alkaloids and other substances. The fewest side effects result from ingesting a cold-water extract of the ground or crushed seeds. Cold-water extracts have distinct hallucinogenic effects that are, however, not exactly the same as those of LSD. Visions of “small people” are typical (Turner and Szczawinski 1992, 178*). The effects have narcotic and hypnotic components that Indian shamans utilize for their soul journeys. Most Westerners who have experimented with morning glory seeds typically have little desire to repeat the initial experiment.

The seeds also have a stimulating effect upon the uterus, probably because of the presence of ergonovine (Der Marderosian et al. 1964).

Commercial Forms and Regulations

In nurseries and flower shops, the seeds are usually sold under the name *Ipomoea tricolor*. The plant is not subject to any legal restrictions.

Perhaps inspired by a good dosage of seeds from *Ipomoea violacea*, one American wave band took its name, Morning Glories, from that of the psychedelic vine (CD cover 1994, Cargo Records). The British band Oasis recently raised some eyebrows with its album (*What's the Story*) *Morning Glory?* (1995).

Ipomoea spp.

Ipomoea Species

Family

Convolvulaceae (Morning Glory Family); Sub-family Convolvuloideae, Ipomoeae Tribe

A variety of both wild and cultivated vines in the Family Convolvulaceae can be found in all the vegetation zones of Mexico. One very common plant in the Indian areas is the sweet potato (*Ipomoea batatas* L.), which is grown for food. Today, many species of these vines are grown throughout the world as ornamentals for their colorful, funnel-shaped flowers. The number of species has been estimated to exceed five hundred (Schultes and Farnsworth 1982, 151*). Some species are esteemed for their medicinal properties, e.g., jalap bindweed (*Exogonium purga* (Wender.) Benth. [syn. *Ipomoea purga* (Wender.) Hayne, *Convolvulus jalapa* Schiede non L.]; cf. Veit 1993, 543 ff.). But of all the species of Mexican vines, only two have been ritually ingested in shamanic contexts: ***Turbina corymbosa*** and ***Ipomoea violacea***, in all known variations.

“The nomenclature of the some 400 species encompassed by the genus *Ipomoea* is rather confusing. Some specialists also include within it species that other scientists assign to the genera *Pharbitis* and *Quamoclit*.”

JAN TYKAC AND FRANTISEK SVEREA *KLETTERPFLANZEN UND RANKENDE PFLANZEN* [CLIMBING PLANTS AND PLANTS WITH TENDRILS]
(1985, 128)

***Ipomoea batatas* (L.) Poir.—sweet potato, batate**

This commonly grown *Ipomoea* species has small pink flowers and develops thick tubers containing starches and sugars that many Indians use for food. Although it has sometimes been suggested that the seeds may contain alkaloids (cf. Schultes and Hofmann 1980, 367*), there is no evidence to support this assertion. In the culture of inebriants, the sweet potato has played a role solely as a fermenting agent for making **beer** and as an additive to coca quids (cf. ***Erythroxylum coca***). It likely originated in Mexico but had already spread far into South America and even to Polynesia in pre-Columbian times. *Ipomoea tiliacea* (Willd.) Choisy [syn. *Ipomoea fastigata* (Roxb.) Sweet] is presumably the wild form from which the sweet potato was cultivated (Dressler 1953, 135*). Tubers infected with *Ceratocystis fimbriata* contain sesquiterpenes (Inoue et al. 1977).

***Ipomoea* sp. aff. *calobra*—weir vine**

This vine, found in only a limited area of southern Queensland (Australia), apparently contains LSD-like indole alkaloids. In addition to their psychoactive effects, these alkaloids also have potent toxic properties (at least on sheep and cattle) (Dowling and McKenzie 1993, 117 f.*).

***Ipomoea carnea* Jacq. [syn. *Ipomoea fistulosa* Mart. ex Choisy, *Ipomoea carnea* ssp. *fistulosa* (Mart. ex Choisy) D. Austin; cf. Hubinger T. et al. 1979, 33*]—manjorana, canudo, toé**

This vine species produces flesh-colored flowers. It is found throughout the entire Amazon basin as well as in adjacent regions (Almeida Falcão 1971). In Ecuador, it is known as *florón* and *borrachera*, “inebriator” (Patzelt 1996, 178*), the same names used for many ***Brugmansia*** species, and as

matacabra (“goat killer”). The concentrations of ergot alkaloids appear to be very high. To date, the ergoline alkaloids agroclavine and α -dihydrolysergol have been detected in the plant (Asolkar et al. 1992, 371*; Schultes and Farnsworth 1982, 151*). This makes the seeds of this vine, the effects of which are often stronger than those of *Ipomoea violacea*, a potent precursor substance. In Ecuador, the seeds (which contain **ergot alkaloids**) are said to be still used as a shamanic inebriant (Lascano et al. 1967; Ott 1993, 127*). In the Ucayali region of Peru, the vine is known as *toé* (“inebriant”). In the Pucallpa area, it is used as an additional inebriating ingredient in **ayahuasca** (Mellington Curichimba Marín, pers. comm.). In Amazonia, where the plant is feared as a poison, it is known by the names *manjorana*, *canudo*, and *algodão bravo*.

The plant is known as *chok’obkat* in Yucatec Mayan. There, the flowers are considered a source of honey (Téllez V. et al. 1989, 67*; cf. **honey**).

In the older literature, this South American plant can be found under the synonym *Ipomoea fistulosa*, which is now regarded as the subspecies *Ipomoea carnea* ssp. *fistulosa* (Mart. ex Choisy) D. Austin (Austin 1977; Hubinger T. et al 1979, 33*). In Argentina, the Pilagá Indians use the ashes of this subspecies (known locally as *we’daGaik’gel’ta*) to treat burns and boils (Filipov 1994, 186*).

Ipomoea carnea (= *Ipomoea fistulosa*) is regarded as one of the most potent morning glories.

The botanical identity of many morning glories (*Ipomoea* spp.) is difficult to ascertain. (Photographed in the Kathmandu Valley, Nepal)

The flower of the sweet potato (*Ipomoea batatas*).

***Ipomoea crassicaulis* Robinson [syn. *Ipomoea fistulosa* Mart.]**

This plant, which develops large white flowers, is known in Mexico as *palo santo de castilla*, “sacred tree of castilla” (Martínez 1987, 1137*). This name may indicate a former use for psychoactive purposes. The seeds contain **ergot alkaloids** (Ott 1993, 127*).

***Ipomoea hederacea* Jacquin [syn. *Convolvulus hederaceus* var. *beta* L., *C. trilobus* Mach., *Ipomoea barbiger* Sweet, *I. coerulea* Roxb., *I. desertorum* House, *I. punctata* Pers., *I. scabra* Gmel., *I. triloba* Thunb., *Pharbitis hederacea* (L.) Choisy]—Japanese morning glory**

This annual vine, which can grow as long as 2 to 3 meters, is known as *asagau*, “morning flower,”¹⁹⁰ in Japanese. It is regarded as an aphrodisiac in Asia and for this reason is sometimes seen in Japanese erotic art (Marhenke and May 1995, 49*). The beautiful, blue-flowered plant can be found in the Himalayas at altitudes of up to 2,000 meters and has also gone wild in the American tropics. It even occurs (introduced) in the Selva Lacandona, where it is easily mistaken for *Ipomoea violacea*. In Mexico, it is known by the name *manto de la virgen*, “coat of the Virgin” (Martínez 1987, 1137*). The

seeds are regarded as poisonous in Iran (Hooper 1937, 130*).

Ipomoea hederacea possesses pubescent seminal leaves and forms capsules with four to six seeds. The seeds have a certain importance as a pharmaceutical raw drug (pharbitidis semen, kaladana) for kalana resin. **Ergot alkaloids** have been detected in the seeds (Abou-Char 1970; Veit 1993, 535). Seeds from Pakistan have been found to contain the alkaloids lysergol, chanoclavine, penniclavine, isopenniclavine, and elymoclavine (Asolka et al. 1992, 372*).

***Ipomoea involucrata* P. Beauv.**

Among the Central African Fang, this African vine is known as *nguenga*. The medicine men of the Fang (cf. ***Tabernanthe iboga***) use the fresh, whole plant to make a magical medicine with stimulating effects that is used to treat victims of magic (Akendengué 1992*). Whether this medicine does in fact have psychoactive properties is a subject for future research.

***Ipomoea muricata* (L.) Jacq. [syn. *Calonyction muricatum* (L.) G. Don]—lakshmana**

In India, this white-blossomed vine with heart-shaped leaves is known as *lakshmana*¹⁹¹ and is associated with Lakshmi, the goddess of good fortune. It is said that the root provides nourishment for the immaterial kundalini serpent (cf. ***Cannabis indica***), which rests in the pelvic region of the lower abdomen and represents the creative sexual energy. In Ayurvedic medicine, *lakshmana* is one of the most important *vajikarana* (aphrodisiacs). According to one tantric recipe, the plant is mixed with bezoars and ground to produce an ointment that is applied to the forehead. This ointment is said to make love magic and mystical experiences possible. The root is attributed with healing powers for snakebites. Snake charmers use the root as a magical protection against cobras (Kumaraswamy 1985; Rätsch 1990, 51*). It has even been suggested that this climber is identical to the Vedic **soma**.

All parts of the plant contain up to 3.7% behenic acid, which has stimulating effects upon the central nervous system and also appears to have psychoactive and aphrodisiac effects. The seeds have been found to contain **ergot alkaloids** (Veit 1993, 535) as well as the alkaloid ipomine (Asolkar et al. 1992, 372*). In the pharmaceutical trade, the seeds are available under the name *kaladana*.

The Aztecs knew one morning glory species (possibly *Ipomoea heterophylla* Ort.) as *totoyxcitl* (“bird claw”). (From Hernández, 1942/46 [Orig. pub. 1615]*)

Lysergol

The deep violet flowers of *Ipomoea hederacea*. (Photographed in Kathmandu, Nepal)

Ipomoea nil is common throughout Asia and Oceania.

The beach morning glory *Ipomoea pes-caprae*. (Photographed in the Seychelles)

The purple morning glory, *Ipomoea purpurea*, is commonly found in cultivation.

A color variant of *Ipomoea purpurea*.

Behenic acid

Damascenone

In the Yucatán, the seeds of one *Ipomoea* species known locally as *xtontikin* are used for ethnogynecological purposes as a postpartum treatment. (Photographed in the Yucatán)

***Ipomoea murucoides* Roem. et Schult.**

This white-blooming *Ipomoea* species grows as a shrub or tree. In Mexico, where it is known as *palo bobo*, “inebriating tree,” or *arbol del muerto*, “tree of the dead,” it is considered to be a poisonous plant and is said to cause paralysis (Jiu 1966, 252*). The Aztecs knew the plant as *micacuahuitl*. In Sonora, it is still known today as *palo santo*, “sacred tree” (Martínez 1987, 1137*). Whether the plant was or is used for psychoactive purposes is unknown.

***Ipomoea nil* (L.) Roth [syn. *Convolvulus hederaceus* L., *C. hederaceus* var. *zeta* L., *C. nil* L., *C. tomentosus* Velloso, *Ipomoea cuspidata* Ruíz et Pav., *I. githaginea* A. Richard, *I. scabra* Forssk., *Pharbitis nil* (L.) Choisy, *Ipomoea hederacea* auct. non. Jacq.]**

This blue-blossomed vine (there are also violet-blue and purple-red forms) is almost indistinguishable from *Ipomoea hederacea* and is often confused with that species (both have pubescent seminal leaves). It is found in tropical regions throughout the world. In Japan, it has been cultivated as an ornamental (*Ipomoea nil* cv. *Imperialis*) since the fifteenth century. In Mayan, it is known as *tsotsk’abil*, “hairy arm,” and is probably one of the sources of nectar for producing a **honey** that is used ritually. The seeds, which are listed in the pharmaceutical literature under the name *pharbitidis semen*, contain glyco-sides and approximately 0.5% **ergot alkaloids** (consisting of lysergol, chanoclavine, penniclavine, isopennyclavine, and elymoclavine, but no ergometrine) (Veit 1993, 535 f.). The alkaloids lysergol, chanoclavine, penniclavine, isopenniclavine, and elymoclavine have been extracted from seeds of a Pakistani sort (Asolka 1992, 372*). Gebberellin is also present in the seeds (Koshioka et al. 1985). The seeds are the source of the pharmaceutically important kaladana resin.

***Ipomoea pes-caprae* (L.) Brown [*Ipomoea pescaprae* (L.) Brown var. *brasiliensis* Ooststroom; syn. *Ipomoea biloba*]—beach vine**

This prostrate species grows on sandy beaches. In Mexico, it is known by many names, including *hierba de la raya*, “plant of the stingray” (Martínez 1987, 1138*). This is an interesting association, as stingray spines were used in the ancient Mayan culture for ritual bloodletting, a part of the vision quest (Furst 1976c*). The leaves of this vine find ethnomedicinal use throughout the world to treat ailments such as rheumatism. In Thailand, extracts of the leaves are used to treat inflammations and jellyfish stings. The leaves contain β -damascenone and *E*-phytol, both of which have antispasmodic effects very similar to those of **papaverine** (Pongprayoon et al. 1992). The seeds contain **ergot alkaloids**. Whether the seeds are suitable for psychoactive use is unknown, although they are used as an ingredient in the initiatory drink of the Afro-American Candomblé cult (see **madzoka medicine**).

***Ipomoea purpurea* (L.) Roth [syn. *Pharbitis purpurea* (L.) Voigt; *Ipomoea purpurea* var. *diversifolia* (Lindl.) O'Donnell [syn. *Ipomoea mexicana* Gray]—early-blooming morning glory (numerous cultivars)**

This climber, which can grow as long as 3 meters, is native to the American tropics but is now found as an ornamental around the world (Tykac and Severa 1985, 128). The plant as well as its seeds are very often confused with ***Ipomoea violacea*** and its seeds (Ott 1993, 162*). While it is often claimed in the literature that *I. purpurea* seeds contain ergo-line and other ergot alkaloids, most studies (except one: Wilkonson et al. 1986) have reported an absence of alkaloids. The flowers may be purplered, white, pink, light blue, or deep violet. The seeds are available in nurseries (usually under the name *purple morning glory*). The seeds are considerably smaller (3 mm by 4 mm) and rounder than those of ***Ipomoea violacea***.

The following morning glory species contain **ergot alkaloids** and/or **indole alkaloids** and may possibly be used for psychoactive purposes (Ott 1993, 127*; Schultes and Farnsworth 1982, 187*):

Ipomoea argyrophylla Vatke

Ipomoea coccinea L.¹⁹² [*Ipomoea coccinea* L. var. *hederifolia* House; syn. *Quamoclit coccinea* Moench]

Ipomoea leptophylla Torr.

Ipomoea littoralis Blume

Ipomoea medium Choisy

Ipomoea muelleri Benth.

Further studies of the genus *Ipomoea* certainly represent a highly interesting field of ethno-pharmacology and will require extensive pharmacological studies with human subjects (Heffter technique!).

Two vines that are related to *Ipomoea* are sometimes claimed to be psychoactive or hallucinogenic: *Merremia tuberosa* (cf. ***Argyreia nervosa***) and *Stictocardia titiaefolia* (Choisy) Hall f. (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*).

Juniperus recurva Buchanan-Hamilton ex D. Don

Drooping Juniper

Family

Cupressaceae (Juniper Family)

Forms and Subspecies

There is a dwarf form that does not have its own botanical name. *Juniperus recurva* var. *squamata* (Don) is the variety that grows in Kashmir (Weyerstahl et al. 1988).

Synonyms

Juniperus macropoda Auct. non Boiss.^{[193](#)}

Juniperus squamata D. Don

Folk Names

Apurs (Pakistan), bsang (Tibetan, “incense”), dhupi (Nepali, “incense tree”),^{[194](#)} drooping juniper, hapusha (Sanskrit), hochgebirgswacholder, shang-shing (Tamang, “incense tree”), weeping blue juniper

Drooping juniper (*Juniperus recurva*) can be recognized by its downward-curving branch tips. (Photographed in Langtang, Nepal)

An incense powder (*dhup*) for use in rituals is produced simply by rubbing the branches of *Juniperus recurva*.

History

Species of juniper are found throughout the world and are especially common in Europe, Asia, and North America. In almost every region, they are used for ritual, magical, and medicinal purposes. In most of the cultures in which shamanism is found, juniper is an **incense** of the shamans. It is likely one of the oldest fumigants of humankind. The earliest written documents of ancient times (e.g., from Dioscorides and Pliny) provide evidence of numerous juniper species. Alexander the Great was presumably acquainted with the Himalayan juniper. We do not know how long this juniper has been used in the Himalayas for ritual purposes. The first botanical description of the plant was made in the nineteenth century.

Distribution

Drooping juniper occurs from Pakistan to southwestern China and is particularly common in Nepal (Langtang and Helumbu), where there are entire forests of the tree (Shrestha 1989). It grows at altitudes of at least 3,000 meters and up to 4,500 meters. In the subalpine zones, it sometimes forms large forests (“incense forests”).

In northern India, it is said that the juniper forests of the Himalayas are the abode of the gods. Certain sacred sites (e.g., in Muktinath) have solitary juniper trees, some of which are very old, that are venerated as sacred trees.

Cultivation

Unknown; this species presumably is propagated and cultivated in the same manner as common juniper (*Juniperus communis* L.) and Chinese juniper (*Juniperus chinensis* L.)

Appearance

Drooping juniper can grow as tall as 12 meters but often attains a height of only 3 to 5 meters. It usually grows in a stocky or prostrate fashion. The species name is derived from the fact that the tips of the branches curve downward. The relatively soft needles are 6 to 8 mm long. The large, oval fruits (8 to 13 mm) contain just one seed and are violet-brown to black in color (Polunin and Stainton 1985, 390).

Drooping juniper is very easily confused with the closely related species *Juniperus excelsa* M.

Bieb. (Goodman and Gharfoor 1992, 52*).

“Everything has come together in the kitchen, the center of the house, and while those in search of healing are still conversing, the shaman is already beginning to sing. Behind him, juniper is being burned. He groans, for he is soon singing so rapidly that he has difficulty taking a breath. It appears to be a mild hyperventilation, for he can fight for air only once in a while. While he recites in song, he arranges the table before which he kneels as an altar. Now, completely surrounded by billows of juniper smoke, he blows, utters inarticulate sounds, and breathes more and more heavily until high, sharp screams pass over his lips—signs of the approaching deity.”

AMÉLIE SCHENK

WAS IST SCHAMANENTUM? [WHAT IS SHAMANISM?]
(1996, 23*)

Psychoactive Material

—Fresh or dried branch tips

—Heartwood

—Resin

Preparation and Dosage

Drooping juniper is one of the most important materials for the manufacture of Tibetan incense and is made into incense powders and sticks. The branch tips are used for the former, while both the tips and the (heart)wood may be used for the latter. Most Tibetan incense blends based upon drooping juniper also contain other *Juniperus* species, branch tips of the Himalayan cypress (*Cupressus torulosa* D. Don), and various *Artemisia* species (cf. ***Artemisia* spp.** and **incense**).

Nepali shamans use freshly ground twigs, white sandalwood (*Santalum album* L.), and *nepali kagas* or daphne paper (*Daphne papyracea* Wall. ex Steud. [syn. *D. cannabina* Lour.]) to make incense cones approximately 10 cm long that they use in rituals. Normally, however, the fresh, half-dried, or dried branch tips are simply strewn onto glowing coals and the resulting smoke is deeply inhaled. Concrete information about dosages is almost impossible to ascertain, as the amounts used can range from small branch tips to entire bundles or even large branches.

Ritual Use

Drooping juniper is sacred to almost every Himalayan people. Branches of the plant are often attached to the ends of the masts holding prayer flags (as a symbol of the World Tree or shamanic tree). Wanderers in the mountains also use the branches as amulets to protect them from falling or being hit by rocks; the branches are offered to the mountain spirits at the piles of stones typically found at passes. But the primary ritual use of the plant is as an incense.

The Tibetans characterize the incense they make from drooping juniper as a “food of the gods.” The incense is associated with a special ritual of purification they call *bsang* (pronounced “shang”), which is the same name they give to the tree. In this ritual, branch tips are burned while special mantras (conjunction formulas) are recited. The shamans of western Tibet also use juniper as a trance-inducing incense (Schenk 1994*).

The Buddhist peoples of the Himalayas (Tibetans, Bhotyas, Tamang, Sherpas) use fresh or dried juniper branches as an incense during their morning prayers (*puja*) to the Buddha Shakyamuni. The Sherpas fumigate with juniper when conjuring spirits and cremating bodies.

Nepali shamans (*jhākri*) use a variety of incenses, the most important of which is juniper. They use either the branches or the resin. Drooping juniper has definite psychoactive effects upon these shamans:

It was striking that the shaman (*jhākri*) began the exorcising activities by bending over an

incense bowl filled with glowing juniper needles of *recurva* (other species are not used) and clumps of resin and deeply inhaling the smoke before drumming himself into trance with the aid of a large lama drum. (Knecht 1971, 218)

In Pakistan, juniper is venerated as a sacred tree that the shamans of the Dards use as an incense. The shamans and trance dancers (*bitaiyo*) of the neighboring Hunza also inhale juniper smoke:

The state of true trance is attained by inhaling the smoke of a juniper fire, by biting on juniper branches, and by drinking the blood from the severed head of a male kid goat. . . . The trance dancer (*bitan*) runs around jumping wildly. . . . He repeatedly interrupts his fast run, . . . to listen to the musical instruments and, finally, breaking down over a drum, he sings his prophecy in an ancient language that he is incapable of speaking or understanding when he is awake. (In Knecht 1971, 219)

The Hunza attribute shamanic abilities directly to the effects of juniper smoke:

In Hunza, the *bitaiyo* are regarded as persons with supernatural powers whose services as prophets, magicians, and healers were called upon. They manifest their abilities only after inhaling the smoke of burning juniper branches and drinking warm goat's blood. After this, they danced to rhythmic drum beats until they had attained the trance state. When asked about the future, they passed on the messages of the fairies in the form of songs. (Felmy 1986, 19)

To increase the psychotropic effects, juniper needles may be mixed with the seeds of Syrian rue (*Peganum harmala*) before being cast onto a fire.

Artifacts

Branches and trunks of drooping juniper may be erected at cloisters and shrines as symbols of the World Tree or shaman's tree. Juniper (and other materials) is burned as incense in numerous incense vessels. The vessels usually are made of bronze or brasslike alloys and typically are decorated with Buddhist symbols (the eight auspicious symbols, dragons, et cetera).

Medicinal Use

In Darjeeling, an area that is under Indian jurisdiction but culturally is part of Nepal, the branches are burned to dispel insects and mosquitoes.

Although *Juniperus* species are used throughout the world for both ritual and medicinal purposes, only the species *Juniperus recurva* has a reputation for being psychoactive. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633.)

In Darjeeling and in Sikkim (formerly a tiny Himalayan kingdom, now a part of India), the ripe fruits are added to the locally brewed millet and rice **beer** for flavoring (Biswas 1965). In other regions, they are used to perfume homemade millet schnapps (*rokshi*). Juniper berries are said to have a purifying effect upon the aura and the subtle body and therefore find use as incense in both Ayurvedic and tantric medicine. In Ayur-veda, the berries are ingested as a diuretic and to improve digestion. They also are made into a paste that is applied externally to treat arthritis, swelling, and pain (Lad and Frawley 1987, 214*).

Traditional representation of a high mountain species of Juniper (*Juniperus pseudosabina*) on a Tibetan medical thangka.

Constituents

Droping juniper is rich in an **essential oil** whose composition presumably is similar to that of the

essential oil of *Juniperus communis* L.¹⁹⁵ The essential oil is most heavily concentrated in the tips of the branches, the fruits (0.46 to 0.88%), and the heartwood. Isocedrolic acid and 4-ketocedrole have been found in the entire plant. The needles contain biflavones, cupressoflavones, and their derivatives (Asolkar et al. 1992, 380*). The composition of the essential oil of the Kashmiri variety *squamata* has been worked out; it consists of 23.6% limonene, 16.3% sabinene, 14.6% α -pinene, and some α -thujone, myrcene, terpinene, and Δ -cadinene, as well as trace amounts of other substances (Weyerstahl et al. 1988, 260). The dried leaves have yielded biflavones (amentoflavone, hinokiflavone, isocryptomerin) and flavonol-O-glycosides (quercetin-O- α -L-rhamnosides and kaempferol-3-O- β -D-glucoside) (Ilyas et al. 1977).

The smoke of *Juniperus recurva* has been chemically investigated for psychoactive components. The gaseous phase contains over forty substances, the primary components of which have been identified as acetone, benzole, toluole, ethylbenzole, o-xylol, m-xylol, and most likely limonene (Knecht 1971, 220). To date, no actual psychoactive component has been discovered or isolated and pharmacologically studied.

Some sources in the literature have asserted that norpseudoephedrine is present in this species of Himalayan juniper (Schuldes 1995, 45*). Such claims most likely are incorrect (cf. **ephedrine**).

Effects

Indian and Nepali scientists have determined that the smoke from the fresh wood has emetic effects causing prolonged vomiting (Suwal et al. 1993, 72*); the extract of the branch tips appears to have anticarcinogenic effects.

Drooping juniper often has been attributed with the ability to produce psychoactive effects. However, it is uncertain whether the scent has a psychological effect or the smoke has a pharmacological effect. It is possible that only certain specially endowed individuals are able to experience the psychoactive effects of the smoke.

In my own experience, the smoke promoted the recall of memories. I found myself immediately transported to the Himalayas, where I mentally participated in archaic shamanic rituals.

Commercial Forms and Regulations

In Nepal and India, the dried branch tips are sold in herb markets and by sellers of incense (e.g., around the stupa of Bodnath, near Kathmandu). Drooping juniper is not subject to any restrictions.

ZAUBERKRÄUTER [MAGICAL PLANTS] (1986, 151f.*)

Justicia pectoralis Jacquin

Justicia

Family

Acanthaceae (Acanthus Family)

Forms and Subspecies

There is one variety that occurs chiefly in Venezuela and Ecuador and is of ethnopharmacological importance: *Justicia pectoralis* Jacq. var. *stenophylla* Leonard.

Synonyms

Dianthera pectoralis (Jacq.) Murr.

Eclobium pectorale (Jacq.) Kuntze

Psacadocalymma pectorale (Jacq.) Bremek

Rhytiglossa pectoralis (Jacq.) Nees

Stethoma pectoralis (Jacq.) Raf.

Folk Names

Boo-hanak, buhenak, carpenter bush, carpenter grass, curía,¹⁹⁶ fresh cut, garden balsam, herbe à charpentier, justicia, justizia, kokoime, kumaruka’a (Ka’apor, “tonka bean plant”), mahfarahenak (Maitá), marica (Shipibo-Conibo), masci-hiri, masha-hara-hanak, mashahari, masha-hiri (Waika), mashi-hiri, mashihíri, paxararok (Ninam), pirapishî-ka’a (Ka’apor, “fish(?) -plant”), sua-ka-henako (Yanomamö, “leaves to use on women”), tilo (Cuba), tilo casero, tilo criollo, tilo de jardín, tilo natural, toyeau, trebo, yacu piri-piri, ya-ko-yoó (Puinave), zeb shêpantyê

History

The first report of the Venezuelan Indian use of justicia as a **snuff** was made in 1953 (Schultes 1990, 61). The ethnopharmacology and chemistry of the plant are still essentially unknown.

Distribution

The plant grows along waterways in the tropical rain forests of Mexico and Central America, on the Caribbean islands (Cuba), and in northern South America. The variety *stenophylla* occurs only in South America.

Cultivation

Propagation occurs via the seeds or the planting of rootstocks that have been separated from another plant. The simplest method is to use cuttings that have begun to develop roots or scions (stems that have developed roots on the lower nodes). In South America, the plant is cultivated as an ornamental. The Yanomamö Indians cultivate it for the manufacture of psychoactive **snuffs**. They grow the plant in the semishaded areas between banana trees. The plant does not tolerate frost.

Appearance

The plant, which can grow as tall as 70 to 80 cm, develops vertical stalks that lean at the tops and

sometimes develop roots on their lower nodes. The numerous light green, somewhat rough leaves are narrow and lanceolate, 2 to 5 cm long and 2 to 3 cm wide. The flowers, which are typical of those of the family, develop at the tips of the stalks. The calyxes are only 5 mm long and are usually white or light violet in color. In the tropics, the flowering period is from November to April. The fruits, which contain the flat, reddish brown seeds, develop from December to March.

The variety *stenophylla* is chiefly distinguishable by a more stocky pattern of growth (up to 30 cm tall) and narrower leaves (1 to 2 cm wide).

The plant is very easily confused with other *Justicia* species, some eighty of which occur in Mexico alone. Worldwide, there are approximately four hundred species in the genus (cf. Daniel 1995).

Psychoactive Material

—Leaves, fresh or dried

Preparation and Dosage

A sedative tea can be made by pouring hot water over a handful of fresh leaves. Allow to steep for five to ten minutes, and sweeten with **honey** as desired.

In Guadeloupe (Caribbean), the fresh herbage is steeped in **wine**, sweetened with **honey**, and used as a love drink (Müller-Ebeling and Rätsch 1986, 126*).

Only leaves that have been dried in the shade are used for psychoactive purposes. These are ground into a fine powder and used primarily as an additive to the **snuff** known as *epená*. Justicia powder often is mixed with the dried resin of *Virola* spp. (Prance 1972a, 17*).

Today, the dried leaves are often mixed with marijuana (*Cannabis indica*) for smoking (see **smoking blends**); the mixture has a pleasant aroma. *Justicia pectoralis* also appears to be used as an ingredient in the tobacco preparation known as *chimó* (see *Nicotiana tabacum*).

The leaves of the South American *Justicia pectoralis* var. *stenophylla* are used primarily as an aromatic additive to psychoactive snuffs.

Ritual Use

The most important use of the leaves of the variety *stenophylla* is as an additive to psychedelic **snuffs** that are based on the dried resin of DMT-containing species of the genera *Anadenanthera* and *Virola*.

The dried leaves acquire an aromatic scent. They are used in this way by various tribes in the Amazon region. The Waika or Yanomamö use *Justicia* leaves and *Virola* resin to manufacture a snuff they call *machohara*. They say that while each of the two ingredients can be snuffed by itself in order to induce mild visions, the combination of the two has better effects and is more potent (Schultes 1990, 68).

It is possible that *Justicia pectoralis* may have been used as a **snuff** in prehistoric Mexico.

The Shipibo say that the plant awakens the spirit of work in humans and brings good fortune in fishing. To achieve these benefits, a person should drink a decoction of the leaves (Arévalo V. 1994, 185*).

Artifacts

Yanomamö women place bundles of the leaves into holes in their earlobes for decorative purposes.

Medicinal Use

The Yanomamö use *Justicia pectoralis* var. *stenophylla* as an aphrodisiac for women (Schultes 1990, 64f.) The Kofán Indians of Colombia make a decoction of a related species, *Justicia ideogenes* Leonard, which they use to treat the symptoms of old age (Schultes 1993, 131*).

In Cuba, *Justicia pectoralis* is known as *tilo*,¹⁹⁷ more rarely as ***tila***, and is drunk as a mild nerve tea (sedative) that has an aromatic/sweet taste. Moreover, the plant is used in Cuban folk medicine as a remedy for heartburn, epilepsy, arteriosclerosis, baldness, runny nose, blindness, colic, lack of appetite, weakness, sleeplessness, headache, scurf, coughing, and depression (Seoane Gallo 1984, 876*). In the Caribbean, teas made from the plant are used chiefly for coughs and colds. The freshly pressed juice of the leaves is dripped onto bleeding wounds (Seaworth 1991, 70*). In Trinidad, a decoction is drunk to treat flu, fever, cold chest, coughing, pneumonia, and vomiting (Wong 1976, 139*). The plant is used as an aphrodisiac in Guadeloupe (Müller-Ebeling and Rätsch 1986, 126*).

In Mexican folk medicine, the plant known locally as *trebo* is administered to treat elevated body temperatures (Argueta V. et al 1994, 1519*).

Constituents

The leaves were at one time determined to contain ***N,N*-DMT**, a finding that later was discovered to be incorrect (Ott 1993, 410*). However, this possibility has again been raised (Schultes 1990).

Known to be present are betaine, umbelliferone, an **essential oil**, various **coumarins** (**scopoletin** and others), benzopyrane, and justicidine B (Macrae and Towers 1984; Seaworth 1991, 70*). Small amounts of vasicine and traces of tryptamines also have been detected (Schultes 1990, 66).

Large quantities of **coumarins** are produced as the leaves dry, and these give the raw plant material its characteristic scent (Schultes 1990, 68). The genus *Justicia* is also known to contain lignans (Ghosal et al. 1979).

Effects

The plant is sometimes described as hallucinogenic (Daniel 1995, 75). Apart from its mild sedative effects, however, little is known about the psychoactive properties of the plant. There are some reports of hypnotic and sedative effects, which can be attributed to the **coumarin** the plant contains (Macrae and Towers 1984).

Commercial Forms and Regulations

The seeds are occasionally available through sources specializing in ethnobotanical plants.

“*Chonó-Rau*, *Chonó Ininti*, or *Rimon Ininti* (*Justicia* sp.) [is one] master plant that smells like lemons; it is ingested especially by the

students of the shamans [of the Shipibo-Conibo Indians]. During a two-week long dietary period (abstinence), the student drinks the initiatory water of the leaves. Afterward, he takes ayahuasca and encounters the lord of the plants either in the resulting visions or in his nocturnal dreams.”

Lactuca virosa Linnaeus

Wild Lettuce

Family

Compositae: Asteraceae (Aster Family); Subfamily Cichorioideae, Lactuceae Tribe

Forms and Subspecies

The taxonomy of the wild *Lactuca* species has not been completely clarified. It is possible that there may be several varieties of *Lactuca virosa*.

Synonyms

Lactuca agrestis nom. nud.

Lactuca sylvestris nom. nud.

Folk Names

Bitter lettuce, German lactucarium, giftlattich, giftsalat, kompaßpflanze, lactuca agresti, lactucke, laitue vireuse (French), lattichopium, lattig, latuga velenosa (Italian), leberdistel, lettuce, lettuce opium, lopium, prickly lettuce, stinksalat, totenkraut, wild lettuce, wilder lattich

History

Egyptian grave paintings dated to approximately 4500 B.C.E. depict plants whose appearance is strongly reminiscent of a wild lettuce species or a cultivated form bred from it (Whitaker 1969, 261). There was already some confusion about the name and source of *Lactuca* pharmacologic material in ancient times (Schneider 1974, 2:222 ff.*). Thus, we still do not know with certainty which lettuce species was known to and used by the ancient Egyptians. It may have been *Lactuca scariola* L. [syn. *Lactuca serriola* Torner], *Lactuca virosa*, or a form of *Lactuca sativa* (Harlan 1986, 7). The garden salad *Lactuca sativa* presumably was derived from *Lactuca scariola* in ancient Egypt (Lindqvist 1960).

Wild lettuce clearly had a ritual (divination) and medicinal significance in ancient times:

The wild lettuce, which the prophets knew as “Titan’s blood,” Zoroaster as *pherumbros*, the Romans as *Lactuca silvatica*, is similar to the garden lettuce but has a sturdier stalk, whiter, thinner, coarser, and bitter-tasting leaves. Overall, it is similar in its effects to the poppy, which is why some also mix its juice into opium. . . . It generally is able to make one sleepy and relieve pain. Furthermore, it promotes the catamenia and is also drunk for scorpion and spider stings. The seed is taken like that of the garden lettuce and inhibits pollution and coitus. After it has been dried in the sun, the juice that is pressed from it is stored in earthen vessels like the other juices. (Dioscorides 2.165)

It may be that the “twelve gods’ herb” that Pliny praised as a panacea was a species of *Lactuca*, perhaps even wild lettuce itself (see **Dodecatheon**). The Arabic physician Avicenna (= Ibn Sina, 980–1036), who established the use of opium (cf. *Papaver somniferum*) in Islamic medicine, wrote, “Opium is sometimes also produced from the seeds of *Lactuca agrestis* (lettuce), this is only mildly

sedating” (*Qanun*, 5.526).

Hildegard von Bingen certainly played a role in establishing the psychoactive reputation of the plant:

The lettuces, which can be eaten, are very cold, and when eaten without spice they make the brain of man empty with their useless juice. . . . But the wild lettuces have almost the same nature. For anyone who would eat lettuces, which are useless and are called weeds, either raw or cooked, would become mad, that is insane, and he will become empty in the core, because those are neither warm nor cold, but simply a useless wind that dries out the fruit of the earth and brings forth no fruit. And those lettuces grow from the foam of the earth’s sweat and are therefore useless. (*Physica* 1.90/91)

In 1543, Leonard Fuchs depicted a lettuce plant in his *Kräuterbuch* [Herbal] under the name *Lactuca capitata*, a wild or already cultivated species of *Lactuca* (Whitaker 1969, 262).

Wild lettuce was once an important opium substitute (Coxe 1799; Schneider 1974, 2:226*). It has been claimed that some North American Indians smoked lettuce (Miller 1993, 48*). In 1792, a physician in Philadelphia named Kore invented lactucarium, the thickened latex (Bibra 1855, 254*).

The stalks and leaves of the forest lettuce, regarded as the “fourth race of incense spice,” are also said to contain an opium-like juice. Unfortunately, it is no longer possible to botanically identify the plant in question. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Wild lettuce (*Lactuca virosa*) in bloom.

Lactucarium, obtained from the latex of wild lettuce, is regarded as an opium substitute.

“There is also a form of white lettuce which the Greeks called opium lettuce because a juice with sleep-promoting powers flows richly within it. It is thought, however, that all lettuce species bring sleep. This was the only species of lettuce that grew in Italy in ancient times and is recalled in the Latin name for lettuce [*lactuca*], which is derived from the word for milk.”

PLINY
NATURAL HISTORY
 (19.38)

“The salad or lettuce (*Lactuca sativa*) increases the milk of the sucklers and lessens the fire of love. The sharp eye of the eagle is said to be due to the fact that it eats lettuce from time to time.”

K. RITTER VON PERGER
DEUTSCHE PflANZENSAGEN [GERMAN PLANT LEGENDS]
 (1864, 201*)

“Among the most important attributes of the fertility god Min is lettuce. At the festival of the god, a small bed with this plant was included in the procession. Lettuce was depicted in numerous relief images of Min (and borrowing from him, in a special form of Amun as well, e.g., in the temple of Luxor). The plant was regarded as an aphrodisiac, which also explains its popularity as a cultic gift of offering

(preserving the procreative power = life).”

MANFRED LURKER

LEXIKON DER GÖTTER UND SYMBOLE DER ALTEN ÄGYPTER [LEXICON OF THE GODS AND SYMBOLS OF THE ANCIENT EGYPTIANS]

(1987, 124)

Distribution

Lactuca virosa’s original range was in southern Europe. It now grows wild in many parts of central Europe, where it was once cultivated as a source of lactucarium. Wild lettuce is also widespread in southern North America, where it was introduced from Europe.

Cultivation

Propagation occurs via the seeds (just as with garden salad). The seeds are simply broadcast over the ground in spring (Grubber 1991, 66*). Lettuce prefers loose, well-drained humus soil (topsoil).

Appearance

Lactuca virosa is an annual or sometimes biennial plant that can grow from 60 to 150 cm tall. It has a round stalk that branches into panicles at the top. The leaves are spinose and toothed, and their midveins have spines on the lower side. The flowers are light yellow and basket-shaped. The blackish fruits are narrow and resemble wings. The plant is most easily recognized by the white latex that flows through all of its parts and issues when the plant is injured.

Lactuca virosa is easily confused with prickly lettuce, *Lactuca scariola* [syn. *Lactuca serriola* L.]. The leaves of the latter, however, are deeply incised/retuse. Lettuce is also sometimes confused with various species of the genus *Sonchus* (cf. *Erythroxylum coca*).

Psychoactive Material

—Thickened juice (latex): lactucarium,¹⁹⁸ lactu carium germanicum

—Dried leaves¹⁹⁹

Preparation and Dosage

The dried leaves can be smoked alone or in **smoking blends** with other herbs.

Lactucarium is obtained in a variety of ways:

The juice of the plant can be obtained by using an electric juicer and then drunk. More frequently, the upper part of the plant is cut repeatedly and the milk that emerges collected. This is allowed to dry and can then be smoked. The entire plant can also be dried and smoked. The largest single dosage of lactucarium was 0.3 g, the maximum daily dosage 1 gram. (Schuldes 1995, 46*)

Lactucarium can be obtained simply by collecting the latex and allowing it to dry. The dried latex then can be either dissolved in **alcohol** and drunk or mixed together with other herbs (mint, hemp, thorn apple; cf. **smoking blends**) and smoked:

Lettuce opium was often used by North American Indians who smoked the dried resin or sap obtained from the plant. They cut the flower heads off, gathered the sap that drained, and then let it air dry. This process was repeated over a two-week period by cutting just a little bit off the top each time. (Miller 1985, 96)

The leaves and lactucarium were also ingredients in the so-called **witches' ointments**.

A psychoactive dosage of wild lettuce leaves is 28 g (Miller 1985, 96*). When used for medicinal purposes, the largest single dosage of lactucarium is 0.3 g, while the total daily dosage is 1.0 g (Roth et al. 1994, 444*).

Ritual Use

Lettuce was sacred to the popular Egyptian god Min (Keimer 1924), who was already being worshipped in the time of the Old Kingdom. The Greeks saw Min as a form of their lusty god Pan (cf. ***Arundo donax***). Min was usually portrayed with an erect penis. He was the god of the desert, the lightning, and the sandstorm as well as a god of fertility and procreation. He wore a headdress made of ostrich feathers. His symbols were the phallus and the lettuce. His festival, which was a kind of harvest celebration, was celebrated during the first month of summer. At this festival, a statue of Min was carried in a sacred procession on a bed of lettuce (Harlan 1986, 6).

Artifacts

Lettuce was frequently depicted in Egyptian works of art and is often found in association with representations of the god Min (Lurker 1987, 124). Min's ceremonial procession is depicted in many wall paintings in buildings from the time of Ramses II, Ramses III, Herihor, Seti I, Amenhotep III, Sosestris, and Thutmosis III (Harlan 1986, 6).

Medicinal Use

Aphrodisiacs were once made from lettuce and the lactucarium it yields. The ancient Egyptians possessed a book of love agents, which has unfortunately been lost. For this reason, the Egyptians' recipes for aphrodisiacs based upon lettuce are unknown. Oddly enough, the ancient Greeks attributed lettuce with the opposite effect, namely that of an anaphrodisiac (Harlan 1986, 8).

In the modern period, lactucarium was used as a sedative and as a substitute for opium (cf. ***Papaver somniferum***).

In homeopathy, *Lactuca virosa* is used according to the medical description (which differs from that for *Lactuca sativa*) to treat sleeplessness, dry cough, and other ailments (Roth et al. 1994, 444*):

This agent primarily affects the brain and the circulatory system. Delirium tremens with sleeplessness, cold and tremor. Hydrothorax and ascites. Impotence. Feelings of lightness and tightness that affect the entire body, especially the chest. It appears to be a true lactagogue. Pronounced effects upon the extremities. (Boericke 1992, 460*)

Constituents

Lactucarium contains the sedative sesquiterpene lactone/bitter substance (guaianolide) lactucine ($C_{15}H_{16}O_5$) and its p-hydroxyphenylacetic acid ester, lactupicrine (= lactucopicrine),²⁰⁰ along with triterpene alcohols (lactucerosol), a melampolglycoside (lactuside A), and other guaianolides (11 β ,13-dihydrolactucine, 8-deoxylactucine, jacquineline, zaluzanin derivatives) (Stojakowska et al. 1993, 1994). The older literature speaks of the presence of a "hyoscyamine-like alkaloid" (cf. **tropane alkaloids**) (Frohne and Pfänder 1983, 67 f.*).

It should be noted that opium-like alkaloids are also present in garden salad or lettuce (*Lactuca sativa* L.) (Bibra 1855, 259*). When the cabbage lettuce forms its stalk, a white, milky sap develops that contains alkaloids with sedative effects (Rätsch 1995a*, 1995c*). The variety *Lactuca sativa* var.

capitata L., which is grown for use in salads, is also known as lettuce opium and French lactucarium (Brown and Malone 1978, 23*).

Effects

Lactucarium has analgesic, sedative, and cough-suppressing effects (Stojakowska et al. 1993). The effects were once compared to those of the deadly nightshade (*Atropa belladonna*) (Harlan 1986, 10). They also have been used to explain the effects of kava (see *Piper methysticum*). The effects have been described as a “languid dream state” (Miller 1985, 97*) or an aphrodisiac high.

The pioneer Freiheer Ernst von Bibra (1806–1878), who experimented with lactucarium a great deal, came to the following conclusion: “Quite similar to opium, lactucarium from various species and varieties of *Lactuca* species also possesses somewhat diverging properties, but in its main effects, just as with opium, it is the same” (Bibra 1855, 255*).

The sedative effects are attributed to the sesquiterpene lactones of the guaiane type that occur in the latex and often are present in the form of glycosides (Stojakowska et al. 1994, 93).

Commercial Forms and Regulations

All preparations of *Lactuca virosa* may be sold without restriction.

Recently, lettuce preparations (such as Lettucene) have been sold as “extra strong” hashish substitutes under such provocative names as *hash oil* and *hashish* (see *Cannabis indica*). These consist of damiana (*Turnera diffusa*) and extracts of *Lactuca sativa* and sometimes also contain yohimbé bark (*Pausinystalia yohimba*).

The flower of *Lactuca sativa* var. *sativa*.

A cultivated form of the garden salad (*Lactuca sativa* cv.), here shown in flower, during which phase it produces a narcotic juice.

Latua venenata Phil. (misspelling in the literature)

Latua venenosa Phil.

Lycioplesium pubiflorum Griseb.

Folk Names

Árbol de los brujos (Spanish, “tree of the magicians”), baum der zauberer, latua, latue, latué (Mapuche, “he who kills”), latúe, latue-hue, latuhue, latuy,²⁰¹ latuyé, palo de bruja (“tree of the witch”), palo de brujos (“tree of the magicians”), palo mato (“tree of death”), tayu, tree of the magicians, witches tree

History

It appears that this plant was already being used for shamanic purposes in southern Chile in pre-Spanish times. Sources from the colonial period do not mention any kind of use. The genus and species were first described by the German botanist Rudolph A. Philippi (1858). The name *latúe* is from the Mapudungun (Mapuche) language and means “that which causes death.” In Chile, many rumors circulate concerning the lethal effects of the tree, which is generally so feared that no one will speak of it (which does not make research any easier!).

In earlier times, Chilean fishers used the shrub as a fish poison. They combined the juice of the plant with bark from the sacred shamanic tree known as *canelo* (*Drimys winteri* Forst; see **incense**) (Plowman et al. 1971, 74). The not-unpleasanttasting plant juice was or is used to poison food (Houghton and Manby 1985, 100*). Such use occurs primarily as a method of taking revenge on people who are the objects of desire but do not reciprocate the feeling.

Distribution

Latua pubiflora is endemic to Chile (Hoffmann 1994, 222) but is found only in very clearly delimited areas, e.g., in the Cordillera Pelada near Osorno (Mösbach 1992, 104*). The shrub is somewhat more common on the mountain ridges of the Cordillera de San Juan la Costa, which is in the center of the Mapuche region. *Latua* is also said to be indigenous to the island of Chiloé, but it is extremely rare there (Plowman et al. 1971).

Latua pubiflora is one of the rarest of all psychoactive plants. To date, it has never been cultivated

anywhere else, nor has it been spread by humans.

Cultivation

Propagation can occur with pregerminated seeds (experiments are presently being carried out). The Mapuche propagate the beautiful plant using cuttings taken from green branches. *Latua* requires a mild, frost-free climate with much rain. However, the soil should not become too moist.

The leaves of the latúe plant grow considerably larger, and its appearance is (even more) beautiful when it is grown in the shade.

Appearance

While this perennial shrub can attain heights between 2 and 10 meters, it usually grows to 3 to 4 meters. The plant has one or more main stems that become woody and can grow up to 25 cm in diameter. The gray branches grow curiously in all directions. On some plants, these branches are thickly covered with long, sharp, hard thorns, while on other individuals the thorns are almost entirely absent. The gray-green, lanceolate leaves are alternate and can grow as long as 8 cm (although they usually reach only 3 cm). The violet, bell-shaped flowers hang from the thorny branches as if in panicles and attain a length of some 4 cm. The fruits are small, round, yellow-green berries that contain a great number of tiny seeds. Flowering occurs between October and March, although individual shrubs may flower more than once a year. The fruits typically ripen in March. Pollination occurs via hummingbirds (Plowman et al. 1971, 68).

Latua is easily mistaken for *Dasyphyllum diacanthoides* (Less.) Cabr. [syn. *Flotowia diacanthoides* Less.], known as *tayo* or *palo santo* (“sacred tree”), which is used in folk medicine (Plowman et al. 1971, 70).

Psychoactive Material

—Leaves, fresh or dried, and the juice obtained by pressing them

—Stem/wood

—Bark, fresh or dried

—The entire plant except for the root (tot.)

—Flowers, fresh or dried

Latua pubiflora, known as the tree of the magicians, is one of the rarest of all shamanic plants. Its range is restricted to a small area in southern Chile. (Photographed near Osorno)

The raw plant material from *Latua pubiflora* is used for folk medicinal purposes.

Rhamphithamnus spinosus, which is used as an antidote for *Latua* overdoses, has a similar appearance to the tree of the magicians, especially in its long thorns. (Photographed in Chiloé)

Preparation and Dosage

The shamans of the southern Chilean Mapuche (so-called *machi*; cf. Bacigalupo 1995) normally use a juice obtained by pressing freshly harvested leaves, which they dilute with water. The freshly pressed plant juice is also mixed with **wine**; occasionally, a decoction made from the bark of young shoots is preferred. Dried parts of the plant are used to make a tea (infusion) (Houghton and Manby 1985, 100*). Unfortunately, no information is available concerning the quantities that are used.

The Mapuche shamans ingest some of the tea every twenty to thirty minutes. In this way, the effects gradually become evident and overdoses can be avoided (Plowman et al. 1971, 81).

There are many recipes for (psychoactive) latúe incense (*saumerio de latúe*). Usually, equal parts of *canelo* bark (*Drimys winteri*), *romero* herb (*Fabiana imbricata*), and palqui leaves (*Cestrum parqui*) are mixed with *Latua* leaves. Another recipe calls for equal parts of *Fabiana*, *Latua*, and *Cestrum parqui*. A third recipe lists a mixture of *Latua*, wheat, maté (*Ilex paraguariensis*), and *Fabiana*, to which horse bones are sometimes added (Nakashima Degarrod n.d., 11f.).

The flowers and leaves are dried in the shade, after which they can be smoked. Initial experiments have indicated that the dosage should not exceed 1 g per person.

For external treatments, alcohol extracts (*licor*) are prepared from the leaves, often in combination with other herbs. A handful of the dried raw plant (tot.), boiled in water, is used as a bath additive to treat rheumatism (*baño de reumatismo*).

The traditional antidote for *Latua* overdose is a decoction of *hierba mora* (*Solanum nigrum*; see *Solanum* spp.) and the herbage of an *Oxalis* species or the fruit of *Rhamphithamnus spinosus* (A. Juss.) Moldenke (Plowman et al. 1971, 75).

Ritual Use

This plant formerly was used by the shamans (*machi*) of the Mapuche in the region of Valdivia.²⁰² Most Mapuche shamans are female; only a very few men hold this position (Philip 1994).

One Mapuche group, the Huilliche, still revere the plant as a shamanic tree, for it brings power, knowledge, and realization; offers magical protection; and can heal (Nakashima Degarrod n.d., 8).

An offering (bread, cooked chicken, wheat porridge, tobacco) must be made to the plant before it is harvested. Then a short but important prayer is said to the spirit of the plant: “Little plant, come to me,

I will take something of you so that you will give me health.”

Many shamans claim that they acquired their powers and abilities by consuming latúe preparations during their initiation (Nakashima Degarrod n.d., 11).

For the Mapuche shamans, latúe is the most important **incense** for dispelling evil spirits, bad moods, worries, and grief. To this end, the herb, which is always mixed with other substances (see above), is scattered over an open fire.

The plant is also used by black shamans (*kalku*) for their nefarious deeds (witchcraft, death magic).

Artifacts

No artifacts are known. However, it is possible that the Mapuche shamans do manufacture or use some.

Medicinal Use

Latúe is considered to be an aphrodisiac and was utilized as an ingredient in love drinks (Bodendorf and Kummer 1962). The Mapuche believe that small doses of the plant help develop physical strength and that children should be given some *Latua* so that they become “big and strong” (Nakashima Degarrod n.d., 13). Mapuche shamans administer weak infusions of the leaves and fruits internally to alleviate pain (Nakashima Degarrod n.d., 15).

In Chile, the bark of the bush, known as *tayu*, is used in folk medicine as a decoction for treating contusions and bruises (Schultes 1970, 48*). Shamans recommend a decoction of latúe, ***Fabiana imbricata***, and palqui (***Cestrum parqui***) as a medicinal bath additive. A *licor de latúe* is applied externally to treat rheumatism, arthritis, coughing, pain, et cetera.

“The Huilliche [a Mapuche tribe] believe that *Latua pubiflora* is inhabited by a spirit and is thus sacred. It is thought that the plant can bring physical strength, healing, death, and good luck and contains shamanic powers. These powers, however, are only associated with the female plant. The female plant is considered to be that one which produces fruits and has thorns, which are lacking in the male plant. Only the female plant is used by the Huilliche. It is thought that the plant is jealous and possessive. For this reason, the people keep the rituals associated with it secret. In addition, they show the plant a deep respect, for they believe that they will otherwise be severely punished. Several conceptions about the plant exhibit syncretism with Christianity. For some people, the plant is sacred because it is associated with Jesus: the thorns are said to have been used to crown Christ before the crucifixion.”

LYDIA NAKASHIMA DEGARROD

CONTEMPORARY USES OF THE LATUA RUBIFLORA AMONG THE HUILLICHE OF CHILE

(N.D.)

Constituents

The entire plant contains the **tropane alkaloids atropine** and **scopolamine** (Schultes and Farnsworth 1982, 166*); the concentration of atropine (0.18%) is greater than that of scopolamine (0.08%) (Plowman et al. 1971, 86). The leaves contain 0.18% hyoscyamine (= atropine) and lesser amounts of scopolamine (Bodendorf and Kummer 1962). Earlier analyses suggested that the leaves contain the highest concentrations of active constituents, while the stem contains less and the fruits are devoid of alkaloids. Yet other analyses have indicated that the stem contains the highest alkaloid content and the seeds and leaves only slight amounts (Plowman et al. 1971, 86).

Effects

Latúe is said to cause severe delirium and visual hallucinations and induces pronounced dryness of the mouth, pupillary dilation, headaches, and confusion. The effects last up to three days; aftereffects (similar to those of ***Brugmansia***) can linger for weeks. Even a tea made from the leaves is capable of inducing hallucinations and cramps (Houghton and Manby 1985, 100*). It is also said that *Latua* can

produce permanent “imbecility” (Murillo 1889). The shamans are apparently not harmed by the plant; on the contrary, it helps them learn about things that are otherwise hidden.

Smoking the dried leaves produced in me very pleasant bodily effects with aphrodisiac sensations and great mental relaxation with associative thoughts (very similar to the effects of various species of the genus *Brugmansia*).

Commercial Forms and Regulations

None

A statue of El Brujo, “the magician,” lord of *Latua pubiflora*. (Sculpture in the Museum of Ancud, Chiloé)

Ledum palustre Linnaeus

Wild Rosemary

Family

Ericaceae (Heath Family); Subfamily Rhododendroideae

Forms and Subspecies

Two Eurasian subspecies are distinguished: *Ledum palustre* L. ssp. *palustre* (European wild rosemary) and *Ledum palustre* ssp. *sibiricus* (Siberian wild rosemary). The Greenland wild rosemary has recently been recognized as a subspecies: *Ledum palustre* ssp. *groenlandicum* (Oed.) Hult. (Zander 1994, 341*).

The genus itself consists of only a few species.^{[203](#)}

Synonyms

Ledum groenlandicum Oed.

In the summer of 1996, the American Horticultural Association incorporated the genus *Ledum* into the genus *Rhododendron*. Whether this taxonomic innovation will gain acceptance remains to be seen. Whether it is botanically justified is also an open question.

Folk Names

Altseim, baganz, bagen, bagulnik, bieneheide, bienenscheide, böhmischer rosmarin, borse, brauerkraut, bûpesbupt (Makah, “cranberry”), cistus ledonfoliis rosmarini ferugineis, einheimischer lorbeer, flohkraut, getpors (Swedish, “goat porsch”), gichttanne, gräntze, gruitkraut, gruiiz, grund, gruut, hartheide, heidenbienenkraut, Hudson’s Bay tea, kiefernporst, kienporst, kienrost, klopovnik, kühnrost, Labrador tea, labradortee, ledó, ledón des marais, ledumporst, ledum silesiacum, lunner, marsh tea, mirtus, moerasrozenmarijn, moor-rosmarin, morose, mottenkraut, mutterkraut, myrto, nûwaqwa’ntû (Quinault), pors, porsch, porskraut, porst, post, postkraut, rausch, rosmarinkraut, rosmarinus sylvestris, roßkraut, sautanne, schweineposse, sqatram, sumpfporst, tannenporst, ti:mapt (“tea plant”), waldrosmarin, wanzenkraut, weiße heide, wilder rosmarin, wild rosemary, zeitheide, zeitheil

History

It appears that the authors of antiquity were not aware of wild rosemary. Pliny, however, does mention a plant named *Ledum* that had narcotic effects (Rowell 1978, 271*). In the later herbals of the fathers of botany, the plant appears under the name *Ledum silesiacum* (Clusius) or *wild rosemary* (Tabernaemontanus). Although the woodcuts that were included in the works of such authors as Tabernaemontanus and Gerard are botanically accurate and clearly identifiable, the first scientific description of the plant was made by Linnaeus, who even wrote a medicinal work about the plant in 1775 (Vonarburg 1995, 78).

Wild rosemary (*Ledum palustre* ssp. *palustre*) in bloom.

Greenland tea (*Ledum palustre* ssp. *groenlandicum*) is a North American species.

The fruits of wild rosemary (*Ledum palustre* ssp. *palustre*).

The North American wild rosemary species *Ledum glandulosum* ssp. *columbianum*.

The leaves of an as yet unidentified species of wild rosemary (*Ledum* spp.) collected in North America are almost twice as long as the leaves of related species.

“The shamans of the Giljak and the other Amur natives bend over a thick, strongly scented smoke that develops when dried leaves of wild rosemary (*Ledum palustre*) are laid onto glowing coals. Wold. Aerseniew was able to determine that every true shamanic activity of the Orotsha (as compared to the shamanic games) is begun by rubbing the knee with heated leaves of *Ledum palustre*.”

GEORG TSCHUBINOW

BEITRÄGE ZUM PSYCHOLOGISCHEN VERSTÄNDNIS DES SIBIRISCHEN ZAUBERERS [CONTRIBUTIONS TO A PSYCHOLOGICAL UNDERSTANDING OF THE SIBERIAN MAGICIAN]
(1914, 44*)

Distribution

Wild rosemary occurs almost exclusively in high and transitional bogs, often growing in association with pine and birch trees. Although very widespread, it is only rarely found in the wild. It grows in the region of the Alps and in northern Europe and in central, eastern, and northern Asia (Siberia), as well as Japan. A closely related species occurs in North America. In Germany, this rare plant is protected.

Wild rosemary is regarded as a relic from the ice age, as it is adapted to a cool and moist climate.

Cultivation

Propagation is possible from seed. However, there are few reports concerning experiences with cultivation.

Appearance

Wild rosemary is a shrublike evergreen plant that can grow to a height of 1.5 meters. It has lanceolate leaves that are hairy on their undersides and white flowers in terminal corymbs. The capsule fruits are ovate and hang down. The plant flowers in May and June.

Wild rosemary is very easily confused with several closely related American species. The glandular wild rosemary (*Ledum glandulosum* Nutt. ssp. *columbianum* [Piper] C.L. Hitchc.) is especially similar and also has a similar scent.

The name *wild rosemary* (*Rosmarinum sylvestre*) originally was applied because the plant's morphology, particularly the structure of the resinous leaves, was reminiscent of that of the kitchen spice rosemary. The two plants, however, are not related (Greve 1938a, 1938b).

Psychoactive Material

—Blooming wild rosemary herbage (*herba ledi palustris*, *ledii palustris herba*), dried or fresh; also the young shoots (used to produce alcoholic extracts and the homeopathic mother tincture)

Preparation and Dosage

The blooming herbage is air-dried in the shade. It then can be used by itself as an **incense**. When dried, wild rosemary is easily ignited and burns with a bright and crackling flame. When the burning branch tips are blown out, the leaves and stalks will continue to glow and give off a white, aromatic smoke. The scent is resinous, fragrant, pleasant, and somewhat reminiscent of that of juniper and fir. A delicate, resinous scent with a slightly acrid character lingers in the room. When used for psychoactive purposes, large amounts must be burned and inhaled.

Little information is available concerning dosages for oral use. When the herbage is prepared as a tea, psychoactive or toxic effects are rare. In contrast, alcohol extracts, which are rich in the essential oil, can have pronounced effects.

To produce Labrador tea, the leaves are collected in May (before the plant blooms) and roasted in an oven. The tea is made simply by brewing the roasted leaves with boiling water (Turner and Efrat 1982, 65).

Ritual Use

In addition to juniper (cf. *Juniperus recurva*), the shamans of the Tungus (whose language has given us the word *shaman*) and the neighboring Gilyak used especially wild rosemary as a ritual and trance-inducing **incense**. They inhaled deep breaths of the smoke in order to enter a shamanic state of consciousness. Sometimes they would chew the root as well as inhale the smoke. The shamans of the Ainu, the aboriginal inhabitants of northern Japan, also esteemed wild rosemary incense. Ainu shamanesses would prepare a potent tea of wild rosemary to treat menstrual pains and coliclike lower abdominal cramps (Mitsuhashi 1976).

While wild rosemary was used in Europe for medicinal purposes, its primary significance was as an inebriating additive to **beer** (*grutbier*) and as a ritual plant. Alongside henbane (*Hyoscyamus niger*) and thorn apple (*Datura stramonium*), wild rosemary was the most important psycho-active additive to the Germanic beers (Wirth 1995, 146) that were brewed prior to the Bavarian Purity Law of 1516 (cf. **beer**, *Humulus lupulus*). Because wild rosemary oil can provoke aggressive behavior, it has been suggested that the berserkers obtained their legendary “berserker rage” by drinking porst (wild rosemary) beer, which was common in Scandinavia (Sandermann 1980; Seidemann 1993).²⁰⁴

“When administered in excess, porsch irritates the mucous membranes of the stomach and intestines. Muscle and joint pains also appear, heart palpitations, cold shivers, persistent sensations of coldness, shortness of breath, sweating, sudden states of excitation, depressed moods, appearance of a sensation of sedation and drunkenness . . .”

PAUL GREVE

LEDUM PALUSTRE L.— MONOGRAPHIE EINER ALTEN HEILPFLANZE [*LEDUM PALUSTRE* L.— MONOGRAPH ON AN OLD MEDICINAL PLANT]
(1938a, 80)

Artifacts

No artifacts have become known to date.

Medicinal Use

In Siberia, wild rosemary has a long history of use as a folk remedy. Bone and joint pains were

treated by rubbing the joints with the fresh plant, and partially or completely dried herbage was burned to ward off insects. In Russia, wild rosemary was given to those who were as “drunk as a fish” (Rowell 1978, 21*).

Because of its narcotic effects, wild rosemary is used in folk medicine to treat whooping cough; patients both ingest it internally and inhale its smoke as a medicinal incense. The Sami (Lapps) inhale the steam of decoctions of the plant for colds. They also use a decoction to bathe painful joints and areas affected by frostbite. They drink a tea made from the plant for coughs. The Poles use wild rosemary as a fumigant to treat all manner of lung ailments (Greve 1938b, 76f.).

Many Indian tribes of northern North America drank Labrador tea as a tonic (Gunther 1988, 43*).

Because ledol, one of wild rosemary’s constituents, has abortifacient effects, preparations of wild rosemary were once used to induce abortions. This was often accompanied by strong toxic reactions.

Various potencies are used in homeopathy to treat articular rheumatism, sciatica, rheumatism of the shoulder, contusions, et cetera (Vonarburg 1995).

Constituents

The entire plant contains an **essential oil** (0.5 to 1% in the leaves) composed of ledol (= ledum camphor), palustrol, myrcene, ericoline, and other substances. It also contains the glycoside arbutine, the flavonoids hyperoside and quercetin (cf. *Artemisia absinthium*, *Fabiana imbricata*, *Humulus lupulus*, *Psidium guajava*, *Vaccinium uliginosum*), resins, and traces of alkaloids (Roth et al. 1994, 452; Tattje and Bos 1981; Vonarburg 1995, 78).

Effects

The **essential oil** can induce states of inebriation and spasms, but also abortions. Ledol has potent inebriating and narcotic effects that definitely can assume an aggressive nature. The effects of the alcoholic extract are very similar to those of **alcohol. Beer** that has been brewed with wild rosemary or to which it has been added (*grutbier*) has much more potently inebriating effects as a result. Generally speaking, ledol potentiates the effects of alcohol (similar to *Piper methysticum*).

The isolated resin exhibits potent anesthetizing effects that may possibly account for the plant’s cough-suppressing properties (Greve 1938b, 79).

Commercial Forms and Regulations

Wild rosemary can be obtained from pharmacies without a physician’s prescription as a mother tincture under the name *Ledum (D1)* (Hahnemann himself introduced wild rosemary as a homeopathic agent). This preparation is produced from the dried, resinous leaves (*HAB4a*).

Wild rosemary is a protected plant in many areas and tends to grow in regions that are protected.

An early illustration of wild rosemary, which was placed near the aromatic cistus (*Cistus ladaniferus* L.) because of its resinous scent. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

Leonurus sibiricus Linnaeus

Siberian Motherwort

Family

Labiatae (Lamiaceae) (Mint Family); Subfamily Lamioideae (= Stachyoideae), Lamieae (= Stachydeae) Tribe, Lamiinae Subtribe

Forms and Subspecies

Two varieties are said to be distinguished in East and Southeast Asia (Hasler n.d., 1).

Synonyms

Leonurus artemisia

Folk Names

Altamisa, amor mío (Spanish, “my love”), chinesischer löwenschwanz, chinesisches mutter-kraut, coda di leone, gras zum segen der mutter, ich-mau-thao (Vietnamese), i-mu-tsao (Chinese), mahjiki (Japanese),²⁰⁵ marihuanilla (Spanish, “little marijuana plant”), marijuanillo (Spanish, “little hemp”), mehajiki (Japanese), motherwort, rangadoronphul, Siberian motherwort, sibirischer löwenschwanz, sibirisches herzgespann, sibirisches mutterkraut, t’uei, yakumosos (Japanese)

History

Siberian motherwort appears in the ancient Chinese *Shih Ching*, the Book of Songs (ca. 1000–500 B.C.E.), under the name *t’uei* (Keng 1974, 402*). It was sometimes praised as a medicinal plant in later ancient Chinese herbals.

It is not known when the plant spread into the New World, nor is it known when it was first smoked as an inebriant.

Distribution

Siberian motherwort is found in southern Siberia, China, Korea, Japan, Vietnam, and Southeast Asia. It now grows wild in Brazil (coastal regions) and Mexico (Chiapas).

Cultivation

Propagation occurs through the seeds. These are lightly covered with soil, moistened well, and exposed to sunlight. The seeds germinate and the plant grows surprisingly quickly. The seeds also can also be sown directly in the garden. Seedlings can be planted in pots or garden beds. The plant does not tolerate frost and should overwinter indoors in a pot. In areas free of frost, it can develop into a perennial bush. The plant can be given much water and fertilizer but will also thrive under less ideal conditions.

Appearance

The plant, which grows straight up and usually has a single stem, can attain a height of over 2 meters. The stem branches in a maxilliform manner. The dark green leaves are finely pinnate. The violet flower spikes develop at the ends of all the branches and can develop into long, attractive

inflorescences.

Leonurus sibiricus is easily confused with motherwort (*Leonurus cardiaca* L.), *Leonotis quinquelobatus* Gilib. [syn. *Leonurus villosus* Desf. ex Spreng.], and especially the East Asia and Siberian species *Leonurus japonicus* Houtt. [syn. *Leonurus artemisia* (Lour.) S.Y. Hu, *Leonurus heterophyllus* Sweet, *Leonurus sibiricus* auct. non L.] (cf. Kartnig et al. 1993, 648) and *Leonurus lanatus* (L.) Pers.

Psychoactive Material

—Flowering herbage

—Dried leaves

—Root

Preparation and Dosage

The leaves, collected while the plant is in bloom, are dried and smoked as a marijuana substitute (cf. *Cannabis indica*). Typically, 1 to 2 g of dried leaves is sufficient for one joint. No truly toxic dosage is known. In laboratory experiments with rats, even very high dosages (750 to 3,000 mg *Leonurus sibiricus* extract per kg body weight *per os*) did not result in the death of the animals (Hasler n.d., 4).

Because the effects of the pure herbage are not especially pronounced, they can be synergistically potentiated by mixing the herbage with *Cannabis indica* or *Cannabis sativa* (cf. **smoking blends**).

Ritual Use

The flowers are used in the *pujas* (devotional and offering activities) of Hindus in Assam (Boissya et al. 1981, 221*). No traditional or ritual use for psychoactive purposes is known.

In Veracruz, Mexico, the plant is used in folk magic intended to make the “groom return” (Argueta V. et al 1994, 114*).

Artifacts

None

Medicinal Use

The seeds and fruits are thought to have medicinal value. The dried herbage can be found in any Chinese herb pharmacy (Keng 1974, 402*). It is used to treat loss of potency, overly heavy menstruation, postpartum bleeding, and painful menstruation (Stark 1984, 81*). It also is used as a diuretic (Ott 1993, 411*). North American Indians are said to have used the herbage as an aid in labor (Kartnig et al. 1993, 653). In southern Mexico, the root is drunk in the form of a tea to treat women’s ailments and to induce menstruation. Leaves macerated in **alcohol** are applied externally to treat rheumatism (Argueta V. et al. 1994, 114*).

In Mexico, Siberian motherwort (*Leonurus sibiricus*) is known as *marijuanillo*, “little hemp.” (Photographed in Chiapas)

The Asian species *Leonurus heterophyllus* is very similar in appearance to Siberian motherwort. The herbage is used in traditional Chinese medicine. (Photographed in Songlisan, South Korea)

“In the first period after the influx of L.s. [= *Leonurus sibiricus*, 2 x 1 gram, smoked], little happened apart from the fact that I got into a basic meditative state in which all material things appeared to increase in depth and importance. Cognitive abilities and emotional

experience remained largely unchanged. During the hour after the smoking, no additional increase in the effects occurred.”

FELIX HASLER *LEONURUS SIBIRICUS* (N.D., 6)

Isoleosiberine

Leosibiricine

Leosibirine

The motherwort found in Germany (*Leonurus cardiaca* L.) is an old folk remedy for nervousness, sleeplessness, ill humor, and anxiety states. (Woodcut from Brunfels, *Novi Herbarii Tomus Secundus*, 1532)

Constituents

Most of the active components of the plant appear to be unstable and occur in the herbage in only low concentrations. The plant has been found to contain 0.1% of the flavone glycoside rutin (cf. *Psidium guajava*) (Hayashi 1963). The alkaloid leonuridine has been detected in the seeds. The herbage contains 0.02 to 0.04% of the alkaloid leonurine (chemical formula $C_{14}H_{21}O_5N_3$), which apparently is a guanidine derivative (Hayashi 1962). A total of four guanidine derivatives (4-guanidinobutanol, arginine, 4-guanidine butyric acid, and leonurine) have been described (Reuter and Diehl 1970, 1971). Chinese researchers have described an alkaloid “A” (with the chemical formula $C_{20}H_{30}(32)O_{16}N_6$) for the leaves. Also present is L-stachydrine, which is characteristic for the Family Labiatae (Reuter and Diehl 1970), as well as glycosidic bitter substances, syringic acid, rosmarinic acid, and caffeic acid depsides. Of particular interest for the discussion of the psychoactive effects was the discovery that the **essential oil** contains three new **diterpenes**: leosibiricin, leosiberin, and the isomer isoleosiberine (Savona et al. 1982). These diterpenes may have effects similar to those of **salvinorin A**. Leosibiricine and leosibirine also occur in motherwort (*Leonurus cardiaca*) and presumably in many other species of the genus *Leonurus* (Knöss and Glombitza 1993). Leonurine is also present in *Leonurus japonicus* (Kartnig et al. 1993, 649).

Hasler has argued that it is likely that *Leonurus sibiricus* also contains other substances that have not yet been detected (methoxylated phenyl bodies, amides) that may be biologically transformed into psychoactive methoxyphenylalkylamines (Hasler n.d., 8).

Effects

The effects are occasionally described as mildly narcotic or cannabis-like. They are by no means spectacular, unless the plant is combined with other substances.

In animal experiments, the administration of an extract produced distinct CNS activity. The alkaloid “A” elevates the tone of the uterus (Hasler n.d., 3).

Animal studies using an extract of the related species *Leonurus quinquelobatus* Gilib. [syn. *Leonurus cardiaca* L. ssp. *villosis* (Desf. ex Urv.) Hyl.] observed clear sedative and narcotic effects (Rács and Rács-Kotilla 1989).

Commercial Forms and Regulations

Both the herbage and the live plant are freely available (but usually difficult to obtain).

Lolium temulentum Linnaeus

Bearded Darnel

Family

Gramineae: Poaceae (Grass Family); Hodeae Tribe

Forms and Subspecies

One variety has been found throughout Egypt since ancient times, i.e., for at least five thousand years (Germer 1985, 215*): *Lolium temulentum* var. *macrochaeton* A. Br.

Synonyms

Lolium maximum Willd.

Folk Names

Bearded darnel, borrachera (Canary Islands, “inebriator”), cizaña, darnel, darnel grass, delirium grass, dolik (Dutch), dower, drunken lolium, hammerl (Austria), hierba loca (Spanish, “crazy herb”), hueshuescachu (Mapuche, “crazy plant” or “plant that makes crazy”), ivraie (“inebriating”), ivraie enivrante (French), jamdar (Persian), jollo, joyo, loglio ubriacante (Italian), lolch, ollo, rauschgras, schwindelhaber, schwindelhafer, schwindelweizen, tares, taumelloch, tobgerste, tollkorn, tollkraut (Bahamas)

History

Bearded darnel has been found in Stone Age deposits in Europe and was well known among the ancient Egyptians (Christiansen and Hancke 1993, 118*). It may even have been mentioned in the Bible, which speaks of separating the “wheat from the chaff,” an indication that the wheat fields may have been infested with *Lolium* (Germer 1985, 215).

Because it produces an inebriating cereal grain, bearded darnel may have been associated with the cult of the goddess Demeter (Ruck 1995, 141*; cf. **kykeon**). On the Canary Islands, the plant apparently was used as the source of an inebriant (Daria et al. 1986, 188). The Gauls are also said to have taken advantage of the “staggering effect” of the plant and used it to brew **beer**. During the Middle Ages, bearded darnel frequently found its way into cereal grain plantings and was consequently harvested and baked into bread, which induced psychoactive effects when ingested and caused staggering (hence the many folk names referring to this effect). Incidents of mass cases of toxic symptoms—similar to those resulting from ergot (*Claviceps purpurea*)—are said to have resulted (Roth et al. 1994, 465*). Bearded darnel also may have been one of the components of the **witches’ ointments**.

Distribution

The grass may have originated in the Near East; it has been found in association with humans since the early Egyptian period (Aichele and Hofmann 1991, 142*). It is especially common in central Europe, where it prefers grain fields, roadsides, and wastelands.

Cultivation

Lolium temulentum is easily propagated from seed, which normally needs only to be broadcast onto the ground. Bearded darnel prefers calciferous soils and grows well between oats and barley.

Appearance

This annual grass, which is green to bluish green in color, has stiff, upright, coarse stalks that can attain a height of up to 75 cm (more rarely 100 cm). The stalks are often branched at the base but do not exhibit any leaf shoots. The ears can be as long as 20 cm and possess long awns (beards). The glumes are two to four times longer than the lemmas. The flowering period is from June to August. The brown fruits are elongated.

It was once thought that the bearded darnel was infested with ergot (*Claviceps purpurea*) (Hooper 1937, 137*). But the grass is actually infected by one or more fungi: *Endoconidium temulentum* Prillieux et Delacroix, *Chaetium kunzeanum* Zopf, and/or *Gibberella subinetii* (Mont.) Saccardo (Blohm 1962, 11*; Christiansen and Hancke 1993, 118*). As many as 80% of bearded darnel seeds may be infected with a fungus (Germer 1982, 215*):

When the seeds germinate, the fungus grows up through the entire plant to the new grains and is thereby transmitted to the next generation. This kind of long-lasting relationship between host plant and fungus is known as a cyclic symbiosis. As far as we are aware, it is only the fungus which receives an advantage from this coexistence. The fungus does not harm the grass, but the grass does not benefit from it. (Christiansen and Hancke 1993, 118*)

“The darnel, bearded darnel (*Lolium temulentum*), is known everywhere for its harmfulness. In addition to its sedative effects, it is also said to make one stupid. But it has a favorable effect upon fruit trees, for when one sees that their fruits fall off while still unripe, they need only be surrounded by a wreath of darnel, whereupon the fruit will be preserved until it is ripe.”

K. RITTER VON PERGER

DEUTSCHE PflANZENSAGEN [GERMAN PLANT LEGENDS] (1864, 97*)

The species *Lolium multiflorum* is a close relative of bearded darnel.

A ripe spike of bearded darnel (*Lolium temulentum*).

“Home brewers often used cheap surrogates for their top-fermenting beer instead of the expensive hops; the old beer brewers of Gotha, for example, used ‘dower,’ the seeds of the annual spike grass ‘Taumel-Lolch’ (*Lolium temulentum* L.), which caused one to ‘dower,’ or stagger after drinking such a beer, thus feigning the effects of a potent drink. It was easy to collect this weed in the summer grain.”

OTTO LUDWIG

IM THÜRINGER KRÄUTERGARTEN [IN THE THURINGIAN HERB GARDEN] (1982, 180*)

Bearded darnel is easily confused with Italian ray grass (*Lolium multiflorum* Lamk. [syn. *Lolium italicum* A. Br.]), which is very similar in appearance (Aichele and Hofmann 1991, 142*). Bearded

darnel also resembles the common ray or rye grass (*Lolium perenne* L.), which contains loliolide (cf. *Salvia divinorum*).

Psychoactive Material

—Spikes (fructus lolii temulenti, lolii temulenti fructus, bearded darnel fruits, seeds, darnel fruits)

Preparation and Dosage

The seeds of bearded darnel were used as an ingredient in **witches' ointments**, as a fermenting agent for producing fermented or distilled drinks (**alcohol**), and as an additive to **beer** (Europe) or **chicha** (Peru): “The seed was also sometimes purposely mixed into the grain in order to make the beer more inebriating” (Aichele and Hofmann 1991, 142*).

In an animal (mice) experiment with the primary active constituent, loline (= temuline), dosages as high as 200 mg/kg injected intraperitoneally did not produce any toxic effects (Ott 1993, 159f.*).

Ritual Use

It has been rumored that a secretive mystery cult in Lebanon macerates the seeds of bearded darnel in water. They drink the extract to induce a state of religious ecstasy (Ott 1993, 155*).

Artifacts

None

Medicinal Use

“The bearded darnel is little used in the healing arts; only in homeopathy is it used for rheumatic and gout ailments, stomachaches, dizziness, and trembling limbs” (Wirth in Bauereiss 1995, 144*). The plant was or is used in folk medicine as an abortifacient (Blohm 1962, 11*). In the Canary Islands, the seeds were used in folk medicine as a tranquilizer (Ott 1993, 155*).

Constituents

The spikes contain up to 0.06% of the pyridine base temuline (Roth et al. 1994, 465*). Two as yet unidentified alkaloids are also present. Perloline has been detected in the stalks (Dannhardt and Steindl 1985). The narcotic or inebriating alkaloid tenuline, also known as loliin (= loline), is a metabolic product of the parasitic rust fungus *Endoconidium temulentum*, which almost always grows on the grains (Christiansen and Hancke 1993, 118*).

Effects

Bearded darnel is said to induce profound perceptual changes (Blohm 1962, 11*): “Drunkenness, staggering, headaches, clouding of the thought process, disturbances of vision, violent vomiting, colic, sleepiness or sleeping sickness, death resulting from respiratory paralysis. Lethal outcomes are rare, but the central effects can persist for days” (Roth et al. 1994, 465*).

“The constituent temuline induces disturbances in the coordination of movement, motor paralysis, and can provoke a spontaneous respiratory paralysis. Its atropine-like effects are manifested as a dilation of the pupils” (Wirth in Bauereiss 1995, 143*).

When darnel seeds are mixed into cereal grains, the bread or beer that is made from them can make one “crazy” (Mösbach 1992, 64*).

The characteristic “staggering” effects can also be induced by *Chaerophyllum temulentum* L. (Apiaceae), which contains a volatile alkaloid (chaerophylline?) (Roth et al 1994, 210*).

Commercial Forms and Regulations

Lolium temulentum is listed as an endangered plant (Roth et al. 1994, 465*). Apart from this, there are no regulations concerning the plant.

The mother tincture (= TM), *Lolium temulentum*, can be obtained in German pharmacies.

The inebriating properties of bearded darnel have been known since antiquity. This botanically correct illustration is from the early modern period. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Lonchocarpus violaceus (Jacquin) DC.

Balche' Tree

Family

Leguminosae: Papilionaceae (Fabaceae) (Legume Family); Subfamily Papilionoideae: Dalbergieae, Lonchocarpaceae Tribe

Forms and Subspecies

It is possible that the tree the Lacandon cultivate is a variety or an as yet undescribed subspecies.

Synonyms

Lonchocarpus longistylus Pittier

Lonchocarpus maculatus DC.^{[206](#)}

Lonchocarpus punctatus

Lonchocarpus violaceus H.B.K.

Lonchocarpus yucatanensis Pittier

Lonchocarpus violaceus Rth. (Pool 1898; Neuwinger 1994, 623*); described for India but is likely a different species, and the name is probably obsolete

Folk Names

Baälche, bá'alché' (modern Yucatec Mayan), ba'che', balche (Mayan),^{[207](#)} balche' (Lacandon, “thing of wood/essence of the forest”), balché, balche'baum, lancepod, lance-pod (Trinidad), palo de patlaches (Mexico), patachcuahuitl (Nahuatl), pitarilla (Spanish), saayab, sakiab, samea (Chiapas), sayab (Yucatán),^{[208](#)} violet lancepot, xbalché (colonial-period Mayan)

History

The tree was known to the pre-Columbian Maya, who used it for ritual purposes. It was first mentioned in early colonial sources from the Yucatán (Diego de Landa's *Relación de las cosas de Yucatán*, Mayan dictionaries). In 1665, de Rochefort described one member of the genus for the Antilles (Allen and Allen 1981, 396*). Balche' was first scientifically described in the nineteenth century.

Distribution

The main range is the tropical rain forests of southern Mexico (Chiapas, Yucatán; cf. Steggerda 1943, 209*) and the neighboring Petén region (Guatemala). The tree also grows on Trinidad and Tobago (Graf 1992, 558, 1033*) and has been described as native to Puerto Rico, the Lesser Antilles, Isla Margarita, Venezuela, and Colombia (Morton 1995, 44*).

Several species of the genus grow wild in the forest^{[209](#)}; they are called *matabuey* in the local Spanish (Berlin et al. 1974, 277*). The very similar species *Lonchocarpus santarosanus* Donn., which is known in Huastec as *ehtiil i thal te'* (“like the *thal* tree”), is found on the Gulf Coast (Alcorn 1984, 691*).

Cultivation

The Lacandon (Chiapas, Mexico) know the tree only in its cultivated form. They propagate the tree primarily through cuttings, which are started from thin branches (approximately 30 cm long) that are set in the ground. The seeds can be germinated and planted as well. The tree requires a moist, tropical climate. It grows very quickly and will even grow back after the trunk or branches have been removed.

Appearance

Balche' is a midsized tree that can attain a height of up to 10 meters in cultivation. It has a smooth, light bark that is often covered with lichens (Rätsch 1994). The leaves are lanceolate. The violet flowers are in panicles. The fruits, which contain only one or two seeds, are flat pods 8 to 12 cm in length. The plant flowers in May, and the fruits ripen in January and February.

The tree is easily confused with the common fish-catcher (*Piscidia piscipula* [L.] Sargent [syn. *Piscidia erythrina* (Loefl.) L.]), which is frequently encountered in the rain forests of Mexico. In Lacandon, the fish-catcher is known as *ya'ax balche'* ("first balche' tree") and is regarded as a very toxic wild relative of the true balche' tree.

The wonderfully scented panicle of the balche' tree, *Lonchocarpus violaceus*. (Photographed in Naha', Chiapas, Mexico)

The typical spearlike fruits of *Lonchocarpus violaceus*. (Photographed in Naha', Chiapas, Mexico)

Psychoactive Material

—Fresh bark, more rarely the fresh flowers

Preparation and Dosage

The bark is knocked off the freshly cut trunk by beating it with a piece of wood. To prepare the ritual drink that is also known as **balche'**, the Lacandon add two to ten pieces of bark (1 meter long, 10 to 20 cm wide) to approximately 180 liters of water. The more fresh bark that is added to the balche' drink, the more potent are its psychoactive effects. Fresh flowers are sometimes added to the finished balche' drink.

Ritual Use

The drink that is prepared from the bark is consumed communally only in ritual contexts (offering ceremonies, harvest festivals, initiations, the treatment of illnesses) (see **balche'**).

Artifacts

Strangely, the tree has not been identified in pre-Columbian Mayan art. Only drinking scenes, drinking vessels, and ceremonial offerings of the drink were depicted (e.g., in the *Codex Dresdensis*). It is quite possible that some Mayan art was inspired by experiences with balche'.

The Lacandon use a multitude of ritual and drinking vessels, some of which are carved with decorations and other ornaments.

Medicinal Use

Mayan recipe books from the colonial period contain a number of recipes using balche'. Crushed fresh leaves were rubbed onto lesions caused by smallpox, a disease introduced from Europe. A tea made from the leaves was drunk for “loss of speech” (Roys 1976, 216*).

Constituents

The bark and the seeds contain rotenone²¹⁰ (which can be clearly recognized by its scent; cf. Morton 1995, 44*) as well as several rotenoides or saponins, flavonoids, and tannins (Delle Monache et al. 1978; Menichini et al. 1982; Neuwinger 1994, 623*). Also present in the bark are the prenylated stilbenes A-, B-, C-, and D-longistyline (Delle Monache et al. 1977; de Smet 1983, 140*). The fruits (pods and seeds) appear to contain the highest concentrations of rotenone (Morton 1995, 44*). It is sometimes thought that an alkaloid is also present. An initial analysis of a balche' drink made with *Lonchocarpus violaceus* did not detect any alkaloids (Hartmut Laatsch, pers. comm.).

The seeds of the closely related *Lonchocarpus sericeus* (Poir.) H.B.K., which are thought to be poisonous, have been found to contain 0.5% enduracidine and a related acid (Fellows et al. 1977). Whether these substances also occur in *Lonchocarpus violaceus* is unknown.

Effects

The longistylines are chemically related to kavains and kavapyrones (cf. *Piper methysticum*) and to hispidine (see “*Polyporus mysticus*”) and likely elicit similar effects. Rotenone is found in a number of plants, including the tuba root (*Derris elliptica* [Sweet] Benth.²¹¹; Fabaceae); it is regarded as an abortifacient and is thus dangerous to ingest during pregnancy (Roth et al. 1994, 298*). The effects of the balche' drink are likely due to the presence of the longistylines:

Chemically, the structures of the longistylinines leave some room for interpretation. Thus, for example, it may be that an aminisation in the body (similar to that of myristicine from nutmeg [cf. *Myristica fragrans*]) into mescaline-like alkaloids is responsible for the effects. But the structural similarity with the styryl pyrones of *Piper methysticum* suggests that the drink is more likely on the same level as kavakava, which also agrees quite well with the effects that you have described. (Hartmut Laatsch, pers. comm., July 1, 1987)

Rotenone (chemical structure $C_{23}H_{22}O_6$; synonyms derrin, tubatoxin, 1,2,12,12 α -tetrahydro-2 α -isopropenyl-8,9-dimethoxy[1]-benzopyrano-(3,4- β)furo (2,3H)[1]benzopyran-6(6 α H)-on) belongs to the group of pyrano derivatives (Roth et al. 1994, 912) and is regarded as a potent fish poison. In humans, the lethal dose (LD₅₀) is estimated to lie around 0.3 to 0.5 g/kg (912*). The toxic effects are said to be more pronounced when the constituents are inhaled rather than ingested. Symptoms include numbness of the mucous membranes, nausea, vomiting, tremors, tachypnoea, and respiratory paralysis; “rotenone excites the nerves; spasms occur, which result in nerve paralysis, finally leading to exitus” (299, 912*). Rotenone does not appear to be responsible for the psychoactive effects (at least not by itself).

In South America, *Lonchocarpus* species with high rotenone contents (*L. rariflorus*, *L. floribundus*, known as *timbó* or *barbasco*) are used as fish poisons (im Thurn 1967, 234; Heizer 1958; Schultes and Raffauf 1990, 244f.*). One species (*Lonchocarpus utilis*) is even used as a curare substitute (Schultes and Raffauf 1990, 308*). Rotenone is the primary active component of the common fish-catcher *Piscidia piscipula* (L.) Sargent [syn. *Piscidia erythrina* (Loefl.) L.; Fabaceae] (Roth et al. 1994, 573*), known in Lacandon as *ya'ax ba'che'* (“first balche' tree”):

“Toxic symptoms: Following consumption of too large a quantity of the alcoholic [rotenone] tincture, vomiting, salivation, sweating, numbness, and shaking were observed” (Roth et al. 1994, 573*).

Longistyline

Rotenone

“And so it shall remain for the creatures of the earth. For always shall it be so for them. They shall receive the seeds of the tree and plant them. Oh, it is true, only when it is planted does the tree grow, the true balche’ tree. Not all balche’ trees are good, only this one here. With it, the creatures of the earth will not die. They will plant it always. The creatures of the earth shall plant it. . . .

“And so is it until today. They make the balche’ drink. They drink it. As my father told me, if the gods had not shown us the proper tree, we would have died. But so, as Hachäkylum the original ancestor showed, so it has remained until today. We make the balche’ drink for our lords.”

Lophophora williamsii (Lemaire ex Salm-Dyck) Coulter

Peyote Cactus

Family

Cactaceae (Cactus Family); Subfamily Cactoideae, Cereeae (= Cactaeae) Tribe, Echinocacteinae (= Echinocactinae) Subtribe

Forms and Subspecies

The Huichol differentiate among several forms of the peyote cactus on the basis of their graphic structure. One form resembles the flower of a *Solandra* species and is consequently called *kieri*; another is reminiscent of maize (***Zea mays***). Both of these forms are especially useful for the shamans. Another form is referred to as “doors to the other world,” while the Native American Church refers to a form with twelve or fourteen segments as “chief.” A cactus afflicted by a virus (as sometimes happens) is known as *culebra*, “snake.”

One form with deep violet-pink flowers has been described botanically: *Lophophora williamsii* (Lem.) Coult. f. *jordanniana*.

The flower of the peyote cactus, which the Huichol lovingly call *tútu*. (Botanical illustration from 1888)

History

In the region of Trans-Pecos, Texas, peyote buttons have been discovered in archaeological contexts approximately six thousand years old (Boyd and Dering 1996, 259*; Furst 1966*). In archaeological excavations in northeastern Mexico, remains of peyote have been recovered that have been dated to approximately 2500 to 3000 B.P. (Adovasio and Fry 1976*; Schultes and Hofmann 1995, 132*). A cave burial in Coahuila (810–1070 C.E.) yielded pieces of peyote that still contained alkaloids (Bruhn et al. 1978).

In Mexico, peyote was already being used as a ritual entheogen during the prehistoric period. In colonial times, Indians were forbidden to use peyote, and the Inquisition punished its use severely (Leonard 1942). The Huichol peyote cult, which has largely survived since the pre-Hispanic period and has been preserved in a relatively pure form, has been well studied (Schaefer and Furst 1996).

The ritual use of the peyote cactus presumably was spread into North America by the Mescalero Apache and apparently also by the Lipan of Mexico (Opler 1938). The first description of the use of peyote in the area that now is part of the United States dates to around 1760. During the American Civil War, peyote use was already established among many tribes of the Plains (Schultes 1970, 30*). The peyote cult is quite widespread in North America; its members can be found in almost every North American tribe. Most, however, are members of the tribes of the Southwest. The number of peyotists has been estimated to be over 250,000 (Evans 1989, 20). During the past one hundred years, the North American Indian peyote cult has been very well documented and the subject of numerous studies (Gerber 1980; Goggin 1938; Gusinde 1939; Hayes 1940; La Barre 1989; Opler 1940; Slotkin 1956; Stewart 1987; Wagner 1932).

The taxonomic history of this magical plant is rather confusing and reflects the scientific vanity often found among botanists (Schultes 1937a, 1937b; 1970, 32*). The first botanically accurate description comes from Hernández (1615), who used the name *peyote zacatecensis* (Schultes 1970, 30*). He also described a *peyote xochimilcensis*, which is likely *Cacalia cordifolia* (cf. **Calea**

zacatechichi), an herbaceous plant that is still sold in Jalisco today as an aphrodisiac (Schultes 1966, 296*). The cactus was first described in terms of modern botanical taxonomy in the mid-nineteenth century by the French botanist and cactus aficionado Antoine Charles Lemaire (1800–1871), who gave it the name *Echinocactus williamsii* (1839). Later, the German botanist Paul Christoph Hennings (1841–1908) also described the cactus, which he named *Anhalonium lewinii* in honor of Louis Lewin (1850–1929) (Hennings 1888). It was long thought that these two names referred to different species or at least subspecies or varieties. Today they are regarded as synonyms for *Lophophora williamsii*. In 1894, the North American botanist John Merle Coulter (1851–1928) assigned the cactus to the genus *Lophophora*. The first chemical analyses were published by Louis Lewin (1888) and Arthur Heffter (1894).

Peyote is one of the best studied of all psychoactive plants (Bruhn and Holmstedt 1974). The **mescaline** that was isolated from it at the end of the nineteenth century revolutionized European psychiatry. At the beginning of the twentieth century, peyote became a drug of fashion in artistic and occult circles (Rouhier 1996). Tinctures of peyote were formerly available without restriction (Gartz 1995).

Distribution

The peyote cactus occurs in desert areas from Texas to central Mexico (Tamaulipas, Coahuila, Nuevo León, San Luis Potosí, Zacatecas). In Pecos (Texas), the peyote grows naturally under mesquite trees (*Prosopis juliflora* [SW.] DC.). North of Mexico, the most important natural occurrence of the cactus is in the Mustang Plains of Texas (Morgan 1983a, 1983b).

The peyote cactus (*Lophophora williamsii*), one of the classic plants of the gods, in flower.

Cultivation

Propagation occurs chiefly through the seeds. The seeds need only be pressed lightly into sandy or clayey cactus soil and moistened a little each day. Germination may take several weeks. Because the seedlings are very small, they are easily overlooked. Overly heavy watering may wash them away and consequently hamper their growth. The seeds can be planted throughout the year. The cactus does not tolerate any frost.

Peyote requires a porous, clayey soil rich in minerals and nutrients. Apart from this, it is not demanding and will survive even some withering. In the summer, it should be exposed to the sun and

watered in moderation, but never kept moist. It requires almost no water in the winter (Hecht 1995, 60*).

After a five-year growing period, a peyote cactus is large enough to be harvested for use. In time, the stump will grow new heads. Peyote is one of the slowest growing of all cacti. There is, however, a gardening technique for accelerating its growth:

Since peyote grows so slowly, one can quadruple the growth rate by splicing a button to a similar diameter limb of a *T[richocerus] pachanoi* or any other *Trichocereus*. This is done by carefully cutting each surface perfectly flat and smooth before grafting them. Until the graft takes, the peyote button may be held to the surface of the *Trichocereus* by spreading multiple strings with small weights attached to them across the top of the button. A light ring of petroleum jelly should be painted around the cut to prevent desiccation of the contacting surfaces.

In four years the button will be very large. It may then be cut off, re-rooted and returned to the soil. (In DeKorne 1994, 87*)

Appearance

The fleshy, thornless cactus can grow up to 20 cm in height. Although it usually appears as a single head, it can have numerous ribs and take on different shapes. Clusters of fine hairs grow along the ribs. The carrot-shaped root grows from 8 to 11 cm in length. The light pink flowers develop from the center of the head, reaching a diameter of up to 2.2 cm. They fade after a few days. The flowering period is from March to September. The fruit is a club-shaped pink berry that contains the black, coarse, 1 to 1.5 mm long seeds.

Lophophora diffusa (Croiz.) Bravo [syn. *Lophophora echinata* var. *diffusa*] is the only other species in the genus; in Mexican Spanish, it is known as *peyote de Querétaro*, “peyote from Queretaro” (the only place where it occurs) (Diaz 1979, 88*). It contains the alkaloid O-methylpellotine (Bruhn and Agurell 1975).

The peyote cactus has been repeatedly confused with other cacti (Schultes 1937b; see table on pages 337 and 338). Most similar is *Turbinicarpus lophophoroides* (Werderm.) Buxb. et Backeb. (Brenneisen and Helmlin 1993, 707). Peyote also can be confused with the African *Euphorbia obesa* Hook.

Psychoactive Material

—Buttons (*Lophophora williamsii* shoot, *Lophophora williamsii* head, *Lophophora williamsii* crown, mescal buttons, peyote buttons)

The potency of the buttons decreases very little even when they are stored for long periods (Schultes 1970, 31*).

Preparation and Dosage

Peyote buttons are the heads of the cactus cut off above the root. The buttons can be either eaten fresh or dried and then chopped or powdered for later use. The fresh or dried buttons can be boiled or decocted in water. Both the buttons and the tea produced from them have an extremely bitter taste.

Dosages vary considerably, both between individuals and in rituals. Dosages ranging from four to thirty buttons may be ingested (Schultes 1970, 33*). Among the Kiowa, ten to twelve buttons are usually consumed per person per night (Havard 1896, 39*). Strong psychedelic effects and visions appear only when an amount corresponding to 200 to 500 mg **mescaline** is ingested (Ott 1996). Approximately 27 g dry weight corresponds to some 300 mg mescaline (DeKorne 1994, 88*).

Antonin Artaud (1896–1948) made an interesting observation about dosages among the Tarahumara (1936):

It is with the peyotl as it is with all that is human. It is a wonderful magnetic and alchemical principle as long as one knows how it should be taken, that is, in the prescribed and then eventually larger dosages. . . . Anyone who has *truly* drunk ciguri [= peyote], the proper amount of ciguri, of the PEOPLE, not of the undetermined GHOST, he knows how the things are made, and can no longer lose his mind, because God is in his nerves and controls him from there. But ciguri drinking means in particular not to exceed the dosage, for ciguri is the infinite, and the secret of the therapeutic effects of medicines is tied to the extent to which our organism takes them in. To exceed what is necessary means to DISTURB the effects. (Artaud 1975, 19f.)

This peyote cactus has been grafted onto a stalk of *Trichocereus pachanoi*.

The African *Euphorbia obesa* is a perfect example of plant symmetry. This surge is sometimes mistaken for the true peyote cactus.

The Tarahumara formerly produced an **incense**, “supposedly a resin [of *Pinus* sp.?] to which pieces of peyote had been mixed,” for use in their rituals (e.g., the Chumari Dance) (Zabel 1928, 264). Dried peyote pieces may be smoked, both by themselves and in **smoking blends** with other plants. Peyote powder is used as an additive in alcoholic beverages (**beer, chicha, balche’** [?], pulque, and mescal [cf. *Agave* spp.]):

In Naráachi, dried *jíkuri*, i.e., peyote and other cactus species [*Ariocarpus fissuratus*, *Coryphantha* spp., *Echinocereus* spp., *Mammillaria* spp., *Pachycereus pecten-aboriginum*], are ground, mixed with water to make *tesgüino* [maize beer], and drunk; it was also formerly added as an additive to *tesgüino* so that it would be “more enjoyable.” (Deimel 1980, 78)

A *tinctura de peyotl* can be produced using 50 g of dried ground peyote. The powder is first moistened with a little water and then 100 ml of a spirit with a high percentage of **alcohol** is added. The mixture is allowed to stand in a sealed vessel for two days. The extract is then filtered. A medicinal dosage (e.g., for heart ailments) consists of thirty drops taken three times a day (Deimel 1986, 87).

The homeopathic mother tincture is obtained from fresh peyote buttons with **alcohol**:

Manufacture [of *Lophophora williamsii* hom. *HPUS78*]: To prepare 1000 ml of the mother tincture, add 754 ml of 94.9% alcohol (V/V) to a moist plant mass consisting of 50 g solid material and 283 ml of supplemented plant juice. . . . Medicinal content 1/20. (Brenneisen and Helmlin 1993, 711)

Approximately 31/2 tablespoons of the mother tincture will produce psychedelic effects.

Ritual Use

The ritual use of peyote has its roots deep in prehistoric times and can be demonstrated for both Pecos (Texas) and Mexico (Furst 1965, 1996*). The Aztecs were well acquainted with the cactus and its effects. In the chapter “in which the names of the many plants that make one confused, crazy are named” (Sahagun), the following is said about peyote:

This peyote is white and grows only in the northern region known as Mictlan. It exerts an effect like a mushroom upon those who eat or drink of it. That person will also see many things that make him afraid or cause him to laugh. It influences one for perhaps a day, perhaps two days, but then it leaves in the very same way. And yet it still causes harm to one, stirs one up, inebriates one, exerts an influence upon one. I take peyote, I am stirred up. (Sahagun, Florentine Codex 11:7*)

In his *Natural History of New Spain* (1615), the Spanish physician Francisco Hernández wrote the following about peyote, which he called *peyotl zacatecensis*:

This root is attributed with wondrous properties, if you can believe the things that are said about it. Those who take it receive the divine gift of clairvoyance and are able to know future things, like prophets. . . . The Chichimec believe that the power of this root makes it possible.

The Aztecs generally referred to the nomadic tribes of the north as the Chichimec. Among these peoples were most likely the ancestors of the Huichol, who now live in the Sierra Madre, and the

Tarahumara, from the high north. Both the Huichol and the Tarahumara (along with other cultures, such as the Yaqui and the Cora²¹⁵) have preserved the peyote cult, which can be traced back to prehistoric times (Benzi 1972; Deimel 1980; Lumholtz 1902; Rouhier 1927). As a result of contact with the Spanish conquerors, however, some Catholic elements have made their way into the Huichol ceremonies (Zingg 1982).

The desert region the Aztecs called *mictlan*, “realm of the dead,” is the Huichol paradise that they know as *wirikuta*. In the Third Song of the Peyote, it is said, “In Wirikuta grows a flower that speaks, and you understand it” (Benítez 1975, 78).

Once a year, the *mara’akame*, the Huichol shamans, make a pilgrimage to *wirikuta*, traveling to their mythic origin and to the venerated peyote grounds. They undertake this journey “to find their lives” and to hunt the peyote they require for this purpose. For them, the peyote is fundamentally feminine. The peyote cactus is both the origin and the center of the universe. In the cosmology of the Huichol, it is symbolized as Grandfather Fire (= the sun), as a deer, and as a maize plant. This trinity reflects the foundation (diversity and integrity) of the Huichol culture: Gathering (peyote), hunting (deer), and agriculture (maize) form an inseparable mythical and practical unity (cf. Hell 1988).

An early colonial illustration of the Mexican peyote cactus (*Lophophora williamsii*), showing the root and flowers.

The journey to *wirikuta* is a journey to the origins of the world and of culture. Here in *wirikuta*, the gods created the world in all its manifestations; here is where time began, with all its consequences; here is where the peyote grows, which keeps alive the memory of creation by leading humans back to the source of all being, thereby enabling them to take part in the divine. Following the ritual preparations, during which the shamans consecrate the peyote fields with a *muvieri* (“fan,” a wooden staff with feathers), the peyote cactus is hunted with a small bow and arrows. The cactus is the blue deer of creation, and when the “flesh that has been hunted” is eaten, it opens the pilgrims’ eyes to the beginning of the world. The pilgrims travel together to the source and return from it like newborns. They collect large numbers of peyote buttons that they take back home with them (Myerhoff 1980). They need the peyote buttons for festivals and shamanic journeys, and to treat the sick, most of whom will take peyote either by themselves while under the supervision of the shaman or together with him or her (Berlin 1978).

The earliest botanical illustration of the peyote cactus, included in the article “Eine giftige Kaktee, *Anhalonium Lewinii* n. sp.” (Henning 1888)

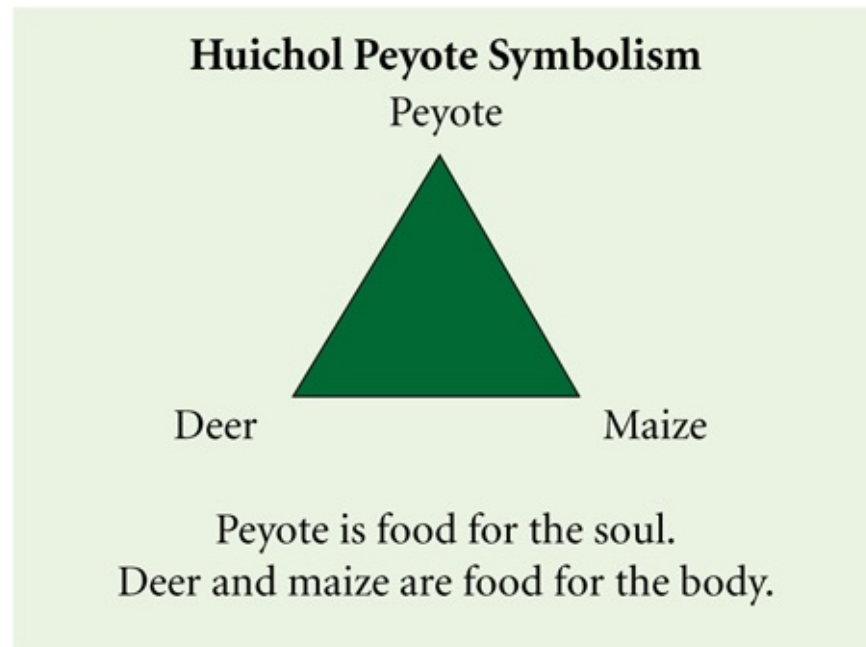

The peyote altar in the form of a thunderbird. The flute at the top represents the beak, under which is Father Peyote, placed precisely in the middle of the half moon, symbolizing the peyote way. The long fire for lighting cigarettes (at the bottom) forms the tail of the thunderbird.

At the great peyote festivals (*híkuri neirra*), all Huichol, whether young or old—including even the elderly, small children (!), and pregnant women—ingest the sacred cactus (Haan 1988, 128ff.; Schaeffer 1997). While they consume the peyote, they also smoke great quantities of a **smoking blend** made of *Nicotiana rustica* and *Tagetes lucida* (see *Tagetes* spp.) (Schaefer and Furst 1996, 154).

The Tarahumara, who live in northern Mexico, once had an extensive peyote cult that apparently has disappeared in recent years (Deimel 1996). Peyote was consumed communally, especially at the tribal festivals (dances) (Artaud 1975; Zabel 1928). The legendary long-distance runners of the

Tarahumara used peyote or *chilitos* (fruits of *Mammillaria* spp., *Epithelantha micromeris*) as a (ritual?) doping agent. In former times, the Tarahumara used peyote for divination, diagnosis, and treating the ill and as a protection from harmful magic, thieves, and enemies (Deimel 1980, 80ff.). The use of peyote among the Yaqui Indians of Sonora and Arizona was similar (e.g., in the Pascola or Deer Dance). The uses of peyote and the visions of mescalito described in Carlos Castaneda's books (1973, 1975) have no connection to the Yaqui tradition, and anthropologists have raised serious doubts about their veracity (cf. Fikes 1993; La Barre 1989, 271–75, 307f.).

The Blackfeet, who did not become acquainted with the peyote cactus until the twentieth century, used it to support their vision quests (Johnston 1970*).

In North America, the most important use of peyote is as a sacrament in peyote meetings—ritual circles—of the Native American Church. The history and ritual forms of the Native American Church have been very well documented (Brave Bird 1993; Dustin 1962; Smith and Snake 1996; Wagner 1932). Today, most people call the Native American Church the peyote religion or the peyote way (Aberle 1991; Gerber 1980; Stewart 1987). The peyote religion, which transcends individual tribes, is a syncretic form of organized spirituality that combines elements of Indian traditions and ideas from Christianity (Steimmetz 1990).

North American peyotists offer so-called dream catchers before gathering the buttons in Texas peyote fields.²¹⁶ The peyote ritual itself begins with the smoking of cigarettes made with homemade tobacco (preferred brand: Bull Durham; cf. *Nicotiana tabacum*) or sometimes with smooth sumac leaves (*Rhus glabra* L.; cf. **kinnikinnick**) that have been rolled in cigarette papers or corn husks (Schultes 1937a, 138f.). The branch tips of red cedar (*Juniperus virginiana* L.; cf. *Juniperus recurva*) are the preferred ritual **incense** at peyote meetings. A variety of *Artemisia* species (see **Artemisia** spp.) may also be used for fumigation (Schultes 1937a). The Kiowa and neighboring tribes often wore necklaces of mescal beans (*Sophora secundiflora*) at the peyote rituals (Schultes 1937a, 148), a practice that has led some researchers to suggest that the North American peyote cult may have grown out of a prehistoric psychoactive mescal bean cult (cf. La Barre 1957, 1989).

Representation of peyote cacti, arranged like the four cardinal points. (Huichol yarn painting)

A wooden Huichol mask, decorated with colored woolen yarn. The mouth is a peyote cactus. Beneath the eyes are peyote symbols, which are worn as face paintings during the peyote hunt and at tribal festivals.

Representation of a *peyotero* or peyote pilgrim. (Huichol yarn painting)

The typical peyote meeting usually takes place in a tepee, less often in a hogan (Navajo round building), but always at night. The tepee symbolizes the entire universe; in its middle burns a fire, which is surrounded by the circle of people. In front of the fire, which must be maintained throughout the night, an altar in the shape of a half-moon is built. Upon this altar are placed the ritual objects: a talking stick, a gourd rattle, drums, and flutes. The talking stick symbolizes the connection between heaven and earth, between the Great Spirit and humans; the rattle or rattles are seen as direct prayers to God; and the drum is the heart and the drumbeat the heartbeat. A large, living peyote cactus is placed between the fire and the altar. This is addressed as Chief Peyote or Grandfather Peyote and is venerated as an incarnation of the Great Spirit. The participants (men, women, young people, children) sit in a circle around the fire and the altar. The leader of the ritual, who is usually known as a roadman (Brito 1989), first smokes and purifies the tepee with **incense**, offers prayers, may read something from the Bible, and sings songs. He distributes the fresh peyote buttons, the powder, or the tea. When possible, each participant determines his or her own dosage. The participants should not speak to one another and should not leave the circle until the following morning. They may step outside only if the roadman has given them permission to do so. As the cactus manifests its effects, the talking stick, rattles, and drums are passed around in a clockwise direction. Whoever holds the talking stick sings his own peyote songs. He accompanies himself with the rattle or the drum. Sometimes a special drummer accompanies the participants. The objects go around several times, interspersed with periods of silence. From time to time, more peyote may be ingested, incense burned, and water drunk. Sometimes, tobacco is also smoked and fanned with the peyote fan. The Sioux medicine man Leonard Crow Dog has described the meaning and purpose of the ritual:

Grandfather Peyote unites us all in love, but first he must separate us, cut us off from the outer world in order to bring us to look into ourselves. . . . A new understanding dawns within you—joyful and hot like the fire, or bitter like the peyote. . . . You will see people that bend themselves into a ball, as if they were still in the belly of their mother, remember things that happened before you were born. Time and space grow and shrink in an inexplicable manner—an entire lifetime of being, learning, understanding, compressed into a few seconds of insight, or time stands still, does not move at all, a minute becomes an entire lifetime. (Lame Deer and Erdoes

The peyote meetings do not take place according to any calendrical schedule but rather at agreed-upon times.

Westerners have drawn upon the North American peyote meeting as a model for modern ritual circles in which a variety of psychoactive substances (MDMA [cf. **herbal ecstasy**]; *Psilocybe cyanescens*, *Psilocybe semilanceata*, LSD [cf. **ergot alkaloids**]) may be used (Müller-Ebeling and Rätsch n.d.; Rätsch 1995d).

Artifacts

Numerous artifacts, especially several clay figurines, discovered in western Mexico (Colima, Nayarit, Guerrero) are clearly related to the pre-Columbian shamanic peyote cult. Many clay figurines from shaft-and-chamber tombs (200 B.C.E. to 500 C.E.) in northwestern Mexico depict shamans in ritual positions and gestures (Furst 1965, 1969). One of these figurines shows a man putting a peyote-like object into his mouth (Gerard 1986, fig. 78). A ceramic object from Colima (first century C.E.) shows a child holding a peyote cactus in each hand (cf. Guerra 1990, 125*). A vessel decorated with plants, including what are clearly ten peyote roots, was recovered in the same area (Gerard 1986, fig. 88; a similar piece can be seen in Kan et al. 1989, 163). A ceramic vessel (ca. fifth century B.C.E.) found in Monte Albán (Oaxaca) apparently was used as a pipe for ingesting **snuff**; it represents a little deer with a peyote button in its mouth (Furst 1976b, 155*; Schultes and Hofmann 1992, 133*).

In Aztec poetry, peyote cacti are metaphorically referred to as “flowers” (Brinton 1887*), and their praises are sung often (Quezada 1989*). In Aztec magical formulas, the cactus is invoked as the “green woman” (Ruiz de Alarcón 1984*).

Most of the modern artifacts that have been inspired by peyote experiences or allude to the cactus and its magical effects are from the Huichol Indians of Mexico.

After the peyote festival, and after peyote experiences in general, the Huichol manufacture offering gifts as thanks for the visions they received and the healings those visions brought. The gifts are offered at mountain shrines (piles of rocks), at sacred places, on the “tree of the wind” (*Solandra* spp.), et cetera. The most important offerings are *nierika* (votive offerings), *rukuri* (prayer cups, votive snakes), and *tsikuri* (“god’s eyes”). The word *nierika* (= *nearika*) refers to “the entrance to the other world, where after the dark passage it becomes light again” (Bollhardt 1985, 30). *Nierika* originally were simple disks of wood with a hole (shields) or carved wooden objects, e.g., animals (snakes) or humans (such as the earth goddess Nakawé or the peyote goddess Wuili Uvi), covered with glue and decorated with colorful threads (wool yarn) or glass beads (Lumholtz 1989). The most common ornamentations are representations of peyote in various degrees of abstraction or symbols of the peyote cactus (stylized deer, maize plants, birds, et cetera). Like the visions (which because of their personal nature should not be discussed), the *nierika* often were very personal and were utilized only as votive offerings.

In their ritual importance, *nierikas* are faces as well as mirrors with two sides. They represent the external appearance of humans, things, or even elements. The hole that every *nierika* has in its center symbolizes a magical eye through which gods and humans look at one another. It also enables one to see things from a great distance. *Nierikas* can be found in temples, caves, and at springs. Like all other articles of offering, these too are carried to *wirikuta*. (Haan 1988, 162)

The *rukuri* are made from the lower portion of gourds and are decorated in the same very colorful

manner as the *nierika*. The *tsikuri* are yarn crosses that symbolize mystical or visionary sight and are used as magical protection for the house and farm, for example to ward off the “evil eye” (Haan 1988, 160ff.). Similar offerings to the peyote deity were being made during the colonial period, as Ruiz de Alarcón has described (1984, 50*).

Among the Huichol, these offering goods have developed into a highly unusual art form. Visions perceived while under the influence of peyote are represented by colorful woolen yarn glued onto large, flat pieces of wood (Berrin 1978; Straatman 1988; Valadez 1992). These yarn paintings, which are now sold throughout the world under the name *nierika*, can be characterized as true psychedelic art, for they are the products of psychedelic experiences. “The yarn paintings reproduce the visions in both color and idea. Looking at them takes one into the other world” (Müller-Ebeling 1986, 290*). According to the Huichol, there are two types of yarn paintings being produced today: those that “are produced for purely commercial reasons and have only a decorative value, and those that express the personal spiritual experience of the invisible made visible and are of profound magico-religious significance” (Haan 1988, 169).

The Huichol also manufacture a variety of jewelry pieces (armbands, necklaces, chains for amulet bags, earrings) from woven yarn or glass beads. These pieces are largely and sometimes exclusively decorated with more or less abstract representations or symbols (deer) of peyote. The Huichol also weave images of peyote in varying degrees of abstraction into their festive and ritual clothing (Schaefer 1989, 1993a, 1993b).

The silver jewelry of the tribes of the Southwest shows the peyote bird in a variety of forms, styles, and interpretations. This long-necked bird is known as *anhinga* or, in the regional English, as snake bird, water bird, or water turkey. It is a cormorant-like bird (*Anhinga anhinga*; Anhingidae) from the Gulf Coast whose feathers are very desired for the production of peyote fans (Bahti 1974, 61), which apparently are used to induce hallucinations or visions. The first peyote birds appeared in Navajo silver work around 1940 (Bahti 1974, 61).

A great deal of paraphernalia is used in the North American peyote cult, including staffs, fans, rattles, and drums. Over the years, a particular, recognizable (i.e., standardized) style has evolved in the production of these artistic objects that immediately reveals their association with the peyote cult (Wiedman 1985).

Toward the end of the nineteenth century, North American Indians began to paint pictures of peyote ceremonies and the visions they experienced there. One of the first to do so was the Kiowa Silverhorn, also known as Haungooah (Wiedman and Greene 1988). The peyote cult is an important theme in the paintings of many modern Indian artists (e.g., Archie Blackowl, *Peyote Mother*; Woody Crumbo, *Religious Peyote Ceremony*; Jerry Ingram, *Peyote Dream*; Al Momaday, *The Peyote Dreamers*; Alfred Whiteman, *Peyote Chief*).

Peyote and experiences with peyote have been worked into numerous comic stories. Magical rituals with the peyote cactus were featured in the issue “Jikuri” (no. 3 in the series *Julian B.*) by Plessix and Dieter (1993). Jeronaton used an Aztec story as the basis of his comic *Im Reich Peyotls* [In the Kingdom of Peyotl] (1982). Gilbert Shelton (born 1940) has his Freak Brothers encounter Carlos Castaneda’s Don Juan in the parody *Die mexikanische Odyssee* [The Mexican Odyssey] (Berlin: Rotbuch Verlag, 1990). The Freak Brothers take peyote with Don Juan and see Mescalito, the peyote spirit. In Shelton’s comic short “Ein Indianer kommt zu Essen” [“An Indian Comes to Dinner”] (in *U-Comix* no. 45 (1984): 58-59), an Indian visits an average American family. The television is broken—the picture is only in black and white—and needs repair. The Indian pulls a couple of peyote buttons from his pocket. After he and the two white people have eaten four buttons each, the pictures appear in color once more. The whites, filled with enthusiasm, decide to quit their jobs.

The picture story *Im Reiche des Mescal* [In the Kingdom of Mescal] describes an Indian boy’s first

experience in the visionary world of peyote (Schäfer and Cuz 1968).

The Sirens of Titan (1959), the lovingly sarcastic novel of the future by American cult author Kurt Vonnegut, appears to have been influenced by peyote experiences. In the book, the hero repeatedly states that he thinks he is on a peyote trip. Richard Wilson wrote a science-fiction book about peyote, *Der Sonnentanz* [The Sun Dance], in which one can read, “Stick to the peyote” (Wilson 1981, 10). The Beat poet Allen Ginsberg wrote numerous poems while under the influence of peyote and referred to the cactus itself in some of them: “Peyote is certainly one of the world’s great drugs” (Ginsberg 1982, 43). Peyote generally appears to have been one of the more important sources of inspiration for the poets of the Beat generation (e.g., Michael McClure, Ken Kesey). The best-selling Indian author Natachee Scott Momaday (born 1934) incorporated a peyote experience into his novel *House Made of Dawn* (Momaday 1968). The peyote cactus also peers from between the lines in some of his other works (Momaday 1969).

The peyote bird has become the symbol of the peyote religion or cult. Its appearance is taken from the water bird *Anhinga anhinga*. The peyote bird is regarded as the bringer of visions.

“The gods were already present in the head of the *mara’akame* when he took the peyote, but the drug caused their voices to appear to sing down directly from heaven.”

RONALD SIEGEL

HALLUCINATIONS (1995b, 39*)

“The peyotl leads the self back to its true source. When someone has experienced such a visionary state, it is impossible for one to confuse the lie with the truth as before.”

ANTONIN ARTAUD

DIE TARAHUMARAS [THE TARAHUMARAS]

(1975, 28)

“This small, wooly rascal turns on like a lamp. Daddy Peyote is the plant representation of the sun.”

NATACHEE SCOTT MOMADAY

Peyote has also provided a great deal of musical inspiration (see the box on page 334). Mexican Indians have traditionally used and passed down tribal and healing peyote songs. And singing plays a central role in the modern North American peyote cult. Songs are the primary means by which participants communicate with one another during the ceremonies so that they can bond together and open themselves to the world of visions. These ritual peyote songs are not folk songs in our sense of the phrase but are individual works of art that serve to control altered states of consciousness. Many Indians who follow the peyote road say that the cactus teaches each person his or her own songs. These songs have power and function as “medicine.” Only rarely are the songs composed of text (words); instead, the songs usually consist of a series of sounds and notes to which certain meanings are attributed (Merriam and d’Azevedo 1957). In most cases, the songs are accompanied by drums and/or rattles. The monotonous rhythm usually has about two hundred beats per minute.²¹⁷ A comparative ethnomusical study containing transcriptions of numerous peyote songs was produced in the late 1940s (McAllester 1949).

Peyote has appeared in the music world many times, often in very different forms. The contemporary composer Györgi Ligeti (born 1923) wrote the opera *Le Grand Macabre* during the years 1974 to 1977. The main role is sung by a female character named Mescalina. Unfortunately, the composer has not let it be known whether he was influenced by the soul of the cactus.

The Seattle grunge band Pearl Jam, the most successful “alternative music” group of the mid-1990s, took its unusual name from the jam that lead singer Eddie Vedder’s grandmother (Pearl) used to make from peyote and other magical plants. During the mid-1990s, a psychedelic band named The Wild Peyotes appeared in San Francisco. The country rock singer Calvin Russell issued an album entitled *Dream of the Dog*, the cover of which is decorated with a picture of peyote in the style of the Huichol. The singer, who is of Indian descent and whose grandmother was a Comanche peyote woman, makes direct reference to the Indian “medicine.” Other musicians and bands have also used Huichol peyote images as cover art, both to demonstrate their ties to Indian culture and spirituality and to give expression to their own psychedelic experiences (e.g., Santana, *Shangó*, 1982 CBS).

Medicinal Use

To the Indians, peyote is *the* medicine per se, a kind of all-purpose remedy, especially for the body and spirit (Crow Dog 1993). The Indian uses of the cactus for medicinal purposes are correspondingly numerous (Anderson 1996a; Deimel 1985; Schultes 1938):

Without a doubt, peyote is the most important medicine now being used by the North American Indians. It has replaced the older, less spectacular plant medicines [e.g., *Sophora secundiflora*]. It is used in daily life as a home remedy. And all peyote ceremonies, whether by Mexican or by North American Indians, are definitively healing rituals in which the sick are given high dosages of the cactus. (Schultes 1938)

The cactus was already being used for medicinal purposes during Aztec times: “Peyotl. It is a fever medicine. It is eaten, it is moderately drunk, only some” (Sahagun, Florentine Codex 11:5, 30*). Decoctions of peyote were administered as **enemas** to treat high fever, a method that is still in use among the Huichol today. They utilize a cold-water decoction made from dried, powdered peyote.

The Kickapoo Indians of northern Mexico use freshly cut slices of peyote to treat headaches or sunstroke. They use a linen cloth to tie the cactus slice to the head of the afflicted person. A decoction of peyote is drunk for arthritis (Latorre and Latorre 1977, 350*). In Mexico, peyote also is used to treat overdoses of toloache (*Datura innoxia*) (Nadler 1991, 95*). It also finds use in Mexican folk

medicine. The local Spanish term *empeyotizarse* means “to treat oneself with peyote.”
The Native American Church has used peyote with success to treat alcoholism (cf. **alcohol**) (Albaugh and Anderson 1974; Pascarosa and Futterman 1976).

In homeopathy, Anhalonium (Anhalonium lewinii hom. *HAB34*, Lophophora williamsii hom. *HPUS78*) is used in the dilutions D3 to 6 to treat depression and other disorders (Boericke 1992, 62 f.*; Brenneisen and Helmlin 1993, 710f.):

- Russell, Calvin
Dream of the Dog (SPV Recordings, 1995)

In homeopathic therapy, it has been in use for several decades. . . . In addition to circulatory

problems, the following therapeutic indications are given for Anhalonium: clouded consciousness, headaches, migraines, hallucinations, sleeplessness, emotional disease states, weak nerves, and brain exhaustion. . . . Yet how modest these areas of application are in contrast to the transdimensional and exotic otherworldliness of the peyotl inebriation. A little bottle of the agent is a part of that power that can take the earth out of its course and lift our spirit to the heavens, and also a part of that guiding hand without which life and law are impossible. (Gäbler 1965, 199, 204f.)

Constituents

To date, more than fifty alkaloids have been isolated from the peyote cactus and described. A fresh cactus that has been well watered has a total alkaloid content of approximately 0.4%, while specimens that live under extremely dry conditions have as much as 2.74% and dried buttons up to 3.7% (Brenneisen and Helmlin 1993, 708f.). The alkaloid concentration can exhibit considerable variation (Todd 1969).

In addition to **mescaline**, the primary alkaloid, peyote also contains the β -**phenethylamines** tyramine, *N*-methyltyramine, hordenine, candicine, anhalamine, lophophorine, pellotine, *O*-methylpellotine, *N,N*-dimethyl-3-methoxytyramine, dopamine, epinine, 3-methoxytyramine, *N*-methyl-mescaline, *N*-formylmescaline, *N*-acetylmescaline, *N*-formylanhalamine, *N*-acetylanhalamine, isoanhalamine, anhalinine, anhalidine, anhalotine, isoanhalidine, anhalonidine, and various derivatives (Mata and McLaughlin 1982, 105f.*). Apparently only mescaline has definite psychoactive effects (McLaughlin and Paul 1966). In spite of the popular misconception, the cactus's hairs do *not* contain **strychine**.

Lophophora diffusa contains pellotine, lophophorine, anhalamine, anhalonidine, **mescaline**, and *O*-methylpellotine (Mata and McLaughlin 1982, 105f.*).

Effects

Depending upon the dosage used, peyote can have healing, aphrodisiac, or psychedelic/visionary effects. The psychedelic effects typically begin some 45 to 120 minutes after ingestion. Nausea and vomiting commonly occur prior to the onset of the visions; for this reason it is said that with peyote, the hangover comes before the effects. The psychedelic effects last for six to nine hours. Aftereffects are rare; there are a few reports of headaches the following day. The visionary world opened by peyote is very similar to the "other reality" induced by **psilocybin**, *Psilocybe* spp., LSD (cf. **ergot alkaloids**), and **mescaline**.

Among the Huichol, the visions peyote induces appear to exhibit many constants and are all of a mystical nature (Myerhoff 1975). The late renowned Huichol shaman Ramón Media Silva gave a very precise description of the effects of peyote and the special nature of the effects upon shamans:

The first time one puts the peyote into one's mouth, one feels it going down into the stomach. It feels very cold, like ice. And the inside of one's mouth becomes dry, very dry. And then it becomes wet, very wet. One has much saliva then. And then, a while later one feels as if one were fainting. The body begins to feel weak. It begins to feel faint. And one begins to yawn, to feel very tired. And after a while one feels very light. The whole body begins to feel light, without sleep, without anything.

And then, when one takes enough of this, one looks upward and what does one see? One sees darkness. Only darkness. It is very dark, very black. And one feels drunk with the peyote. And when one looks up again it is total darkness except for a little bit of light, a tiny bit of light,

brilliant yellow. It comes there, a brilliant yellow. And one looks into the fire. One sits there, looking into the fire which is Tatewarí. One sees the fire in colors, very many colors, five colors, different colors. The flames divide—it is all brilliant, very brilliant and very beautiful. The beauty is very great, very great. It is a beauty such as one never sees without the peyote. The flames come up, they shoot up, and each flame divides into those colors and each color is multicolored—blue, green, yellow, all those colors. The yellow appears on the tip of the flames as the flame shoots upward. And on the tips you can see little sparks in many colors coming out. And the smoke which rises from the fire, it also looks more and more yellow, more and more brilliant.

Then one sees the fire, very bright, one sees the offerings there, many arrows with feathers and they are full of color, shimmering, shimmering. That is what one sees.

But the mara'akame [= shaman], what does he see? He sees Tatewarí, if he is chief of those who go to hunt the peyote. And he sees the Sun. He sees the mara'akame venerating the fire and he hears those prayers, like music. He hears praying and singing.

All this is necessary to understand, to comprehend, to have one's life. This we must do so that we can see what Tatewarí lets go from his heart for us. One goes understanding all that which Tatewarí has given one. That is when we understand all that, when we find our life over there. But many do not take good care. That is why they know nothing. That is why they do not understand anything. One must be attentive so that one understands that which is the Fire and the Sun. That is why one sits like that, to listen and see all of that, to understand. (Myerhoff 1974, 219–220)

For many North American Indians, it is particularly important that they receive a vision through the peyote that will provide them with direction for their lives (Anderson 1996b, 92 ff.). Navajos have reported that their dream experiences are disturbed by frequent peyote use (Dittmann and Moore 1957). There are many reports of mystical experiences, which are valued even more highly than visions:

Peyotists seldom have visions and regard them as mere distractions from what is important. It can perhaps be said that mystical experience consists in the harmony of all immediate experience with that which the individual regards as the highest good. Peyote has the remarkable ability to provide a person with a mystical experience of unlimited duration. (Tedlock and Tedlock 1978, 107)

Western peyote users have compared the visionary or psychedelic effects of peyote with the higher yogic states of consciousness described in the literature of India (e.g., James 1964) but have also disparaged it as “drunkenness” or characterized it as an artificial psychosis (cf. **mescaline**). It has repeatedly been reported that the psychoactive effects of peyote are much more significant, more profound, and more spiritual when they are experienced as part of an Indian ritual (Ammon and Patterson 1971).

An extract of the cactus has antibiotic properties (McCleary et al. 1960). Huichol women claim that peyote stimulates lactation.

The peyote cult, which has spread like wildfire among the Indians of North America, has also generated numerous recordings of peyote songs. This movement can be seen as a Western, high-technology manifestation of Indian medicine. (CD cover, 1994, Soar Sound of America Records)

“Peyote is for learning; those with strong hearts will receive messages from the gods.”

A HUICHOL INDIAN

IN “THE CROSSING OF THE SOULS” (SCHAEFER 1995, 45)

“We will fly over this little mountain. We will travel to Wirikuta, where the sacred water is, where the peyote is, where Our Father comes up.”

FROM A HUICHOL STORY IN

PEYOTE HUNT (MYERHOFF 1974, 179)

Commercial Forms and Regulations

During the colonial period (seventeenth century), the Inquisition forbade the Indians of Mexico to use peyote for ritual and religious purposes and threatened them with severe penalties if they were caught using it (Leonard 1942). The Indians of North America were also long forbidden to use peyote (Bullis 1990; Camino 1992). In the United States, the members of the Native American Church have been allowed to use peyote for religious and sacramental purposes since 1995. They are permitted to collect the cactus in the peyote fields of Texas and to buy peyote powder in prepackaged tea bags. The cactus, which is becoming increasingly rare, is covered by the Washington treaty on endangered species (Deimel 1996, 24).

In Germany, live peyote cacti are not covered by the current drug laws, so it is permitted to buy and sell the cactus (Körner 1994*). But the main active constituent, **mescaline** (as well as preparations containing mescaline), is included among the “narcotic drugs for which trafficking is not allowed” in Appendix I of the German drug laws. If the cactus was not subject to the drug laws because of its mescaline content, then it would be a medicine requiring a prescription (Brenneisen and Helmlin 1993, 710). Only those homeopathic preparations diluted at D4 or greater are allowed to be sold. Recently, the mother tincture has become available through pharmacies, but it is difficult to obtain.

Nevertheless, living peyote plants do occasionally make their way into cactus and flower shops (sometimes under the name *living rocks*). Seeds are available from ethnobotanical specialty sources.

This richly illustrated children's book, *Im Reiche des Mescál* [In the Realm of Mescal], is based upon an Indian story in which a child has a peyote experience that teaches him about the other reality, the "realm of mescál." (Title page, Synthesis Verlag, 1968)

Cactus aficionados consider the North American sand dollar cactus (*Astrophytum asterias*) to be the most beautiful star cactus. Members of the Native American Church regard it as a symbol for the peyote cactus.

Astrophytum myriostigma, known in Germany as *bischofsmütze* (“bishop’s miter”), is called *peyote cimarrón* (“feral peyote” or “wild peyote”) in northern Mexico.

The very rare ball cactus *Aztekium riterii* occurs only in the Mexican state of Nuevo León.

The red fruit of the small ball cactus *Epithelantha micromeris* is used as a doping agent.

In Mexico, some species of the genus *Ferocactus* are called *biznaga*, a name also given to the peyote cactus. Several species contain β -phenethylamines.

Mammillaria heyderi, known by the name *híkuli* or *peyote*, produces edible red fruits (so-called *chilitos*) that have a wonderful taste. (Photographed in Teotihuacan)

The rare cactus *Obregonia denegrii* is from Tamaulipas.

Peyote Substitutes and Plants with the Name *Peyote*

(From Anderson 1996b, 162f; Bruhn and Bruhn 1973; Bye 1979b*; Deimel 1996, 22; Díaz 1979*; Martínez 1987*; Ott 1993*; Schultes 1937a, 1937b, 1966*; Shulgin 1995*; expanded.)

ORCHIDACEAE		
<i>Oncidium cebolleta</i> (Jacq.) Sw. ²¹⁹ [syn. <i>O. ascendens</i> Lindl., <i>O. longifolium</i> Lindl.]	híkuli	alkaloids (?)

An *Oncidium* species from northern Mexico. Several Mexican species of *Oncidium* bear a strong resemblance to *Oncidium cebolleta*, known as *híkuli* (“peyote”). Whether this or a closely related species does in fact have psychoactive effects is a subject for future research.

In the future, bromeliads of the genus *Tillandsia*, which live on trees and branches, may become important as psychoactive plants. One species in northern Mexico is regarded as a peyote substitute and is said to produce psychoactive effects.

“The ocean drew itself out of the ocean,
and after the ocean
came the gods.
The gods stepped forth
like flowers.
In the way of the flowers
they followed the ocean
and they came to the womb
to the place of origin
to the place of birth.”

HUICHOL PEYOTE SONG

IN *RAUSCH UND ERKENNTNIS* [INEBRIATION AND KNOWLEDGE] (HÖHLE ET AL. 1986, 53*)

“I speak to the peyote as if to a mother. She praises me and she rebukes me. She strengthens me and gives me good advice.”

A NAVAJO

IN *NUR DER ADLER SPRACH ZU MIR* [ONLY THE EAGLE SPOKE TO ME]

(F. ABEL 1983, 85)

The Mexican peyote cactus has inspired numerous comic book artists such as Jeronaton and stimulated them to develop fantastic stories about the magical effects of this plant of the gods. (Title page, Edition Becker & Knigge, 1982)

Facsimile title page of Rouhier 1927.

Mammillaria spp.

Mammillaria Cacti

Family

Cactaceae (Cactus Family); Cacteeae Tribe, Echinocactinae Subtribe

Species

The genus *Mammillaria* is composed of 150 to 200 species. It thus has more species than any other genus in the Cactus Family except *Opuntia*. Species of ethnobotanical relevance:

Mammillaria craigii Lindsay [syn. *Mammillaria standleyi* (Britt. et Rose) Orcutt] (a peyote substitute)
Mammillaria grahamii Engelm. (a peyote substitute)
M. grahamii var. *oliviae* (Orcutt) L. (a peyote substitute)
Mammillaria heyderi (Mu.) Britt. et Rose (a peyote substitute)
M. heyderi var. *coahuilensis* (Boedeker) J. Lüthy comb. nov.
M. heyderi var. *gummifera* (Engelm.) L. Benson
M. heyderi var. *hemisphaerica* (Engelm.) Engelm.
M. heyderi var. *macdougalii* (Rose) L. Benson
M. heyderi var. *meiacantha* (Engelm.) L. Benson
Mammillaria longimamma DC. [syn. *Dolichothele longimamma* (DC.) Britt. et Rose, *Dolichothele uberiformis* (Zucc.) Britt. et Rose, *Mammillaria uberiformis* Zucc.] (a peyote substitute)
Mammillopsis senilis (Lodd.) Weber [syn. *Mammillaria senilis* Lodd.] (a peyote substitute)

Among the immediate relatives of *Mammillaria crinita* (order Stylothelae), the following species have been shown to contain an alkaloid that may have psychoactive properties (the so-called *M. wildii* profile) (Lüthy 1995):

Mammillaria anniana Glass et Foster
Mammillaria aurihamata (after Reppenhagen 1991)
Mammillaria bocasana Poselger [syn. *M. eschauzieri* (Coult.) Craig]
Mammillaria brevicrinata Boedeker (after Reppenhagen 1991)
Mammillaria crinita DC. [syn. *Mammillaria zeilmanniana* Boedeker (Mother's Day cactus),
Mammillaria gilensis Boedeker]
Mammillaria duwei Rogozinski et Braun (after Reppenhagen 1991)
Mammillaria erythrosperma Boedeker
Mammillaria fittkaui Glass et Foster
Mammillaria limonensis Reppenhagen [= *Mammillaria fittkaui* ssp. *limonensis* (Reppenhagen) Lüthy comb. nov.]
Mammillaria mathildae Kraehnbuehl et Kraiz [= *Mammillaria fittkaui* ssp. *mathildae* (K. et K.) Lüthy comb. nov.]
Mammillaria monancistracantha Reppenhagen
Mammillaria ojuelensis n.n.
Mammillaria puberula Reppenhagen

Mammillaria pygmaea (Britt. et Rose) Berg

Mammillaria schwarzii Shurly

Mammillaria variabilis Reppenhagen

Mammillaria wildii A. Dietrich [= *Mammillaria crinita*, which is propagated and sold on the international market under the name *Mammillaria wildii*]

Synonyms

See above.

Mammillaria senilis Lodd. = *Mammillopsis senilis* (Lodd.) Weber

The Mexican ball cactus *Mammillaria compressa*.

Because it flowers frequently, *Mammillaria bocasana* is a popular specimen for the home.

Folk Names

Biznaga de chilillos, biznaga de chilitos, falscher peyote, false peyote, híkuli, jículi, jícuri, mammillaria cactus, mammillarienarte, Mother's Day cactus, muttertagskaktus, peyote, warzenkaktus, wichuriki

History

The genus and several of its many species were described at the beginning of the nineteenth century. Today, the genus is well studied and has been the subject of several taxonomic revisions (Lüthy 1995). Many members of the genus are now in international demand as ornamentals.

Distribution

The genus *Mammillaria* is American in origin and is most heavily concentrated in northern Mexico. Most species live in hot and dry regions (deserts), some on rocky and craggy soils as well as on sandy and volcanic soils.

Cultivation

Many mammillaria cacti can be easily grown from seed. The tiny seeds need only be lightly pressed into porous soil and covered with pure sand. Keep very moist and in the sun at first. The time to germination is two to six weeks (at 20 to 25°C). In central Europe, the plant can be grown only as a houseplant or in a greenhouse.

Appearance

Those species of ethnobotanical and chemotaxonomic interest are all rather similar in appearance. They are small, spherical, heavily thorned, piliferous woolly cacti with flowers approximately 1.5 cm in length. The flowers, which may be white, pink, red, or violet, appear between March and May. The fruits typically are small red pods reminiscent of chili pods (*Capsicum* spp.). For this reason, they are known as *chilitos* in Mexico.

Psychoactive Material

- Fruits (*chilitos*)
- Cactus flesh

Preparation and Dosage

For use as a doping agent, a handful of the fresh fruit is recommended. The cactus flesh, dried and powdered, was drunk in maize beer (**chicha**) as a peyote substitute (see *Lophophora williamsii*).

Ritual Use

The Tarahumara of northern Mexico used some species of *Mammillaria* as peyote substitutes (see *Lophophora williamsii*) (Bye 1979b*; Deimel 1996, 22; Díaz 1979, 80*). *Mammillaria craigii* purportedly was formerly eaten by Tarahumara shamans wanting to obtain “clear vision” so that they could “see” witches and sorcerers (*brujos*) (Bye 1979b, 30*). The flesh of *Mammillaria grahamii* var. *oliviae* was consumed by shamans and participants in secret ceremonies so that they could undertake a journey into a realm of brilliant colors. It is said that a person will go insane if he or she consumes this cactus immoderately (Bye 1979b, 31*).

Artifacts

Several illustrations can be found on postage stamps.

Medicinal Use

It is possible that the Tarahumara used *mammillaria* cacti for folk medicinal purposes similar to the ways in which they used the true peyote.

Roasted pieces or heart pieces of *Mammillaria heyderi* are placed in the ear canal to relieve headaches. The long-distance runners of the Tarahumara eat its fruits (*chilitos*) for doping purposes. This cactus is also thought to prolong life (Bruhn and Bruhn 1973, 244).

Mammillaria species containing latex are sold at Mexican markets as folk remedies and to counteract witchcraft.

Mammillaria heyderi is alleged to have potent psychoactive effects; however, no reports of experiences with the cactus are available.

Mammillaria zeilmanniana is known as Mother's Day cactus because its luminous flowers appear around May, the month in which Mother's Day falls.

Mammillaria wildii, a cactus that contains an active alkaloid.

The fruits of several mammillaria cacti are known as *chilitos* (“little chilis”). In Mexico, *chilitos* are regarded as doping agents, and the long-distance runners of the Tarahumara eat them to maintain their strength.

These Laotian postage stamps show two Mexican mammillaria.

“Among the most important ‘false Peyotes’ of the Tarahumara Indians are several species of *Mammillaria*, all of them round and stout-spined plants.”

RICHARD EVANS SCHULTES AND ALBERT HOFMANN

PLANTS OF THE GODS

(1992, 48)

Hordenine

Constituents

Several species contain the alkaloid hordenine (Howe et al. 1977). Other β -**phenethylamines** have been more frequently reported (Knox et al. 1983; West and McLaughlin 1973). To date, **mescaline** has not been detected (Shulgin 1995*).

The flowers and fruits of those species exhibiting the *M. wildii* profile have yielded a new alkaloid whose probable chemical formula is $C_{13}H_{13}NO_3$ (Lüthy 1995, 58 f.). Most mammillaria contain a latex composed of terpenes.

Effects

Hordenine and other **β-phenethylamines** may have psychoactive effects. Whether the newly discovered alkaloid is indeed psychoactive must be determined by further human pharmacological research.

Commercial Forms and Regulations

Many species of the genus *Mammillaria* can be found in cactus and flower shops. Because the genus is very popular among cactus aficionados and collectors, the best shops will often have a large selection. However, care must be exercised as far as the botanical information is concerned. Numerous species are sold under the name *Mammillaria zeilmanniana*.

Mandragora officinarum Linnaeus

Mandrake

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solaneae Tribe, Mandragorinae Subtribe; chemotaxonomic subgroup composed of the genera *Mandragora* and *Scopolia* (cf. *Scopolia carniolica*) (Jackson and Berry 1979, 511)

Forms and Subspecies

Mandragora officinarum probably occurs in several varieties that were originally described as separate species (Jackson and Berry 1979):

Mandragora officinarum L. var. *haussknechtii*

Mandragora officinarum L. var. *hybrida*

Mandragora officinarum L. var. *officinarum*

Mandragora officinarum L. var. *vernalis* (very early-blooming form)

Synonyms

Atropa acaulis L. 1762

Atropa mandragora L.

Atropa mandragora (L.) Woodville 1794²²²

Mandragora acaulis Gaertn.

History

The mysterious mandrake or *Mandragora*—the queen of all magical plants—is not a character from a fairy tale but a real plant that is found especially in the eastern Mediterranean region. There are only two European species, the botanical identity of which was long uncertain (cf. ***Mandragora spp.***). Mandrake has quite correctly been described as “the most famous magical plant in history” (Heiser 1987*). Its medicinal and magical uses, its aphrodisiac and psychoactive effects, and its mythology and the legends surrounding the plant all raise it above the level of any other magical plant (Schlosser 1987; Schöpf 1986*; Starck 1986). There is probably no other plant about which such a rich and varied literature has been produced (cf. Hansen 1981*).

Probably the oldest written mention of the mandrake occurs in the cuneiform tablets of the Assyrians and the Old Testament; these refer primarily to the area of Babylon. In Assyrian, the mandrake was known as *nam-tar-gir(a)* (isnam tar-*gir₁₂).²²⁶ Nam Tar was the god of plagues; (*g*)*ira* means “male.” An Ugaritic cuneiform text from Ras Shamra (fifteenth to fourteenth century B.C.E.) appears to refer to a ritual; the text reads, “[P]lant mandragoras in the ground . . .” (Schmidbauer 1968, 276). Mesopotamian cunei-form texts make frequent mention of a wine known as cow’s eye, which was purportedly a wine mixed with mandrake. “The effects of the man-drake upon the pupils could thus be the reason for the strange name ‘cow’s eye’ ” (Hirschfeld and Linsert 1930, 162*).

In ancient times, mandrake was an enormously important ritual, inebriating, and medicinal plant. The German name *alraune* suggests an Old Germanic use of the plant: “Alraun comes from Alrun, and originally meant ‘he who knows the runes’ or the ‘all knowing’ ” (Schmidbauer 1969, 281). The Germanic seeresses (*seidkona*, *wölwas*), who by late ancient times were known far beyond Europe’s borders for their miraculous abilities (e.g., Albruna and Weleda; one was even active in Egypt!), would enter a prophetic ecstasy with the aid of such magical agents and shamanic techniques (Derolez 1963, 240*). With the Christianization of Germania, *Mandragora* (as an ancient pagan ritual plant) was demonized. Hildegard von Bingen was the first to denounce the mandrake:

The Alraun is warm and somewhat watery and is spread by that ground from which Adam was made; it somewhat resembles a person. With this plant, however, also because of its similarity to a person, there is more diabolical whispering than with other plants and it lays snares for him. For this reason, a person is driven by his desires, whether they are good or bad, as he also once did with the idols. . . . It is harmful through much that is corruptive of the magicians and phantoms, as many bad things were once caused by the idols. (*Physica* 1.56)

The legendary mandrake (*Mandragora officinarum*), shown here in bloom. (Wild plant, photographed in Cyprus)

Although *Mandragora* is numbered among the witches' plants (cf. **witches' ointments**), it was often counterfeited during the Middle Ages because it was also valued as a talisman and bringer of luck. Surrogates were sold in pharmacies even as late as the twentieth century. Because of the difficulty in obtaining actual plant material, mandrake has never attained much significance as a psychoactive plant in the hippie subculture or among the modern closet shamans. Surprisingly, the psychoactivity of the root has never been the object of any systematic study.^{[227](#)}

Distribution

Mandragora officinarum is found in southern Europe from Portugal to Greece; it is quite common in Greece and Italy (Festi and Aliotta 1990*; Viola 1979, 175*). It never occurs in the wild north of the Alps (Beckmann 1990, 129*). But the root is winter-hardy and can be grown in central and northern Europe. It is also found in North Africa, Asia Minor, and the Middle East and on most of the Mediterranean islands (Cyprus, Crete, Sicily) (Georgiades 1987, 50*; Sfikas 1990, 246*). It often thrives in dry, sunny locales, usually along paths and around ancient temples. However, it is one of Europe's rarest plants.

Cultivation

Propagation occurs through the seeds (which are very similar in appearance to the seeds of *Datura innoxia*). It is best to pregerminate the seeds (as with those of *Datura discolor*). The seedlings should be transplanted into very large pots, as the plant will develop a very large root over the years. The first flowers will develop when the plant is in its fourth year. The plant can be grown in topsoil to which a small amount of sand has been added. The plant should never be overwatered, especially when it is in its dormant stage.

The ripe fruits of the mandrake (*Mandragora officinarum*) exude an exhilarating scent that in ancient times was thought to incite love. (Wild plant, photographed in Cyprus)

The seeds of *Mandragora officinarum* are very similar to those of some species of *Datura*. (Photograph: Karl-Christian Lyncker)

Although the plant does not actually tolerate frost, it can be maintained as a perennial in central Europe. To achieve this, the plant or its location should be covered with a pile of leaves in the fall. The leaves should then be removed in the spring. In central Europe, the plant does not develop leaves until early summer.

Appearance

The mandrake is a stemless perennial plant whose fleshy root can grow as long as 100 cm, sometimes taking on a bizarre or anthropomorphic shape. Most of the year, the plant is hidden in the ground.

Once every year, the long, wide leaves, which form a characteristic rosette, grow directly out of the roots. The bluish or violet, bell-shaped, quinquelobate flowers grow on short stalks from the center of the rosette. The leaves wither as the yellow berries (fruits) mature. But the root remains alive and will develop leaves and flowers again the following spring. The golden yellow fruits have a fruity scent (similar to that of the fruits of *Physalis* spp.) but taste more like tomatoes (fellow members of the Nightshade Family). The leaves have a scent somewhat reminiscent of that of fresh tobacco

(*Nicotiana tabacum*).

Mandragora officinarum can be easily confused with the autumn mandrake. Both European species are very similar in their anatomy. However, the rhizome of *M. officinarum* is larger than that of *M. autumnalis*. The primary difference between the two is their flowering period. *M. officinarum* blossoms in May, while *M. autumnalis* blooms in the fall (September to November) (cf. *Mandragora* spp.).

In the ethnographic literature and in literature pertaining to the history of medicine, the true mandrake is frequently confused with the may-apple (*Podophyllum peltatum* L.) and other plants (see the table on page 347).

Psychoactive Material

—Root (mandragorae radix, mandrake root)

—Root cortex

—Leaves

—Fruits (mandrake fruits, love apples, dudaim, Arabic lofah)

Preparation and Dosage

The fruits should be consumed only while fresh. No overdoses have been observed, even with quantities as high as ten fruits.

The leaves can be either chewed while fresh or dried for later use. They are best collected before the fruiting period and dried in the shade. They can be smoked alone (as a tobacco substitute; cf. *Nicotiana tabacum*) or mixed with other herbs into **smoking blends**. They also can be used as **incense**.

The root can be burned as incense as well. While the burning root pieces give off a rather unpleasant aroma reminiscent of that of burned food, the smoke itself is rather easy to inhale. When used as an incense, mandrake can be combined with the pleasant-smelling olibanum (cf. *Boswellia sacra*). When smoked or used as an incense, the psychoactive effects of mandrake are very subtle.

The most common use involves tinctures of the dried root. It is only seldom eaten. The alkaloids present within the plant are quite water soluble, which is why tinctures are derived from an aqueous whole extract.

The mandrake is very suitable for making or improving **beer** and **wine**. Mandrake beer is brewed in the same manner as henbane beer (see *Hyoscyamus niger*). Fifty grams of dried root should be used for 20 liters of liquid. Cinnamon sticks and/or saffron (*Crocus sativa*) can be added to improve the taste of mandrake beer. As little as ½ to 1 liter of mandrake beer can produce very noticeable effects. Care should be exercised when determining dosages!

The ancient Greeks frequently added the fresh or dried root to wine (cf. *Vitis vinifera*) for use as a love drink. Dioscorides has passed on a complete recipe for making mandrake wine (περί μανδραγοριτω):

Mandrake wine. Cut the cortex of the root and add ½ mine [= 8 ounces], wrapped in linen, to 1 metrete [= 36.4 liters] of must and allow to sit for three months, then pour into another container. The average dosage is ½ cotyle [= 5 ounces]. It is drunk with the addition of twice the amount of must. It is said that 1 hemine [= 10 ounces] of this, mixed with 1 chus [= 10 pounds = 120 ounces], will cause sleep and sedate; 1 cup, with xestes [= 1 pound, 8 ounces] of wine, can kill. When used correctly, it has analgesic effects and thickens the discharges. Whether used as a fumigant, as an enema, or as a drink, it has the same effects. (5.81).

When I wish to make mandrake wine, I add a handful (approximately 23 g) of chopped man-drake root (mandragorae radix conc.) to a bottle of retsina (0.7 liter). The mixture is then allowed to steep for a week. Do not filter out the root pieces; allow them to remain in the wine until it has been drunk. A few (two or three) cinnamon sticks and 1 tablespoon of saffron (cf. **Crocus sativus**) can be added if desired; this will considerably improve the earthy, slightly bitter taste. One liqueur glass (40 to 60 ml of wine) is an effective dosage.

Plants That Were Used as a Substitute for or to Counterfeit the True Mandrake

(From Brøndegaard and Dilg 1985; Dahl 1985; Emboden 1974*; Rätsch 1986, 1987, 1994; Wlislöcki 1891, 90*; modified and supplemented.)

American mandrake ²²⁶ (= mandrake root)	<i>Podophyllum peltatum</i> L.
Belladonna root	<i>Atropa belladonna</i>
Calamus root	<i>Acorus calamus</i>
Canna	<i>Canna edulis</i> Ker-Gawl. (cf. <i>canna</i>), <i>Aureliana canadensis</i> ²²⁷
Carrot root	<i>Daucus carota</i>
Cimbola, cimitrk root ²²⁸ (= common celandine)	<i>Chelidonium majus</i> L.
Common tormentil, five fingers	<i>Potentilla erecta</i> (L.) Räuschel [syn. <i>Tormentilla erecta</i> L.]
False mandrake	<i>Allium victorialis</i> L.
Galangal	<i>Alpinia officinarum</i> Hance, <i>A. galanga</i> (cf. <i>Kaempferia galanga</i>)
Ginseng (sometimes called the mandrake of the East)	<i>Panax ginseng</i> , <i>Panax pseudochinseng</i> Wall., <i>Panax</i> spp.
Iris root	<i>Iris pseudacorus</i> L.
Jangida root	<i>Withania somnifera</i>
Karengro root	<i>Orchis mascula</i> (L.) L.
Kougoed root (sometimes called the mandrake of the South)	<i>Sceletium tortuosum</i>
Orchids (sometimes called the mandrakes of the North)	<i>Orchis</i> spp.
Scopolia root	<i>Scopolia carniolica</i>
Shang-luh	<i>Phytolacca acinosa</i>
White bryony	<i>Bryonia cretica</i> L. ssp. <i>dioica</i> (Jacq.) Tutin ²²⁹ [syn. <i>Bryonia dioica</i> Jacq.], <i>Bryonia alba</i> L.

The root of the true mandrake (*Mandragora officinarum*) is the most renowned magical agent in European history.

In the early modern period, the rhizome of the Asian (= East Indian) *Alpinia galanga*, a member of the ginger family, was fraudulently sold as mandrake root.

An aphrodisiac drink can also be made using the following recipe (after Miller 1988, 51*; modified):

1 bottle white wine (variety as desired)

28 g vanilla pods (*Vanilla planifolia* Andr.)

28 g cinnamon sticks (*Cinnamomum verum* J.S. Presl)

28 g rhubarb root (*Rheum officinale* Baill. or *R. palmatum* L.)

28 g mandrake root (*Mandragora officinarum*)

Coarsely chop all of the ingredients and allow to steep in the wine for two weeks. Shake once a day if possible. Then filter the liquid through a sieve and, if desired, color with St. John's wort (*Hypericum perforatum* L.) or saffron (***Crocus sativus***). **Honey** (preferably in combination with royal

jelly) may be added to sweeten the drink. Experiment to obtain the desired dosage.

The root pieces can also be added to any type of spirits (**alcohol**). Alcoholic drinks containing mandrake roots are still prepared in Romania, where it is said, “A few mandrake fibers in wine or schnapps keeps the bartender’s customers” (Eliade 1982, 226).

In ancient times, the very thin root cortex of the mandrake was used in a variety of ways:

A juice is prepared from the cortex of the bark by crushing this while fresh and pressing this; it must then be placed in the sun and stored in an earthen vessel after it has thickened. The juice of the apples is prepared in a similar manner, but this yields a less potent juice. The cortex of the root that is pulled off all the way around is put on a string and hung up to store. Some boil the roots with wine until only a third part remains, clarify this and then put it away, so that they may use a cup of this for sleeplessness and immoderate pain, and also to induce lack of sensation in those who need to be cut or burned themselves. The juice, drunk in a weight of two obols with honey mead [cf. **mead**], brings up the mucus and the black bile like hellebore [*Veratrum album*]; the consumption of more will take life away. (Dioscorides 4.76)

The literature very rarely includes information about dosages. According to *Hagers Handbuch*, the therapeutic dosage is fifteen to thirty drops of the tincture of an aqueous extract of the root in alcohol (Roth et al. 1994, 485*). Thirty to fifty drops of the mother tincture will induce aphrodisiac/psychoactive effects.

Mandrake is purported to have been an ingredient in **witches’ ointments**.²³²

Ritual Use

In ancient times, the primary ritual significance of the mandrake was in erotic cults. Because of the poor quality of the sources that have come down to us, however, only rudimentary information about these practices is available. The most important source about the use of mandrake in the Orient is the Old Testament, where the fruits (love apples) are mentioned numerous times under the Old Hebrew name *dûdâ’îm*, and namely as an aphrodisiac (not all interpreters of the Bible recognize the identification of *dûdâ’îm* with *Mandragora*).²³³ According to Rabbi Jacob ben Asher (1269–1343), the name *dûdâ’îm* has its basis in numerology. The numerical value of the word is identical to that of the Hebrew word *ke’adam*, “like a human,” and is an allusion to the anthropomorphic shape (Rosner 1993, 8). It is possible that the mandrake, which according to kabbalistic principles is a symbol for becoming one, may have been used in secret mystical rites in ancient Israel (Weinreb 1994, 252–67).

The aphrodisiac quality was attributed primarily to the scent of the ripe, golden yellow fruits (Fleisher and Fleisher 1994). The Book of Genesis contains an account of what may have been an archaic magical ritual:

And Reuben went in the days of wheat harvest [May], and found mandrakes [*dûdâ’îm*] in the field, and brought them unto his mother Leah. Then Rachel said to [her sister] Leah, Give me, I pray thee, of thy son’s mandrakes. And she said unto her, Is it a small matter that thou hast taken my husband? and wouldest thou take away my son’s mandrakes also? And Rachel said, Therefore he shall lie with thee tonight for thy son’s mandrakes. And Jacob came out of the field in the evening, and Leah went out to meet him, and said, Thou must come in unto me; for surely I have hired thee with my son’s mandrakes. And he lay with her that night. And God hearkened unto Leah, and she conceived, and bare Jacob the fifth son. (Genesis 30:14–17)

A similar ritual with the magical fruit appears to be the basis of the much cited text of the erotic

Song of Solomon: “[T]here will I give thee my loves, The mandrakes give a smell.” (Song of Solomon 7:12, 13)

In the Near East today, the aromatic fruits of the mandrake are still regarded as aphrodisiacs (Fleisher and Fleisher 1994; Moldenke and Moldenke 1986, 137ff.*) and used in love magic (Rosner 1993, 7).

Because the true mandrake is not indigenous to central Europe, the fleshy root of the native bryony (*Bryonia* sp.) was once used to carve counterfeit “little mandrake men.”

In another legend from the postbiblical period, the creation of the mandrake is attributed to Adam himself:

When Adam was separated from his wife Eve for a long period, the long abstinence played a trick on him. He fantasized about her presence with such ardor that his semen, which shot forth as a result of the loving embrace and sprayed onto the floor, gave rise to a plant which took on human form, the *Caiumarath*, the mandragora. (Müller-Ebeling n.d., 97; Starck 1986, 21)

The most extensive description of this magical and erotic root and the ritual surrounding its harvest is from Flavius Josephus (first century), who wrote in Greek so that he could make the customs of the people of Judea more comprehensible to the Greeks. It is possible that he obtained his magical and botanical knowledge from the Essenes, with whom he lived for some time (Kottek 1994, 163*):

In the valley that is on the north side of the city (Machairos)²³⁴ is a special place known as Baaras, where a root of the same name grows. Every evening, it shines with a fire red glow²³⁵: But if someone wishes to approach it to pull it out, then it is difficult to take hold of, it pulls away from the hands and cannot be held until one has poured menstrual blood or urine onto it. But even then, any direct contact with the root means sudden death, unless one carries it in the hand so that the tip of the root faces down. Alone, one can also take possession of the root without any danger

in the following way: You dig the earth up all around it, so that only a small piece of the root remains covered by the soil. Then a dog is tied to it. When this tries to follow the person who has tied it, it will of course quite easily pull the root from the ground. But in that moment the dog will die, as if to atone for he who has really taken away the plant. From then on, one can take hold of the root without fear. The reason that this root is so sought after in spite of its dangerous nature is to be found in its peculiar effects: for it has the power to dispel the so-called demons, that is the spirits of evil deceased persons who enter into the living and kill them if they are not aided, simply by coming near the afflicted. (Flavius Josephus, *History of the Judean War* 7.6, 3)

In ancient Egypt, mandrake fruits were used as gifts of love during courtship and probably were eaten as aphrodisiacs. The love plant appears to have been associated with Hathor, the goddess of love. The mandrake **beer** that was consecrated to her played an important role in the famous myth describing the destruction of the human race and the creation of heaven (Brunner-Traut 1991, 101–6).

The sun god Ra was angry with humans because they had contrived to attack him. In his anger, he created the terrible lion-headed goddess Sekmet (an early form of Hathor) to punish the race of humans. She raged among the people for an entire day and was not yet finished when the sun set, for she wanted to utterly extinguish humanity. But Ra did not want this, and he thought of a trick to end the goddess's deadly rampage. He had mandrake fruits brought to him from Elephantine, an island in the Nile (Brugsch 1918, 31; Tercinet 1950, 17; Thompson 1968, 43); according to other versions and/or translations, hematite²³⁶ or “red ocher” was brought as well (Brunner-Traut 1991, 103). At the same time, he ordered the production of a huge amount of barley beer (seven thousand jugs). He mixed the mandrakes (and the hematite or red ocher) into this and had the fields covered in the bloodred beer (the “sleeping drink”). The following sunrise, when the goddess saw the beer, she first perceived her reflection and thus recognized herself. Because of its red color, she thought the beer was human blood, and she eagerly drank it to the last drop. “Her countenance became gentle as a result, and she drank; this did her heart well. Drunken did she return, without having recognized the people” (Brunner-Traut 1991, 104).

Out of thankfulness, humans never again rose up against Ra. Sakmet transformed herself into the cow Hathor and carried Ra into the heavens.²³⁷

In commemoration of these dramatic events, which took place at the beginning of time, Ra established the Hathor festival (literally, “festival of drunkenness”), during which young maidens consecrated to the goddess would make a beer known as *sdr.t* (= “sleeping drink” [?]) using a similar recipe. The Hathor festivals were ecstatic orgies with obscene performances, sacrificial activities, and wild music (Cranach 1981*). Later, Hathor was celebrated as the inventor of beer and the “mistress of drunkenness without end” (Thompson 1968, 46).

The mandrake was also a sacred love magic in ancient Greece. Even the plant's collection took place under the auspices of the love goddess: “One should, it is said, make three circles around the mandrake with a sword and cut it while facing west.²³⁸ And when cutting the second piece, one should dance around the plant and speak as much as possible about the mysteries of love” (Theophrastus, *History of Plants*, 9.8).

The Cypriot cult of Aphrodite developed directly out of the Oriental cult of the love goddess Ishtar, Astarte, Asherot, et cetera. J. Rendel Harris proposed the theory that the Greek cult of Aphrodite could be traced back to the Greek assimilation of the Oriental conceptions about the mandrake (Harris 1917). Aphrodite was also known as Mandragoritis (“she of the *Mandragora*”; Greek μανδραγοριτις ἡ Ἀφροδιτη), a name passed down to us by Heschius (*Lexicon*; cf. Rahner 1957, 201, 364, note 21*; Schlosser 1987, 22; Thompson 1968, 55). The *Mandragora* thus had an intimate connection to the love goddess and was sacred to her (cf. *Papaver somniferum*). In the late ancient

Mysteries of the Great Goddess, Aphrodite was identified with Hecate (Apuleius, *Metamorphoses*). Thus, the “mandrake of Hecate” was nothing other than the sacred plant of the love goddess.

The mandrake, and especially its root, was the plant of Hecate. The chthonic goddess (also known as Enodia or Trivia) was from Kairen (Asia Minor) and bore many Asian attributes. As the goddess of the three paths, she had three forms, three heads, and six arms. She was simultaneously rooted in heaven, on earth, and in the underworld. As the goddess of the nocturnal spooks (visual hallucinations), she was accompanied in her wild activities by barking dogs and noisy specters (auditory hallucinations). Hecate was both the harmful witch goddess (poison foods) and the goddess of birth (aphrodisiacs, erotic hallucinations). A description of Hecate’s magical garden is contained in the saga of the Argonauts: “Many mandrakes grow within” (*Orph. Argonaut.* 922f.).²³⁹

Eusebios (ca. 260–339 C.E.), the Christian and Greek church author, held Hecate, the goddess of the underworld, to be the “ruler of all evil demons,” the “black one,” or a “demon of love madness” that was the equivalent of Aphrodite. She is the mother of Italy’s Circe and Colchis’s Medea, the “cosmic super witch” (Luck 1962, 61*).²⁴⁰ She sends to humans dampening sleep and heavy dreams and causes epilepsy (the “sacred disease”) and madness (*mania*); in other words, she is capable of inducing altered states of consciousness. It almost appears as though the dark goddess would reveal herself only through the effects of the mandrake juice. As Democritus (ca. 470–380 B.C.E.), the “laughing philosopher,” described in his lost work *Cheirokmeta* (“things made by hand”), one could invoke the goddess with the mandrake:

Now it is known that the book *Cheirokmeta* is from Democritus. And how many adventurous things is this man able to report, who after Pythagoras was the most dedicated student of magic! He reports about the plant *aglaophotis*, which received its name because of the wonder of humans for its special color, and which thrives in the marble quarries of Arabia on the Persian side, which is why it is also called *marmaritis* [= marble plant]; the magicians use it when they wish to invoke the gods. (Pliny 24.160)

Many late ancient conjurations (magic papyri) appeal to Hecate as the most important goddess. She was usually invoked in love magic, and then often in association with dogs, and even with Cerberus (Luck 1990, 129ff.*). In the magic papyri, Medea was sometimes invoked in place of Hecate (Luck 1990, 50*).

The mandrake was also the plant of Circe (Dierbach 1833, 204*). The daughter of Helios, she was knowledgeable about magic and lived on the Italian coast above Sicily (Pliny 25.10f.). Today, Monte Cicero remains as the sacred mountain of Circe.

It is possible that the mandrake was already identified with **moly** at an early date.

We can only speculate about the ritual use of mandrake in Germania. The mandrake apparently was associated primarily with love magic and divination but also with magical and ritual healing. Hildegard von Bingen described a small ritual to influence the psyche (a kind of ritual healing of depression):

And when a person is so confused in his nature that he is always sad and always in distress, so that he often has weakness and pain in his heart, he should take mandrake after it has already been pulled with its root from the ground, and he should place it for a day and a night in a spring . . . and then place it, washed by the spring, next to him in his bed. The plant will become warm from his sweat, and he should say: “God, who makes humans from the dirt of the earth without pain. Now I place this earth, which has never been stepped over, beside me, so that my earth will also feel that peace which you have created.” (*Physica* 1.56)

In Renaissance magic and in early modern occultism, mandrake was utilized as an **incense** that was under the influence of the moon. In Mecklenburg, mandrakes formerly were placed under the pillow so that one would have prophetic dreams (Schmidbauer 1969, 281f.).

In Romania, an erotic mandrake cult existed into the early twentieth century (Eliade 1942). In this cult, the mandrake was regarded as the plant of life and death and was seen as an aphrodisiac and magical love agent. The plant was harvested during the full moon between Easter and Ascension Day. The harvest was conducted according to ritual guidelines:

The plant should be collected without others knowing; . . . women and girls dance naked around the mandrake, sometimes they are content with simply letting down their hair. . . . The couples caress and embrace one another. To collect the leaves of the mandrake, the girls lie on one another in the manner of the sex act. . . .

Four young girls pluck the mandrake and speak magical formulas over it; they bury it in the middle of the street, where they then dance completely naked. During the dance, four young boys remain close by to watch over them; they repeat:

“Mandrake, good mother,
marry me in this month,
if not in this, then in the next,
but make it so that I remain a girl no longer.” (Eliade 1982, 223, 219)

Offerings (salt, bread, sugar, **wine, alcohol**, eggs, et cetera) were placed into the hole from which the mandrake was taken. The root was carried home, carefully washed, and worn as a talisman.

Artifacts

Since ancient times, mandrake root has been used as an amulet and has been prepared for this purpose (Scanziani 1972). The root was carved into so-called mandrake men (*atzmann*, gallows’ man) or fashioned into dolls. These dolls needed to be magically animated. For example, “an Italian charlatan animated a human figure that had been carved from a mandrake root using a hemp seed [*Cannabis sativa*] placed in the pudenda” (von Luschan 1891, 742). In southern Tirol, this custom is still alive today:

The so-called “Galgenmandl” [little man of the gallows], the root of the mandrake in anthropomorphic form, could often be found in the pantries and entryways of the houses of the old farms. The “Galgenmandl” was regarded as a good house spirit, and the “Weibele” [little woman] as the protectress of the grain chest. . . . In December 1968, a little mandrake coffin was discovered during the “Rauter over Francis’ Festival.” It had been walled in over the door of the kitchen. It was estimated to be 300 years old. (Fink 1983, 74)

There are even crucifixes made of mandrake roots (root crosses) that are preserved in churches as “miraculous objects” (Bauer 1993).

The mandrake apparently was brought from Palestine to Egypt during the Eighteenth Dynasty (New Kingdom; 1551–1305 B.C.E.); it became a houseplant in Egypt (Germer 1985, 170*; Manniche 1989, 117*). Gardens were sacred to the goddess Hathor, which is why mandrakes were also grown there (Hugonot 1992). A collar containing mandrake fruits that were cut in half was discovered in the grave of Tutankhamen (Germer 1985, 171*). The yellow fruits (love apples) appear often in Pharaonic art (Scanziani 1972, 50 f.). In the love songs of the New Kingdom, the fruits (*rrm.t*) are often mentioned

in conjunction with lotus flowers (*Nymphaea caerulea*) (Emboden 1989)²⁴¹:

Celebrate a beautiful day! . . .

Give balsam and pleasant scents to your nose,
garlands of lotuses and love apples on your chest,
while your wife, who is in your heart, sits by your side.

The mandrake also appears in Greek poetry. Lucian (app. 120–180 C.E.) states that a person under the influence of *Mandragora* will fall asleep (*Timon* 2). The fictional island of Hypnos (“sleep”), the island of the darkly rising dreams, is the place “where only high shooting poppies [*Papaver somniferum*] grow rampant and *Mandragora* blooms, while silent butterflies, the only birds of this land, flutter around” (Lucian, *Verae historiae* 2.33).

A tiny fragment (thirty-two verses) from a comedy by the Attic writer Alexis (app. 372–270 B.C.E.) has come down to us. It bears the name η Μανδραγοριζομεχ ν , “the woman sedated by *Mandragora*.” This fragment demonstrates the use of mandrake for purposes of love (Schlosser 1987, 46; Starck 1986, 8, 15).

The unscrupulous Renaissance politician and writer Niccolò Machiavelli (1469–1527) wrote a comedy, *La Mandragora*, about the power of the mandrake to promote fertility (Schmidbauer 1969, 277; Tercinet 1950, 105). The plant also appears in many other works of world literature, e.g., by Apuleius (*Metamorphoses*, *The Golden Ass*), Shakespeare (*Romeo and Juliet*, *Macbeth*, and other works), E. T. A. Hoffmann (*The Little Zuck*), Goethe (*Faust*), Gustave Flaubert (*Salammbô*, *The Temptation of Saint Anthony*), Marcel Schwob (*Le Roi au Masque d’Or*), Gustav Meyrink, and many others (Peters 1886; Tabor 1970*; Tercinet 1950). In 1810, Friedrich Baron de la Motte Fouqué (1777–1849) published *History of the Little Man of the Gallows*, which influenced other literary works (Fouqué 1983). The “little man of the gallows,” the mandrake produced by the last discharge of a hanged man, has been the subject of numerous literary works (Schlosser 1987). In 1940, John Palmer published *Mandragora*, an English novel that takes place in India and involves a number of psychoactive drugs.

The occult author Hanns Heinz Ewers (1871– 1943) immortalized the magical root and the female being that arises from it in his novel *Alraune* (1911). There have been several film versions of this book, the first in 1918 (director unknown). The second, made in 1927 by director and screenwriter Henrik Galeen, was also titled *Alraune*. The first sound version, directed by Richard Oswald, appeared in 1930 (Seesslen 1980, 93, 99; Seesslen and Weil 1980, 139). In the film, the mandrake is

In former times, the true mandrake (*Mandragora officinarum*) was construed as a little mandrake man. (Woodcut from the herbal of Matthiolus, 1627)

“The magic of roots is as old as humankind. Roots were at home in those places where the dead were buried and where one conceived of the underworld, the realm of shadows. And yet roots are the intermediaries of life. In a way that is difficult to comprehend, both realms seem to be near and familiar—to life and to death. It is in such magical domains that the spirits and enchanted ones live, the dwarves and the goblins. The mandrake is also a rare and fabulous being between the worlds—powerful and dangerous at the same time.”

MARIE-LUISE KREUTER *WUNDERKRÄFTE DER NATUR* [MIRACULOUS POWERS OF NATURE] (1982, 204*)

“On the Babylonian dedaim trees, human heads hang like fruits; mandrakes sing, the root Baaras slips through the grass.”

GUSTAVE FLAUBERT

THE TEMPTATION OF SAINT ANTHONY (1979, 188*)

the product of an act of artificial insemination in which a scientist uses a murderer’s semen to impregnate a prostitute. He raises the child, primarily because he wishes to prove his theory that the character of a person is shaped much more by the environment and education than by nature. But even with the best intentions, Alraune can not be freed of her criminal disposition. But the film suggests that it is not just the genetic makeup that is responsible, but also the “soulless” act of its procreation, which makes her into a human monster, a mechanistic vamp whose sole purpose in life is to drive men to ruin, destruction, and suicide. (Seesslen 1980, 93)

A mandrake appears in a television version of Hoffmann’s *The Little Zack*. A woman named Mandrake/Mandrax appears in the fantasy film *The Magic Bow* (USA 1981; directed by Nicholas Corea).

In his story *Alräunchen* [Little Alracine], esoteric author Manfred Kyber (1880–1933) tells of a child of the same name who is a “changeling, a little root man, who is rooted deep in the earth and becomes a changeling when the roots are ripped from the ground” (Kyber 1985).

In his 1990 novel *Another Roadside Attraction*, inspired in part by *Psilocybe* spp., American cult author Tom Robbins (born 1936) describes the effects of mandrake in a dialogue between Jesus and Tarzan: “John the Baptist turned me on to mandrake roots. It was a great experience, but once was

enough.” He [Jesus] shielded his eyes from the brilliant memory of the visions. “These days I am stoned on my own, one could say naturally” (Robbins 1987, 335).

The mandrake, the little mandrake man or woman, the little man of the gallows, and the themes related to this group of myths have been featured in illustrations since ancient times. In ancient Hellas, the mandrake became an important symbol of pharmacology and the healing arts. The oldest preserved manuscript of *De materia medica* (= *Περὶ ἁλῆς ἰατρικῆς*), written about 68 C.E. by Dioscorides Pedanius of Anarzaba (Cilicia), is the *Codex Vindobonensis medicus graecus 1* (also known as the Viennese Dioscorides, ca. 512 C.E.). It contains an illustration that demonstrates the central role mandrake played in Greek pharmacy and medicine: Folio 5v shows an ancient studio in which book illustrations were made. The goddess Epinoia (“power of thought”) is in the room, holding a mandrake plant in her hands. To the left of her sits the illustrator,²⁴² who is capturing a little mandrake man on the canvas. Dioscorides is visible on the right, studying a book (on medicinal plants) and communicating information to the illustrator (Stückelberger 1994, 82, table 17). Dioscorides is also shown sitting in Folio 4 of the *Codex medicus graecae*, no. 5. Here, Hereusis, the goddess of scientific research, is handing him an anthropomorphic mandrake (Krug 1993, 107, fig. 42*). At the bottom of the illustration is a dying dog, the means by which it was possible to obtain the mandrake.

Since the dawn of the Middle Ages, the magical hunt for the mandrake has been a popular subject of illustrations in herbals and books on health (Heilmann 1973). In 1974, there was even an entire exhibit in Prague about mandrake illustrations from the fifteenth to the seventeenth centuries (Vrchoťka 1974).

The mandrake has rarely been a subject of paintings. One work from Otto Boyer (nineteenth century), called *Alraun*, depicts an old witch offering Victorian ladies a little mandrake man.

In contrast, the mandrake has figured often in comic book art. Stimulated by John Donne’s poem “Mandrake Root,” Lee Falk began producing the comic series *Mandrake* in 1934. In this series, Mandrake is a mysterious magician from the Himalayas who is capable of overcoming both time and space. In the French comic *The Smurfs*, by Peyo, an “evil magician” is constantly using mandrakes to enchant the little blue mushroom dwellers (cf. *Veratrum album*). In the story “Blue Smurfs and Black Smurfs” (Carlsen Comics 1979), the magician uses mandrake roots and snake venom to make a little smurf (i.e., a homunculus). In the story “An Alchemist Awakes,” author Alexis portrays his hero hallucinating the life of a normal citizen while under the influence of a “mandrake baked with cheese” (in *Einsame Phantasien*, 37–38; Linden: Volksverlag, 1983). The psychedelic comic artist Caza illustrated a fantasy story titled “Mandragore,” in which a magical ritual transforms a mandrake dug out from under a gallows into a seductive but ominous woman (in *Gesammelte Werke 4*; Linden: Volksverlag, 1980). The Italian comic artist Paolo Eleuteri Serpieri published a volume titled *Mandragora* (1995) as part of his extremely bizarre and erotic science-fiction series *Morbus Gravis*, which is heavily influenced by psychedelic experiences. The story is actually about a “miracle flower.” One comic artist of the psychedelic avant garde has even identified himself with the plant and now draws under the pseudonym Mandryko (Rätsch 1986, 97–99).

The mandrake has left few traces in music. The magical root was the subject of the rock band Deep Purple’s “Mandrake Root” (Oh-Boy 1-9048, bootleg; original on the album *Shades of Deep Purple*, EMI, 1968). The psychedelic band Gong released a song entitled “Mandrake” on their album *Shamal* (Virgin Records 1975/1989). The acid-rock band Mandrake Paddle Steamer, active from 1969 to 1971, took their name from the plant (Forgotten Jewels Records FJ 001, 1989). In the mid-1990s, a neopsychedelic underground band named Mandragora formed in England and released an album titled *Over the Moon* (Delec CD 027, ca. 1995).

Clothed and “animated” little mandrake men. (Dutch copperplate engraving, eighteenth century)

Medicinal Use

The ancient Assyrians used mandrake as an analgesic and anesthetic. It was administered to treat toothaches, complications associated with childbirth, and hemorrhoids. The root was powdered and given in **beer** to treat stomach ailments and burned as a fumigant to dispel “poison from the flesh” (exorcism) (Thompson 1949, 218f.*). In Egypt, mandrake has certainly been used for medicinal purposes since the beginning of the New Kingdom. The identification of mandrake in the even older *Papyrus Ebers* (ca. 1600 B.C.E.) is contested (Heide 1921). If it is correct, however, then the *Papyrus Ebers* contains seven recipes with mandrake (even “mandrakes from Elephantine”). These include preparations to treat *pend* worms, pain (or “pain demons”), inflammations of the skin, and bone pain; to “make the skin smooth”; “to soften hardening of the joints”; and to treat a “sick tongue.”

Few plants in ancient times had such a wide spectrum of uses as the mandrake. It was used as a sleeping agent, analgesic and anesthetic, antidote, abortifacient, aphrodisiac, and inebriant and also in love magic. The medical indications for which it was used were correspondingly numerous and included the following ailments: abscesses, arthritis, inflammations and diseases of the eyes, discharge, anxiety, possession, depression, swollen glands, inflammation, uterine inflammation, complications during labor, painful joints, tumors, ulcers, gout, hemorrhoids, skin inflammations, hip pains, hysteria, impotence, bone pains, headaches, cramps, liver pains, stomach ailments, melancholy, menstrual problems, amenorrhea, spleen pains, sleeplessness, snakebite, pain, side pains, scrofula, tubercles, infertility, poisoning, callosities, loss of speech, worms, wounds, erysipelas, and toothaches (Rätsch 1994).

The use of mandrake root as a sleeping agent was a widespread practice in early ancient times (Valette 1990, 468*). In fact, the term *hypò mandragóra katheúdein* (literally, “sleep under the mandrake”) was synonymous with *sleepy*. Two recipes for such use have been preserved in the late ancient Leiden papyrus (Griffith and Thompson 1974*):

Another [agent] when you wish to have a man sleep for two days: mandrake root [μανδρακορροριζα], one ounce; licorice [?], one ounce; henbane [*Hyoscyamus muticus*], one ounce; ivy [*Hedera helix*], one ounce; you crush these together. . . . If you wish to do this skillfully, give to each part the four-fold amount of **wine**, you moisten everything from the morning until the evening, you shake it off, you have it drunk; very good. (*Col.* 24.6–14)

The *Corpus Hippocraticum* notes that man-drake root was used as a sedative and anesthetic agent, as well as a remedy for psychological anxiety and depression. The Hippocratics used man-drake to treat melancholy (*Corp. Hippocrat.* 420, 19) and for severe spasms (Berendes 1891, 223*). According to Aristotle (384–322 B.C.E.), the mandrake, along with opium (cf. *Papaver somniferum*), wine (cf.

Vitis vinifera), and bearded darnel (*Lolium temulentum*), belonged to the Hypnotica class of plants; in his work *On Sleep and Wakefulness*, he listed mandrake as a sleeping agent (Kreuter 1982, 24*; Starck 1986, 8). In *The Republic*, the philosopher Plato (427–347 B.C.E.) described *Mandragora* as an anesthetic comparable to **mead** (488c). The Greek physician Aretaios (second century C.E.) referred to *Mandragora* as an anesthetic for use in surgical procedures. Generally speaking, mandrake was the most important narcotic or anesthetic agent of ancient and late ancient times and in the Middle Ages (cf. **soporific sponge**).

The physician and natural scientist Aulus Cornelius Celsus, who was active in the time of Tiberius (14–37 C.E.), mentioned mandrake fruits as a sedative; he used the root to treat the flow of mucus in the eyes and a decoction of the root as a remedy for toothache (121, III, Ch. 18). He wrote:

There is another, more effective method of inducing sleep. Crush mandrake with opium and henbane seeds [*Hyoscyamus niger*] in wine.

For headaches, ulcers, inflammations of the uterus, hip pains, liver, spleen, or side pains, or for all cases of female hysteria and loss of language, a bolus of the following recipe, supported by rest, will heal the affliction. A drachma each of silica, acorns, Syrian rue [*Peganum harmala*]. Two drachmas each of rhizinus and cinnamon; three drachmas each of opium, panacea root, dried mandrake fruits, flowers of the round cyperus grass [cf. *Cyperus spp.*], and 56 peppercorns [cf. *Piper spp.*]. Each must be crushed alone and then everything should be mixed together. Passum should be added from time to time, so that it acquires a certain consistency. A small amount is given in the form of a little ball or, when dissolved in water, as an enema. (In Thompson 1968, 101f.)

The root of the greater celandine (*Chelidonium majus* L.) was used in magical contexts as a substitute for the true mandrake. Although the greater celandine is a member of the Poppy Family (Papaveraceae), it is not known to induce any psychoactive effects. (Woodcut from Fuchs, *Läebliche Abbildung und Contrafaytung aller Kreüter*, 1545)

“If you so much as turn the black of your eye, then a little mandrake will slip on by!”

“The true mandragoras is the ‘tree of knowledge’ and the love that arises from consuming it is the source of the human race.”

HUGO RAHNER

GRIECHSICHE MYTHEN IN CHRISTLICHER DEUTUNG [GREEK MYTHS IN CHRISTIAN INTERPRETATION]
(1957, 221*)

Rufus of Ephesus (first century C.E.) mixed a decoction of mandrake root with poppy (*Papaver somniferum*) and chamomile (*Matricaria recutita*) (Tercinet 1950, 24). The renowned physician Galen (131–210 C.E.) has passed down an interesting recipe, calling for a preparation of mandrake root mixed with myrrh (*Commiphora* sp.), cassia (*Cinnamomum cassia* Blume), cedar (*Cedrus libani* Rich.), pepper (*Piper* spp.), saffron (*Crocus sativus*), and henbane seeds (*Hyoscyamus niger*) as an application to painful areas of the body (13.92; cf. Tercinet 1950, 24). The important role mandrake played as an analgesic is confirmed in a variety of sources, including Serenus Samonicus (first century C.E.). Even into the early Renaissance, mandrake preparations were the sole anesthetic (cf. **soporific sponge**).

In an early medieval Persian manuscript that presumably drew upon much older original sources, *Mandragora* is listed along with opium, *Datura metel*, and hemp (*Cannabis indica*) as agents for inducing sleep (Berendes 1891, 43*).

In his book *The Passover Plot*, the Englishman Hugh J. Schonfield has argued that “Jesus was given a sponge dipped in vinegar while on the cross, which is a third, albeit very hidden indication of *Mandragora* in the gospels.” Schonfield believes that the vinegar contained mandrake juice, which induced a deathlike state in Christ. This was done so that he could be removed from the cross as quickly as possible and be brought back to life with the aid of a physician. “The plan failed when one of the soldiers—unexpectedly and entirely in violation of the rules—pierced Christ in the side with his lance” (Hansen 1981, 27 f.*). It is not possible to determine whether this story is true or even has an element of truth to it. However, it was customary among the Romans to administer to those who were being crucified a mandrake wine, which the literature of the early Middle Ages (fifth century) referred to as *morion*, “death” drink (Thompson 1968, 225). In general, even into the early modern period, it was a common practice to give mandrake preparations to condemned people before their sentences (torture, execution) were carried out. The story of the little man of the gallows becomes understandable in this light (see Schlosser 1987; cf. Beckmann 1990, 130*):

And thus the hangman dripped the juice of crushed seeds [of henbane, deadly nightshade, and mandrake fruits, or fly agaric mushrooms] into the water which they, only appearing to be heartless, would use to refresh the unconscious victim during their tortures and awaken them to new torments. (Golowin 1970, 30)

In Romania, mandrake has been used for a variety of folk medicinal purposes. A decoction of mandrake was applied externally and/or ingested for pains in the limbs, the sacrum, and the back and for fevers. Fresh leaves were chewed to treat toothaches. Mandrake leaves were burned and the resulting smoke inhaled for coughs (Eliade 1982, 227). Mandrake also was burned to treat headaches (cf. **incense**). For this purpose, pieces of mandrake roots were combined with mugwort (*Artemisia* spp.), mint (*Mentha* spp., *Mentha pulegium*), and cloves.

The root was used in Russian folk medicine in similar ways (Rowell 1978, 269*). The root also found use in European folk medicine. In her *Herbal*, Elisabeth Blackwell wrote: “This plant is used

externally for all inflammations, acute ulcers, and enlarged and hardened glands. Some drip the juice into the eyes to treat heat and redness in the same. Because this plant is rarely found in this land, henbane [***Hyoscyamus niger***] is commonly used in its place (for example in the unguent Populeon [cf. **witches’ ointments**])” (Heilmann 1984, 94*). In southern Tirol, mandrake juice was rubbed onto women in labor who were giving birth at home to alleviate their pains (Fink 1983, 238).

The Ancient Meaning of the Mandrake (*Mandragora*)

There are a number of related roots and magical plants that are regarded as anthropomorphic and have magical effects.

There are the (three) species of *Mandragora*, two of which are similar and are construed as male and female.

The fruits are the love apples; these are female.

The root is a male phallus.

The mandrake is a plant of the gods:

—The love apples are sacred to the love goddess (Astarte, Aphrodite, Hathor, etc.).

—The root is consecrated to the chthonic deity of the underworld (Hecate).

—It is a phallic plant of the god of the heavens and lightning (Ra, Zeus).

The plant may be harvested only ritually (through magical acts, conjurations, sacrifices).

The plant, and especially the root, is an amulet.

The plant is a medicine and provides a typical *pharmakon*:

—It is a poison and can kill.

—It stimulates fertility and gives life.

The plant is an aphrodisiac:

—The fruits are the “love” apples.

—The scent of the fruits incites desire.

—The root ensures the readiness of the opposite sex for love.

—The root products stimulate potency.

The root and its juice are the source of a medically valuable narcotic; it is:

—analgesic

—sedative

—anesthetic

The mandrake was the connection between

—heaven and earth

—divine favor and human art

The mandrake was added to alcoholic drinks (beer, wine, etc.) to improve their psychoactive effects.

These little mandrake men from southwest Asia were carved from roots of *Mandragora officinarum*. They were used to ensure good fortune and as love magic. (From von Luschan 1891)

“The Mandragorae is a plant which causes such a deep sleep that one could cut a person and they would not feel the pain. For the mandragoras symbolize aspiration through contemplation. This tranquility makes it possible for a person to fall into a sleep of such delightful sweetness that he will no longer feel anything of the cutting which his earthly enemies visit upon him, that he no longer pays attention to any worldly things. For the soul has now closed its eyes to all that is outside—it lies in the good sleep of the internal.”

THOMAS CISTERCIENSIS *HOHELIED-EXEGESE* [SONG OF SOLOMON EXEGESIS]
(CITED IN MÜLLER-EBELING 1987, 145)

“The symbolism of its form and its hallucinatory effects made the mandrake into a mythical plant that was a part of two worlds, the worldly and the underworldly.

JACQUES GÉLIS
DIE GEBURT [THE BIRTH] (1989, 63)

In acid rock music, *Mandragora* has often been used as a symbol for psychedelic and heavenly experiences. (Record cover, ca. 1969)

In homeopathy, preparations of mandrake made from the root (*Mandragora* hom. *HAB34*, *Mandragora officinarum* hom. *HPUS88*, *Mandragora e radice siccato* hom. *HAB1*, *Mandragora*, ethanol Decoctum hom. *HAB1*) are administered in accordance with the medical description for such ailments as headaches.

Constituents

Mandrake, especially its root (0.3 to 0.4%), but also its leaves, contains the psychoactive and anticholinergic **tropane alkaloids scopolamine** ([L]-scopolamine/[D,L]-scopolamine; Roth et al. 1994*), atropine, apoatropine, L-hyoscyamine, mandragorine, cuscohygrine (= bellaradin),²⁴³ norhyoscyamine (= solandrine), 3 α -tigloyloxytropine, and 3,6-ditigloyloxytropine (Jackson and Berry 1973 and 1979; Maugini 1959; Staub 1962). This alkaloid mixture was previously described under the name *mandragorine* (Ahrens 1889; Hesse 1901).

The dried root contains between 0.2 and 0.6% alkaloids. The tropane alkaloid belladonnine occurs only in the dried roots (Jackson and Berry 1973). In addition to the alkaloids, the root also contains coumarins (scopoline, **scopoletin**), sitosterol, sugars (rhamnose, glucose, fructose, saccharose), and starches (Müller 1982; Tercinet 1950).

It was once thought that the fruits were poisonous and hence inedible; they are actually quite harmless, containing only trace amounts of alkaloids (Germer 1985, 170*). The fruits also contain β -methylesculetin.

The aromatic components of the scent of the mandrake fruit have recently been chemically identified. The composition, and especially the high concentrations of sulfuric chemicals, is unusual for an aromatic substance. The **essential oil** is composed primarily of ethyl acetate, ethyl butyrate, butyl acetate, butanol, butyl butyrate, hexyl acetate, hexanol, ethyl octanoate, ethyl-3-hydroxy butyrate, 3-methyl thiopropanol, 3-phenylpropanol, and eugenol. Also present are methyl butyrate, ethyl-2-methyl butyrate, hexanal, propyl butyrate, limonene, (E)-2-hexanal, ethyl hexanoate, amyl alcohol, 3-hydroxy-2-butanone, isopropyl benzole, propyl hexanoate, hexyl butyrate, octyl acetate, benzaldehyde, indanone, linalool, octanol, ethyl 3-methyl-thiobutyrate, ethyl decanoate, ethyl benzoate, α -terpinol, γ -hexa lactone, benzyl acetate, carvon, decanol, isobutyl decanoate, β -phenethyl isobutyrate, ethyl laurate, benzyl alcohol, henylethyl alcohol, 3-phenylpropyl acetate, methyl eugenol, γ -octalactone, 2-ethyl-4-hydroxy-5-methyl-3(2H)-furanone, ethyl cinnamate, γ -decalactone, (E)-cinnamyl acetate, cinnamoyl alcohol, (E)-isoeugenol, γ -dodecalatone, and vanillin (Fleisher and Fleisher 1992 and 1994).

Effects

Although the mandrake has been one of the most renowned of all psychoactive medicinal plants for millennia and has provided inspiration for a great number of authors, the enormous amount of literature it has generated contains very few experiential reports. One of the earliest is from the church patriarch Augustine (354–430 C.E.), who reports in his own words that he bit into a root but only “found a disgustingly bitter taste” (Rahner 1957, 201*). The late ancient lexicographer Suidas stated that the mandrake has “a fruit which has hypnotic effects and allows everything to sink into forgetfulness” (*Lexicon* 136; *Lexicographi Graeci* 3.317). The folk saint and seeress Hildegard von Bingen (1098–1179 C.E.) noted that the mandrake produced “illusions” (*Physica* 1, 56).

Schenk (1954, 36*) claimed that the root produces “inebriation, narcosis, hallucinations, visions”; he provided only a single example:

Here is also the place to mention the peculiar case of a 40-year-old painter who was the victim of

an unusual *Mandragora* poisoning. Since his childhood, he had suffered from headaches during the foehn.²⁴⁴ An acquaintance advised him to treat his affliction with a tea cure, specifically with a “mandrake tea.” He procured three mandrake roots, boiled them, and drank several cups of the decoction. The next day, his pupils were extremely dilated, his mouth was dry, and apart from a slight sensation of dizziness, he was otherwise without complaints. During the next three days, he repeatedly drank of this tea. In the meantime, however, the alkaloids had certainly become more concentrated, for the roots had been left in the teapot. On the fourth day, the painter was in an utterly confused state, his face had become very red, and he was racing around in his dwelling. He carried his bed into the stairwell, and tried to throw furniture and paintings from the window. The horrified landlady called the doctor, who had him taken to the hospital. His face remained red for some time, the pupils were immoderately dilated. He fumbled with the bed covers with his hands. He had lost any sense of orientation. But after two days, he was able to be released without any complaints. (Schenk 1954, 37 f.)*

“There is an animal that is called the elephant. No sexual drive dwells within this animal. When it wishes to produce children, it goes back to the East, close to paradise. It is there that the so-called mandragora tree grows. That is where the female and the male go. The female takes the fruit from the tree first, offers it to her spouse as well, and plays with him until he too takes of it, and when he has eaten, he unites with the female from behind, because of the fact that they do not have any harmony with one another. Only once does he have coitus, and she immediately becomes pregnant.”

PHYSIOLOGUS (43)²⁴⁵

Roth et al. (1994, 485*) maintain that the effects of mandrake are similar to those of *Atropa belladonna*. Typical clinical symptoms include dryness of the mouth and other mucous membranes, dilated pupils, farsightedness, and muscular atony, as well as, according to Roth et al. (1994, 485), increase in the frequency of the pulse. All of these symptoms of “mandrake intoxication” are very similar to the homeopathic medical description (cf. Mandl 1985, 133*).

On several afternoons, I have consumed a glass of wine in which mandrake root had been steeped. The effects become apparent in some fifteen to twenty minutes. These are associated with a slight sense of euphoria. Pleasant, sometimes lusty sensations run through the body. Visual perception is only mildly affected; a slight farsightedness manifests. During the nights that have followed the consumption of mandrake wine, I have always experienced increased dream activity, often with erotic content. After consuming 0.5 liter of mandrake beer, I noted the following:

The effects of the alcohol are not apparent. I notice a slight pressure in my head, as also occurs with henbane or thorn apple. It is more fun to dance than to sit at the computer. It is a desire to fall into the rhythm of the music. . . . Obliviousness to self, pleasurable bodily sensations . . . pleasant tingling on the scalp. Slightly dry lips, distinct changes in the visual field, as if the perspective had shifted somewhat. (Protocol, December 28, 1994)

When I was in Cyprus, I ate all of the ripe man-drake fruits I could find in order to test their aphrodisiac or mind-altering properties. I did not notice any direct psychoactive effects. But I had an increased number of erotic dreams during those nights.

Commercial Forms and Regulations

When *Mandragora officinarum* makes it into the pharmaceutical trade, it is normally in the form of the chopped root (*mandragorae radix conc.*). In Germany, *Mandragora conc.* can be purchased only from a pharmacy, and because of recent regulatory changes, a prescription is now needed. Even the homeopathic preparations now require a prescription. The seeds are only very rarely available

through flower or ethnobotanical sources.

The mandrake has been the subject of numerous literary treatments. In the age of comic books, it became a magician with mysterious supernatural powers. (Title page of an Italian edition; the original appeared in 1941)

“There is a trick in which an egg that is placed under a hen produces a humanlike figure, as I myself have seen and am also able to perform. The magicians attribute miraculous powers to one such figure, which they call mandrake.”

HEINRICH CORNELIUS AGRIPPA VON NETTESHEIM

Mandragora spp.

Mandrake Species

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solaneae Tribe, Mandragorinae Subtribe

Currently, four to six species are botanically accepted in the genus *Mandragora*. All occur only in Eurasia and northern Africa (D'Arcy 1991, 78 f.*; Symon 1991, 147*).

The autumn mandrake (*Mandragora autumnalis*) was once regarded as the “little mandrake woman.” (Woodcut from the herbal of Matthiolus, 1627)

***Mandragora autumnalis* Spreng. [syn. *Mandragora autumnalis* Bertol., *Mandragora microcarpa* Bertol., *Mandragora foemina* Gersault, *Mandragora foemina* Thell., *Mandragora haussknechtii* Heldr., *Mandragora officinalis* Moris ex Miller, *Mandragora officinarum* Bertol. non Linnaeus]—autumn mandrake**

Since ancient times, the autumn mandrake has been known as the “female” mandrake, the counterpart to the “male” *Mandragora officinarum*. It was said:

One kind [of *Mandragora*] is female, black, called *thridakias*, it has narrower and smaller leaves with an ugly and pungent scent, is spread over the earth, and has apples like the fruits of the rowan tree [*Sorbus domestica* L.], yellow, pleasant scented, among them a fruit like the pear, the roots are very large, two or three, grown together, black on the outside, white within, and with a thick rind. It does not develop a stalk. (Dioscorides 4.76)

Pliny (first century) reported on the psycho-active and medicinal properties of the plant:

It is not the mandrake of all countries which produces a juice; but if it does provide one, then it is collected at the time of the wine harvest [cf. *Vitis vinifera*]. It then has a potent aroma, that of the root, but mostly that of the fruit. The fruit is collected when it is ripe; it is dried in the shade, and the juice is thickened by the sun after it has been extracted. The same is done with the juice of the roots, which is obtained either by pressing or by boiling in red wine until it has been reduced to a third. The leaves are best stored in a strong brine (salt water); their juice is a poison that cannot be healed; this harmful property is not completely removed by the brine when the leaves are stored therein. Its specific scent is oppressing to the head, but there are countries in which the fruits are eaten. Persons that are unfamiliar with its properties are convinced that the scent of this plant would make them mute and that too high a dosage of the juice is deadly. If a dosage is given that is appropriate to the strength of the patient, the juice has an anesthetic effect; a medium dosage is a cyathus. It is also given for wounds from snakes and before the body is cut or pierced to lower the sensitivity to pain. (Pliny 25)

The leaf crown of *Mandragora autumnalis*.

Mandragora autumnalis is easily confused with *Mandragora officinarum* (Berry and Jackson 1976). The primary distinction between the two is the time at which they flower. The autumn mandrake blooms in the fall (September to November).²⁴⁶ Both species are found in southern Europe, from Portugal to Greece (Festi and Aliotta 1990*; Viola 1979, 175*). Autumn mandrake is also common in northern Africa (Morocco).

In Morocco, where the autumn mandrake is known variously as *taraiba*, *taraila*, *bid l'gul*, and *bioe al ghorl*, a finger-sized piece of the root is taken together with a nutmeg (*Myristica fragrans*) in order to produce a “good head” (Vries 1984*; 1989, 39, 40, 44*), and the root is still used there for hunting treasures (Vries 1989, 39*). Apparently it is also used in a magical **incense**.

Mandragora autumnalis contains the same **tropane alkaloids** as *Mandragora officinarum*. Little is known about its effects:

After consuming vegetables that had been contaminated with *Mandragora autumnalis* leaves, fifteen people developed symptoms of poisoning. The latent period was 1 to 4 hours, with a mean of 2.7 hours. No association between the latent period and the degree of intoxication was observed. All patients exhibited disturbances of vision, dry mouth, tachycardia, mydriasis, and reddening of the skin. Also observed were, in 14 of the 15 patients, dry skin and mucosa,

hallucinations, and overactivity; in 9 of 15 patients, agitation/delirium, confusion, headaches, and problems with micturition; in 8 patients, difficulties swallowing and stomachaches. One patient developed an acute psychosis of short duration. (Mechler 1993, 765)

***Mandragora caulescens* C.B. Clarke [syn. *Anisodus humilis* (Hook. f.)]—Himalayan mandrake**

Four subspecies of Himalayan mandrake have been described to date (Mechler 1993, 765):

Mandragora caulescens ssp. *brevicalyx* Grierson et Long

Mandragora caulescens ssp. *caulescens*

Mandragora caulescens ssp. *flavida* Grierson et Long

Mandragora caulescens ssp. *purpurascens* Grierson et Long

This yellow-blooming species, known as *kattuchooti* or *chi'ieh shen*, is found in the high Himalayas, primarily at altitudes between 3,000 and 4,000 meters (Polunin and Stainton 1985, 287, plate 93*). Its range extends through Tibet and into western China (Deb 1979, 94). It is common in Sikkim and Darjeeling and grows in western Sichuan, northwestern Yunnan, and eastern Xizang (Tibet) at altitudes between 2,200 and 4,200 meters (Lu 1986, 81f.). In Sikkim, this mandrake species is used for magical rituals (Mehra 1979, 162*) and sometimes as an alternative to ***Withania somnifera***; it also has been interpreted as the Vedic *jangida*. It is used in traditional Chinese and Tibetan medicine to treat stomach ailments (Mechler 1993, 765). The root contains 0.13% hyoscyamine and may possibly also contain mandragorine. **Scopolamine** and cuscohygrine have not been detected (Mechler 1993, 765).

***Mandragora chinghaiensis* Kuang et A.M. Lu—Chinese mandrake**

Also known as *chinghai chi'eh shen*, this recently described mandrake species is endemic to the Qinghai-Xizang Plateau of western China, where its root is used in local folk medicine (Lu 1986, 82). In Tibet, it is used to treat pain and as a substitute for *Mandragora caulescens*. The entire plant contains 0.19% hyoscyamine and 0.12% **scopolamine**; the root contains 0.21% hyoscyamine and 0.48% scopolamine (Mechler 1993, 765).

***Mandragora morion* nom. nud.**

The plant that is listed in the older literature under the name *Mandragora morion* is identical to a *Mandragora* species, to ***Atropa belladonna***, or to some other species of nightshade (cf. ***Solanum* spp.**, ***Withania somnifera***). The ancient literature has the following to say about *Mandragora morion*:

It has been reported that there is also another species [perhaps *Mandragora turcomanica* or *M. caulescens*] called *morion* [from *moria*, “dullness of the senses,” or *morion*, “male member”] that grows in shady places and around rocky caves; it has leaves like those of the white *Mandragora*, but smaller and about as long as a span, white, and arranged in a circle around the root, which is tender, white, a little larger than a span, and as thick as a thumb. This, when drunk in the amount of a drachma [ca. 3.8 g] or eaten with pearl barley in bread or a side dish, is said to induce a deep sleep; a person will namely sleep in the same position as they were in when they partook of it, without any sensation, for three to four hours from the time at which they ingested it. The physicians also use this when they wish to cut or burn. The root is also said to be an antidote [*antidoton*] when taken with the so-called *Strychnos manikos*.²⁴⁷ (Dioscorides 4.76)

***Mandragora shebbearei* Fischer—Tibetan mandrake**

This species or variety of mandrake is said to occur only in Tibet. It may be identical to *M.*

caulescens.

***Mandragora turcomanica* Mizgireva—Turkoman mandrake**

This rare species, which grows only in Turkmenistan, produces violet flowers and has been used as a medicine by the people of the Sumbar Valley since antiquity. It appears that Asian authors of the Middle Ages, such as Abu-Reichan Beruni (973–1048), identified this Asian species with the European *Mandragora* of the ancient literature, and according to Khlopin (1980, 227), it is identical to the “male” *Mandragora* of Dioscorides (cf. *Mandragora officinarum*). Its large, juicy, golden yellow fruits were regarded as edible (when eaten in moderation). The Turkoman mandrake thrives only in clayey soils at altitudes of 600 meters (Khlopin 1980).

The Parsis had a sacred plant with inebriating or entheogenic qualities that was known as haoma and was mentioned often in the Avesta. In our time, the botanical identity of **haoma** is as uncertain as that of the Indian **soma** or the Greek ambrosia. It is possible that the word *haoma* was used to refer to a number of plants (cf. *Peganum harmala*). It has long been suggested that *haoma* and the mandrake were one and the same. The discovery and description of the Turkoman mandrake has provided this hypothesis with renewed support:

When one compares the description of the haoma of the Avesta with the white male *Mandragora* of the ancient and medieval scholars, then it can be seen that these are possibly the same plant. Otherwise, this white male *Mandragora* would have to be identified with the Turkoman *Mandragora*. In other words, the Avestan Aryans [the ancient Parsis] used the Turkoman species of *Mandragora* to produce the divine drink and called it haoma. . . . When the Indian Aryans penetrated into northern India from the west after the fall of the Indo-Iranian union, they found the Himalayan species of *Mandragora*, which received the name **soma**. (Khlopin 1980, 230f.)

The plant that Leonhard Fuchs depicted under the name *Mandragora morion* appears to be the deadly nightshade (*Atropa belladonna*). (Woodcut, 1545)

“There are a few more wondrous stories about these plants [mandrakes]. It is said of the root that it has a very similar appearance to the organs of procreation of both sexes. Although it is only rarely found, when a root looks like the male organ and comes into a man’s possession, then it will secure for him the love of a woman. In this way, the lesbian Phaeon was loved in such a passionate manner by Sappho. Much has been said about this, not only by the magicians, but also by the Pythagorean philosophers.”

Mesembryanthemum spp.

Ice Plants

Family

Aizoaceae (Ice Plant Family)²⁴⁸

It is likely that the ancient Assyrians used a species of the genus *Mesembryanthemum* (which they called *dilbat*) in combination with Indian hemp (*Cannabis indica*) as a medicine for “suppressing the spirits” (Thompson 1949, 222*).

In northern Peru, one *Mesembryanthemum* species is known in the local Spanish as *hierba de la señorita*, “plant of the maiden.” Folk healers of the San Pedro cult (see *Trichocereus pachanoi*) use its fleshy leaves in herbal amulets (known as *seguros*, “insurances”), especially for love magic (Giese 1989, 252*).

Today, two or more species are known in South Africa as **kanna** (also *channa* or *kougoed*). It has been suggested that the *kanna* or *channa* that was described some 250 years ago as a plant that the Hottentots chewed for its inebriating effects was a *Mesembryanthemum* species. More recently, a plant used as kanna was identified as *Sceletium tortuosum*.

Mesembryanthemum crystallinum L. [syn. *Cryophytum crystallinum* (L.) N.E. Br., *Gasoul crystallinum* (L.) Rothm.], an ice plant from the foothills of the Cape of Good Hope, is cultivated for use as a vegetable and in salads. In 1785, Liebig suggested it for use as a medicine in Germany, where the species became known by the name *Hottentot fig*. Around 1900, it was said that the flowers of the plant (*flores candiae*) were being used for “superstitious purposes” (Schneider 1974, 2:322*). It has been claimed that the Hottentots of the Kalahari Desert chewed or sniffed the roots (**snuffs**), and there have been reports that this ice plant, which contains mesembrine and oxalic acid, has induced (psychoactive) intoxications (Festi and Samorini 1995, 32f.).

The Bantu use the roots of *Mesembryanthemum mahonii* N.E. Br. to brew a potently inebriating **beer**. In South Africa, the closely related species *Trichodiadema stellatum* (Miller) Schwantes is used as a yeast substitute for baking bread and brewing beer. The roots purportedly possess potent inebriating properties (Festi and Samorini 1995, 31).

The ice plant, *Mesembryanthemum crystallinum*, received its name because its leaves appear as though they are covered with ice.

South African species of *Mesembryanthemum* are sometimes called midday flowers because their flowers are often open only during that time.

Hottentot fig, *Carpobrotus edulis* (L.) N.E. Br. [syn. *Mesembryanthemum edule* L.]. The plant has sedative properties and may be psychoactive (Festi and Samorini 1995).

Tribal peoples of South Africa used another species in the same family, *Rabaiea albinota* (Haw.) N.E. Br. [syn. *Nananthus albinotus* N.E. Br.], as an additive to smoking and sniffing tobacco (*Nicotiana tabacum*, **snuffs**) (D. McKenna 1995, 101*).

The alkaloids mesembrine and mesembrinine and six additional derivatives are known to occur in the genus (Frohne and Jensen 1992, 125*; D. McKenna 1995, 101*). They have analgesic effects and stimulate circulation (Tyler 1966, 280*). Mesembrine has both sedative and **cocainelike** properties (Scholz and Eigner 1983, 75*). According to information provided by the chemist K. Trout, some members of the genus contain **N,N-DMT**.

The alkaloid mesembrine has also been detected in several other species of the Family Aizoaceae: *Drosanthemum hispidum* (L.) Schwantes [syn. *Mesembryanthemum hispidum* L.], *Sceletium anatomicum* (Haw.) L. Bolus [syn. *Mesembryanthemum anatomicum* Haw.], ***Sceletium tortuosum*** (L.) N.E. Br. [syn. *Mesembryanthemum tortuosum* L.], *Trichodiadema barbatum* (L.) Schwantes [syn. *Mesembryanthemum barbatum* L.], *Trichodiadema bulbosum* (Miller) Schwantes [syn. *Mesembryanthemum stellatum* Miller], and *Trichodiadema intonsum* (Haw.) Schwantes [syn. *Mesembryanthemum intonsum* Haw.] (Festi and Samorini 1995, 32).

Mimosa tenuiflora (Willdenow) Poiret

Jurema, Tepescohuite

Family

Leguminosae: Mimosaceae-Fabaceae (Mimosa-like); Subfamily Mimosoideae

Forms and Subspecies

A variety from the Guianas that was recently described under the name *Acacia tenuiflora* var. *producta* Grimes may be a form of this taxonomically uncertain species (Grimes 1992).

Synonyms

Acacia tenuiflora Willd.

Mimosa cabrera Karst.

Mimosa hostilis (Mart.) Benth.

Mimosa jurema nom. nud.

Mimosa nigra Huber nom. nud.

Mimosa tenuifolia L. (misspelling in the literature)

Mimosa tenuiflora Karst.

Folk Names

Ajúcá, cabrero (“goatherd”), carbón (“charcoal”), carbonal, espineiro, jurema, jurema negro,^{[249](#)} jurema preta, jurema prêta, tepescahuite, tepescohuite, veuêka, vinho da jurema

History

The Aztecs already knew of the mimosa tree during pre-Columbian times. The name *tepescohuite*, which is now common in Mexico, is derived from the Aztec *tepus-cuahuitl*, “metal tree,” a reference to the tree’s extremely hard wood. The Mexican tree was botanically described in 1810. Only in the past few years was it recognized that this tree is the same species as the Brazilian *Mimosa hostilis* (Ott 1996b, 11*). The jurema cult, in which drinks made from this *Mimosa* are consumed, was first described in 1788. Until recently, it was thought that the cult had died out, but it is now experiencing a great renaissance.

Distribution

The tree grows wild in southern Mexico (it is common in Oaxaca and on the Pacific coast of Chiapas), Central America, Venezuela, and Brazil (especially in the northeast: Minas Gerais, Bahia, Pernambuco). It thrives best in tropical lowlands but can grow at altitudes of up to 1,000 meters (Sánchez León 1987).

Cultivation

Until recently, little was known about methods for cultivating the plant. Initial experiments have demonstrated that it is likely possible to propagate the tree through cuttings.

Appearance

This mimosa is a bushy tree that can grow as tall as 8 meters. It has pinnate leaves and short, sharp thorns along its branches. The white flowers occur in clusters, and the fruits are small and lanceolate (2 to 4.5 mm wide, 5 to 7 mm long). The pods each contain three or four of the fruits (Sánchez León 1987).

Psychoactive Material

—Dried trunk cortex

—Dried root cortex

Preparation and Dosage

In Brazil, *vinho do jurema* is sometimes made with passionfruit juice (cf. *Passiflora* spp.). An **ayahuasca analog** can be made by combining 9 to 12 g of the dried root cortex with 3 g of *Peganum harmala*.

Ritual Use

In former times, the Pancarú Indians and many Indians of the eastern Amazon region (such as the Karirí, Tusha, and Fulnio) used the root to make jurema drinks (*ajucá* or *veuêka*), which could induce shamanic states of consciousness (Gonçalves de Lima 1946). Unfortunately, only very rudimentary information about the exact preparations and the rituals is available. According to the older ethnographic literature (summarized in Schultes and Hofmann 1980, 153 ff.*), the “mysterious drink” gave the shamans fantastic and meaningful dreams and brought on “an enchantment, transporting them to heaven.”

Known in Mexico as *tepescohuite*, *Mimosa tenuiflora* is an excellent source of DMT. (Photographed in Chiapas, Mexico)

In Mexico, *tepezcohuite* bark is used to produce numerous preparations for treating wounds and as general tonics.

“*Mimosa tenuiflora* has become the most important source of DMT for anahuasca [= ayahuasca analogs].”

JONATHAN OTT
PHARMACOTHEON
 (1996d, 254*)

An old master of ceremonies, wielding a dance rattle decorated with a feather mosaic, would serve a bowlful of the infusion made from jurema roots to all celebrants, who would then see glorious visions of the spirit land, with flowers and birds. They might catch a glimpse of the clashing rocks that destroy souls of the dead journeying to their goal or see the Thunderbird shooting lightning from a huge tuft on his head and producing claps of thunder by running about. (R. H. Lowie, in Schultes and Hofmann 1980, 154*)

The Indian use of jurema decreased significantly during the twentieth century, partly as a result of the destruction of indigenous cultures and partly due to the increasing popularization of **ayahuasca** and the ayahuasca churches.

Since the beginning of the twentieth century, the ritual use of *vinho do jurema* has been integrated into the Afro-Brazilian Candomblé and macumba cults. It is likely, however, that *Mimosa tenuiflora* has rarely been used to prepare the *vinho do jurema*; the more likely source is ***Pithecolobium diversifolium***.

In contemporary Brazil, jurema is ritually consumed in a variety of circles of different ethnic origin (Novaes da Mota 1987).

To date, no evidence of any ritual use of *Mimosa tenuiflora* in Mexico is known.

Artifacts

Some Afro-Brazilian ayahuasca cults venerate Indian spirits (*caboclos*) as saints. Among these saints is Cabocla Jurema, who is regarded as the goddess of the forest. She is presumably a personification of *Mimosa tenuiflora*.

Medicinal Use

In Mexican folk medicine, the powdered bark of the trunk is used—apparently with great success—to

treat burns, inflammations, and wounds (Grether 1988; Sánchez León 1987). The analgesic effects of the powdered bark for the treatment of burns became known throughout the world when the international press reported its successful use in the treatment of victims of two catastrophes, a natural gas explosion in 1982 and an earthquake in 1985, as a result of which the death rate of the burn victims declined significantly (Anton et al. 1993).

In Mexico, the powdered bark, contained in gelatin capsules, is taken as a tonic, often in combination with the ground bark of *uña de gato* (*Uncaria tomentosa*). Among the rural Brazilian population, the bark of the trunk also is used as a home remedy for exhaustion and debility.

Indian women in Brazil use the fresh root cortex as an aphrodisiac love magic by rubbing it onto the soles of the feet of the men they desire. Whether this occurs with the knowledge of the men is an open question.

Constituents

The bark of the trunk has been found to contain several triterpene saponins (mimonosides A, B, and C) as well as steroid saponins (3-O- β -D-glucopyranosyl-campesterol, 3-O- β -D-glucopyranosyl-stigmasterol, 3-O- β -D-glucopyranosyl- β -sitosterol) that are clearly bioactive (Jiang, Beck, et al. 1991; Jiang, Weniger, et al. 1991b; Lara Ochoa and Marquez Alonso 1996, 99*). Also present are lupeol, campesterol, stigmasterol, and β -sitosterol. The bark contains large amounts of calcium oxalate crystals and a great deal of starch and tannins (Anton et al. 1993), as well as small quantities of alkaloids, of which ***N,N*-DMT**, 5-hydroxytryptamine, and **β -carbolines** have been identified (Lara Ochoa and Marquez Alonso 1996, 99*; Meckes-Lozoya et al. 1990). New chalcones have been detected in the bark and were named kukulkanins, after the Mayan deity Kukulcan (“feathered serpent”) (Dominguez et al. 1989).

Recent studies of the Mexican root cortex, which is rich in alkaloids, have yielded sensational results. The dried root cortex contains approximately 1% *N,N*-DMT. The root bark of Brazilian plants has been found to contain 0.57% *N,N*DMT (Farnsworth 1968, 1088*; Pachter et al. 1959*; Schultes and Hofmann 1980*).

Effects

When spread onto burns, the powdered trunk bark produces analgesic effects that last for two to three hours and clearly shortens the regeneration period of the epidermis. The bark appears to have a stimulating effect on the immune system (Anton et al. 1993).

If the ethnographic literature is accurate, then a decoction of the root produces psychedelic effects when ingested orally. No information is available as to whether the Indians also use MAO-inhibiting additives in such cases. But if the root cortex does contain β -carbolines, then the tea could indeed be orally efficacious. In modern contexts, the only additive that has been observed being used is passionfruit juice (see ***Passiflora* spp.**). The oral efficacy of a decoction of the root cortex presumably is increased by the addition of the passionfruit juice, which allegedly has MAO-inhibiting properties.

I smoked 1 g of dried, coarsely chopped Mexican root cortex (corresponding to approximately 100 mg of *N,N*-DMT) in a pipe. As it was being lit, the smoke immediately emitted an almost overly obvious characteristic DMT scent. However, I felt only very mild DMT effects. It is possible that a bark extract (cold-water decoction!) concentrated by evaporation may be sufficiently concentrated to produce good DMT effects.

Commercial Forms and Regulations

In Mexico, tepescohuite is available as dried bark and as powdered bark in markets, drugstores, and

natural foods stores. It is unclear whether tepescohuite may be imported into Europe. Because of the presence of the alkaloids, it was not allowed to be approved for medicinal use in Europe (cf. Anton et al. 1993, 156).

Mimosa spp.

Mimosa Species

Family

Leguminosae: Mimosaceae-Fabaceae (Mimosa-like); Subfamily Mimosoideae

The family is composed of some five hundred species, the majority of which occur in South America. They require a tropical or subtropical climate (Schultes and Raffauf 1990, 246*). *Mimosa* species are often confused with acacias (see *Acacia* spp.) and with *Anadenanthera peregrina* and *Anadenanthera colubrina*.

Many mimosas in Central and South America, Australia, and Oceania contain DMT and other tryptamines. This copperplate engraving from Sibly's appendix to Culpeper's herbal associates the (psychoactive) mimosas with the (psychoactive) mandrake (bottom left).

Mimosa pudica L.—sensitive mimosa

It is possible that the well-known sensitive mimosa, whose leaves immediately fold together when touched, has a certain importance as a psychoactive substance. In Amazonia, where the plant is known as *chami*, it is made into a tea for treating sleep disorders (Duke and Vasquez 1994*). In Belize (Arvigo and Balick 1994, 215*) and on the Caribbean island of La Réunion, the stalks, leaves, and roots are used as sedative and sleeping agents. In Brazil, the plant is called *jurema*, while the variety *acerba* Benth. is known as *jurema branca* (cf. *Mimosa tenuiflora*, *Pithecellobium* spp.). Both forms are used as ingredients in the initiatory drink of the Afro-American Candomblé cult (see **madzoka medicine**).

The plant is known as *punyo-sisa* in Quechuan. Its leaves are placed in the pillows of old people and children so that they will sleep better (Schultes 1983, 261*). In the Amazon region, women soak the leaves in the juice pressed from the roots and smear the resulting juice between their breasts and on the soles of their feet. They claim that this gives them “increased sexual power” (Gottlieb 1974, 66*).

In the Philippines, *Mimosa pudica* is regarded as an aphrodisiac for frigid women. They pick and boil the leaves. The leaves fold together when picked and open up again when boiled. The opened leaf is a symbol for the vagina when it is open for sexual activity.

In India, the leaves are chewed and the resulting mush is spread onto fresh wounds to stop bleeding (Bhandary et al. 1995, 154*).

The plant contains norepinephrine (Schultes and Raffauf 1990, 246*). The narcotic effects are thought to be due to the alkaloid mimosine (Wong 1976, 123*). The aerial parts of the plant contain two C-glycosylflavones: 2''-O-rhamnosylorientine and 2''-O-rhamnosylisoorientine (Englert et al. 1994). The root contains tannin (Wong 1976, 123*).

The delicate and modest sensitive mimosa (*Mimosa pudica*) folds its pinnate leaves together at the slightest touch.

The seeds of *Mimosa scabrella*, a DMT-containing species.

Mimosine

***Mimosa scabrella* Benth.—bracaatinga**

The bark of this small tree contains ***N,N*-DMT**, MMT, *N*-formyl-MMT, and 2-methyl-1,2,3,4-tetrahydro- β -carboline—i.e., both psychedelic tryptamines and MAO-inhibiting β -**carboline**s. The bark presumably is suitable for making **ayahuasca analogs**. No traditional psychoactive use is known.

***Mimosa verrucosa* Benth.**

This species is rumored to be psychoactive or hallucinogenic (Schultes and Farnsworth 1982, 188*). However, there are no chemical analyses of or detailed reports about any possible use of the plant.

***Mimosa* spp.**

There appears to be a number of mimosas that may be of chemical interest and may possibly be suitable as sources of ***N,N*-DMT** for other **ayahuasca analogs**. There also appears to be a variety of species that are smoked as marijuana substitutes (cf. ***Cannabis indica***) in Central America.

Literature

Mitragyna speciosa Korthals

Kratom

Family

Rubiaceae (Coffee Family)

Forms and Subspecies

None

Synonyms

Mitragyna religiosa nom. nud.

Mitragyne speciosa (Korth.) (misspelling in the literature)

Folk Names

Biak, biak-biak, gra-tom, katawn, kratom, kraton, kutum, mabog, mambog, mitragyne

History

In the nineteenth century, it was reported that kratom was being used in Malaysia as an opium substitute and to heal “opium addiction” (Beckett, Shellard, and Tackie 1965, 241; Tyler 1966, 285*; Wray 1907a, 1907b). Phytochemical research into the plant began around 1920 (Field 1921). Pharmacological studies of the main active constituent began soon thereafter (Grewal 1932a, 1932b).

Distribution

The tree is indigenous to Thailand and from the northern Malay Peninsula to Borneo and New Guinea (Macmillan 1991, 416*).

Cultivation

The tree grows in marshy regions. No information about propagation is available.

Appearance

This tropical tree or shrub often grows to a height of only 3 to 4 meters, although it will sometimes grow as tall as 12 to 16 meters. It has a straight trunk with forked branches that grow upward obliquely. The oval, green leaves have a very large surface area (being 8 to 12 cm long) and are tapered at the ends. The deep yellow flowers grow in globular clusters attached to the leaf axils on long stalks. The seeds are winged (Emboden 1979, 184*).

Kratom is easily confused with other members of the genus *Mitragyna*, such as the African species *Mitragyna brunonis* (Wall. ex G. Don) Craib.

Psychoactive Material

—Leaves (kratom)

Preparation and Dosage

The dried leaves can be smoked, chewed, or made into the extract known as *kratom* or *mambog* (Wray

1907b). They also can be powdered, brewed with hot water, and drunk as a tea; 8.8 g has been given as a dosage (Macmillan 1991, 416*). Another method of preparation involves powdering the dried leaves and boiling them in water until a syrup results (which is easy to preserve); a dosage of this is 0.38 g. The syrup can be mixed with finely chopped leaves of the palas palm (*Lincuala paludosa*) and made into pills. This product is known as *madat* in Malaysia and is smoked in long bamboo pipes (Macmillan 1991, 416*).

The fresh leaves can be chewed together with betel nuts (*Areca catechu*) (Scholz and Eigner 1983, 75*). Salt is often added to prevent constipation. A typical user will chew three to ten mouthfuls of leaves through the day (Suwanlert 1975).

The main active constituent, mitragynine, appears to be well tolerated and has few toxic effects even when taken in high dosages. In studies with mice, even extreme dosages of 920 mg/kg body weight did not produce any toxic effects (Jansen and Prast 1988, 117).

Ritual Use

In Thailand, kratom is used primarily as an opium substitute. It is possible that some type of ritual method of use similar to opium smoking may have developed (see *Papaver somniferum*). Unfortunately, this area has not been the subject of ethnographic research.

Branch tip and flower of the kratom tree (*Mitragyna speciosa*).

The typical leaf arrangement of the genus *Mitragyna*.

“*Mitragyna speciosa*. . . Its leaves have narcotic properties like opium. Just as with opium, regular use of the plant can lead to addiction.”

H. F. MACMILLAN

TROPICAL PLANTING AND GARDENING

(1991, 416*)

Artifacts

None

Medicinal Use

In Thai medicine, kratom is used to treat diarrhea (Ott 1993, 413*). Drivers of *tuk-tuks* (three-wheeled motorized “taxis”) in Bangkok consume kratom as an amphetamine substitute (Schuldes 1995, 52*). In Malaysia, the leaves are used as a folk medicinal treatment for worms (Said et al. 1991).

In West Africa, the related species *Mitragyna stipulosa* (DC.) O. Kuntze is used in folk medicine as a local anesthetic. The bark is drunk in **palm wine** (cf. *Cocos nucifera*) to counteract poisoning and as a diuretic (Ayensu 1978, 222*).

Constituents

The plant contains numerous **indole alkaloids**: mitragynine, ajmalicine, corynanthedin, isomitraphylline, mitraphylline, mitraversine, paynantheine, speciogynine, speciofoline, speciophylline, stipulatine (= rotundifoline), rhynchophylline, mitragynaline, corynantheidinaline, mitragynalinic acid, and corynantheidinalinic acid (Beckett, Shellard, Philipson, and Lee 1965; Beckett, Shellard, and Tackie 1965; Houghton et al. 1991; Tyler 1966, 286*).

The main active constituent, mitragynine (66% of the total alkaloid mixture), is present especially in the leaves. Young leaves of plants of Thai origin contain 7 α -hydroxy-7*H*-mitragynine (1.6% of the total alkaloid mixture) (Pongluxe et al. 1994). A total of approximately 0.5% alkaloids is present in the dried leaves (Beckett, Shellard, and Tackie 1965, 242). A new indole alkaloid, 3-dehydromitragynine,

was discovered in the fresh leaves (Houghton and Said 1986).

Mitragynine is chemically related to **psilocybin** and other **ergot alkaloids** (D. McKenna 1995, 102*), e.g., alstovenine (cf. *Alstonia scholaris*). Mitraphylline and isomitraphylline belong to the **yohimbine** type (Ponglux et al. 1994).

The fresh leaves also contain (–)-epicatechine. Several flavonoids are present in the dried leaves. Both the dried and the fresh leaves have been found to contain ursolic acid (Said et al. 1991).

The alkaloid mitraspecine is present in the wood and bark (Beckett, Shellard, and Tackie 1965).

Several of these alkaloids also occur in other species (e.g., *Mitragyna parvifolia*) (Jansen and Prast 1988, 115; Shellard 1974, 1983).

Effects

Self-experiments, the descriptions contained in the literature, and the pharmacological properties of the constituents indicate that the effects of kratom are simultaneously stimulating like those of coca (*Erythroxylum coca*) and sedating like those of opium (see *Papaver somniferum*)—in other words, paradoxical (Ponglux et al. 1994). Kratom's effect is as if one were chewing coca while smoking opium (Jansen and Prast 1988). When fresh leaves are chewed, the stimulating effects can begin in as soon as five to ten minutes (Suwanlert 1975).

The pure alkaloid mitragynine has the following primary effects: “a) increase in the excitability of the cranio-sacral and sympathetic portion of the involuntary nervous system, b) increase in the excitability of the medulla and the motor centers of the CNS” (Scholz and Eigner 1983, 75*). These are indeed indications of a paradoxical substance (cf. Grewal 1932a, 1932b; Jansen and Prast 1988). The effects of mitragynine have even been compared to those of **codeine** (Macko et al. 1972).

The alleged kratom addiction is said to be a Thai cultural phenomenon (Jansen and Prast 1988, 117).

Commercial Forms and Regulations

Although the plant does not produce addiction per se, it does alter behavior, and it is now illegal in Thailand (D. McKenna 1995, 102*; Said et al. 1991; Schuldes 1995, 52*). Apart from this, the plant is not subject to any regulations. Unfortunately, no commercial forms are available.

Mitragynine

Mucuna pruriens (Linnaeus) DC.

Cowhage

Family

Leguminosae-Papilionaceae (Legume Family): Sub-family Papilionoideae: Phaseoleae, Erythrinae
Tribe

Forms and Subspecies

The species can be divided into at least two or three subspecies (Zander 1994, 385*; Lassak and McCarthy 1992, 66*):

Mucuna pruriens (L.) DC. ssp. *deeringiana* (Bort) Hanelt

Mucuna pruriens (L.) DC. ssp. *pruriens*

Mucuna pruriens (L.) DC. ssp. *gigantea* (15 cm long fruits)

Mucuna utilis Wall. ex Wight, once considered a species in its own right, is now regarded as a variety (Allen and Allen 1981, 448*): *Mucuna pruriens* (L.) DC. var. *utilis* (Wall. ex Wight) Backer.

Synonyms

Dolichos pruriens L.

Mucuna deeringianum (Bort) Merr.

Mucuna prurita Hook. f.

Mucuna prurita Wight

Mucuna utilis Wall. ex Wight

Mucuna utilis Wall. ex Wight var. *utilis* Backer ex Burck

Stizolobium deeringianum Bort

Stizolobium pruriens (L.) Medik.

Stizolobium pruritum Piper

Folk Names

Acharriya-pala, afrikanische juckbohne, akushi (Bengali), baidhok, balagana, chiikan (Mayan), chipororo, chiporro, cowhage, cowhage-winde, cowitch, cow itch, demar pirkok (Cuna), haba, huacawuru (Shipibo), itchweed, jeukboontje (Dutch), juckbohne, juckende fasel, juckfasel, kachaguli, kawanch, kiwach (Hindi, “bad to rub”), korodu, kuhkrätze, mucunán, ojo de vaca (Spanish, “eye of the cow”), ojo de venado (Spanish, “eye of the deer”), ojo de zamuro, oyobe, pica pica, pois à gratter, pois pouillieux, pwa gwatê, shabun baranti (Shipibo), siliqua hirsuta, velvet bean, wich yuk (Lacandon, “deer eye”), wodza, zizi, zootie

History

Almost nothing is known about the early history of the plant. In India, it has long been used for ethnomedicinal purposes. The genus name *Mucuna* is derived from the Tupí word *mucunán*, which is used in Amazonia to refer to several members of the genus (Allen and Allen 1981, 446*). In 1688, Hans Sloane brought to London a collection of cowhage seeds that were exhibited there as “itch

powder” (Allen and Allen 1981, 447*). One substance obtained from the plant, L-dopa, has become rather well known and has revolutionized the treatment of Parkinson’s disease (Remmen and Ellis 1980).

“The total indole alkylamine content [of cowhage] was studied from the point of view of its hallucinogenic activity. It was found that marked behavioral changes occurred which could be equated with hallucinogenic activity.”

RICHARD SCHULTES AND ALBERT HOFMANN

PLANTS OF THE GODS

(1992, 50*)

Distribution

It is no longer possible to determine where cowhage originated, although it may have come from tropical Asia (Zander 1994, 385*). It is now found in tropical regions in both hemispheres (the Americas, Africa, and Asia). It often grows in cultivated areas and at the borders of forests, near the ocean, and in sandy soils.

Cultivation

The plant can be grown from pregerminated seeds and also propagated vegetatively. Little is known about its cultivation.

Appearance

Cowhage is a vigorous climber that produces clusters of luxuriant violet inflorescences. The seedpods are approximately 8 to 10 cm long and covered with fine hairs. The pods contain the large, round, flat seeds, which are dark brown with a darker stripe.

Cowhage is easily confused with a wisteria species (***Wisteria sinensis***). The genus *Mucuna* is composed of some 150 species, many of which are very similar to one another (Allen and Allen 1981, 446*).

Psychoactive Material

—Seeds

—Leaves

Preparation and Dosage

For aphrodisiac and ethnomedicinal purposes, the dried seeds are ground and ingested with liquid. They also may be suitable for use in producing **ayahuasca analogs**. An aphrodisiac dosage (for men) is regarded as 15 g (Argueta V. et al. 1994, 1151*).

For medicinal purposes, the fruits are boiled (decoction).

The dried leaves—which dry in one day even in the humid tropics—can be smoked; one to two cigarettes is regarded as an effective dosage (Anonymous 1995).

Ritual Use

In India (Karnataka), the seeds are used to produce an aphrodisiac; two ground seeds are taken in cow’s milk in the evening (Bhandary et al. 1995, 155*). It is possible that aphrodisiacs made from cowhage seeds are also used in sexual rituals of the tantric cult (cf. ***Alstonia scholaris***). A folk love magic for strengthening the procreative powers suggests that this might be so:

Here, two plants are used: *Mucuna pruritus* [sic] and *Feronia elephantum* [= *Limonia acidissima*

L.; Rutaceae]. These are dug up with the following words: “Oh plant, you have been uprooted by bulls. You are the bull who foams over from lusty strength: And now you are being dug up by me for a bull of this kind!” . . . After they have been chopped and softened in water, decoctions of [the plants] are mixed with some milk. The patient, who sits upon a club or an arrow, drinks the mixture while reciting the magical formula for procreative power . . . : “Oh Indra, give power to this agent; its heat is like that of the fire. Like the male antelope, you, oh plant, possess all the power there is, you brother of the great soma.” (I. Shah 1994, 198*)

Artifacts

The large seeds are made into amulets wherever they are found, including Mexico, Guatemala, the Caribbean, tropical Africa (Ghana), and India. The seeds are often used in necklaces or as pendants (Madsen 1965, 110).

Medicinal Use

In Mexico, the powdered seeds are regarded as a potent aphrodisiac (Martínez 1994, 255*). A Mexican folk medicinal practice involves washing the eyes of newborns with a decoction of the seeds to prevent eye inflammation (Patten 1932, 210). In Puebla, a decoction of the fruits is drunk as an anthelmintic (Argueta V. et al. 1994, 1151*). In Brazil, the plant is used as an aphrodisiac and nerve tonic. The Cuna Indians also use it as an aphrodisiac (Duke 1975, 290*). In Trinidad, crushed seeds are ingested with sugarcane juice to treat intestinal worms (Wong 1976, 126*).

The seeds have long been used in Ayurvedic medicine and the Unani system as an aphrodisiac (Bhattacharya et al. 1971, 53). The tribal peoples of Bastar use the seeds to increase semen production and to cure “nocturnal dreams” (wet dreams?) (Jain 1965, 241*).

In the folk medicine of Nepal, the seeds are prescribed as a treatment for nervous disorders. In India, four or five hairs from the seedpod are taken with milk or buttermilk as an anthelmintic (Bhandary et al. 1995, 155*).

A common belief in Southeast Asia is that the seeds of *Mucuna pruriens* var. *utilis*, which are known as *achariya-pala*, can suck out the venom of a scorpion simply by being placed on the wound (Macmillan 1991, 424*). In the countries of the region, “herbal medicine [uses] a decoction of the root and the hulls as a diuretic and to alleviate inflammations of the nasal cavities” (Stark 1984, 69*).

The seed is also used as an anthelmintic in West African folk medicine (Ott 1993, 400f.*).

Homeopathic medicine uses a tincture made from the hairs of the seedpods known as *Dolichus pruriens*—Cowhage (Schneider 1974, 2:334*). Extracts of the seeds may be suitable for the treatment of Parkinson’s disease (Hussain and Manyam 1997).

The fruits of *Mucuna pruriens* ssp. *gigantea*. (Photographed in Palenque, Mexico)

This cowhage (*Mucuna pruriens*) seed, which contains DMT, is being used as the centerpiece of a traditional necklace made by the Lacandon of the rain forest of southern Mexico.

Flower and seed pod of an as yet undescribed *Mucuna* species from Panama, which may be a potent source of DMT.

Constituents

The seeds contain *N,N*-DMT, DMT, DMT-*N*-oxide, **5-MeO-DMT**, and **bufotenine** along with two β -**carboline**s (Bhattacharya et al. 1971). Serotonin (= 5-hydroxytryptamine) and L-dopa have also been detected (Argueta V. et al. 1994, 1151*; Ott 1993, 400*), as have the alkaloids mucunine, mucunadine, prurienene, prurieni-nine, mucuadine, mucuadinine, mucuadininine, prurienidine, and **nicotine** (Allen and Allen 1981, 447*). Tryptamines are present in the leaves.

The substances apoteine and mucunaine occur in the hairs on the seedpods and are responsible for the skin irritation (Seaworth 1991, 142*).

The cells contain a phenoloxidase, tyrosine, that is transformed into L-dopa when given to the cells as a substrate (Woerdenbag et al. 1989; cf. also Remmen and Ellis 1980).

It is likely that other members of the genus *Mucuna* also contain appreciable amounts of psychoactive tryptamines. L-dopa has been detected in several *Mucuna* species (Remmen and Ellis 1980; Yoshida 1976).

5-MeO-DMT

DMT

Effects

Animal experiments (with rats) have demonstrated that an extract of the seeds probably has hallucinogenic effects (Bhattacharya et al. 1971). Very few pharmacological experiments with humans have been conducted. There is one very interesting report describing the effects of smoking the leaves:

Smoking a joint the size of a cigarette will produce a general CNS stimulation (a pounding “tryptamine high”). The ingestion of 3 grams of harmala [seeds of *Peganum harmala*] and two smoked mucuna joints led to a pounding in my head, accompanied by colorful geometric patterns. A slight irritation developed within an hour to a delicate feeling (pulsating colorful patterns moved around me in a spiral fashion, I felt a strong need to lie down. Very delicate and detached.). (Anonymous 1995, 33)

Commercial Forms and Regulations

The seeds are sometimes sold as beads in shops that trade in artwork and antiquities from Africa and other overseas locations. The plant is not subject to any specific regulations.

“In Spain, these beans [of *Mucuna pruriens*] are set in silver and worn to ward off illness, headache, and the evil eye. . . .

“ . . . They are also known as ‘haba’ (bean), a name that is usually given to the shell of the dry snail.”

Myristica fragrans Houttuyn

Nutmeg

Family

Myristicaceae (Nutmeg Family)

Forms and Subspecies

It is likely that there are a number of varieties and cultivars that differ especially in regard to their psychoactive effects.

Synonyms

Myristica amboinensis Gandoger

Myristica americana Rottb.

Myristica aromatica Lamk.

Myristica aromatica Swartz

Myristica moschata Thunberg

Myristica officinalis L. f.

Myristica philippensis Gandoger

Folk Names

Almendra de la semilla, balla (Banda), Banda nutmeg, bazbaz (Persian), bisbâsa al-hindî (Arabic/Yemen), buah pala (Malayalam), bush-apal, chan-thet (Laotian), hindî, jaephâl (Hindi), jan-thet (Tahi), jauz-i-bûyâ (Arabic, “fragrant nut”), ju-tou-k’ou, juz, mada shaunda, massa, miskad, moscada, moscata miristica (Italian), moschocaria, moschocarydia, muscade, muscadier, muscadier cultivé, muscatennußbaum, muschatennuß, muskach’u (Callawaya), muskatnußbaum, musque, myristica moschata, noix muscade, nootmuskat (Dutch), noz moscada, nuce muscata, nuez moscada, nutmeg, nutmeg tree, pala banda, roudoukou (Chinese)

History

It is very likely that the nutmeg tree originated on the island of Banda (Meister 1677, 57*; Van Gils and Cox 1994, 118), where it was derived from a wild form through cultivation. Nutmeg appears to have first arrived in Europe with the Crusaders (Norman 1991, 46*). During the seventeenth century, the trade in nutmeg seeds flourished. The Dutch Vereenigde Oostindische Compagnie (V.O.C.), which held the monopoly on the Spice Islands, controlled the trade.

In England, abortions were once induced by grinding nutmeg and adding it to **beer** (Fühner 1943, 240*). During the 1950s and 1960s, great quantities of nutmeg powder were ingested in the United States as a marijuana substitute. Today, the plant is regarded as hallucinogenic (Bastien 1987, 138*). In Indonesia, it appears that a psychoactive use was (formerly) unknown (Van Gils and Cox 1994, 124). However, Rumphius (1741–1755) does report of an incident on Banda Island in which two soldiers slept beneath a nutmeg tree and woke up the next morning completely drunk (Van Gils and Cox 1994, 123).

Distribution

The nutmeg tree is endemic to the Indonesian province of the Moluccas, formerly known as the Spice Islands (Van Gils and Cox 1994, 117). It is now planted in numerous tropical areas.

Cultivation

Propagation is via seeds, which must be pregerminated with care. The seedlings can then be planted in the desired location.

The tree requires a tropical climate with heavy precipitation (2,210 to 3,667 mm per year). It especially prefers rich, volcanic soil and actually thrives only in a maritime environment (Van Gils and Cox 1994, 118). In cultivation, the tree first produces fruits when it is seven or eight years old and then continues to produce for many years (twenty to thirty) (Pahlow 1995, 72*). Although it bears fruits throughout the year, April and November are the main harvest periods (Van Gils and Cox 1994, 120).

One of the earliest European illustrations of the nutmeg tree, this depiction is botanically quite correct. (Woodcut from Garcia da Orta, *Colloquies on the Simples and Drugs of India*, 1987)

Appearance

The tree, which can attain a height of 20 meters, bears evergreen leaves (approximately 8 cm in length) on short stalks. The inconspicuous, whitish flowers are diclinous and hang in loose clusters. The tree is dioecious, although some plants have male and female flowers. The pale yellow fruits are reminiscent of apricots but are somewhat longer. When they ripen, they split open from top to bottom, exposing the dark brown seed and the surrounding red arils (Isaac 1993).

The nutmeg tree (*Myristica fragrans*), with a ripe fruit that has opened to offer a glimpse of the “nut” and the surrounding mace “flower.”

One type of *Myristica fragrans* from the Seychelles has very darkly colored “nuts” and deep orange arils.

The true nutmeg tree is very easily confused with *Myristica argentea* Warb. (New Guinea), *M. malabarica* Lam. (India), *M. speciosa* Warb., and a species indigenous to the Moluccas, *Myristica fatua* Houtt. The seeds and arils of these and other species (see table below) were sometimes sold as nutmeg counterfeits (Schneider 1974, 2:339*).

Two species of nutmeg trees indigenous to Australia (*Myristica insipida* and *Horsefieldia australiana*) develop fruits and “nuts” that are very similar to those of the true nutmeg tree. The Aborigines use all parts of the tree, including the so-called nuts, as sources of materials, food, and medicines (Wightman and Andrews 1991, 14*). It is entirely conceivable that they also discovered the psychoactive effects of nutmeg oil.

An ancient Chinese illustration of the nutmeg, known as *ju-tou-k'ou*.

Psychoactive Material

- Nutmeg (myristicae seed, myristicae nux, nuces aromaticae, nuces nucistae, nuclei myristici, nux moschata, semen myristicae)
- Arils (macis, mace, gul-i-jauz, flower of nutmeg, nutmeg flower, arillus myristicae)
- Nutmeg oil (myristicae aetheroleum, aetheroleum myristicae, macidis aetheroleum, myristici essentia, oleum macidis, oleum myristicae, oleum myristicae aethereum, oleum nucis moschati, oleum nucis moschati aethereum, essential oil of nutmeg, mace oil)

Other Species of the Genus *Myristica* That Are Sources of Nutmeg and Mace (From Isaak 1993; Pahlow 1995, 73*)

Stock Plant	Trade Name	Source
<i>Myristica argentea</i> Warb. [syn. <i>Myristica finschii</i> Warb.]	Horse nutmeg, Macassar nuts, Papua nuts, Papuan nutmeg/mace, akum, gagog, heen, Macassar mace	Indonesia, New Guinea
<i>Myristica impressinerva</i> J. Sinclair		
<i>Myristica iners</i> Bl.		
<i>Myristica malabarica</i> Lam. [syn. <i>Myristica fatua</i> Houtt., <i>M. dactyloides</i> Wall. non Gaertn., <i>M. notha</i> Wall., <i>M. tomentosa</i> Graham non Thunb.]	Malabar nuts, Bombay mace	India
<i>Myristica malaccensis</i> Kh.	Malacca nuts	Indonesia
<i>Myristica succedanea</i> Reinw. ex Bl. [syn. <i>Myristica speciosa</i> Warb., <i>M. radja</i> Miq., <i>M. resinosa</i> Warb., <i>M. schefferi</i> Warb.]	Batjang nutmeg, pala maba, onem, tidore, gosara onim	Moluccas
<i>Myristica umbellata</i> Elmer		

Preparation and Dosage

Seeds obtained from the ripe fruits are dried in the sun, over a charcoal fire, or in drying houses and then limed. Originally the seeds were covered with lime to inhibit their ability to germinate; today, the lime serves to protect the seeds from insect infestation and damage (Pahlow 1995, 72*).

The nutmeg flowers (arillus, macis) are separated from the seeds after the fruits have ripened. They are then pressed flat and dried in drying houses or in the sun. As they dry, their brilliant red color typically transforms into a warm yellow.

The light yellow essential oil of nutmeg is obtained by steam distillation of the seeds and seed coats (Isaac 1993, 868; Van Gils and Cox 1994, 120). Steam distillation can also be used to extract an

essential oil from the green leaves. The essential oil of the leaves is used chiefly to adulterate or counterfeit the true nutmeg oil (Isaac 1993, 869).

The following recipe is used to produce a mixture known as *obat penenang*, “sedative medicine” (this amount corresponds to the dosage for a child; an adult should use 1.5 times this amount):

- 9 leaves of *violtjes* (*Viola odorata* L.)
- 3 leaves of *daun seribu* (*Achillea millefolium* L.)
- 2 arils of mace (*Myristica fragrans*)
- 1 piece of rhizome (app. 4 cm long) of *jahe merah* (***Zingiber officinale***)
- 1 piece of rhizome (app. 4 cm long) of *dringo* (***Acorus calamus***)

The calamus and ginger roots are chopped into small pieces, mixed with the other ingredients, placed in a pot with three glasses of water, and boiled for fifteen minutes. The liquid is then strained off and sweetened with **honey** to taste. A glass of this is drunk two or three times daily for a period of one to two weeks (Van Gils and Cox 1994, 123).

In the Moluccas, nutmeg seeds are combined with *jahe merah* (***Zingiber officinale***), *sereh* (lemongrass, *Cymbopogon nardus* [L.] Rendle; cf. ***Cymbopogon densiflorus***), cloves (*Syzygium aromaticum*), and soaked raw rice to produce an ointment for medicinal purposes (Van Gils and Cox 1994, 122).

Powdered nutmeg also can be used as an ingredient in **smoking blends** and **snuffs** (Weil 1965). The information regarding dosages for psycho-active purposes varies considerably. In 1576, Lobelius reported that a pregnant English woman fell into delirium after having eaten ten or twelve nutmeg seeds (Van Gils and Cox 1994:123). Malcolm X, alias Malcolm Little (1925–1965), noted in his autobiography that a matchbox full of nutmeg powder produced a “high” corresponding to that produced by three to four joints of marijuana (Schleiffer 1979, 100*). Usually, two or three nutmeg seeds is regarded as a hallucinogenic dosage (Sherry et al. 1982, 61). Controlled experiments have determined that a dosage of up to 15 g of seed powder will produce unequivocal psychoactive effects (Isaac 1993, 884). According to Leung (1995, 157*), 7 to 8 g will induce hallucinations and euphoria.

Fruits Referred to as “Nutmeg” and Used as Substitutes or Counterfeits		
(From Isaac 1993, 881)		
None of these surrogates contains myristicin, and only a few contain safrol.		
Name	Stock Plant	Family
Brazilian nutmeg	<i>Cryptocarya moschata</i> Nees et Mart.	Lauraceae
Calabash nutmeg	<i>Monodora myristica</i>	Annonaceae
California nutmeg	<i>Torreya californica</i> Torr.	Taxaceae
Chilean nutmeg	<i>Laurelia sempervirens</i> (R. et P.) Tulasne	Monimiaceae
Kua kung	<i>Laurelia sempervirens</i> (R. et P.) Tulasne	Monimiaceae
Large mace bean	<i>Acrodictidium puchurymajor</i> (Mart.) Mez.	?
Mace bean	<i>Monodora myristica</i>	Annonaceae
Madagascan nutmeg	<i>Ravensara aromatica</i> Sonn.	Lauraceae
Nuces caryophyllatae	<i>Ravensara aromatica</i> Sonn.	Lauraceae
Otoba nutmeg	<i>Dialyanthera otoba</i> (H. et B.) Warb.	Myristicaceae
Owere seed	<i>Monodora myristica</i>	Annonaceae
Pichurim nut	<i>Acrodictidium puchurymajor</i> (Mart.) Mez.	?
Plum nutmeg	<i>Atherosperma moschatum</i>	Monimiaceae

When using the essential oil, as little as a few drops can be sufficient to produce clear psychoactive effects. Nutmeg oil is applied sublingually, i.e., under the tongue, from whence it slowly disperses. The medicinal and toxicological literature does not contain any definitive information concerning toxic amounts. In one source, it was noted that rabbits die within thirteen hours and five days of

ingesting 8 to 21 g of nutmeg oil (Isaac 1993, 871).

Ritual Use

In ancient India, the nutmeg seed was known as *mada shaunda*, “stupefying fruit,” and was utilized as an aphrodisiac, as an additive to **betel quids**, and as an important ingredient in curries. It was used not only in the kitchen but also in medicine (Ayurveda) and magic. In Malaya, nutmeg seeds were eaten to treat possession; in other words, a psychoactive substance was used to treat a mental illness. During the Middle Ages, it was regarded as an agent that incited to the “traffic of Venus.” An unusual love magic practice has continued into modern times (see margin text on the next page).

Smoking mace flowers in order to get “high” is common practice among students in Papua New Guinea (David Orr, pers. comm.). Such use is likely more hedonistic than ritual in nature. It has been observed that finely ground nutmeg seeds are sniffed during the Indonesian shadow theater (*wayang*) (Weil 1965) (cf. **snuffs**).

In the Moluccas, nutmeg seeds are used in religious healing rituals. When all other methods have failed to help a seriously ill child, then nutmeg seeds will be placed around his or her neck. Prayers are spoken that ask God to heal the child and reveal his or her fate (Van Gils and Cox 1994, 123).

Artifacts

None

Medicinal Use

The nutmeg seed plays an important role in traditional Indonesian medicine. It is used in treatments for stomachaches, stomach cramps, kidney problems, rheumatism, nervousness, vomiting, whooping cough, and other ailments. On the Moluccas, nutmegs are used primarily as sedatives for children and for those suffering from sleep disorders. The powdered seeds are ingested with milk or a banana drink. The mixture *obat penenang*, “calming medicine” (see above), is said to be especially efficacious; however, indigenous healers are of the opinion that a person can become somewhat “dependent” on this drink (Van Gils and Cox 1994, 123). A mixture of mace, *Viola odorata* leaves, red ginger (***Zingiber officinale***), and *Phaseolus radiatus* L. beans is said to improve concentration.

In Malaysian medicine (and in the medicine of the Malaysian Muslims), nutmeg seeds and flowers are used as stimulants, digestives, aphrodisiacs, and tonics. They are even ingested in treatments for malaria and “imbecility” (Van Gils and Cox 1994, 122). To relieve headaches, oil of nutmeg is applied to the temples or ingested in tea (one drop). An ointment known as *param* is applied externally for rheumatism and limb pains.

In the Moluccas, the oil of the related species *Myristica malabarica* Lam. is also used to treat headaches (Van Gils and Cox 1994, 122).

“This massa or balla in the Bandamic language, known as the nutmeg tree in German, grows, as is now thought, on the island of Banda, and as the coconut tree is the most useful in the world, this may be the rarest, because it does not grow in any place in all of India other than here. . . . The fruit or green nut, when preserved in the same manner as our Welsh nuts, and eaten early on an empty stomach with its outer green shell, is a superb preservative from unhealthy air. Indeed, it can greatly refresh even the ill and cheer them up with fresh spirits. . . . The good doctors can judge how the usefulness of this noble fruit and its true heart can be made use of in oil, water, and other things suitable for medicine, but this is a little different than the Indians [= Asian Indians/Indonesians] believe that it is good to use. The nut is said to strengthen the brain, sharpen the memory, warm and fortify the upset stomach, dispel flatulence or wind, impart good breath, dispel urine, constipate the red dysentery, in sum, for all types of ailments of the head, brain, stomach, liver, and mother’s complaints, while the oil alone is said to be better and more powerful than the seed for all ailments now conceived. But the flower is said to help a cold, upset stomach and dispel all evil moistures and uprising winds beyond all measure. . . . The seeds are of two kinds, the male and the female, the male is blackish brown and twice as long as the female, but this last type genus feminini is the best and most powerful.”

GEORGE MEISTER

(1677, CH. 8, 3*)

“Like peppercorns, the nutmeg seed is used for an unappetizing love magic: The girl swallows it, and when the seed has come out again, she powders it and mixes it into the food of her beloved (Franconia). As a result of the physical admixing, the aphrodisiac steers the boy’s kindled desire for love solely toward this girl.”

AIGREMONT

VOLKSEROTIK UND PFLANZENWELT [FOLK EROTICISM AND THE PLANT WORLD]

(1986, 2:83*)

In India, preparations of nutmeg are used in place of opium (see *Papaver somniferum*) when opium is contraindicated for a patient. A tonic is obtained using brandy (**alcohol**) and salt (Isaac 1993, 884). In Yemen, the seeds are used as tranquilizers and the “flowers” (arils) to treat headaches (Fleurentin and Pelt 1982, 92 f.*). Use of nutmeg as an aphrodisiac was and still is very widespread (from India to Arabia and into Europe; Weil 1965).

In homeopathic medicine, tinctures of nutmeg seeds and mace flowers (*Myristica fragrans* hom. *HAB1*, *Nux moschata* hom. *PFX*, *Nux moschata* hom. *HPUS88*) are often used in accordance with the medical description to treat nervous complaints and perceptual disturbances (Isaac 1993, 886).

Constituents

The **essential oil** of the nutmeg seed consists of approximately 4% myristicin, 39% sabinene, 13% α -pinene, 9% β -pinene, 4% α -phellandrene, 4% limonene, 1% γ -terpinene, 1% \neq -cymene, 1% terpinolene, and traces of other substances (safrole, eugenol, isoeugenol). The composition can vary considerably (Janssens et al. 1990). The essential oil obtained from the leaves contains 80% α -pinene and 10% myristicin (Bastien 1987, 138; Isaac 1993, 869).

Myristicin, elemicine, and safrole appear to be responsible for the psychoactive effects. Apparently an amination takes place during metabolism that transforms these substances into centrally active amphetamine derivatives (Isaac 1993, 883; Shulgin and Naranjo 1967; Weil 1965, 1967). Amination of myristicin yields MMDA (= 3-methoxy-4,5-methylendioxyamphetamine), a known entactogenic compound (Shulgin and Shulgin 1991*). Elemicine is transformed into TMA (3,4,5-trimethoxyamphetamine), a substance related to mescaline. Aminization of safrole results in MDMA (3,4-methylendioxyamphetamine), which is now known in counterculture circles as ecstasy or the “love drug” (cf. **herbal ecstasy**). Although myristicin has been pharmacologically demonstrated to have a mild MAO-inhibiting effect (Isaac 1993, 883), it is likely not suitable for use as an **ayahuasca analog**. The trimyristine that is present in the extract has a sedative effect upon chickens (Sherry et al. 1982).

Because they are sold as nutmeg “flowers,” the arils (mace) that envelop the nutmeg seed were once thought to be the actual flowers of the nutmeg tree. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Effects

Hildegard von Bingen provided an early description of the psychoactive powers of nutmeg seeds and their MDMA-like, empathogenic effects (cf. **herbal ecstasy**):

The nutmeg seed has great warmth and a good mixture in its powers. And when a person eats the nutmeg seed, it opens his heart and cleanses his mind and brings him to a good understanding. Take, as always, nutmeg and the same weight of cinnamon and some cloves and powder these. And then make some little cakes of this powder and bread crumbs and some water and, and eat these often, and it will subdue the bitterness of the heart and of your mind, and it opens your heart and your dull mind, and it makes your spirit happy and cleanses your mind, and it diminishes all of the harmful juices in you, and it imparts a good juice to your blood, and it makes you strong. (*Physica* 1.21)

The pharmacologist Johann E. Purkyne provided a very detailed description of the psychoactive

effects of nutmeg in his work *Einige Beiträge zur physiologischen Pharmacologie* (1829):

On the narcotic effects of nutmeg. . . . I first ingested an entire seed one morning, in pieces with sugar, which was not unpleasant. The effects that I felt were unimportant; some indolence in the outer senses and in the locomotor system, rather persistent in that they lasted the entire day, but not disturbing, whether on the thinking or on the other faculties; only I did notice that a small glass of wine after eating affected me in a disproportionately strong manner. One afternoon, after a moderate meal, I ingested three nutmeg seeds. The effects soon manifested themselves: an irresistible sleepiness overcame me, and I spent the afternoon slumbering on a small sofa, in what was otherwise an uncomfortable position, reveling in pleasant, peaceful dreams that were occasionally interrupted by external disturbances. . . . After these effects had completely subsided, I made another experiment in which I grated some two drams [= 8.74 g] of nutmeg into pure brandy and drank this. Here, too, I found the effects to be significantly different, in that instead of a calm sleepiness, I was affected by a general unease in the muscular system and dizziness. (In Sajner 1965, 16ff.)

Prison inmates who have used nutmeg as a substitute drug (for *Cannabis indica*) have reported visual and auditory hallucinations, sensations of floating, and disturbances of the body schemata (Van Gils and Cox 1994, 123).

Nutmeg oil has induced out-of-body, shamanic experiences (Devereux 1992).

Commercial Forms and Regulations

Nutmeg seeds and flowers are classified internationally as spices, i.e., foodstuffs, and are subject only to the various regulations pertaining to food. Grades of differing quality are available. The legal situation pertaining to the essential oil is not entirely clear. The essential oil is sometimes available from sources dealing in aromatic substances.

“Because mescaline-like metabolites are produced from myristicin and elemicine, the nutmeg seed has also been tested as an inebriating drug. The danger of addiction, however, can be ruled out completely, for anyone who has willingly ingested an overdose of nutmeg to order to experience the hallucinogenic effects acquires such an aversion to this spice that he can no longer take it.”

Nicotiana rustica Linnaeus

Turkish Tobacco, Wild Tobacco

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Nicotianeae Tribe, Rubiflorae Subtribe

Forms and Subspecies

A number of varieties have been named that are distinguishable from one another primarily on the basis of their phytogeography (Hartwich 1911, 29*):

Nicotiana rustica L. var. *rustica* (indigenous to Texas and Mexico, also occurs in Brazil)

Nicotiana rustica L. var. *texana* Comes (indigenous to northern Mexico, Sonora, and Texas)

Nicotiana rustica L. var. *jamaicensis* Comes (Mexico, Guatemala, Jamaica)

Nicotiana rustica L. var. *brasilia* Schrank (indigenous to Brazil, cultivated in Hungary)

Nicotiana rustica L. var. *asiatica* Schrank (cultivated in Syria, Arabia, Persia, and Abyssinia)

Nicotiana rustica L. var. *humilis* Schrank (cultivated in Peru)

There are apparently also several cultivars, as well as a hybridogenic cultivated race known as Machorka.

History

The genus *Nicotiana* is named after the French envoy Jean Nicot, who in 1560 sent seeds of *Nicotiana rustica* from Portugal, where he had grown the plant in his garden, to Paris, thereby promoting awareness of the plant (Schneider 1974, 2:359*).

It is very likely that wild tobacco was being cultivated in Mexico in pre-Columbian times (Dressler

1953, 138*). Apparently, it was not derived from a wild form but arose through hybridization and further cultivation—possibly from *Nicotiana paniculata* L. and *Nicotiana undulata* Ruiz et Pav. (Schultes and Raffauf 1991, 41*; Wilbert 1987, 6; cf. ***Nicotiana* spp.**).

Analyses of plant material left as grave goods have revealed that *Nicotiana rustica* was in use in ritual contexts in the Andes at the time of the flourishing of the Tiahuanaco culture (Bondeson 1972). This tobacco species was first described by Francisco Hernández (1651). In Europe, it initially was known under the name *Hyoscyamus peru-vianus*, or Peruvian henbane (cf. ***Hyoscyamus* spp.**) (Schneider 1974, 2:360*). Sahagun (11.7) documented the plant's psychoactive powers. However, as an agent of pleasure, wild tobacco never achieved the same significance as ***Nicotiana tabacum***.

Many Egyptian mummies have been found to contain **nicotine**, but it is not known how the nicotine got into the bodies. The simplest answer would be through smoking. But what might the ancient Egyptians have been smoking? It is generally accepted that the genus *Nicotiana* originated in the New World. Does this mean that the Egyptians had established trade relationships with pre-Columbian peoples there? The chemist Svetlana Balabanova, who took part in the investigations of the mummies, has hypothesized that wild tobacco, which is also widely known under the name *yellow henbane*, is an Old World plant that the Egyptians used as an **incense** and which was used even later as the European “strong tobacco”²⁵² (Pahl 1996). But there is no evidence to suggest that the nicotine might not have come from another source or have been the product of thousands of years of deposition and storage. Nicotine is also present in some species of the genus ***Datura***. Investigating whether the mummies also contain **tropane alkaloids** may yield interesting insights into these questions.

This illustration may be the earliest non-Indian representation of the nicotine-rich wild tobacco (*Nicotiana rustica*). (From Francisco Hernández, *Rerum Medicarum Novae Hispaniae thesaurus*, Rome, 1651)

The yellow flowers of wild tobacco (*Nicotiana rustica*).

Distribution

Today, wild tobacco is found throughout the world. It originated in either Mexico or northern South America. It grows wild in Nayarit, Jalisco (Mexico), and the Andes, where it is found even at altitudes above 3,400 meters (Bastien 1987, 153*). In pre-Columbian times, it is said to have occurred as far north as Canada (Hartwich 1911, 32*).

Cultivation

The plant is propagated from seeds. It usually is sufficient simply to scatter the seeds over loose soil. Like the seeds of *Nicotiana tabacum*, they also can be pregerminated. In temperate zones (central Europe), the seeds should be sown between March and May. The plant does well in normal soil. The Huichol prefer to cultivate the plant in soil that has been fertilized with the ashes of burned trees.

In pre-Columbian times, wild tobacco was grown in the Andes, Mexico, and what is now the southwestern and eastern United States. It is now cultivated on a large scale as a source of **nicotine** for the manufacture of insecticides (Rehm and Espig 1996, 252*).

Appearance

This annual herbaceous plant grows to a height of 60 to 80 cm. Its leaves are smaller and more rounded than those of *Nicotiana tabacum*, and its yellow flowers are somewhat shorter and smaller. The flowering period is in June and July. The fruits are round capsules that contain numerous tiny, reddish brown seeds.

Wild tobacco can be confused with other *Nicotiana* species (e.g., with *Nicotiana langsdorffii* Weinm.; see *Nicotiana* spp.).

Psychoactive Material

—Leaves

Preparation and Dosage

The leaves are dried in the sun in a well-aired location. They are then usually powdered and mixed with other substances (lime or *Tagetes lucida*; cf. *Tagetes* spp.). This method of preparation was recorded in the early colonial period:

Those who sell *piciete* crush it with lime and then powder both between the hands. Some do this with the incense of the earth, then take it in their hands and their mouth to soothe headaches or induce drunkenness. (Sahagun 11)

The Aztecs mixed the leaves with various unidentified plants and the gum (used as an **incense**) of the American storax, *Liquidambar styraciflua* L. (Emboden 1979, 4*). The Warao (Venezuela) mixed tobacco leaves with the resin of *Protium heptaphyllum* (Aubl.) March., known as *caraña*, *curucay*, or *tacamahaca*, which normally was used as an **incense** in **ayahuasca** rituals (Wilbert 1991, 183). The Huichol use the powdered leaves as a ritual **incense**. The Mazatec use the powder they call San Pedro (cf. *Trichocereus pachanoi*) in all of their rituals. They also ingest it.

The juice pressed from the fresh leaves is used for shamanic purposes. The fresh or dried leaves can be prepared as a cold-water extract, infusion, or decoction. Such extracts can be drunk or administered as an **enema**.

In North America, the leaves are added to **kinnikinnick** and other **smoking blends** (Hartwich 1911, 32*). The Warao roll cigarettes up to 90 cm in length for shamanic initiations.

In Iran and Iraq, the leaves are made into sniffing tobacco (cf. **snuffs**). The leaves are placed in *arrak* (palm sugar/palm alcohol; cf. **alcohol**, **palm wine**), dried, and then mixed with the ashes of *Ephedra pachyclada* Boiss (cf. *Ephedra* spp.), known locally as *huma*, or they are perfumed with jasmine oil (cf. *Jasminum* spp.) (Hooper 1937, 143f.*).

In the Himalayan region, a smoking blend known as *khamera* is made from leaves of wild tobacco that have been perfumed with *keora* (*Pandanus tectorius* Parkins. ex Du Roi [syn. *Pandanus odoratissimus* L. f.]; cf. *Pandanus* spp.), leaves of the moschatel *Delphinium brunonianum* Royle (cf. *Delphinium consolida*), powdered sandalwood (*Santalum album* L.), rose petals (known as *gúl-kand*), the fruits of *Zizyphus jujuba* Mill. [syn. *Zizyphus vulgaris* Lam.], cardamom, and the wilted leaves of the betel palm (*Areca catechu*). The tobacco dealers do not reveal the relative amounts of the different ingredients they use (Atkinson 1989, 756f.*).

Wild tobacco has an extremely high nicotine content and is considerably more potent than *Nicotiana tabacum* and all other *Nicotiana* species. For this reason, it should be used with great care. Dosages can vary so greatly from one individual to the next that it is not possible to provide any specific guidelines (cf. **nicotine**).

Ritual Use

Wild tobacco (*picietl*) was sacred to the Aztecs, who used it like peyote (*Lophophora williamsii*) or ololiuqui (*Turbina corymbosa*) for magical healing with incantations and in divination (Ruiz de Alarcón 1984):

The tobacco gourds of the Huichol are used to store and transport the powder they produce from *Nicotiana rustica*. (From Lumholtz, *Symbolism of the Huichol Indians*, 1900)

Clay figure of the Aztec goddess Cihuacoatl, the “soul of wild tobacco.” (From Krickeberg)

Preparation of wild tobacco for a *singando*.

Folk healers (*curanderos*) drinking a wild tobacco extract through their noses (a practice known as *singando*). (Photographed at the Laguna Shimbe, Las Huarinas, northern Peru)

When they smoked it and became inebriated from it, they called to the demons to find out about future events and to ask for advice for the requests of others who had retained them for this purpose. (Fuentes y Guzmán, in Maurer 1981, 347)

The colonial chronicler J  ronimo Mendieta wrote in his *Historia eclesi  stica indiana*:

Others say that some see the plant called *picietl*, which the Spanish call tobacco, as the body of the goddess Ciuacoatl. And that for this reason it has several medicinal effects. It must be smoked with great care, for it is very dangerous, as it takes away the minds of those who partake of it and makes them behave crazy and insane. (In Maurer 1981, 347 f.)

Among the Aztec, Ciuacoatl or Cihuacoatl, “woman-snake,” was a mother and earth goddess. She was the patroness of midwives and watched over the sweat bath. She—the soul of wild tobacco—was described in the following manner:

In this garb does she allow herself to be seen by people—adorned with lime, like a lady from the palace—: she wears ear pegs of obsidian, she appears in a white garment, she is dressed in a white costume, is completely white; she wears her woman's coiffure put up. During the night, she cries, she screams, she is also a portent of war. Her image is adorned in the following manner: her face is half red [and] half black, she wears a crown of eagle feathers, she wears a golden ear peg, she wears a collarlike outer garment, she carries a blue weaver's knife. (Sahagun 1.6)

The fact that the goddess is adorned with lime may be an indication of wild tobacco being prepared with lime.

The Huichol regard this tobacco species as a manifestation of the fire god Tatewari, who was originally a falcon but was transformed into a plant (Siegel et al. 1977, 16). Wild tobacco is sacred to the Huichol and is a part of all of their ceremonial activities (peyote rituals, drinking festivals, peyote pilgrimages; cf. *Lophophora williamsii*). It sometimes is smoked in combination with *Tagetes lucida* (see *Tagetes* spp.).

The Mazatec refer to wild tobacco as San Pedro (St. Peter²⁵³), thereby associating the plant with the saint that holds the key to heaven (cf. *Trichocereus pachanoi*). Tobacco, powdered and mixed with lime, is exchanged or offered both as an agent of pleasure for establishing social structures and in magico-religious contexts at all ceremonies (shamanic healings, divinations, mushroom circles; cf. *Psilocybe* spp.). The Mazatec regard the smoke as a magical protection against rattlesnakes, scorpions, and giant centipedes.

In South America (Tiahuanaco culture), powdered wild tobacco was used as a ritual **snuff** (Bondeson 1972). Unfortunately, no details are known about such use. This use could still be observed during the colonial period, with the note that the Indians used *sayre*, as they called wild tobacco, for many things and would also sniff the powder “to cleanse their heads” (Bastien 1987, 153*).

The Warao of Venezuela have developed an extremely complex mythology and cosmology on the basis of their tobacco experiences. The anthropologist Johannes Wilbert has been working for decades to decipher and comprehend this complex structure. The Warao use the leaves to make cigars some 90 cm in length that can be smoked only by shamans and initiates. A man must fast and may drink only water during the seven days that precede the use of one of these cigars. Only a few inhalations are taken from the cigar, as most people fall to the ground after their first deep inhalation and enter an extremely altered state of consciousness (Wilbert 1996).

Many shamans acquire their abilities to travel into other realities through the help of tobacco. They learn to enter the house of tobacco, to use the tobacco smoke to ascend into the heavens, and to communicate with the plant spirits of tobacco, which often appear in the form of snakes. When performing healings, shamans often blow tobacco smoke onto the ill person to free him or her of disease spirits or to protect the patient from them. For the initiated shamans, tobacco smoke is a door into another world, the world of visions, the world beyond space and time.

The Cariña Indians use a mixture of wild tobacco and ginger (*Zingiber officinale*) to promote the ability to see at night among those who are being trained to become shamans. The juice of both plants is dripped into the eyes of the candidates so that they later will be able to see and recognize both good and evil spirits (Wilbert 1987, 166).

Peruvian folk healers practice an extreme form of ingesting wild tobacco during their San Pedro rituals (cf. *Trichocereus pachanoi*). The process, which is known as *singando*, consists of the ritual drinking of a decoction of *tabaco blanco* (wild tobacco) through the nostrils. Today, *singando* is still frequently practiced by the *curanderos* of northwestern Peru. The healers consecrate themselves to the mountain gods and fall into a trance-like altered state of consciousness as a result of the potent effects

of the **nicotine**. *Singando* is an important part of the *mesa* rituals, during which San Pedro or, less frequently, *floripondio* (***Brugmansia sanguinea***, ***Brugmansia* spp.**) is drunk. The tobacco decoction is produced by macerating the tobacco leaves, sometimes mixed with other plants, in water, **alcohol**, and scented waters (e.g., eau de cologne, agua florida). The drinking vessels are usually made from the shells of ocean mollusks. Shells of the pearl oyster (*Pteria sterna* [Gould, 1851] [syn. *Pteria peruviana* (Reeve, 1857)]) are preferred, as they are pointed at the ends.

Artifacts

The Huichol Indians make tobacco bottles (*yékwe*) from tree gourds (*Crescentia cujete* L.) for ceremonial purposes. Some of these bottles are decorated with visionary elements or images from peyote experiences (see ***Lophophora williamsii***). They also are used as offerings to ***Solandra* spp.**, the magical “tree of the wind.” The Tzeltal Indians (Chiapas, Mexico) sometimes make a tobacco pouch for **smoking blends** (*bankilal*) containing wild tobacco from the penis (called *yat kohtom*) and/or scrotum of the coati (*Nasua nasua*, *N. narica*).

Many archaeological objects from the Mesoamerican region are related to tobacco, although it cannot be determined which tobacco species they are associated with (see ***Nicotiana tabacum***). In South America, a variety of types of tobacco pipes and forked cigar holders are carved from wood (Wilbert 1987).

Medicinal Use

The Callawaya wandering healers of South America recommend wild tobacco as a treatment for swollen muscles. The fresh leaves are warmed in the sun for a half hour and then massaged into the painful areas (Bastien 1987, 153*). In Peru, a decoction of the leaves is drunk to treat dysentery.

In Aztec medicine, wild tobacco was placed on the lower abdomen to treat swollen stomachs, smoked for asthma, and used to treat uterine ailments, sleeplessness, headaches, inflammations of the spleen, toothaches, syphilis, snakebites, and arrow wounds (Hernández 1959, 81f., 376*; Sahagun 11.7).

In modern Mexico, wild tobacco is smoked together with *Ephedra nevadensis* (see ***Ephedra* spp.**) as a treatment for headaches.

Constituents

Nicotiana rustica is very rich in **nicotine** (3.9 to 8.6%) and other pyrrolidine alkaloids (nornicotine, anabasine). It also contains traces of harmala alkaloids and tobacco camphor (Bastein 1987, 153*; Díaz 1979, 85*). The dried leaves may contain as much as 16% nicotine. Tobacco smoke has been found to contain more than nine hundred substances (Siegel et al. 1977, 18).

Effects

The Italian Girolamo Benzoni described the potent psychoactive effects of *Nicotiana rustica* in his early colonial work *Historia del Mondo Nuovo* (1568):

They light one end of the cigar, place the other end in the mouth, breathe through this, and fill themselves up with the dreadful smoke, so that they lose their minds. Some take so much of it that they fall over as if they were dead and remain unconscious for the greater part of the day or night. (In Maurer 1981, 348)

Wild tobacco can induce hallucinations that shamans are able to utilize. Wilbert (1996) has distinguished the hallucinations wild tobacco produces among the Warao Indians on the basis of their

phenomenological effects:

- dreamlike and chromatic
- multisensory perceptions
- brilliant occurrences of light
- intuitive knowledge and spontaneous insights
- soul-escort by a psychopomp
- tunnel experiences

However, such phenomena appear only among initiated shamans. Nonshamans who consume the same amounts as shamans do may experience toxic effects that can be life-threatening (cf. Wilbert 1991).

“The great magician, who as physician, spirit conjurer, and preserver of the old tribal messages is the most important personage of a Taulipáng community, knows how to enter a trance state by means of excessive smoking and drinking a strong tobacco brew. In this state, visions come to him that he feels he has truly experienced when he awakes. . . . The magic physician must drink a great deal of tobacco juice when curing the ill so that he can send his soul to the mountain spirits, the Mauarí. He searches among them for those Mauarí who know how the sick person can be helped.”

JOSEFINE HUPPERTZ

IN *GEISTER AM RORAIMA* [SPIRITS ON THE RORAIMA] (KOCH-GRÜNBERG 1956, 14f.*)

“South American Indians consider tobacco as food that can be eaten or drunk, and in many societies shamans are referred to as ‘tobacco eaters.’ ”

Nicotiana tabacum Linnaeus

True Tobacco

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Nicotianeae Tribe

Forms and Subspecies

Numerous varieties have been described, most of which can be distinguished on the basis of their phytogeography (Hartwich 1911, 27f.*):

Nicotiana tabacum L. var. *brasiliensis* Comes (indigenous to Brazil and northern South America)

Nicotiana tabacum L. var. *fruticosa* Hook. f. (indigenous to Mexico and Brazil; the most commonly cultivated variety)

Nicotiana tabacum L. var. *havanensis* Comes (indigenous to Mexico, and introduced from there to Cuba and Manila)

Nicotiana tabacum L. var. *lancifolia* Comes (indigenous to Ecuador and Central America)

Nicotiana tabacum L. var. *macrophylla* Schrank (Maryland tobacco; indigenous to Mexico)

Nicotiana tabacum L. var. *virginica* Comes (indigenous to the Orinoco, and introduced from there to Virginia)

All of these varieties have been used to produce numerous hybrids, cultivars, and sorts. The most important market forms are Virgin and Burley.

"In many ways, the history of tobacco is as gripping as any novel. The detectives of science had to make use of all of their acumen to illuminate all of the botanical, national economic, and even linguistic problems that surround this mystical plant, which has completed its triumphant march across the entire globe in the course of the past four centuries."

ØVRE RICHTER FRICH

VITAMIN DER SEELE [VITAMIN OF THE SOUL]

(1936, 9)

History

True tobacco was first cultivated in either Mexico or Peru. Whichever is correct, it spread into the other region at a very early date (Dressler 1953, 138f.*). It apparently was not derived from a wild form but was produced by hybridization (Schultes and Raffauf 1991, 41*). *Nicotiana glauca* Spegazz. et Comes may have been a precursor form. In Central and South America, tobacco is the most important and most commonly used shamanic plant.

In ancient Mesoamerica, tobacco was religiously venerated and was regarded as a plant of the gods. With its aid, priests induced an inebriation that opened contact to the world of the gods (Elferink 1983; Robicsek 1978). The "smoking god" of Palenque (= God K)—which the Lacandon know well and refer to as *k'uh ku ts'uts'*, "the god that smokes"—bears witness to this ritual. Tobacco played a significant role in the pre-Columbian culture of the Maya. In addition to its numerous social meanings, tobacco also is regarded by the Indians as a universal antidote for all types of animal bites and poisonings.

The earliest report about tobacco came from the feather of the monk Romano Pane, a companion of Christopher Columbus (1451–1506), who sent tobacco seeds to Charles V in 1518. The first botanical description is from Hernández (1525), who compared tobacco to henbane (*Hyoscyamus niger*, *Hyoscyamus* spp.), which was well known in Europe (cf. *Nicotiana rustica*). In Europe, tobacco was received as a panacea and miracle agent and used in folk medicine in numerous ways (Kell 1965).

Tobacco appears to have been introduced to the South Pacific during pre-Columbian times (Feinhandler et al. 1979). The Portuguese brought it to India in the fifteenth or sixteenth century (Gupta 1991, 62*). By the sixteenth century, it was apparently well known in India and Nepal.

Tobacco, and the practices of smoking and chewing it, was introduced to southern and Southeast Asia in the seventeenth century by the Dutch. Tobacco finally conquered all of Asia in the nineteenth century. Today, tobacco is one of the most frequently used psychoactive agents of pleasure in the world.

Distribution

True tobacco is a pure cultigen that was originally cultivated in either Central America or Amazonia and the neighboring regions. It is now grown throughout the world. Turkey has become renowned in the tobacco industry for its tobacco, and tobacco plants for commercial production are grown even in Germany. Although it is originally from the tropics, the tobacco plant has adapted very well to subtropical, dry/warm, and temperate climates.

Cultivation

Tobacco is propagated from seeds. In the tropics, the seeds need only be scattered over the earth, which is usually fertilized with ashes. In central Europe, the seeds must be sown between the middle and the end of March in greenhouses or in windowboxes in porous, sandy soil. The seeds should be gently pressed into the soil and will germinate in ten to twenty days when kept at 18 to 20°C. The young plants should then be transplanted into larger pots or beds. Tobacco requires much sun, a great deal of fertilizer, and copious amounts of water. It thrives best in sheltered areas.

If a tobacco plant develops flowers too quickly, they should be removed immediately so that the plant will continue to grow and develop more and larger leaves.

True tobacco (*Nicotiana tabacum*), with flowers and fruits.

When true tobacco (*Nicotiana tabacum*) was first introduced to Europe from the Americas, it was used as a medicinal plant and was listed in the early modern herbals under the name *Indian beinwell*. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“Many Amazonian Indians believe that there is a mighty life-giving and life-preserving power in tobacco. It is also believed that [tobacco] can strengthen the ability to resist harmful influences, purify, and enlighten. As a vehicle of the shaman, tobacco promotes contact with supernatural beings: the expelled smoke forms a kind of ladder to the heavens and [is] the medium through which religious authorities receive their energy. Few healing ceremonies occur in which tobacco smoke is not blown or tobacco leaves laid down. An ailing person must also ingest great quantities of tobacco so that the power of such an immunization can defend against the renewed attacks of disease demons.”

WOLFGANG MÜLLER

DIE INDIANER AMAZONIENS [THE INDIANS OF AMAZONIA]
(1995, 197*)

“Never has a plant that has entered into the circle of culture been laden with such curses or been persecuted with such severe laws as tobacco, and never has one passed so triumphantly across the entire earth—evidence as to how much humans have always been and still are inclined to pursue the enticements of pleasure more quickly than the demands of social welfare.”

JULIUS LIPPERT

DIE KULTURGESCHICHTE IN EINZELNEN HAUPTSTÜCKEN [THE HISTORY OF CULTURE IN INDIVIDUAL MAIN SECTIONS]
(1885, 127)

Appearance

This annual herbaceous plant can attain a height of 2 to 3 meters. Its large leaves (30 to 40 cm long) are oblong-elliptic. The campanulate, funnel-shaped, five-pointed flowers grow in panicles and have a light green calyx and pink petals. In North America and Europe, the plant flowers between July and September. The capsule-shaped fruits contain numerous tiny brown seeds.

True tobacco is occasionally confused with other *Nicotiana* species (*Nicotiana* spp.).

Psychoactive Material

—Leaves (dried and/or fermented; folia nicotianae, nicotianae folium, herba tabaci, herba nicotianae virginianae, tobacco leaves)

—Herbage (*nicotianae virginianae herba*)

Preparation and Dosage

The leaves can be dried in a variety of ways. For the smoking industry, tobacco leaves are “fermented” in a manner that varies depending upon their intended use. Cigarette tobacco is dried slowly in a moist environment. Cigar tobacco is air-dried, chewing tobacco is dried over a fire, and Turkish tobacco is dried in the sun (Macmillan 1991, 419*). Fruit juices are added to some pipe tobaccos. The drying process (“fermenting”) produces the special, preferred aroma. The leaves also can be laid on top of one another to ferment, a process that can require several months.

The Indians hang the leaves in the shade or, rarely, spread them out in the sun to dry.

Smoking tobacco should be yellowish or brown. The leaves are sometimes bleached with sulfur to give them a light yellow color. The taste is improved by adding sugar solutions, spices, salts, and coloring agents to the leaves. Chewing tobacco is produced from tobacco leaves that have been allowed to sit in a tobacco solution. Industrial tobacco snuffs may be aromatized with extracts of juniper berries (*Juniperus communis* L.; cf. *Juniperus recurva*), calamus root (*Acorus calamus*), sassafras wood (*Sassafras albidum*), and spices (Wagner 1985, 172*). In Burma (Myanmar), “the tobacco is doused with urine to improve the flavor” (Hartwich 1911, 113*).

The Lacandon still enjoy smoking cigars rolled from unfermented tobacco leaves.

Tobacco leaves are smoked by themselves or in **smoking blends** with other herbs (e.g., *Cannabis indica*, *Datura innoxia*) (cf. **kinnikinnick**). The Siona roll tobacco leaves in dried banana leaves (*Musa x sapientum*) for smoking (Vickers and Plowman 1984, 31*). In Mexico, tobacco is usually rolled in corn husks (*Zea mays*). The dry yet still elastic tobacco leaves also can be rolled into cigars by themselves, without any additions. Shamans of the Yucatán (Mexico) make cigars from one leaf of *Nicotiana tabacum* and one leaf of *Datura innoxia*. Birch bark is sometimes added to the tobacco to dilute the effects (Hartwich 1911, 91*).

In Siberia, smoking tobacco is mixed with spruce bark (*Picea omorika* [Panc.] Purkyne), scrapings of birch wood (*Betula* spp.), fir wood (*Abies* spp.), and moss (*Polytrichum*) (Hartwich 1911, 110*).

The men and women of Burma (Myanmar) roll different kinds of cigarettes. Men’s cigarettes consist of finely cut tobacco that is wrapped in the foliage leaves of *Ficus* spp., *Cordia dichotoma* Forst. f. [syn. *Cordia myxa* Roxb., *Cordia obliqua* Willd.] (Cordiaceae), *Careya arborea* Roxb. (Barring-toniaceae), or *Tectona grandis* L. f. (Verbenaceae). Women’s cigarettes are wrapped in the epidermis of the spathes of *Areca catechu*, corn husks, or bamboo skin that has been flattened on a

heated stone. The filling is a mixture of chopped tobacco leaves, stems, and roots; the roots of a *Euphorbia* species; the pith of a plant known as *oh'ne* (*Streblus asper* Lour.; Moraceae); sometimes palm sugar (cf. *Cocos nucifera*, **palm wine**); and finely chopped banana leaves (Hartwich 1911, 113*).

In Europe, tobacco is often rolled into joints together with hashish (see *Cannabis indica*, *Cannabis sativa*). From a pharmacological perspective, however, this combination is rather pointless, as the combination of the two substances results in a negative synergy. The tobacco suppresses the effects of the hashish, and the hashish potentiates the effects of the nicotine.

The western Amazon region and Venezuela are home to a practice known as tobacco licking or sucking. Here, tobacco is boiled to produce a kind of syrup called *ambíl* or *chimó* (*chimú*). The syrup is collected on a stick that is then dipped in coca powder (*Erythroxylum coca* var. *ipadú*) or plant ashes (cf. *Erythroxylum coca*) and licked (Kamen-Kaye 1971, 1975). This method of preparation and use has its roots in the pre-Hispanic period. Varying the additives and the quality of the tobacco leaves yields a *chimó manso* (mild), *chimó dulce* (sweet), *chimó bravo* (courageous), or *chimó fuerte* (strong). The *chimó* paste is placed between the lip and the lower front teeth, where it slowly dissolves. The black saliva is spat out. Habitual *chimó* users (whether men, women, or children) use the paste from the morning until the evening (Kamen-Kaye 1971, 17). As with cigarette smoking, tobacco licking has no predetermined dosages.

Indians of the North American prairie make fresh tobacco leaves into braids that are later used as chewing tobacco. (Lakota tobacco braid, from South Dakota)

A *mapacho*, a roll of tightly glued tobacco leaves from the Amazon.

The Siona make their *ambíl* from tobacco leaves that are boiled, pressed, and then boiled again together with the pressed juice until a dark brown syrup results. The ashes of the fruit husks of *cacao colorado de monte* (a *Herrania* species, possibly *Herrania breviligulata*), banana peels (see *Musa x sapientum*), and the bark of *Paullinia yoco* are also added to the syrup. The thick mixture is stored in gourds and can be sucked or even swallowed for use (Kamen-Kaye 1971, 53). The Witoto add avocado seeds (*Persea americana* Mill.) to the boiling tobacco decoction and sweeten their *ambíl* with cane sugar. They usually add a salty plant ash from the wood of rain forest trees of the genus *Lecythis* or palm wood from the genera *Bactris* and *Chamaedorea* (Kamen-Kaye 1971, 36). They often store *ambíl* in the fruit shells of a wild cacao species (*Theobroma glaucum* Karsten; see *Theobroma* spp.); they believe that this improves the taste considerably. The Kogi use manioc flour (*Manihot esculenta* Crantz) or *sagú* (*Maranta arundinacea* L.) to thicken the tobacco decoction. Other Indians use *sugii* (*Sorghum* spp.), a type of millet (Kamen-Kaye 1971, 33; 1975, 58). In Venezuela, the ashes from the wood of an *Erythrina* species (*Erythrina* spp.) are used as well (Plotkin et al. 1980, 295).

Amazonian **snuffs** are made by mixing finely ground, dried green tobacco leaves in equal parts with the ashes of a wild cacao species (*Theobroma subincanum* Mart.; see *Theobroma* spp.). Sometimes, a pinch of chili (*Capsicum* spp.) or some coca powder (*Erythroxylum coca* var. *ipadú*) may also be added (Schultes and Raffauf 1991, 42*). In Europe, Schneeberger Schnupftabak, a type of sniffing tobacco, was made with *Veratrum album* as an additive.

In French Guiana and Suriname, tobacco leaves and an alkaline additive, the ashes of the stem wood of a tree known as *mahot cochon* or *okro-oedoe* (*Sterculia excelsa*, *S. pruriens* [Aubl.] K. Schum.²⁵⁵), are used to produce a liquid that is sucked through the nose. The ashes are sprinkled over the fresh tobacco leaves, which are then moistened with water. After being allowed to sit for a period of time, the treated leaves are then pressed. The juice is sucked into the nose, immediately producing pronounced psychoactive effects characterized as an “overwhelming sensation of ecstasy.” The effects persist for some twenty to thirty minutes (Plotkin et al. 1980).

Peruvian shamans use fresh tobacco leaves to prepare cold-water extracts, often adding other plants, aromas, or **alcohol** (Vickers and Plowman 1984, 31*). This preparation usually is taken nasally before the ingestion of *Trichocereus pachanoi* or *cimora*.

An astonishingly similar use occurs (occurred?) in Africa:

Wherever they [the Wadchichi, Lake Tanganyika] go and stand, they carry a gourd of tobacco

and wear a metal or wooden clamp that hangs from a rope around their necks. From time to time, they fill the gourd with water and press the juice of the moistened tobacco into the hollow of their hand. They sniff this from their hand into their nose, and then the clamp is carefully set in place so that nothing flows out. (Lippert 1885, 28)

Chimó Additives		
Venezuelan <i>chimó</i> preparations are made from tobacco leaves and a number of additives (Kamen-Kaye 1971, 46 f.):		
<i>amapolo</i> (cf. <i>amapola</i>)	opium	<i>Papaver somniferum</i>
<i>anís</i>	anise seeds	<i>Pimpinella anisum</i> L.
<i>cafecito</i>	leaves	<i>Cephalis tinctoria</i> ²⁵⁴
<i>cafecito blanco</i>	<i>chimó</i> leaves	<i>Palicourea chimó</i> ²⁵⁵
<i>chivata/cervata</i>		unidentified
<i>clavo de olor</i>	cloves	<i>Syzygium aromaticum</i>
<i>cocuy</i>	cocui liquor	<i>Agave cocui</i>
<i>curía</i>	justicia leaves	<i>Justicia caracasana</i> [syn. <i>Rhytiglossa caracasana</i> , <i>Ecbolium caracasana</i>], <i>Justicia pectoralis</i>
<i>nuez moscada</i>	nutmeg	<i>Myristica fragrans</i>
<i>panela/papelón</i>	brown sugar	<i>Saccharum officinarum</i> L.
<i>quina negra</i>	leaves	<i>Guetarda sabiceoides</i>
<i>sarrapia</i>	tonka beans	<i>Dipteryx odorata</i> (Aubl.) Willd. [syn. <i>Coumarouna odorata</i> Aubl.]
<i>tamo de caraota</i>	bean straw	Leguminosae spp.
<i>vainilla</i>	vanilla	<i>Vanilla planifolia</i> Andr. [syn. <i>V. fragrans</i> (Salisb.) Ames]
Alkaline additives:		
<i>cernada</i>	plant ashes	<i>Erythrina</i> spp., <i>Musa</i> spp.
<i>uroa</i>	sodium carbonate, sodium bicarbonate	

In Amazonia, a popular pastime involves sprinkling a partially dried tobacco leaf with coca powder (*Erythroxylum coca* var. *ipadú*), rolling it up, and chewing it as a quid (Schultes and Raffauf 1991, 42*). Ingesting the tobacco orally together with slaked lime increases the effects noticeably.²⁵⁸

The Jíbaro mix tobacco juice with *Banisteriopsis caapi* and *piripiri* (probably a *Cyperus* species; see *Cyperus* spp.). The mestizo *ayahuasqueros* of Iquitos mix tobacco juice with *ayahuasca*. Dried tobacco leaves are moistened with saliva and allowed to remain overnight in a hollow that has been cut into the trunk of a *lupuna* tree (*Trichilia tocacheana* C. DC.; Meliaceae). This makes them thoroughly wet, and the leaves also absorb the toxic juice of the tree (Schultes and Raffauf 1991, 42*).

In Mexico, a decoction of tobacco leaves, stems of *capulín agarroso* (*Conostegia xalapensis* [Bonpl.] Don), guava leaves (*Psidium guajava*), avocado leaves (*Persea americana* Mill.), muicle herbage (*Justicia spicigera* Schlechtend. or *Justicia mexicana* Rose; cf. *Justicia pectoralis*), *Dyssodia porophylla* (Cav.) Cav., and garlic (*Allium sativum* L.) is prepared as an external remedy used to treat edema of the legs (Argueta V. et al. 1994, 1301*).

In India, fresh or dried green tobacco leaves are chewed or used as additives to betel quids (Jain and Borthakur 1986, 579*). Indian bidis are sometimes made from unfermented tobacco and thorn apple leaves (*Datura metel*). In the Near East, a smoking blend known as *guracco* is made primarily from hemp (*Cannabis indica*), sometimes opium (cf. *Papaver somniferum*), raw sugar, fruits, the leaves of a *Eugenia* species, the leaves of *Rhododendron campanulatum* D. Don (cf. *Rhododendron caucasicum*), *Marrubium candidissimum* L., and tobacco. A mixture of tobacco and rhododendron

leaves is used as snuff. In the Himalayan region, tobacco is added to homemade **alcohol** (Hartwich 1911, 92*).

Tobacco is added to numerous psychoactive products, including **ayahuasca**, **balche'**, **beer**, **betel quids**, **enemas**, **incense**, **smoking blends**, **snuffs**, and **witches' ointments**.

Forty to 60 mg of **nicotine** represents a lethal dosage for adults (Roth et al. 1994, 517*). Depending upon the type of tobacco and the manner of preparation, this dosage can correspond to very different amounts of tobacco leaves. It is possible for a person to die after consuming just one commercially manufactured cigarette (cf. *Nicotiana rustica*). One “normal” cigarette contains approximately 1 g of tobacco, which usually corresponds to a concentration of 5 to 10 mg of nicotine (calculated as a salt) (Wagner 1985, 172*).

Ritual Use

In Mesoamerica, tobacco has a long history as a plant of the gods. The plant not only was venerated but also was offered to the gods and was always smoked at rituals and ceremonies and during shamanic healings (cf. *Nicotiana rustica*).

Today, tobacco continues to play a central role in Mexican shamanism, although often it is only in the form of industrially manufactured, commercial cigarettes. The Nahuatl offer tobacco leaves or cigarettes during shamanic rituals to treat soul loss (Knab 1995, 160*). Tobacco also is used as a fumigant for magical protection from evil sorcerers, spirits, and snakes. The Mayan shamans of the Yucatán smoke tobacco (usually in combination with *Datura innoxia*) to diagnose diseases and to dispel the spirits that cause them. The Lacandon smoke an especially large number of cigars during their communal **balche'** drinking rituals. They also use cigars as gifts when courting a bride. In general, tobacco and cigars are their most important traditional gifts for establishing or strengthening social relationships.

The priestly and shamanic use of tobacco has also been documented for pre-Columbian Central America and the Caribbean islands. There, tobacco often was mixed with other substances, including the balsam of *Liquidambar styraciflua* L., which was used as **incense** (Elferink 1983). In Colombia, the Indian use of tobacco is widespread and has its roots in pre-Columbian times (Uscátegui M. 1956). Tobacco has great ritual, medicinal, and magical significance for almost every tribe in the Amazon region. It is smoked, chewed, sniffed (cf. **snuffs**), drunk in the form of pressed juice or brew (decoction, cold-water extract), administered rectally as an **enema**, or added to **ayahuasca** (Schultes and Raffauf 1990, 432ff.*).

Freshly pressed tobacco juice (from the leaves and stems) or an aqueous decoction of tobacco is often added to **ayahuasca** to potentiate its hallucinogenic effects. While under the influence of ayahuasca, most Amazonian Indians also smoke thick cigars or snuff tobacco practically without interruption (Schultes and Raffauf 1991, 42*).

In Amazonia, tobacco sniffing is usually hedonistic in nature, although it can also occur in ritual contexts. During **ayahuasca** ceremonies, many Indians in the western Amazon region sniff great quantities of tobacco powder mixed with the bark of a wild cacao species (*Theobroma subincanum* Mart.; cf. *Theobroma* spp.),²⁵⁹ sometimes even mixed with ground chili pods (*Capsicum* spp.) (Reichel-Dolmatoff 1971*; Schultes and Raffauf 1990, 433*²⁶⁰).

“Hachäkyum, our true lord, made tobacco. He planted it, he tried it out: ‘Ah, it is very delicious. That is very good for my creatures, for its smoke dispels the *us* flies, its juice kills the ticks and the flesh worms [Spanish: *colmoyotes*].’ Hachäkyum gave tobacco to the ancestors. But they did not need to die, for they did not inhale the smoke. When you inhale the smoke, your consciousness turns, the heart beats faster, the stomach aches. When you inhale the smoke, you quickly become inebriated, you must vomit, the muscles ache. Then you must drink a lot of water or pour it over the head, then you will become healthy once more.”

A LACANDON MYTH

During shamanic initiations, the Tukanos frequently administer great quantities of tobacco juice to novices so that they will vomit and pass out. Only a person who has survived this “chemical torture”—the amounts administered would quickly kill a “normal” person—is able to become a proper shaman (Schultes and Raffauf 1990, 435*).

The Aguaruna (an Ecuadoran Jíbaro tribe) mix tobacco juice with **ayahuasca** and administer the result as a ritual **enema**. Before receiving the enema, they drink ayahuasca and tobacco water alternately until they have to vomit. The enema is given after this (Schultes and Raffauf 1991, 43*).

Children of the Shuar sometimes receive tobacco water in place of **Brugmansia suaveolens** so that they can find their dream soul (*arutam*) (Bennett 1992, 493*).

The Mapuche burn tobacco leaves to fumigate rooms (cf. **incense**) in which sick people are staying or have stayed in order to dispel the spirits and causes of disease (Houghton and Manby 1985, 100*). Mapuche shamans smoke a great deal of tobacco, often in combination with other plants and tobacco species (*Nicotiana acuminata* [Grah.] Hook., ***Nicotiana* spp.**, ***Nicotiana rustica***), to attain an ecstatic or trancelike state (Houghton and Manby 1985, 100*). They also blow tobacco smoke onto the ill (Mösbach 1992, 105*).

In former times, initiates among the Ayoreo Indians of the Paraguayan Chaco had to drink a cold-water extract (maceration) of tobacco leaves as part of the process of becoming a shaman (*naijna*). Each novice was required to fast for two days before receiving the drink. If he did not have to vomit after ingesting the drink, he could become a shaman. Afterward, he had to fast for another two days and then survive a drink of tobacco leaves and a caper plant known as *najnur* (*Capparis speciosa* Griseb.). Finally, he had to smoke the dried roots of ***Jatropha grossidentata*** and ***Manihot anomala*** (Schmeda-Hirschmann 1993, 109*).

True tobacco, although it did not originate in North America, was cultivated at an early date by many North America tribes, especially in Montana and Virginia (hence the name *Virginia tobacco*) (cf. ***Nicotiana* spp.**). The Crow Indians, a typical Plains tribe, even had a secret society that was dedicated to the growing, care, and use of tobacco (Lowie 1975). The modern peyote ceremony of the Native American Church is opened with tobacco smoking (Bull Durham sort) (see ***Lophophora williamsii***). Today, *Nicotiana tabacum* is a common ingredient in ritual **smoking blends** and in **kinnikinnick**.

The shamanic use of tobacco has spread outside of the New World (Tschubinow 1914, 45*). “Tungus and Sojot shamans smoke imported tobacco to achieve ecstasy. Manchu shamans smoke tobacco and blow it onto sick persons. Tobacco is new to Asia, but inhaling the smoke of various plants in order to enter trance was an ancient practice of the local shamans” (Ruben 1952, 239*) (see ***Juniperus recurva***, ***Ledum palustre***). In eighteenth-century Siberia, “priests who were to divine would rub tobacco leaves between their hands and scatter these in brandy, which they then drank so that they could attain the necessary rapture” (Hartwich 1911, 109*). In Nepal, tobacco is venerated as a sacred plant of Shiva and is used by the shamans of the country (cf. ***Aconitum ferox***, ***Cannabis indica***). Tobacco was also used as a snuff in Nepal.

In Papua New Guinea, shamanism and sorcery are closely linked to the smoking and chewing of both the indigenous and the introduced tobacco species (cf. ***Nicotiana* spp.**). Certain aspects of the mythology and the culture of the Papuas are reminiscent of characteristics of the Australian Aborigines (cf. **pituri**):

Among the Fore of the eastern highlands, the medicine men, who are also called *dream men* or

smoke men, obtain their great knowledge from a knowing that is provided to them in dreams that are induced by psychotropic plants and the inhalation of tobacco smoke. (Michel 1981, 261)

According to the Eipo tribe (New Guinea), tobacco originated at the beginning of time from the excrement of birds (260).^{[261](#)}

Around 1851, an article about witches' flights (cf. **witches' ointments**) appeared in the *Rheinischen Antiquarius*, in which a kind of "tobacco shamanism" was described:

The smoking god of Palenque demonstrates that the smoking of tobacco and other plants was of tremendous ritual and religious significance in pre-Hispanic times. (Relief, ca. eighth century)

But around midnight, when he had lit a tobacco pipe and had smoked a little, he would have fallen into a swoon or sleep as a result of constant tobacco drinking, after which he would have only just dreamed or fancied that he had crept over a deep well or a cistern, constantly in danger of falling into this deep well. But when he awoke before the sun rose, he found himself next to or among his comrades [who sat imprisoned twenty-seven German miles away], in great amazement, and had the tobacco pipe, half-full, in his hands, which he then relit and smoked to the end. He did not know whether he had driven there on a goat or a coat or a poker or in some other manner, but had only been always fancying or dreaming, as if he had dreamed while asleep, how he crept over a deep well. (Stramberg 1986, 50)

Many people see the psychoactive tobacco as a brain food, a “vitamin of the soul.” (Book cover, 1936)

In Europe, the rise of the smoking salon led to the development of ritual forms of communal smoking (smoking clubs), rudiments of which have been preserved in modern times. This includes the act of offering cigarettes in social gatherings.

Artifacts

Ancient Mexican art, especially the art of the Maya, is filled with references to tobacco (cf. *Nicotiana rustica*). There are frequent depictions of smoking gods. In particular, the Mayan god known in the literature as God K has cigars,²⁶² cigarettes, or smoking tubes (*chamal*) as its attributes (Robicsek 1978, 59ff.).²⁶³ God K appears often in Mayan manuscripts and reliefs from the Classic Mayan period (300 to 900 C.E.).

The best-known image of God K is as the smoking god of Palenque. It is possible that tobacco visions provided the inspiration for some of the representations of other worlds (Robicsek 1978; cf. Dobkin de Rios 1974a*).

The use of tobacco has generated countless paraphernalia. The most important, of course, are the pipes, which have become objects of an almost cultic fixation among Western smokers in particular. The invention of the pipe is described in a whimsical story:

In South Africa, people once allowed tobacco to grow in a hole in the earth, and several people would suck the smoke from this hole using tubes. It was a small step to attach a small coal pot and portable smoking altar to the end of the tube itself—and so our tobacco pipe was born. (Lippert 1885, 127)

Containers for storing tobacco preparations (snuff boxes, cigar boxes, tobacco tins) also come in many forms. These objects are often decorated with iconographic elements of cultural significance. One cigar box, for example, featured depictions of mandrakes (*Mandragora officinarum*).

In Venezuela, traditional *chimó* containers (*cajeta*, *cuca*, *chimoera*, *cachita*) are made from cow horns (*cacho*, *cuerna de res*), to which a spatula (*paletica*, *pajuela*) of horn, wood, bone, or silver is usually attached (Kamen-Kaye 1971, 20ff.).

Medicinal Use

Tobacco is used throughout Central and South America as a remedy for snakebites (Schultes and Raffauf 1991, 42*). Today, the Tzeltal still use tobacco plasters as a treatment for this purpose (Berlin et al. 1974, 445*).

In Mexico, the use of tobacco (juice) as a pesticide is found among almost all Indians as well as the mestizos. Tobacco juice (*u yits k'uts*) is applied to insect stings and bites. The term *u yits k'uts*, “the juice of the tobacco,” is used for the tobacco condensate that can be seen in the saliva after a cigar has been smoked. The Lacandon believe that tobacco is poisonous, but that it is precisely for this reason that it is also a general antidote that has the power to neutralize even potent poisons. A ritual still exists in which snake venom is neutralized with tobacco.²⁶⁴ When a venomous snake such as a nauyaca (*Bothrops atrox*) or a rattlesnake (*Crotalus terrificus*) is found in a settlement or milpa, it must immediately be killed. A cigar stub is pushed into the throat of the dead snake to neutralize its venom. The snake is then buried. When spending the night in the jungle, making a circle around the camp with cigar ashes is said to keep away the poisonous snakes. It is possible that the Lacandon may also have once treated snakebites with tobacco (Rätsch 1994b, 55*).

In Venezuela, *chimó* is used in folk medicine as a remedy for scorpion stings, centipede bites, insect stings (wasps, bees, et cetera), and snake-bites. The flesh worms (*Dermatobia hominis*) that live under the skin are also treated and expelled with *chimó*. *Chimó* users believe that the preparation is good for the teeth, for warding off the “evil eye,” for dispelling hunger and exhaustion as well as evil spirits, and for healing a variety of illnesses (coughs, headaches, dysentery, toothaches, asthma, influenza, stomachaches) (Kamen-Kaye 1971, 23ff.).

Among the Maká Indians (Paraguay), only men and those women who are not nursing will smoke or chew tobacco (it is said that tobacco use will cause nursing women to have “bad milk”). The Maká used the resinous tars that remain in the pipe as a remedy for treating wounds (Arenas 1987, 291*).

The Shipibo use combinations of tobacco leaves and the pith of the stems of *Brugmansia suaveolens* as a plaster to treat aching wisdom teeth (Arévalo V. 1994, 259*).

In India, tobacco leaves are crushed together with the leaves of *Erythrina stricta* Roxb. (cf. *Erythrina* spp.) and *Desmodium caudatum* (cf. **ayahuasca analogs, soma**) to make a paste that is applied to the skin to treat ulcers (Jain and Borthakur 1986, 579*).

In German folk medicine, tobacco was smoked, burned, or chewed to treat toothaches (cf. **incense**). Decoctions of the leaves were administered as **enemas** in the treatment of broken bones (Pabst 1887, 2:140*).

In homeopathy, *Nicotiana* or *Tabacum* is usually used in higher potencies in accordance with the medical description to treat such ailments as angina (Roth et al. 1994, 518*):

The symptomatics of *Tabacum* are extremely striking. The nausea, dizziness, deathly paleness, the vomiting, the icy cold and sweating with intermittent pulse, are all highly characteristic. (Boericke 1992, 741*)

Constituents

As of 1989, 2,549 different substances had been detected and described in tobacco! The entire plant contains **nicotine** (primary constituent) as well as nornicotine and other pyridine alkaloids (anabasine, nicotyrine). The alkaloid content can vary considerably, ranging from 0.05 to 4% (Roth et al. 1994, 516*). In addition to the alkaloids, amines, flavones, **coumarins**, pyrrolidine, and piperidine are also present. Fermented tobacco contains up to 0.4% free nicotinic acid (Wagner 1985, 173*).

Sun-dried leaves contain a mixture of aromatics consisting of hundreds of substances (primarily

volatile acids) (Kimland et al. 1973). The substance known as tobacco camphor (= nicotianine) has been characterized as a volatile substance (cf. *Cinnamomum camphora*).

The smoke of commercial cigarettes has been found to contain myristicin (cf. *Myristica fragrans*, **essential oils**). The hallucinogenic effects of tobacco that are sometimes reported may perhaps be due (at least in part) to this component of the smoke (Schmeltz et al. 1966).

The study of the condensate of cigarette smoke for alkaloids has led to astonishing discoveries about its constituents. The principal alkaloid in the analyzed mass is the β -**carboline** harmane, followed by *N*-methylanabasine, nicotinamide, and anabasine. Lower concentrations of 2,2'-bipyridyl, β -nicotyrine, 2,6-dimethylquinoline, and myosmine have also been detected (Brown and Ahmad 1972, 3486; Janiger and Dobkin de Rios 1973, 1976; Poindexter and Carpenter 1962).

The spadixes of the cattail *Typha latifolia* are often smoked as substitutes for real cigars.

Plants That Are Smoked (Sniffed or Chewed) as Tobacco Substitutes

(From Hartwich 1911*; Low 1990*; Ott 1993*; Schultes and Raffauf 1986, 275*; Vickers and Plowman 1984, 13*; modified and supplemented.)

Dried coltsfoot leaves (*Tussilago farfara*) are a popular tobacco substitute.

“The religious leader of his group, who heals illnesses but primarily establishes the connection to the nonhuman persons and powers, also uses tobacco—often to a very considerable degree—the ingestion of which enables him to attain the state that the now almost endless literature refers to as ‘inebriation’ and ‘ecstasy’ but often calls ‘trance,’ ‘possession,’ ‘entrancement,’ ‘rapture,’ or ‘passion’ as well, in which he can directly contact the deities and spirits, have them manifest themselves in his hut or let them enter his body, or search out their location by sending out his spirit double or through an ecstatic journey that the body and the soul undertake together.”

GERHARD BAER

DER VON TABAK BERAUSCHTE [HE WHO IS INEBRIATED ON TOBACCO] (1986, 70*)

Effects

The effects of tobacco are primarily the result of the **nicotine**. Low dosages of tobacco produce invigorating and stimulating effects that suppress feelings of hunger. Moderate dosages can easily result in nausea, vomiting, diarrhea, anemia, and dizziness. High dosages can lead to delirium with hallucinations (cf. *Nicotiana rustica*) and to death due to respiratory paralysis (Wagner 1985, 173*). Reactions to tobacco and to different dosages are greatly dependent upon familiarity with the drug. Chronic smokers can survive sublethal dosages without problem.

Chronic use of tobacco can lead to serious health problems (cancer, lung disorders, throat problems, smoker’s leg). In Mexico, “smoker’s cough” (bronchial catarrh) is treated with damiana tea (*Turnera diffusa*).

Combining tobacco with other substances, e.g., in **betel quids**, can have synergistic effects, about which very little pharmacological data is available.

Commercial Forms and Regulations

Today, tobacco is the only sacred plant of ancient times that is still legally available throughout the world (in the form of cigarettes or rolling tobacco)! In Germany, up to one hundred plants may be privately cultivated without taxation. Any person growing more than one hundred plants must report this to the customs authorities.

In Europe, any tobacco product intended for sale must include a warning about the potential for health problems. In Belgium, smoking has been prohibited in public buildings since 1987. In the United States, smoking in public is increasingly being restricted. The World Health Organization (WHO) has recently adopted an international framework for restricting tobacco advertising.

In Europe, tobacco (*Nicotiana tabacum*) was originally known as the henbane of Peru or *Hyoscyamus peruvianus*. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

Nicotiana spp.

(Wild) Tobacco Species

Family

Solanaceae (Nightshade Family); Subfamily Cestroideae, Nicotianeae Tribe

Today, ninety-five species are botanically recognized in the genus *Nicotiana* (D'Arcy 1991, 78*). Schultes and Raffauf (1990, 432*), however, recognize only sixty-six species, albeit with numerous subspecies. Of these, some forty-five species are indigenous to the Andes region (Schultes and Raffauf 1991, 41*). Sixteen to twenty species are endemic to Australia.

Many *Nicotiana* species are called wild tobacco or Indian tobacco; *Lobelia nicotianaefolia* is also known as wild tobacco and *Lobelia inflata* as Indian tobacco, and *Lobelia tupa* is known as devil's tobacco.

During prehistoric times, only wild tobacco was smoked in North America (Dixon 1921; Setchell 1921).

Nicotiana acuminata (Grah.) Hook.

This wild tobacco occurs in southern Chile as the varieties *multiflora* (Phil.) Reiche and *acuminata*. The Mapuche have been smoking the leaves of this plant, which they call *pëtrem*, since pre-Columbian times. Mapuche shamans (*machi*) smoke a great deal at their healing ceremonies (cf. *Latua pubiflora*); it is said to enable them to enter an ecstatic state (Mösbach 1992, 105f.*).

Nicotiana attenuata Torr. ex Wats.—coyote tobacco

This wild North American species was smoked by the tribes of the Pacific Northwest (Heizer 1940). The leaves usually were mixed with bearberry leaves (*Arctostaphylos uva-ursi* [L.] Spreng.; cf. **kinnikinnick**) or other unidentified native plants (French 1965, 380f.). The Blackfeet cultivated this tobacco, which they called *pistacan* or *mah-watosis* (“hard tobacco”), and developed a tobacco plant ceremony in its honor (Johnston 1970, 319*).

In Europe, many American tobacco species were once known as Peruvian henbane. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Remains of this tobacco species have been identified in 1,300-year-old layers (Basket Maker III period) in the American Southwest (Jones and Morris 1960). The Hopi Indians know this wild tobacco by the name *pí-bû* and use it in various manners in their rituals. Because of this, the plant is also known as Hopi tobacco. The Navajo call it *tzilnát'oo*, “mountain tobacco,” and use it in many ceremonies and healing rituals, in which it is placed in their prayer sticks (see *Phragmites australis*).

The Coahuilla Indians of Southern California refer to this wild tobacco as *pivat-isil*, “coyote tobacco.” They would grind the leaves with a stone, mix it with some water, and chew the result (Barrows 1967, 75*). The neighboring Chumash mixed the powdered leaves with lime obtained by burning shells. The mixture, known as *pespibata*, could be either sucked on as a quid or steeped in water and drunk. The effects were described as profoundly euphoric. This use apparently was also related to the initiation with *Datura wrightii*.

“The old woman also tried to use plant leaves cured over a fire for smoking in a clay pipe. Everybody watched her as she became dizzy and collapsed, and they said: ‘This time she is dying; just let her die.’ But the woman came to again, and the first thing she did was have another smoke. It did her no harm and so everybody learned how to smoke.”

A MATACO INDIAN MYTH

IN *FOLK LITERATURE OF THE MATACO INDIANS*

(WILBERT AND SIMONEAU 1982, 116*)

“In Mexico, a very strong tobacco species whose leaves are smoked, *Nicotiana glauca* Grah. (Solanc.), is also known as marihuana. Of course, this marihuana (also called macuchi) does not do anything other than that which any other strong tobacco does.”

VICTOR A. REKO *MAGISCHE GIFTE* [MAGICAL POISONS]

(1936, 62*)

Blue tobacco (*Nicotiana glauca*), originally from northwestern Argentina, is now grown throughout the world as an ornamental. (Wild plant, photographed near Salta, northwest Argentina)

Nicotiana bigelovii (Torr.) Wats. [syn. *Nicotiana plumbaginifolia* var. *bigelovii* Torr.]—*pespibata*
This tobacco species was sacred to the Southern Californian Chumash. It was used as an offering and was smoked by special tobacco shamans, known as smoke healers, for ritual healings or was mixed with lime and ingested (Timbrook 1990, 252*). Other Indians of the Southwest also smoked or smoke the leaves (Barrows 1967, 74*; Setchell 1921, 404).

The smoke of this plant is so potent that it can cause a person to lose consciousness or fall into a

deep trance. The Indians of California made use of this effect in their initiations and healing rituals. Today, this sacred plant is considered to be very rare.

***Nicotiana clelandii* (Gray)—Cleveland’s tobacco, pavivut**

The Serí Indians of northern Mexico call this wild tobacco *xeezej islítx*, “the inner ear of the badger.” They dry and smoke the small, wide leaves in clay pipes, in the shell of a worm snail (*Tripsycha tripsycha* in the literature; probably *Serpulorbis* spp.), or in pieces of the canes of *Phragmites australis*. The Serí appear to be the only people who still smoke this tobacco species today (Felger and Moser 1991, 369*). In earlier times, it was also used in Southern California (Setchell 1921, 412 f.).

Nicotiana langsdorffii Schrank, one of the many South American tobacco species from Brazil.

***Nicotiana glauca* Grah. [syn *Nicotidendron glauca* (Grah.) Griseb., *Siphaulax glabra* Raf.]—blue tobacco, macuchi**

This shrublike plant, which has bluish leaves and yellow flowers, was first described for the province of Salta (northwestern Argentina), where it occurs at altitudes up to about 3,700 meters. It quickly spread throughout all of the Americas and is now found even in Europe and Asia, where it is grown as an ornamental and has also become wild. Remains of this plant have been found in archaeological layers of the Nazca culture (Bruhn et al. 1976, 45).

In the southern Andes region of Peru, the plant is known by the Quechuan name *supay kayku* (*supay* essentially means “devil”). The plant is made into a medicinal bath to treat diseases that are caused by *suq’a* (“evil spirits”). Traditional healers known as *p’aqus* rub the leaves and add them to **chicha**. They drink this secretly to induce an inebriated state and so that they can diagnose and heal diseases (Franquemont et al. 1990, 100*).²⁶⁶ The plant is known as *belen-belen* or *huelen-huelen* (“very left”) in the Andes and as *palqui extranjero*, “foreign palqui bush” (*Cestrum parqui*), in Chile (Mösbach 1992, 105*).

The Pilagá Indians of Argentina call this shrub *konyel’kaik*. They use its fresh leaves as a plaster for treating headaches (Filipov 1994, 190*).

The Serí Indians of northern Mexico call the plant *noj-oopis caacöl*, “hummingbird that sucks out the large justicia” (Felger and Moser 1991, 369*; cf. *Justicia pectoralis*).

The plant’s main alkaloid is anabasine (Leete 1982). Nornicotine is also present (Argueta V. et al. 1994, 1306*). Although it has sometimes been asserted that the plant contains **nicotine**, this is doubtful

(Roth et al. 1994, 515*). The pharmacological effects of anabasine, however, are very similar to those of nicotine (Blohm 1962, 94*).

***Nicotiana langsdorffii* Weinm.**

This wild tobacco species occurs in southern Brazil and Chile (Hartwich 1911, 29*). The shamans of the Mapuche (*machi*) and other peoples formerly smoked it during their healing rituals (cf. *Latua pubiflora*).

***Nicotiana palmeri* A. Gray**

The Navajo call this wild tobacco species *tipénát’ooh*, “sleeping tobacco,” and use it in numerous ceremonies and healing rituals. They also place this tobacco in their prayer sticks (see *Phragmites australis*).

***Nicotiana plumbaginifolia* Torr.**

California Indians collected and smoked this wild tobacco (Barrows 1967, 74*). The plant also occurs in South America, where it was also smoked (Hartwich 1911, 29*).

This ornamental tobacco plant develops flowers of different colors.

Nicotiana glauca is an important starting plant for breeding ornamental tobaccos.

Red ornamental tobacco (*Nicotiana* x) is sometimes used as a tobacco substitute.

A wild tobacco species (*Nicotiana* sp.), photographed in the ruined city of Yagul (Oaxaca, Mexico).

The wild tobacco (*Nicotiana* sp.) of Altiplano, Peru, is both smoked and used as a ritual incense. (Photographed at Lake Titicaca)

***Nicotiana quadrivalvis* Pursh var. *multivalvis* Gray [syn. *Nicotiana multivalvis* Lindl.]**

This variety of a wild tobacco species was cultivated by the Indians on the Columbia River (Pacific Northwest) and was smoked for hedonistic or ritual purposes (Barrows 1967, 74*). The flowers were smoked as well as the leaves (Hartwich 1911, 31*).

***Nicotiana sylvestris* Spegazz. et Comes—wild tobacco**

This persistent tobacco species blooms throughout the entire year and even tolerates light frost. It is originally from the Bolivian highlands and may have been a precursor of *Nicotiana tabacum*. The

sticky leaves can be dried and smoked.

***Nicotiana trigonophylla* Dunal—desert tobacco**

Desert tobacco is used by the Indians of the Southwest (Barrows 1967, 74*). The Tarahumara call it *bawaráka* or *wipake* and use it as an analgesic (Díaz 1979, 85*). It is also known as *tabaco del coyote*, “tobacco of the coyote.” The Serí Indians of northern Mexico call this wild tobacco species *hapis casa*, “that which is smoked, rots,” and believe that the plant has magical powers. The small, narrow leaves were apparently ritually collected and then slowly dried. The effects are said to be very strong (Felger and Moser 1991, 369*).

Anabasine

***Nicotiana undulata* Ruíz et Pav. [syn. *Nicotiana tabacum* var. *undulata* Sendtner]—Yaqui tobacco**

The Quechua know this Central and South American tobacco species as *kamasayri*. Applied externally, it is used to treat stomachaches (Franquemont et al. 1990, 100*). It is thought that the Maya used a preparation of the leaves as a medicinal or ritual psychoactive **enema**. The hybridization of this species with *Nicotiana paniculata* may have given rise to *Nicotiana rustica* (Emboden 1979, 42*).

The rare wild tobacco species *Nicotiana cordifolia* develops very large leaves that are well suited for rolling cigars.

An unidentified *Nicotiana* species.

A healing ceremony on Hispaniola, showing a shaman smoking some type of tobacco and falling into a trance. (From Benzoni, *La Historia del Mondo Nuevo*, 1568)

***Nicotiana* x—ornamental tobacco**

There have been few chemical studies of the cultivated ornamental tobaccos, which produce a variety of flower colors. Some psychonauts are now investigating and testing these plants for possible psychoactive effects.

<i>Nicotiana</i> Species Used as Chewing Tobacco and Pituri Quids (Australia)	
Species	Alyawara Name (from O’Connell et al. 1983, 108*)
<i>Nicotiana benthamiana</i> Domin.	<i>ngkulpa putura</i>
<i>Nicotiana gossei</i> Domin.	<i>ngkulpa inpiynpa</i>
<i>Nicotiana ingulba</i> J.M. Black	<i>ngkulpa nguninga</i>
<i>Nicotiana megalosiphon</i> Heurck et J. Muell.	<i>ngkulpa ntarrilpa</i>
<i>Nicotiana stimulans</i> Burbidge	
<i>Nicotiana velutina</i> Wheeler	<i>ngkulpa ntarrilpa</i>

***Nicotiana* spp.—various species (wild tobacco)**

There is evidence suggesting that many species of wild tobacco were and still are used in South America for ethnomedical, hedonistic, or ritual purposes. The Indians regard such wild tobaccos, most of which have not yet been identified, as more potent than the cultivated species (***Nicotiana rustica*, *Nicotiana tabacum***). The following species have been smoked (Hartwich 1911, 29ff.*):

Nicotiana alata Link et Otto (Brazil, Uruguay, Paraguay)

Nicotiana alata var. *persica* Comes (Brazil)

Nicotiana angustifolia Ruíz et Pav. (Chile, Brazil)

Nicotiana glutinosa L. (Peru, Chile)

Nicotiana mexicana Schlecht. (Mexico, Guatemala, Bolivia; syn. or var. of *Nicotiana tabacum*)

Nicotiana paniculata L. (Peru)

Nicotiana pusilla L. (Mexico, Cuba)

Nicotiana repanda Willd. (Mexico)

Nicotiana species have been identified in archaeological excavations, including in a grave of the Tiahuanaco culture (in association with *Ilex guayusa*) (Bruhn et al. 1976). Their use appears to be very ancient.

Wild Tobacco in Australia

Some twenty species of the genus *Nicotiana* occur in Australia (Bahadur and Farooqui 1986; Burbidge 1960; Haegi 1979). All of the Australian *Nicotiana* species—usually referred to as wild tobacco²⁶⁷—are small annuals that seldom grow taller than 1 meter in height. All of the species are regarded as poisonous, especially for grazing cattle and sheep (Dowling and McKenzie 1993, 91*). Among the most poisonous species are *Nicotiana megalosiphon* and *Nicotiana velutina*, both of which are used as chewing tobacco.

All of the Australian *Nicotiana* species contain pyridine alkaloids, primarily **nicotine** and nornicotine (Dowling and McKenzie 1993, 92*). The Aborigines used and still use at least six of the indigenous species for psychoactive purposes, usually as chewing tobacco or **pituri** (cf. *Duboisia hopwoodii*). *Goodenia* spp., *Trichodesma zeylanicum*, and other species are used as substitutes (see *Nicotiana tabacum*) (O’Connell et al. 1983, 97 f.*).

Nicotiana gossei is regarded as the most potently effective wild tobacco species, followed by *Nicotiana ingulba* and *Nicotiana benthamiana*. The species *Nicotiana velutina* and *Nicotiana megalosiphon* are considered only weakly effective and are consumed only in extreme emergencies (O’Connell et al. 1983, 98*). The wild tobacco leaves are dried and made into rolls. For use, they are first moistened with saliva, then dipped in plant ashes (from *Acacia* spp., *Eucalyptus micro-theca*, *Eucalyptus* sp., *Ventilago viminalis*, and others), and then chewed (cf. **pituri**).

Until recently, the Alyawara, who live in central Australia, also used wild species of tobacco to produce hunting poisons. The leaves were macerated in water and the resulting extract was poured into the watering sites of emus. When emus drank this toxic water, they became sedated and were easy prey for hunters (O’Connell et al. 1983, 98*).

Wild tobacco was also used in the rituals of the rainmakers.²⁶⁸ It was said that when mixed with saliva, the chewed leaves of *Nicotiana* species smelled like rain. Chewing made it possible for the “life essence” to leave the leaves. To make rain, the rainmaker and his assistants spat the chewed masses into the sky. The rainmaker could also spit the chewed mass onto a smooth stone. He would then take a pearl oyster (*Pinctada margaritifera* L.), which he would wear on a string around his neck at other ceremonies and which had great magical significance and great value to him, and rub it over the mass of leaves and saliva for a while, singing various magical songs as he did so. The pearl oyster was then smeared with blood, placed in mulga leaves, and covered with grass, after which it was hung from a mulga tree (*Acacia aneura* F. Muell. ex Benth.; cf. *Acacia* spp.). The oyster would then attract the rain (Mathews 1994, 26).

“One plant person I know likes tree tobacco [*Nicotiana glauca*] and smokes it, but I’ve always found it rather harsh. Eaten, of course, it can kill just as quickly as does nicotine, and has. Of the wild tobaccos of western North America, *Nicotiana attenuata*, coyote tobacco, is said to be particularly fine. But *Nicotiana acuminata* should also be tried. . . .”

DALE PENDELL

PHARMAKO/POEIA (1995, 33*)

Nuphar lutea (Linnaeus) Sibthorp et Smith

Yellow Water Lily

Family

Nymphaeaceae (Water Lily Family)

The yellow water lily (*Nuphar lutea*), which is indigenous to Europe, produces opium-like effects. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Forms and Subspecies

It was formerly assumed that the genus *Nuphar* was composed of twenty-five or twenty-six species. Currently, only two species are recognized, and *Nuphar lutea* has been divided into nine subspecies (Beal 1956; Slocum et al. 1996, 165*):

Nuphar lutea ssp. *lutea* Beal

Nuphar lutea ssp. *macrophylla* (Small) Beal [syn. *N. advena* (Ait.) Ait. f.]

Nuphar lutea ssp. *orbiculata* (Small) Beal

Nuphar lutea ssp. *ozarkana* (Miller et Standley) Beal

Nuphar lutea ssp. *polysepala* (Engelm.) Beal

Nuphar lutea ssp. *pumila* (Timm) Beal [syn. *N. microphylla* Beal]

Nuphar lutea ssp. *sagittifolia* (Walter) Beal

Nuphar lutea ssp. *ulvacea* (Miller et Standley) Beal

Nuphar lutea ssp. *variegata* (Engelm.) Beal

Synonyms

Nenuphar luteum nom. nud.

Nuphar advena (Aiton) Aiton f.

Nuphar luteum Smith
Nuphar microphylla Beal
Nymphaea lutea L.
Nymphaea luteum S. Sm.

Folk Names

Amello, American spatterdock, andere seerose, Cape Fear spatterdock, carfano maschio, gael seebluomen, geel seeblume, geelseeblumen, gelber mummel, gelbe seerose, gelbe teichrose, gelbe wasserlilie, gele plomp (Dutch), lake rose, madonaïs, mummel, nailufar (Arabic, “water lily”), naunufero, nenuphar, ninfea, ninfea gialla (Italian), ninupharo, nuphar, nuphara, nuphar jaune, nymphe minor, nymphon, pond lily, seeblume, seekandel, spatterdock, teichrose, yellow water lily, yellow water-lily

History

The yellow water lily or lake rose was described by Dioscorides:^{[269](#)}

Other lake rose. There is yet another Nymphaia (some call it Nymphon, its flower is called Nuphar) with leaves similar to that mentioned before [*Nymphaea alba* L.]; it has a large and rough root and a yellow, shiny flower like the rose. The root and the seed, when drunk in dark wine, have a good effect against the flow of women. But it grows in the region of Thessaly on the Peneus River. (3.139 [149])

The root was often used medicinally as an alternative to *Nymphaea alba* L. (Schneider 1974, 2:365*). No traditional use as a psychoactive substance is known.

Distribution

Varieties of the yellow water lily occur in Europe, North America, and Asia. The plant thrives in standing and slowly flowing waters at depths of up to about 1.5 meters.

Cultivation

The yellow water lily is easily propagated through scions taken from the creeping rhizome (Slocum et al. 1996).

Appearance

This perennial plant has oval, heart-shaped, long-stemmed, floating leaves and large flowers the color of egg yolks that tower above its leaves. The capsule fruit is bottle-shaped. The plant flowers between June and August. The rhizome can grow to a length of several meters and a width of up to 10 cm.

The yellow water lily is easily confused with the Japanese water lily (*Nuphar japonica* DC.). However, the latter has slightly reddish leaves and develops orange-red flowers (Slocum et al. 1996, 165*).

Psychoactive Material

—Roots (rhizoma nupharis lutei, nupharis lutei rhizoma, water lily root)
—Seeds

Preparation and Dosage

The fresh root is chopped and macerated in red wine (cf. *Vitis vinifera*). To date, no information regarding psychoactive dosages has become available. The seeds are edible.

Ritual Use

According to Dioscorides, the yellow water lily grew especially in Thessaly. It is possible that the plant may have played a role in the ancient witch cult of the area. The water lily has also been named as an ingredient in the early modern **witches' ointments**.

An old recipe for a magical use has come down to us from central Europe; it appears to suggest a continuation of the ancient witches' use:

The “water lily,” collected at the moment when the sun enters the sign of Cancer, and dried in the air of midnight, is an agent against dizziness if this plant is hung on the wall and merely looked upon. (Schöpf 1986, 141*)

The yellow water lily (*Nuphar lutea*) harbors narcotic powers. (Wild plant, photographed in northern Germany)

“Coebe. Is a type of the Nymphe minor, found frequently in Jappon in watery locations. Its leaves, of the shape of a heart, float upon the water, filled with small veins; the flowers are blue, in shape like Consolida Regalis or larkspur. When its flowers wilt, little balls like onions appear in their place, which are quite watery in taste, and which the Japponese consider to be cold in nature. They, the Japponese, when their sick are unable to sleep, give this onion to the patient in their food or drink, otherwise it is not used in any other way as a medicine.”

Artifacts

None

Medicinal Use

In the medicine of antiquity, the yellow water lily was used in ethnogynecology to treat such conditions as vaginal discharge.

The Japanese water lily (*Nuphar japonica* DC.) is used in Japan as a sleeping agent and sedative (Meister 1677, 114*) and to treat syphilis, circulatory problems, and postpartum complications (Tsumura 1991, 175*).

In homeopathy, the essence of the fresh root is known as Nuphar luteum—Yellow Water Lily (Schneider 1974, 2:365*). The agent is used as an alternative to Yohimbinum (see *Pausinystalia*

yohimba), as some parts of the medical descriptions overlap considerably:

Nuphar luteum. Induces nervous weakness with pronounced symptoms in the sexual domain. . . . Male.—Complete lack of sexual desire; sexual organs are flaccid; the penis withdrawn. Impotence, with involuntary ejaculations while defecating and urinating, spermatorrhea, pain in the testicles and penis. (Boericke 1992, 556f.*)

Constituents

The entire plant, and especially the rootstock (rhizome), contains up to 0.4% nupharine (empirical formula $C_{18}H_{24}O_2N_2$) and β -nuphari-dine. But the primary alkaloid is desoxynupharidine (= α -nupharidine; empirical formula $C_{15}H_{23}NO$) (Reichert et al. 1949, 3:839*; Roth et al. 1994, 520*). The root also contains 5.9% tannic acid, dextrose, 1.2% saccharose, 18.7% starch, meta-rabinic acid, and fat (Reichert et al. 1949, 3:839*).

The rhizome of the Japanese water lily contains the alkaloids nupharidine, desoxynupharidine, and nupharamine. Also present are β -sitosterol, oleic acid, palminic acid, nicotinic acid, and tannins (nupharine-A, -B, and -C) (Tsumura 1991, 175*).

Effects

Nupharine is said to have opium-like effects and to induce trancelike states (Goris and Crete 1919). Atropine- and papaverine-like effects have been observed in animal studies (cf. **atropine**, **papaverine**). Desoxynupharidine has tonic effects and raises the blood pressure (Roth et al. 1994, 520*).

Commercial Forms and Regulations

The plant is protected (as are all indigenous Nymphaeaceae). Apart from this, the plant is a “legal high.”

Nymphaea ampla (Salisbury) DC.

White Water Lily

“The coolness of my foot,
the coolness of my hand,
when I cooled the eruption! [lit.:
“fire”]
Five are my white hail-stones,
my black hail-stones,
[my] yellow hail-stones.
Then I cooled the eruption.
Thirteen are the layers of my red dressing,
my white dressing,
[my] black dressing,
[my] yellow dressing,
when I received the force of the eruption.
A black fan was my symbol,
when I received the force of the eruption.
With me comes the white [aquatic] *ixim-ha*-plant,
when I received the force of the eruption.
With me comes the white *nab*-water-lily,
when I received the force of the eruption.
Shortly ago I applied [to it]
the coolness of my foot,
the coolness of my hand.
Amen.”

MAGICAL FORMULA OF THE MAYA FOR TREATING ERUPTIONS
(ROYS, *RITUAL OF THE BACABS* MS 114 f.)

Family

Nymphaeaceae (Water Lily Family); Apocarpiae Group, Subgenus *Brachyceras*

Forms and Subspecies

The species is divided into two varieties:

Nymphaea ampla var. *pulchella* (DC.) Caspary *Nymphaea ampla* var. *speciosa* (Martius et Zuccarini)
Caspary

Moreover, in Mexico (and elsewhere) there are a number of crosses and hybrids of different *Nymphaea* species, including *Nymphaea ampla* cultivars, that have acquired a certain importance as ornamentals (Slocum et al. 1996*).

Synonyms

None

Folk Names

Apepe, japepe, lolha’ (Mayan, “flower of the water”), mexikanische seerose, naab²⁷⁰ (Mayan), nab, nikte’ha’ (Mayan, “flower/vulva of the water”), ninfa, ninfea, nukuchnaab (Mayan, “large water lily”),²⁷¹ pan de manteca, quetzalxochiatl (Aztec, “Quetzal feather flower”), saaknaab, saknaab (Mayan, “white water lily”), sol de agua (Spanish, “sun of the water”), u k’omin (Lacandon), u k’omin ha’,

water-lily, white water lily, xikinchaak (Mayan, “the ear of the rain god”), zac-nab

History

The white water lily is represented in both pre-Columbian art and in Mayan manuscripts (Emboden 1983). It was first described scientifically in the nineteenth century. The first reports of its psychoactive use were published in the 1970s.

Distribution

In southern Mexico, the plant occurs throughout the entire Mayan lowlands (Emboden 1979a). It is also found on the higher elevated lake plateaus of Chiapas (Lagunas de Montebello, Yahaw Petha’ Lago Metzabok, Laguna de Najá, et cetera) It is common in the cenotes (natural wells, limestone caverns) near Mérida in the northern Yucatán (Roys 1976, 267*) and in Lago Petén Itzá in Guatemala. It is also said to occur in Brazil.

Cultivation

The rhizome can be multiplied and will thrive when placed in a pond with drainage or in slow-moving water.

Appearance

The plant develops a thick rhizome and has long-stemmed cordate leaves. The white flowers protrude some 20 to 30 cm above the floating leaves.

Nymphaea ampla is easily confused with the very similar European *Nymphaea alba* L.

Psychoactive Material

—Buds or flowers

—Rhizome

Preparation and Dosage

The white water lily can be prepared as a tea or decoction. However, no information concerning dosages is currently known (cf. *Nymphaea caerulea*).

The dried buds and flowers can be smoked alone or in **smoking blends**. One or two buds is said to be a psychoactive dosage. The fresh rhizome can be eaten raw or cooked. Eating an entire rhizome produces a mild sensation of being high (Brett Blosser, pers. comm.).

Ritual Use

The water lily appears to have been used as an additive to the **balche’** drink.

It has been said that Brazilians used the flowers as a narcotic inebriant with opium-like effects during the first half of the twentieth century (Emboden 1979a, 51). In the 1960s, “hippies” in Chiapas allegedly used the flowers as a recreational drug.

Artifacts

The water lily is a very common subject in Mesoamerican art. The rain god of Teotihuacan (Tláloc; cf. *Argemone mexicana*) is often depicted with water lily leaves, buds, and flowers. Sometimes he even has the buds in his mouth (Pasztory 1974). Curiously, the renowned ethnomycologist R. Gordon Wasson interpreted these very images of water lilies as representations of entheogenic mushrooms (see *Psilocybe mexicana*). (See Emboden 1981 and 1982 for more on this subject.)

The water lily was portrayed especially often in the art of the Classic Mayan period in icono-

graphic contexts (Rands 1953) that can be interpreted in a variety of ways. There are essentially three motifs: water lilies sprouting from the backs of crocodiles swimming in the water; the head of the “earth monster,” around which water lilies are entwined; jaguars that are either wearing the stalks and buds of water lilies as a head ornament or dancing with water lilies. The association between the jaguar and the water lily is especially dominant (Rands 1953, 88; cf. Emboden and Dobkin de Rios 1981).

The bud and open flower of the white water lily (*Nymphaea ampla*), found throughout southern Mexico and Guatemala. (Wild plant, photographed in Lago Petén Itzá, Guatemala)

The water lily is frequently seen on ceramic vessels that appear to depict primarily visionary scenes from the underworld or other worlds (Coe 1973; Emboden 1979b):

In association with the transforming tadpoles and balche' vessels, the water lily appears to invoke shamanic ecstasy. The tadpole changes its form and becomes a toad; the shaman undergoes a similar transformation and manifests himself in his alter ego. In some cases, the toad is seen in a human form which is offering libations; these may consist of balche' or of balche' to which water lilies have been added, so that the transformation is easier. (Emboden 1979a, 51)

There is even a Mayan hieroglyph known by the name *jaguar–water lily*, which has played an important role in the deciphering of the Mayan writing system (Coe 1993, 257). In all likelihood, the jaguar–water lily is a transformed shaman. In the American tropics, the jaguar is the most important shamanic animal and/or is the animal that is identical to the shaman and whose shape he can assume (Reichel-Dolmatoff 1975*; Walter 1956*).

The *uay* glyph (see illustration on right) may indicate that the shaman was transformed into a jaguar by means of a potent balche' drink and is traveling in another reality. The iconographic element of the water lily may possibly be a symbol for the balche' drink, the water in which the inebriated jaguar swims, the inebriation itself, or the other reality. The water lily also appears as a ritual scepter and is depicted over **balche'** vessels (Emboden 1979a, 50; 1992, 81).

Medicinal Use

The water lily was invoked in numerous Mayan magical conjurations from the colonial period to heal ulcers and skin diseases (Roys 1965, 39 f., 123). It has been said that the plant is still used for

ethnomedicinal purposes in the Yucatán today (Barrera M. et al. 1976*).

Constituents

The flowers have been found to contain aporphine, a substance that is closely related to the **opiate** apomorphine (Tamminga et al. 1978). It differs only in the lack of two hydroxyl groups. It is possible that aporphine can be transformed into apomorphine through processing, storage, or metabolism (Emboden 1979a, 50). Aporphine is also found in the poppy species *Papaver fugax* Poir. (Phillipson et al. 1973; cf. ***Papaver* spp.**). Alkaloids of the aporphine type also occur in the Family Lauraceae (e.g., *Litsea sebifera* Pers., *Litsea wightiana* Hook. f., *Actinodaphne obovata* Bl.) (Uprety et al. 1972). The backbone chain of aporphine is boldine, a substance also contained in the leaves of the boldo tree (*Peumus boldus*), which have traditionally been used as **incense**.

In addition to aporphine, *Nymphaea ampla* appears to contain quinolizidine alkaloids (Emboden 1983).

Effects

A tea made from the buds is said to have psychoactive effects (Dobkin de Rios 1978). It can also have psychodysleptic effects and can induce vomiting, but it does not have any toxic aftereffects (Emboden 1979a, 51). Further human pharmacological experiments are required.

Aporphine

Nymphaea caerulea Savigny

Blue Lotus Flower

Family

Nymphaeaceae (Water Lily Family); Apocarpiae Group, Subgenus *Brachyceras*

Forms and Subspecies

None (cf. Slocum et al. 1996, 164*)

Synonyms

Nymphaea coerulea (misspelling!)

In ancient Egypt, the beautiful blue lotus of the Nile (*Nymphaea caerulea*) was cultivated as a sacred plant. It has now disappeared almost completely from the Nile region. (Copperplate engraving, colorized, nineteenth century)

Folk Names

Blaue lotusblume, blauer lotus, blaue seerose, blue lotus flower, himmelblaue seerose, λωτοσ (ancient Greek), lotus (Roman), νημφαίασ (ancient Greek), nymphaea (Roman), ssn (Egyptian), utpala (Sanskrit)

History

Blue and white lotuses were the most important cultivated (ritual) plants of ancient Egypt. They grew wild in ponds and in the lowlands of the Nile and were planted in all natural and artificial (built) bodies of water (Hugonot 1992). They were esteemed for their beauty, their enchanting hyacinth-like scent, their symbolism, and probably also their inebriating effects. The buds and flowers were popular head and hair ornaments. Both the living and the dead were festooned with garlands made

from the plant. The garlands in the grave of the great pharaoh Ramses II (1290–1223 B.C.E.) were made almost entirely of white and blue lotus leaves (Germer 1988*). The Egyptian lotus (*Nymphaea lotus* [L.] Willd.) was described by Dioscorides, who was certainly aware of the blue lotus as well.

The blue lotus (*Nymphaea caerulea*) is now rare.

The blue lotus was first mentioned in the Egyptian Book of the Dead (Hornung 1993, 167, 364). The ancient Egyptians appear to have eaten the rhizome.

This hybrid water lily was derived in part from *Nymphaea caerulea*.

Distribution

The blue lotus is found only in the Nile delta, the lowlands of the Nile, and, less frequently, Palestine (Zander 1994, 397*). Today, it has almost completely disappeared from around the Nile and is seriously endangered.

Cultivation

The plant can be propagated by placing pieces of the rhizome in still bodies of water.

Appearance

The blue lotus has blue, sky blue, or sometimes slightly violet-tinged flowers that sit on long stems some 20 to 30 cm above the water's surface. The long-stemmed, floating leaves are round.

The blue lotus is easily confused with the violet-blooming *Nymphaea nouchali* Burman f. [syn. *Nymphaea stellata* Willdenow].²⁷²

Psychoactive Material

—Buds or flowers

Preparation and Dosage

Six buds or flowers that have already opened and closed again should be boiled in water. The flowers should be squeezed in a linen cloth so that their greenish brown juice runs into the water.

Ritual Use

In ancient Egypt, the blue lotus was closely linked to the detailed and visionary concepts of the afterlife and rebirth. Numerous buds, petals, and garlands have been found as mummy decorations and grave goods. The flower stands for the enlightened and reawakened consciousness of the deceased; it is “that lotus flower which shines in the earth” (Book of the Dead, chapter 174, line 30; cf. Dassow 1994). In the story of the battle between Horus and Seth, the lotus flower appears as a symbol of the divine, all-seeing eye. When Seth tracks down the resting Horus beneath a tree in an oasis, he rips both eyes from the sleeper and buries them in the sand, whereupon they are transformed into lotus flowers.

Because of the mythological, cosmological, symbolic, and artistic significance of the water lily, William Emboden (1978) has suggested that the ancient Egyptians used the blue lotus for its narcotic effects to produce a shamanic ecstasy among an elite priesthood. Since the blue lotus is usually portrayed in association with mandrakes (*Mandragora officinarum*) and poppy flowers (from *Papaver somniferum* or *Papaver rhoeas*; cf. *Papaver* spp.), it is highly probable that these images represent an “iconographic recipe.” A psychoactive ritual drink consisting of lotus buds, mandrake fruits, and poppy capsules is entirely conceivable (Emboden 1989).

Artifacts

A portrait head of Tutankhamen showing his head emerging from a lotus flower was discovered. The water lily was associated with the sun god Ra as the bringer of light. Usually, blue lotus flowers are portrayed together with yellow mandrake fruits and red poppy capsules (see above). They very often appear in scenes that have a shamanic, visionary, or initiatory character. Stylized lotus flowers were an important ornamental element in the art (container shapes, capitals of columns) of ancient Egypt (Emboden 1989). The blue lotus flower was also a symbol of Osiris, the god of the mystery cult, who was also regarded as the lord of **beer** and wine (see *Vitis vinifera*).

Medicinal Use

In ancient Egypt, water lilies were prescribed to treat the liver, to remedy constipation, to counteract poisons, and to regulate the urine. The petals were used both externally and internally, the latter being primarily in the form of **enemas** (Rätsch 1995, 351*).

Constituents

“No pharmaceutical properties of *Nymphaea lotus* and *Nymphaea coreulea* [sic!] are known” (Germer 1979, 28*). Yet the leaves and flowers are alleged to have narcotic properties. According to Emboden

(1978), *Nymphaea caerulea* presumably contains alkaloids. The flowers produce an exquisite **essential oil** that is said to have aphrodisiac properties.

Effects

Three to six buds, drunk as a tea, are said to induce hypnotic effects. The effects of the decoction become apparent some twenty minutes after ingestion. The initial symptoms include muscle tremors and nausea. Then comes a sensation of calm with alterations of color perception, auditory hallucinations, and other changes in auditory perception. The effects dissipate quickly after some two hours.

Commercial Forms and Regulations

Today, the blue lotus is a rare plant. It is doubtful whether it is sold in any form. The essential oil is only rarely available. When found, it is usually dissolved in sandalwood oil and is extremely expensive (John Steele, pers. comm.).

The white-blossomed Egyptian lotus (*Nymphaea lotus*) had a symbolic meaning in ancient Egypt that was very similar to that of the blue lotus. However, the white lotus does not appear to be psychoactive. (Woodcut from *The Penny Magazine*, July 7, 1834)

Ancient Egyptian representations of the sacred lotus as cut flowers for sacrifice and decoration. (From Engel)

“O you two fighters, tell the Noble One, whoever he may be, that I am this lotus-flower which sprang from the earth. Pure is he who received me and prepared my place at the nostril of the Great Power [Re]. I have come into the Island of Fire, I have set right [*maat*] in the place of wrong. . . . I have appeared as Nefertum, the lotus at the nostril of Re.”

FROM *THE EGYPTIAN BOOK OF THE DEAD*

(DASSOW 1994, CH. 174)

Pachycereus pecten-aboriginum (A. Berger) Britton et Rose

Pitayo

Family

Cactaceae (Cactus Family)

Forms and Subspecies

None

Synonyms

Cereus pecten-aboriginum A. Berger *Pachycereus pectenaboriginum*

Folk Names

Bigi-tope (Zapotec), bitaya mawali (Tarahumara), cardón, cardón barbón, cardón espinoso, cardón pelo, carve, cawé, chave, chawé, echo, hecho, kammbaumkaktus, órgano, pitahayo, pitayo, sagüera, sahueso, shawé (Tarahumara), wichowaka, xáasx (Serí)

History

This striking cactus was certainly already known in prehistoric times and was being used for ethno-botanical purposes similar to those for which it is used today (Strombom and Bruhn 1978). Mexican Indians use the thorny fruit as a hairbrush and plant the cactus as a living fence. In former times, the wood of the cactus was used as a building material. The Tarahumara collect the fruits and seeds for food (Bruhn and Lindgren 1976, 175).

Pachycereus pecten-aboriginum in its natural environment in Baja California (Mexico).

Distribution

The cactus is found only in Mexico: Baja California, Chihuahua, Sonora, Colima, and also near Tehuantepec.

Cultivation

In Mexico, the cactus is propagated by planting pieces that have been cut from young shoots. The cactus is often planted in dense rows to protect houses and gardens as a living fence.

Appearance

This cactus develops long, straight stems that grow upward, parallel to one another, and recall the pipes of an organ. The cactus can grow to a height of 5 to 6 meters, is somewhat thorny, and bears thorny fruits.

This species is easily confused with the closely related *Pachycereus pringlei* (S. Wats) Britt. et Rose [syn. *Cereus pringlei* S. Wats], which is known in Sonora by the names *cardón*, *cardón pelo*, and *sagüera* (Martínez 1987, 1176*). A similar species (*Pachycereus emarginatus* [DC.] Britt. et Rose) is known in Mexico by the names *órgano* and *pitayo* but is cultivated primarily as a living fence (Dressler 1953, 140*). The alkaloid-containing *Pachycereus weberi* (Coult.) Backeb. also has a similar appearance (Mata and McLaughlin 1980).

Psychoactive Material

—Young branches (stalks)

Preparation and Dosage

The fresh cactus flesh is pounded in a hollowed-out stone. The resulting juice is mixed with water (approximately one part cactus juice to three parts water). Unfortunately, there is no information describing the amounts of this solution that must be drunk in order to induce psychoactive effects (Bruhn and Lindgren 1976, 175).

The Tarahumara press the juice from the fresh stalks and drink it to induce visions. The juice is either mixed with *tesgüino* (maize beer, **chicha**) or boiled and fermented (Bye 1979b, 34*).

Ritual Use

In former times, the Tarahumara Indians of northern Mexico drank the cactus juice during secret ceremonies in the western canyons (Bruhn and Lindgren 1976, 175; Pennington 1963, 166f.). Apart from this, the cactus is used as a peyote substitute (see *Lophophora williamsii*).

Artifacts

A pre-Hispanic clay vessel from Colima has the shape of four stalks of a column cactus as a decorative element. It may be a representation of this cactus.

Medicinal Use

The cactus is used in Mexican folk medicine to treat stomach ulcers and cancer (Bruhn and Lindgren 1976, 175). Heated, the fresh cactus flesh of *Pachycereus pringlei* is applied externally to treat rheumatism (Felger and Moser 1974, 421*).

Constituents

The cactus flesh contains the **β-phenethylamines** carnegine (= pectenine), 3-hydroxy-4-methoxyphenethylamine, salsolidine, 3,4-dimethoxyphenethylamine, heliamine, 3-methoxytyramine,

and arizonine (Bye 1979b, 35*; Bruhn and Lindgren 1976; Mata and McLaughlin 1982, 109*).

Effects

Freshly pressed cactus juice, mixed with water, is said to produce effects similar to those of peyote (see ***Lophophora williamsii***), including dizziness and visions (Bruhn and Lindgren 1976, 175; Pennington 1963, 167). The fermented juice also has strong purgative effects (Bye 1979b, 34*).

Commercial Forms and Regulations

None

Literature

Strombom, J., and J. G. Bruhn. 1978. Alkaloids of *Pachycereus pectenaboriginum*, a Mexican cactus of ethnopharmacologic interest. *Acta Pharm. Suecica* 15:127.

This ancient Mexican petroglyph (Olmec horizon) shows a wild cat as it licks a cactuslike plant. This may be a reference to the psychoactive powers of a column cactus of the genus *Pachycereus*. The cat may be a shaman who has transformed himself with the aid of the cactus juice.

Carnegine

Salsolidine

Papaver somniferum Linnaeus

Opium Poppy

Family

Papaveraceae (Poppy Family)

Forms and Subspecies

Over the course of time, numerous sorts, forms, varieties, and subspecies have been described for this highly variable plant. The most important are:

Papaver somniferum var. *album* DC. (white blooms)

Papaver somniferum var. *apodocarpum* Huss. (acaulescent seed capsule)

Papaver somniferum var. *glabra* (produces an especially high-quality opium; Macmillan 1991, 417*)

Papaver somniferum var. *hortense* Huss. (flat stigmal disk)

Papaver somniferum var. *nigrum* DC.

Papaver somniferum ssp. *setigerum* (DC.) Corbière (this may be the wild form; cf. Grey-Wilson 1995, 172*; Macmillan 1991, 417*; Zander 1994, 417)

Papaver somniferum ssp. *somniferum*

An unusual form, called hens and chicks, has the capsule surrounded by small secondary capsules (Grey-Wilson 1995, 173*). In addition, a number of cultivars have been produced as ornamentals, e.g., ‘Black Peony’, ‘Golden Peony’, ‘Pink Chiffon’, ‘White Cloud’, et cetera (Grey-Wilson 1995, 172*).

Papaver somniferum var. *glaucum* (Boiss. et Hausskn.) O. Kuntze is now regarded as a separate species: *Papaver glaucum* Boiss. et Hausskn. (the so-called tulip poppy) (Zander 1994, 416*).

Synonyms

Papaver glaucum Boiss. et Hausskn.

Papaver nigrum DC.

Papaver officinale Gmel.

Papaver setigerum DC.

Folk Names

Adormidera, aguna (Lithuanian), amapola, amapola de opio, biligasgase (Kannada), black poppy, blood-zuipers-bloem (Flanders), calocatanos (Gallic), feldmohn, garden poppy, gartenmohn, guia-guiña (Zapotec), kasa-kasa (Tamil), kashakhasa (Malayam), kavl-a-kûknâr (Persian), kishkâsh (Arabic/Yemen), koknâr (Persian), koquenar, madi-huada (Mapuche, “lovely gourd”), magan, magen, mâgen, mâgenkraut, magesamo, maggona (Estonian), maggons (Latvian), mago, magsat, magsomkraut, mâhan, mahonnus (Vulgar Latin), mahunus, mak (Slavic), manus, mechones, meconium, mekon, miconium, mohn, namtilla (ancient Assyrian, “plant of life”), nocuana-bizuono-huseachoga-becala (Zapotec), oehlmagen, oehlsaamen, opium poppy, papaver (Latin), papâver, papaver album, papavero indiano (Italian), papavero somnolente, papœg, papula, pavot des jardins, pavot somnifère, popig, popœg (Anglo-Saxon), poppy, post (Hindi), pôst-a-kûknâr (Afghani), posto

(Bengali), schlafmohn, schwarzer magsaamen, slaapbol (Dutch), white poppy, ying su ke (Chinese)

This early illustration of the white-blooming variety of the opium poppy is botanically accurate. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

Folk Names for Opium

Affion (Arabic), affium, afin (Kannada), afion, afu-yung (Chinese), afyun (Arabic), ahiphena, amapola (Spanish), amfion (Portuguese), amphion, amsion, aphenam (Sanskrit, “foamless”), aphim (Hindi), aphu (Marathi), arfiun, chandu, maslach (Turkish), meconium, meseri, milk of poppies, misri (Egyptian), nagaphena, O, offion, ofium, opio (Latin), opion (Greek), opium, poust, tschandu, tschibuk

History

The opium poppy is known only as a cultivar. Although it is often thought that the plant was first cultivated in Asia, its home actually lies in central and/or southern Europe (Grey-Wilson 1995, 169*). Poppy was being cultivated in northern Italy, Switzerland, and southern Germany as early as the Neolithic period. It probably was used both as a source of food and as an inebriating plant: “[T]he inebriating and sedative effects of the seeds and the oil obtained from them may not have escaped the lake dwellers. In any case, both the type of use and the frequency of its occurrence and the quantities of poppy seeds that have been found demonstrate that we are looking at an important cultivar of the lake dwellers” (Hoops 1973, 233; cf. Hartwich 1899). Although it has not yet been possible to determine exactly when humans began growing poppies in the southern and northern Germanic territories, the practice certainly dates to a very early time. The Germanic peoples planted poppies (Proto-Germanic *magan*) in poppy or *magan* fields that were known as *odâinsackr* and were regarded as convalescent sites at which Odin/Wotan would effect healing miracles.^{[273](#)}

The poppy is one of the most important medicinal plants in the history of pharmaceuticals. It contains a latex—the “juice of the plant of forgetting” (Ovid)—known in ancient times by such names as *tears of the moon* and *tears of Aphrodite*. When the latex is exposed to air, it coagulates into a

brown mass known as raw opium or simply opium. The methods for obtaining opium were discovered not in Southeast Asia—as is so often assumed—but in Stone Age central Europe, in the area of Lake Constance or in Provence (Hartwich 1899; Seefelder 1996, 11).

The earliest mention of the poppy, however, is on a Sumerian tablet (ca. 3000 B.C.E.), where it is described as the “plant of happiness.” The first literary mention is in Homer’s *Iliad* (cf. **nepenthes**). Our word *opium* is derived from the Greek *opion*, “latex [of the poppy],” which in turn is derived from *opos*, “plant juice.” Roman reports demonstrate that the Gauls were well aware of the opium poppy and its properties (Höfler 1990, 93*). Walahfried Strabo (809–849), in his hexa-metric *Hortulus*, praised the psychoactive effects of the German opium poppy as “sacred to Ceres” (Schmitz 1981, 380; Stoffler 1978, 91). The Vikings are known to have used opium for medicinal purposes, and probably also as an inebriant (Robinson 1994, 547*).

At the present time, we still do not know when the Egyptians first began to use opium. Some authors have conjectured that the poppy was already known and being used in the time of the Old Kingdom, while other authors have suggested that the Egyptians did not become acquainted with and come to appreciate the plant and its opium until the time of the New Kingdom or even late antiquity (Bisset et al. 1994; Merrillees 1962).

In China, opium has been documented as far back as the third century. The Chinese physician Hua To used narcotics of opium and ***Cannabis indica*** in surgical procedures (Geddes 1976, 201). The Arab scholar Avicenna (= Abu Ali al-Hosein ben Abdallah Ibn Sina, 980–1036), who is considered to be the most important physician of the Middle Ages, is known as the “father of sleep” because he introduced the use of opium into Islamic medicine (Seefelder 1996, 52ff.).

In fifteenth-century Beijing, opium was celebrated as the best of all aphrodisiacs and apparently was used in great quantities (Duke 1973, 393). In Siam (Thailand), opium was highly regarded by the kings of Ayutthaya since at least the fourteenth century. At that time, production was probably already in the hands of the mountain tribes, who still number among its most important producers (Geddes 1976, 208). During the Middle Ages, opium was listed in all European pharmacopoeias (Schneider 1974, 3:20*), and opium preparations were used as anesthetics (cf. **soporific sponge**).

In 1670, the English physician Thomas Sydenham invented laudanum, a tincture of opium, saffron (***Crocus sativus***), cinnamon (*Cinnamomum verum*), powdered cloves (*Syzygium aromaticum*), and Spanish **wine** that was to have a far-reaching impact. Until the nineteenth century, laudanum was one of the most effective of all universal remedies and was also drunk for its inebriating effects.

In the seventeenth century, opium was one of the most important trade articles of the Dutch East India Company (Meister 1677, 93*). The Württemberg pharmacopoeia of 1741 characterized opium (= meconium thebaicum) as a “divine medicine” (Schneider 1974, 3:21*). Goethe described it as the “quintessence of the sweet slumber juices” (*Faust* 1). **Morphine**, isolated from opium by the German pharmacist Sertürner (1805), was the first pure active plant substance ever to be extracted and made available; the event revolutionized the pharmaceutical industry.

Opium became famous through the works of many nineteenth-century authors. Thomas de Quincey (1785–1859) saw in opium a manna, an ambrosia, a panacea, a universal remedy, a “mysterious balm to fulfill all human wishes” (De Quincey 1985, 183).

The Opium War of 1840–1842, which the English initiated purely from economic motives, led to far-reaching changes in world politics and the shape of international trade (Behr 1980; cf. Geddes 1976, 202f.; Solomon 1978). In the 1920s, the use of opium took on social forms that appeared threatening to the ruling class and ultimately led to global prohibition (Johnson 1981; Kohn 1992*). Today, opium is important primarily as the starting point for the illegal production of heroin.

Distribution

This cultivar has spread into all regions of the world. Large areas of cultivation—either for the pharmaceutical industry or for illegal heroin production—are found in the Golden Triangle, northern Thailand, central Asia, Turkey, Mexico, Tasmania, and Austria.

In Switzerland, the opium poppy now occurs as a wild or feral plant (Lauber and Wagner 1996, 144*).

Just as the flowers of *Papaver somniferum* can vary in color and size, the seeds also appear in a variety of colors. (Photograph: Karl-Christian Lyncker)

Cultivation

The plant is easily propagated from seeds, which should be broadcast in spring. Some of the seeds will germinate after ten to fifteen days. The seedlings do not like to be transplanted. Once poppies have appeared in the garden, it is relatively certain that they will always reappear, for the plant sows itself quite readily. It also can become wild and begin to appear in neighboring gardens. When harvesting the capsules, care should be taken to leave the heads of some of the plants untouched so that they can ripen and produce seeds for the following year. Poppies will also spread if the dried plants are composted, as the seeds will be distributed with the compost.

Poppies thrive best in warmer soils that are rich in nutrients, contain a great deal of humus, and are well tended. The plant requires a great deal of lime and consequently prefers lime-rich soils (Heeger and Poethke 1947, 236). For more on commercial methods of cultivation, see Griffith (1993).

Appearance

This annual plant possesses a distinct taproot, from which the perpendicular, simple or only slightly branching stem (as tall as 175 cm) develops. The gray-blue or, more rarely, greenish leaves are ovate-oblong with a more or less serrated margin or irregular lobes. The long flower stalk, which can be either hairless or only slightly pileous, bears a single flower with four petals that can vary in color (white, pink, violet, bluish, purple, light red, luminous red, dark red, almost black). The pistil itself already bears a resemblance to the fruit capsule. The smooth, round, capsule-shaped fruit has a corona and ranges in size from 2 to 6 cm, depending upon the location, sort, variety, and subspecies. It can be rather slender in appearance or very obese-gibbous. One capsule may contain up to two thousand of the tiny, kidney-shaped seeds. The seeds can be creamy yellow, brown, blue-green, or black in color. In central Europe, the plant flowers in June and July. The fruits are mature by August at the latest. A white, milky sap (latex) flows throughout the plant.

The opium poppy is easily confused with the tulip poppy, *Papaver glaucum* Boiss. et Hausskn. [syn. *Papaver somniferum* var. *glaucum* (Boiss. et Hausskn.) O. Kuntze], which does not contain any psychoactive alkaloids. It is also occasionally confused with the Oriental poppy (see ***Papaver* spp.**).

The opium poppy (*Papaver somniferum*) is a popular ornamental.

A dark violet–blooming variety of the opium poppy (*Papaver somniferum* var. *nigrum*).

Psychoactive Material

- Fruit capsules (fructus papaveris immaturi, capita papaveris immaturi, pericarpium papaveris, opium capsules, poppy heads)
- Opium (latex)
- Seeds (semen papaveris, poppy seeds)
- Leaves (folia papaveris, poppy leaves)
- Roots

Preparation and Dosage

Opium Substitutes

(From Emboden 1979; Emboden 1986, 165*; Low 1990, 199*; Ludwig 1982, 134f.*; Millsbaugh 1974, 168*; Seefelder 1996; supplemented.)

The following plants and products are or have been used as opium substitutes:

Name	Stock Plant	Notes
Amapola	various	
Amapola silvestre (wild opium)	<i>Bernoullia flammea</i> Oliv.	seeds
Asafoetida	<i>Euphorbia</i> spp.	latex used as medicinal incense
Black tar	<i>Papaver somniferum</i>	raw opium that has been enriched with heroin through diacetylation
California buckeye (fruit shell)	<i>Aesculus californicus</i> (Hippocastanaceae)	1/8 of the potency of true opium
California poppy	<i>Eschscholzia californica</i>	tinctures
Chicalote	<i>Argemone mexicana</i>	latex
	<i>Argemone platyceras</i> Lk. et Otto	latex
Flanders/Corn poppy	<i>Papaver rhoeas</i> L. (see <i>Papaver</i> spp.) <i>Papaver somniferum</i> <i>Papaver bracteatum</i> (cf. <i>Papaver</i> spp.)	
Heroin		synthesized from morphine
Indian pipe	<i>Monotropa uniflora</i> L. (Monotropaceae)	dried herbage
Kratom	<i>Mitragyna speciosa</i>	leaves
Lactucarium (latex)	<i>Lactuca virosa</i> <i>Lactuca sativa</i> L. <i>Lactuca serriola</i> L. [syn. <i>Lactuca scariola</i> L.] <i>Lactuca quercina</i> L.	"Lactuca agrestis"
Morphine		synthesized from thebaine
Ohio buckeye	<i>Aesculus glabra</i> Willd.	hypnotic component aesculine
Pituri	<i>Duboisia hopwoodii</i>	nornicotine
Red buckeye	<i>Aesculus pavia</i> L.	hypnotic component aesculine

The leaves are collected during the period in which the fruit capsules are maturing, and are dried in the shade. They can be smoked alone or in **smoking blends**. A rather subtle opium effect will become apparent after consuming several joints. The dried leaves also can be brewed or boiled to make a tea.

The two most important products are the capsules (poppy heads) and the milky sap (latex). The plant contains the greatest amount of latex at the end of the flowering phase and while the fruit is first ripening. The latex level declines again as the capsule matures. For this reason, both the capsules and the latex are harvested shortly after the flowers have wilted. The capsules are broken off where they connect to the stalk and are used fresh or set out to dry. To dry, they should be spread out in a single layer (perhaps in the sun), as they may otherwise become moldy. The seeds continue to mature as the heads ripen and will be usable for sowing the following year (although they will not be as vital as those of a completely matured plant).

In Southeast Asia, the dried leaves of the kratom tree (*Mitragyna* sp.) are smoked as an opium substitute.

The arils of the Californian chestnut (*Aesculus californicus*) were formerly used as an opium substitute.

The latex, which oozes out of incisions made in the ripe capsules, dries to a brown mass known as raw opium. The highest yield can be obtained when

the capsule wall is cut with a small, special knife perpendicularly or obliquely to the longitudinal axis in the afternoon or evening hours between the 8th and the 10th day after the petals have fallen off. The white latex that emerges quickly hardens and turns brown. The sticky mass can be scraped off and collected the next day. Each capsule can yield app. 20–50 mg of raw opium. At least 20,000 poppy capsules are required to obtain 1 kg of opium. This corresponds to a poppy field approximately 400 m² in size. (Wagner 1985, 162*)

The brown raw opium is then pressed into balls or flat cakes that will slowly dry into a hard, crumbly, solid mass. The balls or cakes should be stored in a dark, airtight location.

Opium is consumed in numerous ways: orally (opium eating, opium drinking), rectally (as a suppository or **enema**), smoked, or, when sterilized and dissolved in a saline solution, injected. Opium has a very bitter and characteristic taste (earthy-herby) that, once tasted, will not be forgotten.

Opium usually contains about 10% **morphine** (although concentrations can vary considerably). A moderate psychoactive dosage consists of the amount of opium that contains about 30 mg of morphine, i.e., around 300 mg (0.3 g) of opium.

In Rome, “slumber drinks,” whose main ingredient was opium, were very popular during the time of the Caesars (cf. **soporific sponge**). These drinks were also known as “pain-relieving *catapotium*.” One recipe that has come down to us lists the following ingredients: *sili* (presumably *Chaerophyllum temulentum* L.²⁷⁴), *Acorus calamus*, *ruta* (the seeds of either *Ruta graveolens* or *Peganum harmala*), castoreum (a glandular secretion of beavers), *cinnamomum* (cinnamon, probably *Cinnamomum verum*), “tears of the poppy” (opium), panax root (undeterminable), *mandragora* (mandrake root, *Mandragora officinarum*), dried “apples” (presumably mandrake fruits), *Lolium temulentum*, and peppercorns (*Piper nigrum*; cf. **Piper spp.**). The ingredients were chopped; raisin wine (cf. *Vitis vinifera*), a very sweet and heavy **wine**, was dripped in; and the entire concoction was then rubbed into a mass (Schmitz 1981, 380; Seefelder 1996, 36). This mixture is strongly reminiscent of the later, opium-laced **soporific sponges** as well as **theriac**.

In China, aphrodisiac “spring agents” were mixed from opium, ginseng roots (*Panax ginseng*), and musk.

A normal and a mutated form of the poppy capsule (*Papaver somniferum*), known as hens and chicks.

There are a number of methods for preparing an opium or poppy tea. The freshly harvested capsules can be boiled in water for fifteen to twenty minutes (until they look like well-cooked vegetables). After the liquid has cooled, strain and drink. A clearly effective dosage consists of two handfuls of capsules per person. The tea tastes like artichoke water. The pods can be boiled together with the juice of half a lemon (which will apparently have a favorable effect upon the solubility of the alkaloids). The dried capsules can be prepared in a similar manner. These, however, are best when ground (e.g., in a coffee grinder), thoroughly moistened with ample lemon juice, and then boiled in water for a short time. Allow to sit for ten to thirty minutes, then strain and drink. This preparation has a slightly unpleasant taste.

The fresh, not fully ripened capsules can be made into an opium and rum pot. A container that can

be completely sealed is filled to the brim with opium capsules, after which rum is added until all the fruits are covered. To improve the bitter taste and to potentiate the effects, several female inflorescences of ***Cannabis indica*** or ***Cannabis sativa*** and flowers of ***Datura metel*** or another ***Datura*** species (***Datura spp.***) may be added. Seal the container and allow the mixture to sit in a relatively warm location for six months. Then pour off the liquid and vigorously squeeze the opium capsules in a strainer. As little as one shot glass of the liquid will induce clearly perceptible opium effects.

In ancient and late ancient times, opium was usually dissolved in wine (***Vitis vinifera***) for consumption (Krug 1993, 14*). Both the poppies and opium were also added to **beer** and **mead**. In his sixteenth-century herbal, Tabernaemontanus provided a recipe for barley mead whose active ingredient was *magsaamen* (= *Papaver somniferum*)! In India, a drink was made from **wine**, hemp seeds (***Cannabis indica***), poppy seeds, and opium (Duke 1973, 392). Opium is also an ingredient in bhang drinks (cf. ***Cannabis indica***). In ancient India, opium was swallowed mixed with *araq* (**alcohol**).

Opium is obtained by making incisions in the unripe fruit capsules of the opium poppy.

“In the name of Allah, the Compassionate, the Merciful. Praise be to Allah, whose might created opium and whose power allows it to heal diseases.”

ABU’L QÂSEM YAZDI

“TRACT FOR OPIUM SMOKERS” IN *VOM RAUSCH IM ORIENT UND OKZIDENT*
(GELPKE 1995, 51*)

“The Indians [= from India/Indonesia] use this afion or amfion [= opium], before the Javanese and Malay, also the Malabarans, Ceylonese, as well as the Moors from the Arabic Coast, as well as the Persians and Turks, usually to increase their sensual pleasures.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]
(1677, CH. 9, 29*)

Opium is one of the key ingredients in the **Oriental joy pills**. In the Orient, opium, either alone or mixed with such other substances as hashish (cf. ***Cannabis indica***), spices, ambergris, musk, olibanum (cf. ***Boswellia sacra***), and powdered pearls and precious stones (lapis lazuli, rubies, emeralds), was made into little balls—which were sometimes even gilded—that were swallowed or administered anally (Croutier 1989, 55). A ball 0.5 to 0.7 mm in diameter was the dosage for a rectal suppository, which was pushed as deeply into the rectum as possible. There it would quickly dissolve, so that the effects would become apparent after as little as ten to fifteen minutes. When administered in this manner, great care needed to be exercised with dosage.

The use of poppy capsules, poppy seeds, and opium as **incense** is very ancient. Opium and bitumen were inhaled as fumigants for treating toothaches (Schmitz 1981, 380). During the Middle Ages, a medicinal and psychoactive incense was made using opium, ***Mandragora officinarum***, and arsenic

(Seefeldler 1996, 200).

In China, smoking opium (*chandu*) is produced by dissolving raw opium in water and bringing it to a boil. The resulting mass, which remains moist, is then allowed to ferment for several days or weeks. Fermentation is complete when an elastic, kneadable mass results. The *chandu* is now ready for use. When used alone, *chandu* is not “smoked” but, rather, heated in the bowl of a pipe and vaporized. The vapor is inhaled deeply (Hogshire 1994, 86). A dosage for an opium pipe is a ball of opium the size of a pea. For noticeable visionary effects, several pipes should be smoked at short intervals. The desired effects typically begin after the fifth pipe.

In twentieth-century Europe, it was believed that opium was a Chinese invention as well as a typical Chinese vice. This led to the image of the Chinese opium den, which continues to etch its way into many people’s minds. (Magazine illustration, Germany, ca. 1920.)

In China and Laos, opium was and is mixed with tobacco (*Nicotiana tabacum*) for smoking (Geddes 1976, 202; Westermeyer 1982, 56). In Laos, the resinous remains (a condensate of the smoke or vapor) are scratched out of frequently used opium pipes, mixed with raw opium, and sold under the name *khe dya-feen*, “little opium tails” (Westermeyer 1982, 56). In Sumatra, opium is mixed with the leaves of *Ficus hypogaea* (von Reis Altschul 1975, 53*). In India, opium is smoked with hemp (*Cannabis indica*) or wild tobacco (*Nicotiana rustica*). In Morocco, dried poppy capsules are smoked to induce sleep (Vries 1984*), and sometimes chicken dung is added to smoking opium to extend it (Bourke 1996, 161*).

Laudanum is a tincture that was originally made of opium, saffron (*Crocus sativus*), cinnamon (*Cinnamomum verum*), clove powder (*Syzygium aromaticum*), and Spanish wine (cf. *Vitis vinifera*). It was later produced using just opium, saffron, and high-proof **alcohol** (70% ethanol) (*opii tinctura*). The pharmaceutically standardized tincture should contain about 1% morphine. The largest single therapeutic dose of opium tincture has been listed as 1.5 g (Wagner 1985, 165*).

Ritual Use

Opium was ingested in the Minoan culture to produce the ecstatic states needed for religious ceremonies (Kritikos 1960). On Crete, seeresses would give oracles and divine the future while under the influence of opium:

Around 1300–1250 B.C.E., in the land of the goddesses of health and healing [Crete], opium was

inhaled or used as an incense; this is evidenced by an ash heap and a tube-shaped vase with an opening on the side that was found during excavations . . . of the divine idols of Gazi. . . . The same effects were expected from opium smoke as were later of tobacco smoke: cheerfulness, forgetfulness, or ecstasy. (Faure 1990, 123*)

Demeter, the earth goddess and mother of grain, who was adorned in wreaths of poppies, was originally venerated on Minoan Crete. From there, her cult spread to the other Greek islands and the mainland. One of her sacred plants was the poppy (cf. **kykeon**):

The inebriating plant can be demonstrated to have been everywhere in the Demeter cult, which was not limited to Eleusis, but was found throughout the entire settlement area of Magna Graecia, for example, in Enna on Sicily, upon whose sacred mountain a Demeter shrine was enthroned in which quite riotous initiation mysteries were also held. Similar rites and festivals were associated with the goddesses corresponding to Demeter, for example, Cybele in Asia Minor and later Ceres in Rome, as the influence of the Greek cults of the gods manifested themselves in the new centers of power. (Seefelder 1987, 19)

In the ancient world, the poppy was regarded as the nourishment of divining dragons, as a mysterious magical plant, and as a sleeping and dreaming agent. According to Theocritus, the poppy grew from the tears that Aphrodite shed as she mourned her youthful lover Adonis. The plant was sacred to many gods and goddesses: The Great Mother goddess Cybele was depicted holding poppy capsules in her hand, as was Hypnos, the god of sleep, the “resolver of cares.” Hermes/ Mercury carried the plant in his left hand (cf. **moly**). Thanatos, or Death, was decorated with garlands of poppies, while Nyx, the goddess of the night, was portrayed with poppies wrapped around her temples.

In late antiquity, poppy seeds were an important ritual smoke offering to Hypnos, the god of sleep, at the Orphic mysteries (a cult of Dionysos). The poppy also symbolized the prophetic dream. Opium appears to have been used in the sacred **incense** of Epidauros and in preparations for inducing the healing and vision-giving temple sleep. Poppies and opium occupied a firm place in the religious healing cult of ancient times (Krug 1993*).

The opium poppy was also a magical and ritual plant among the Germanic tribes. It was sacred to the southern Germanic (Frankish) god Lollus. Ludwig Bechstein described an amazingly long-lived pagan custom in *Der Sagenschatz des Frankenlandes* [Treasury of Tales from Franconia] (1842):

One can still read of a purported pagan idol whose type and name belongs to Franconia quite alone. This is Lollus, Löllus, or Lullus, whose special veneration is said to have taken place on the Main River (near the later city of Schweinfurt). The bronze image of the idol, in the form of a youth with curly golden hair, was found. From around his neck, a garland of *magsamenköpfen* (poppy seed capsules) hung down over his chest. The right hand of the image is reaching for its mouth and grasping the tongue with its thumb and index finger; in the left it holds a cup of wine, in which stand ears of grain. Apart from a loincloth, the body was completely naked. The image is said to have stood in a sacred, enclosed grove by the banks of the Main, and the people are said to have brought it offerings of grapes and ears of grain at certain times. (In Hasenfratz 1992, 109f.*)

The name Loll(us) suggests the German word *lallen* (“slur”). In other words, Lollus was an oracular god who, so to speak, was inebriated from opium and/or **wine** and slurred his words,

perhaps “speaking in tongues.” The name Lull(us) is suggestive of *lullaby*, “to put to sleep.” After all, even in the present day one can sometimes hear of the rural custom of administering some poppy juice (raw opium) to restless or crying children to put them to sleep. Perhaps the image of Lollus represents an iconographic recipe: poppy heads (opium) are added to wine along with grain (perhaps ergot; cf. *Claviceps purpurea*). If a person partakes of this drink, then he or she will “speak in tongues.”²⁷⁵ Speaking in tongues, also known as glossalalia, is a type of unconscious flow of speech that has been known since ancient times and appears both in shamanic rituals and in religious cults (Goodman 1974).

Opium played a role in the meditations and mystical rituals of several Islamic sects and secret societies (Sufis, dervish orders). Because of the secrecy of their traditions, however, no details are known about such activities (Seefeldt 1996, 56).

Women in Oriental harems were quite fond of using opium and developed certain rituals in their dreary solitude:

The nights in the harem swelled with *keyf* (ultimate fulfillment) induced by opium pills and the drowsy peace of sated senses. The women indulged in drawn-out opium rituals, spending the evenings inhaling hookahs or eating opium, the “elixir of the night,” dreaming of faraway lands beyond the latticed windows. Mostly, they preferred eating rather than smoking opium because the effect lasted longer, dreams lingering until the rising of the sun. Amnesia followed; night after night of this induced chronic insomnia. The women began forgetting their distant homes, their lives before the seraglio. In order to remember, they told stories to one another. A thousand stories of faraway lands, stories told in the night. At first it was a thousand nights of stories, but even numbers brought bad luck, so they added one. (Croutier 1989, 56)

In Asia, opium was often used as an aphrodisiac in the erotic rituals of the Taoists and Tantrists (cf. *Camellia sinensis*, **Oriental joy pills**).

In Asia, opium is still used today by fakirs, yogis, sadhus, and shamans (cf. *Aconitum ferox*, *Cannabis indica*). The shamans of the Miao, a mountain tribe in northern Thailand, smoke opium before a healing ceremony in order to enter the trance that is needed to heal (Geddes 1976, 218f.). In this condition, they can travel to heaven and act on behalf of the ill person while they are there. In Thailand, opium is also used as an offering to sacred trees and rocks. According to a legend of the Akha tribe (Thailand), the first poppy plant arose from the heart of a beautiful woman who was killed because she had given herself in love to all the men (Anderson 1993, 117*).

Artifacts

A statue of Tammuz (sacred ram) standing on a plant that was found in Ur and dates to the time of the Sumerians may be one of the oldest poppy artifacts. The flowers depicted on the statue are strongly reminiscent of those of *Papaver somniferum* (Emboden 1995, 100*).

“I dropped some more laudanum into the glass. The night was a coat that provided warmth and security, I pulled it more closely around my body. Time became space, quite thick, like a small chamber that lay no longer inside the pyramid but far below it. Nothing occurred any more, only peaceful quiet, unassailable solitude.”

ERNST JÜNGER *ANNÄHERUNGEN* [APPROACHES] (1980, 203*)

Inebriated
Your sun is stronger than the
sun of Africa.
I have no parasol against it.
If it is true that I inebriate myself,
then it is more on you than on opium.

The poppy flower and the opium that is obtained from its fruit capsule have long been used as seductive names for sensuous perfumes. (Advertisement in a German magazine, ca. 1915)

One of the most spectacular artifacts of ancient times is the Cretan “poppy goddess.” This terra-cotta piece, which dates to the late Minoan period (1400–1100 B.C.E.) and was in the shrine at Gazi, depicts a half-naked woman with raised hands who looks, ecstatically enraptured, into the distance and wears a headband into which three incised opium capsules have been placed. This poppy goddess has been interpreted as a “personification of the goddess of sleep or of death” (Sakellarakis 1990, 91).

In ancient times, the poppy was sacred to the goddess Demeter. Opium, the juice it yields, was known as the tears of Demeter. (Greek relief of Demeter with poppy capsules, Corinth, first century)

A number of incised poppy capsules are depicted on the portal of the former Eleusinion in Athens. A golden tablet from Mycenae shows Demeter giving three poppy capsules to Perseus, the founder of the “mushroom city.” A Boeotian plate shows the same goddess with a torch, two ears of grain, and two opium capsules. A coin of King Pyrrhus of Epirus depicts the goddess as the earth mother with ears of grain and opium capsules. In a terra-cotta relief from the Campani Collection, Demeter peers ecstatically into the infinite while holding spikes of grain and incised opium capsules in her two snake-entwined hands. A bouquet of ears of grain and poppy flowers is clearly recognizable on the mystical chest (*kiste mystica*) of the Eleusinian cult. Poppies and poppy capsules were portrayed on numerous ancient coins dating from the seventh century B.C.E. on (Seefelder 1996, 15).

A set of Chinese utensils for smoking opium. (San Francisco, Chinatown, ca. 1920)

Ancient Egyptian frescoes frequently depict the poppy, usually in association with mandrake fruits (*Mandragora officinarum*) and lotus flowers (*Nymphaea caerulea*). While some authors interpret the poppy that is shown as the opium poppy (Emboden 1995*), others usually see it as the Flanders poppy (*Papaver rhoeas*; Germer 1985*) or, more rarely, as the Oriental poppy (*Papaver orientale*; cf. *Papaver spp.*) (Seefelder 1996, 13). The Egyptian Museum in Berlin houses a (New Kingdom) statue of Isis as a cobra, surrounded by ears of grain and opium capsules.

In Ayutthaya, the ancient Siamese capital, incised poppy capsules were carved into quartz crystals during the fourteenth century. In Thailand (Siam) and Burma, “opium weights”—which were used to weigh other things besides opium—were made of metal alloys fashioned into the shape of animals (ducks, lions, birds, elephants). Regarded as symbols of luck, they were used even as a means of payment (Braun 1983; Greifenstein n.d., 55ff.). Today, they can be found only in antique shops. In the nineteenth century, numerous miniatures (book paintings) with erotic contents were painted in Thailand. Many of these depicted the so-called opium dens. Not only was a great deal of opium smoked in such places, but all forms of erotic play were indulged in as well (Haack 1984, 55, 121).

Over the course of time, numerous devices for smoking as well as inhaling opium have been developed (Hartwich 1911*). An ivory opium pipe found at the shrine of Astarte (a predecessor of Aphrodite) at Kition (Cyprus) was dated to the twelfth century B.C.E. (Karageorghis 1976); it may be the oldest archaeological evidence of opium smoking in Europe. In Thailand, water pipes are usually fashioned from bamboo tubes and round gourds or coconut shells (*Cocos nucifera*). In China, water pipes were made from brass following the same principle. In China, Korea, and Japan, long, thin pipes with small bowls—which held exactly one dose of opium—were especially common. These pipes are frequently depicted in Chinese and Japanese art.

In the Middle Ages, opium was the subject of countless Arabic poems, stories, and novels (Gelpke 1995*). Many of the stories in *The Thousand and One Nights* either were inspired by opium or are direct descriptions of opium and its effects (Croutier 1989, 56).

In the nineteenth century, opium was both a very widespread people’s drug, e.g., as “poppy tea” in England (London et al. 1990), and the drug of choice for many artists (Berridge and Edwards 1987; Kramer 1981). It was supremely important to many poets and writers, who immortalized it in their works (Hayter 1988). Novalis (1772–1801) sang the praises of opium in his *Hymnen an die Nacht* (“Hymns to the Night”), Edgar Allan Poe (1809–1849) wrote most of his work while under the influence of opium, and E. T. A. Hoffmann (1776–1822) also knew of and utilized the effects of opium. Charles Baudelaire (1821–1867) wrote about opium in *The Artificial Paradise* (cf. *Cannabis indica*) and worked his experiences into the collection of poems known as *The Flowers of Evil*.

From a literary point of view, Thomas De Quincey (1785–1859) had an especially important influence and helped set the tone for later authors and imitators. His book *The Confessions of an English Opium-Eater* appeared in London in 1822 and has served as a kind of template for later literary treatments of the effects of opium and its associated dependency.

Descriptions of the joys and sorrow of opium use have made their way into many novels and literary reports of self-experiences (such as diaries) (Cobbe 1895; Cocteau 1948; Detzer 1988; Ekert-Rotholz 1995; Jones 1700; Magre 1929; Schweriner 1910). Even the Opium War has become the subject of literary treatments (e.g., Fraser 1987; Thompson 1984).

In the nineteenth century, opium was the subject of many paintings. Carl Spitzweg (1808–1885) produced a painting in 1856 (*Chibuk Smoking Oriental on a Divan*) that portrays Oriental opium smoking (Seefelder 1996, 61). In his oil painting *The Siesta* (1876), John Frederick Lewis depicts a beautiful woman in Oriental garb, inebriated on opium. His painting *In the Bey's Garden, Asia Minor* (1865) portrays a lady of the harem as she picks flowers next to a large opium poppy plant. Eugène Delacroix (1798–1863) used the same motif as the subject of his oil painting *Odalisque* (1845). The oil painting *Odalisque and Slave*, (1842), by Jean-Auguste-Dominique Ingres (1780–1867), shows a woman, inebriated on opium and almost naked, as her servant plays music for her. The eunuch in Jean-Léon Gérôme's (1824–1904) oil painting *The Guard of the Harem* (1859) is shown holding a meter-long opium pipe in his hand (Croutier 1989, 31, 45, 55f., 124). *The Lascar's Room* (1873), a picture by Gustave Doré (1832–1883), has become a kind of archetype for the opium dens. In the art nouveau movement, the opium poppy was often used as a floral element or was placed at the center of focus.

Many nineteenth-century Japanese woodcuts depict erotic scenes in which lovers are shown smoking opium from long, thin pipes before, during, or after coitus and while drinking tea (*Camellia sinensis*) (Marhenke and May 1995*). The effects of opium also inspired several colored woodcuts by Katsushika Hokusai (1760–1849) (e.g., *Smoking Ghost*).

During the Golden Twenties, opium smoking was often portrayed in pictures and illustrations of Berlin society and other circles in Germany and in San Francisco. The drawings of Paul Kamm, Max Brüning, and D. Fenneker were especially popular and were published in several magazines (*Berliner Leben*, *Der Junggeselle*, and others). These illustrations played a great role in helping to develop the stereotype of the opium den (cf. **morphine**). A German emergency currency note (value two marks) of the time shows a physician armed with an **enema** syringe as he utters the words “I am Doctor Eisenbarth, I cure the people with my own art. The night watchman Didelum, I gave him 10 pounds of opium.”

In several volumes of the popular children's book series Mecki, the hero, an anthropomorphic hedgehog, is shown smoking opium conspicuously often. His visions are shown in words and pictures (*Mecki among the Chinese*, 1955; *Mecki and Prince Aladdin*, 1958; *Mecki on the Moon*, 1959).

Opium is also a subject of several comic books (e.g., Hergé, *Tim and Struppi*, *The Blue Lotus*; Francis Leroi and Marcelino Truong, *The Bamboo Dragon*; Daniel Torres, *Opium*).

In music, the most conspicuous traces of opium can be found in Hector Berlioz's (1803–1869) *Symphonie Fantastique*, which serves as a kind of soundtrack for imagining an opium experience. Apart from this, almost nothing is known about the influence opium may have had on the music of the nineteenth century.

The cover of the album *Spitfire* (1976), by the psychedelic band Jefferson Starship, shows a Chinese woman riding on a dragon growing out of the smoke of her opium pipe. A short-lived British neopsychedelic band of the mid-1990s was called Opium Den. The California avant-garde metal band Tool titled its first album *Opiate* (BMG 1992).

In the 1960s, a film version of De Quincey's *The Confessions of an English Opium-Eater* was made in England.

Medicinal Use

As early as the time of the Middle Kingdom, the Egyptians were aware of the sleep-promoting effects of the poppy: “A remedy for too much crying in a child: Īspn [poppy] seeds; fly dung from the wall; is made to a paste, strained and drunk for four days. The crying will cease instantly” (Papyrus Ebers, 782, in Manniche 1989, 131*).

Such uses of the poppy and poppy juice have been preserved even into our day.²⁷⁶ In modern Egypt, opium is said to incite men to war and to love and to produce spectacular dreams. It is usually eaten mixed with spices, or it may be smoked. It is a popular aphrodisiac, especially in **Oriental joy pills**. The ancient Assyrians valued even the root as an aphrodisiac (Thompson 1949, 227*).

Opium was one of the most important medicines of the ancient Hippocratics, who used it to treat almost all illnesses, especially dropsy, diarrhea, uterine disorders, inflammations of rectal fistulas, hysterical complaints, and, of course, sleep disorders (Krug 1993*; Rätsch 1995a, 240–249*).

In Germanic folk medicine, poppy juice (opium) was taken internally to protect against nocturnal pests, bloodsucking vampires, nightmares, and nickel goblins (Höfler 1990, 94*). As late as the twentieth century, pharmacists were still making poppy pacifiers to calm small children (Nadler 1991, 58*). “The dried poppy leaves are only occasionally used as sedatives in folk medicine” (Heeger and Poethke 1947, 235).

Opium is used throughout the world as a folk medical treatment for coughing (cf. **codeine**) and diarrhea (Fleurentin and Pelt 1982, 92f.*; Paulus and Ding 1987, 394*).

The opium poppy was also an important ingredient in poplar ointment (unguentum populeum; cf. **witches’ ointments**). In her *Kräuterbuch* (“Herbal”), Elisabeth Blackwell wrote, “The leaves are taken among cooling ointments, they are considered useful for burned areas, inflammations, acute swelling, and come to the unguent, Popul.” (Heilmann 1984, 106*).

Opium is used in homeopathy (usually in higher potencies) according to the medical description for such conditions as agitated states (Bomhardt 1994):

“Opium will expand beyond all measures,
Stretch out the limitless,
Will deepen time, make rapture bottomless,
With dismal pleasures
Surfeit the soul to point of helplessness.”

CHARLES BAUDELAIRE “POISON”

“Baudelaire went to a baseball game and bought a hot dog and lit up a pipe of opium.”

RICHARD BRAUTIGAN (1968, 58*)

The art and literature of the Golden Twenties were shaped primarily by the use of opium and other psychoactive substances (morphine, cocaine). (Book title, 1920)

“To Hypnos—
a smoke offering of poppy seeds—
Hypnos, who rules the departed
and mortal humans without exception.
As well as the living beings,
as many as the broad earth nurtures—
For you alone govern them all,
you approach them all,
with softly wrought chains
binding the bodies, a remover of cares,
giving comfort to the exertions
and healing consolation to all afflictions.
You turn away the worries of death
and preserve the souls.”

ORPHIC HYMN

An opium smoker and paraphernalia:
A) spoons for cleaning the pipe bowl;
B) needle for picking up the opium;
C) longitudinal view of the pipe bowl. (From Hartwich 1911)

The resurrection of Kore (Persephone) in spring. The goddess of rebirth, shown here in Minoan garb, bears three poppy capsules in her hand. The two plants to the sides of the goddess may be mandrakes. A man (rhizotome) is shown serving as a birth-helper. (Seal, Boeotia, fourth century B.C.E.)

Hahnemann said that the effects of poppy juice are more difficult to evaluate than almost any other medicine. The effects of opium, as they are expressed in the insensibility of the nervous system, the suppression of bodily functions, the sleepy dazed feeling, the lack of pain, the inactivity, the general sluggishness, and the lack of vital reactions, represent the main indications for the homeopathic use of this drug. (Boericke 1992, 571*)

Constituents

The entire plant (except for the roots and flower petals) contains a latex that coagulates into opium. Opium contains some forty alkaloids, known collectively as **opium alkaloids**. Opium can contain 3 to 23% **morphine**, 0.1 to 2% **papaverine**, 0.1 to 4% **codeine**, 1 to 11% narcotine, and 0.1 to 4% thebaine; the other alkaloids are present in only trace amounts (Heeger and Poetke 1947). The composition of the alkaloids, and in particular the morphine concentration, can vary greatly. Modern techniques make it possible to determine quickly the morphine content of a particular sample (Hsu et al. 1983).

Callus tissue has been found to contain the alkaloids sanguinarine, norsanguinarine, dihydrosanguinarine, oxysanguinarine, protopine, crypto-pine, magnoflorine, and choline (Furuya et al. 1972).

The characteristic scent of opium is the result of some seventy substances, of which pyrazine appears to play an especially important role (Buchbauer et al. 1994).

Poppy seeds contain practically no or only slight traces of alkaloids (Norman 1991, 49*). They are rich in oil, carbohydrates, calcium, amino acids (apart from tryptophan), and proteins. However, **codeine** can be produced from the seeds through the process of digestion with pepsin.

Effects

In the older literature, the effects of opium are compared to those of wine (cf. *Vitis vinifera*) remarkably often (Schmitz 1981, 384). All opium users make a clear distinction between the effects of smoked opium and those of ingested opium (Cocteau 1957, 86). When eaten or drunk, opium usually has stronger physical effects that are perceived as a paradisiacal state and blissfulness:

Opium . . . loosens the soul from its entanglements with everyday things and the outer world. . . . Opium makes one silent and gentle. It inspires and gives flight to the imagination, including the erotic, increases sensitivity and the sense of tenderness, while simultaneously diminishing the need to move and be active, the need to communicate, ambition, sexual potency, emotions, and aggressiveness in general. (Gelpke 1995, 42*)

Descriptions of the effects of opium tend to place great emphasis on the cheerfulness that develops and the soothing effect this has upon the mood:

Opium . . . communicates serenity and equipoise to all the faculties, active or passive: and with respect to the temper and moral feelings in general, it gives simply that sort of vital warmth that is approved by the judgment, and that would probably always accompany a bodily constitution of primeval or antediluvian health. Thus, for instance, opium, like wine, gives an expansion to the heart and the benevolent affections: but then, with this remarkable difference, that in the sudden development of kindheartedness that accompanies inebriation, there is always more or less of a maudlin character, which exposes it to the contempt of the bystander. . . . But the expansion of the more benign feelings incident to opium is no febrile access but a healthy restoration to that state the mind would naturally recover upon the removal of any deep-seated irritation or pain that had disturbed and quarrelled with the impulses of a heart originally just and good. (De Quincey 1998, 41)

Although the contents of the visions may be shaped substantially by the individual, there are many reports of their vegetative nature: “Opium is the only vegetable substance that communicates the vegetable state to us. Through it, we get an idea of that other speed of plants” (Cocteau 1957, 91f.).

Opium users describe encounters with the soul of the plant, often in the form of an enchantingly beautiful and loving woman or goddess (Schwob 1969). Telepathic and clairvoyant states (e.g., seeing through walls) are often said to be characteristic of the effects of opium (Arsan 1974).

With irregular or occasional use of opium, the “ecstasy of the opiophage is strongly permeated with sexual conceptions, while parallel to this a strong arousal of the sexual apparatus [has been] observed” (Hirschfeld and Linsert 1930, 252*).

Opium’s effects are the result of a synergy between the primary alkaloids: The main active constituent, **morphine**, has sedative-hypnotic, narcotic, antitussive, respiratory-suppressing, and constipating effects. **Papaverine** increases the flow of blood into the corpus cavernosum of the penis; **codeine** is the best cough medicine known. The effects of opium are manifested quite rapidly and persist for six to eight hours at an almost constant strength.

Among the undesirable side effects of opium use are constipation, nausea, and vomiting (which usually occurs the following day). Metoclopramide (e.g., Paspertin) is an effective antidote for these symptoms. Chronic use can lead to dependency structures with “addictive behavior.” However, the so-called addictive potential of opium is not as great as portrayed by the sensationalistic press and uninformed politicians.

Commercial Forms and Regulations

The opium poppy is classified as a drug, trafficking in which is not allowed (German BtMG Anlage II). In Germany, only 10 m² of one’s own garden may be planted with opium poppies. Since 1984, only “detoxified” poppy capsules, from which the **morphine** has been removed, may be sold in German flower shops. In Denmark, poppy capsules have been illegal for decorative purposes since 1986 (Roth et al. 1994, 536*).

Opium is subject to numerous drug laws throughout the world and may be prescribed only on special forms. Opium is available for sale today only in India and Pakistan (see ***Cannabis indica***). It appears as though both the pharmaceutical lobby and organized criminals (Mafia) have a great interest in the difficulties associated with prescribing opium. As a result of these difficulties, the former is able to market its very expensive synthetic opiates and the latter are in a better position to sell illegal heroin.

The German band Die Toten Hosen seems not to be propagating a new religion with its album *Opium fürs Volk* (“Opium for the People”) but to be intent on distributing the narcotic. (CD cover, 1996, JKP Records.)

“Here it pleases me well, in
the circle of my light little poems
to now make mention of
the field poppy [*Papaver*], which the mother Latona
partook of in sorrow for the rape of her daughter, so it is said,
that longed-for forgetfulness frees the breast
of its cares.”

WALAHFRIED STRABO

IN HANS-DIETER STOFFLER’S *DER HORTULUS DES WALAHFRIED STRABO*, 1978, 16

“When I am under the spell of opium and the present has pulled away from my mental eye, then Ot-Chen and Chen-Hoa appear to me like two fairy-tale princesses, and it pleases me to rock in old, wonderful dreams. The smoking chamber Chen-Tas expands and becomes a magnificent marble palace in which I care for the divine peace as a sovereign prince. The tumult of Fouchow Road is submerged, and I feel myself surrounded by the majestic calm of the old forests in which my imperial ancestors once walked.”

CLAUDE FARRÈRE *OPIUM*

(1920, 151 f.)

“The Slovakian mother who wishes to heal her epileptic child walks fully disrobed three times around it without anyone seeing her, and uttering a spell, she shakes from a poppy head the seeds into her hand and shakes these around the child; then the poppy is swept together and, with the cut-off nails of the fingers of one hand and the toes of one foot, but crosswise, from the right hand and the left foot or vice versa, she stuffs these into an infernal tube and buries it where the sun will never shine.”

SIEGFRIED SELIGMANN

DIE MAGISCHEN HEIL- UND SCHUTZMITTEL AUS DER BELEBTEN NATUR [THE MAGICAL HEALING AND PROTECTIVE AGENTS FROM THE ANIMATED NATURE]

(1996, 219*)

Papaver spp.

Poppy Species

Family

Papaveraceae (Poppy Family)

The genus *Papaver*, to which ***Papaver somniferum*** belongs, has some seventy species, more than any other member of its family (Grey-Wilson 1995, 128*). While the genus *Papaver* is very rich in alkaloids, psychoactive species are few (Sariyar et al. 1994). Prickly poppy (***Argemone mexicana***), California poppy (***Eschscholzia californica***), and greater celandine (*Chelidonium majus* L.; cf. ***Mandragora officinarum***) are all closely related to *Papaver*.

***Papaver bracteatum* Lindl. [syn. *Papaver orientale* var. *bracteatum* Ledeb.]—Oriental poppy**

This Oriental poppy is endemic to the Caucasus, eastern Turkey (Anatolia), and northwestern Iran. Its taxonomic history is more than confusing. There are many similar types, i.e., ornamental forms that have been produced by breeding this species with other species (Grey-Wilson 1995, 138*). While this species does not contain any opium, **morphine**, or **codeine**, it does contain a large amount of thebaine ($C_{19}H_{21}NO_3$), the precursor substance for the pharmaceutical synthesis of morphine, codeine, and Nalaxon (Morton 1977, 124*). Some chemotypes exhibit concentrations of up to 98% thebaine in the total alkaloid content (Brenneisen and Borner 1985, 303; Kettenes et al. 1981). It is hoped that increasing the cultivation of *Papaver bracteatum* for pharmaceutical purposes will help limit the cultivation of ***Papaver somniferum*** (Kettenes-van de Bosch et al. 1981).

***Papaver orientale* L. [syn. *Papaver pollakii* A. Kerner]—Oriental poppy**

This Oriental poppy is endemic to Anatolia (Turkey) (Grey-Wilson 1995, 156*). It develops into an herbaceous perennial that can grow as tall as 80 cm. As a result of its distinctive beauty, it is an extremely popular garden ornamental. There are numerous cultivars of *Papaver orientale* (e.g., ‘Cedric’s Pink’, ‘Mrs. Perry’, ‘Goliath’) that are widespread ornamentals (Grey-Wilson 1995, 157*). The plant, which is occasionally characterized as psychoactive, is difficult to distinguish from *Papaver bracteatum* and is sometimes mistaken for ***Papaver somniferum***. It does not contain any significant **opium alkaloids**. The main alkaloid is oripavine or isothebaine, which is of interest only to the pharmaceutical industry (Brenneisen and Borner 1985, 303).

Papaver rhoeas* L. [syn. *Papaver strigosum* (Boenn.) Schur]—Flanders poppy, Shirley poppy** The annual Flanders poppy—also called the wild field poppy (or corn poppy, wild poppy, *pavot coquelicot*)—is a wild European and Mediterranean plant that is sometimes confused with ***Papaver somniferum. The variety *Papaver rhoeas* var. *oblongatum* occurs on Cyprus and is one of the sacred flowers of Aphrodite (Georgiades 1987, 2:64*; Rätsch 1995a, 245*).

The ancient Assyrians called the plant *ukushrim* or *irrû* and apparently used it in a manner similar to that of true opium (Thompson 1949, 225*). The plant was formerly used as a children’s sedative and sleeping agent (Schneider 1974, 3:26*). The psychoactive, opium-like effects that are sometimes attributed to the plant are doubtful.

The main alkaloid in the aboveground parts of *Papaver rhoeas* is (+)-rheadine (0.06%). The total

alkaloid content is 0.11 to 0.12% (Roth et al. 1994, 534*). Also present are the alkaloids allocryptopine, protopine, coulteropine, berberine, coptisine, sinactine, (+)-isocorydine, (+)-roemerine, and (+)-rhoeagenine (Kalav and Sariyar 1989). Several of these alkaloids are also present in *Eschscholzia californica*. In contrast, no **opium alkaloids** are present.

Many poppy species (*Papaver* spp.) have extremely colorful flowers.

The Oriental poppy (*Papaver orientale*).

Thebaine

Oripavine

In the wild, the Flanders poppy (*Papaver rhoeas*) can cover entire fields.

This variety of Flanders poppy (*Papaver rhoeas* var. *oblongatum*) is found in Cyprus. (Wild plant, photographed in Cyprus)

The yellow horned poppy (*Glaucium flavum*) is indigenous to the Mediterranean region. (Wild plant, photographed on Naxos, Greece)

The Oriental poppy (*Papaver orientale* var. *bracteatum*), cultivated in many gardens as an ornamental, also contains opiates. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The wild Flanders poppy (*Papaver rhoeas*) has only weak sedative properties. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

***Glaucium flavum* Crantz [syn. *Papaver cornutum* nom. nud., *Glaucium luteum* Scop.]—yellow horned poppy**

The horned poppy is indigenous to the Mediterranean region (Grey-Wilson 1995, 41*). Dioscorides described it under the name *mekon keratitis*:

After eating or drinking this mekon keratitis, the same manifestations appear as with poppy juice [= opium; cf. *Papaver somniferum*]. One also counters it with the same agents. The fruit is collected in the summer, when it is dry. The decoction of the root is taken with **wine** [see *Vitis*

vinifera], it helps against dysentery. (Dioscorides 4.68)

The plant was formerly used in folk medicine together with **honey** to treat ulcers (Grey-Wilson 1995, 36*). The horned poppy is sometimes characterized as psychoactive. The plant does contain glaucine, which has the same effects as **codeine** (Roth et al. 1994, 374*).

Passiflora spp.

Passionflowers, Passion Fruits

Family

Passifloraceae (Passionflower Family); Subfamily Passifloreae

Forms and Subspecies

The genus *Passiflora* encompasses some four hundred, but no more than five hundred, species (Meier et al. 1994, 34; Vanderplank 1991). The following species and subspecies have ethnopharmacological significance:

Passiflora caerulea L. cv. Constance Elliot—blue crowned passionflower

Passiflora edulis Sims var. *edulis* Sims—passion fruit, maracuja, purple passion fruit, purpurgranadille

Passiflora edulis Sims var. *flavicarpa* Degener—granadilla, granadille, yellow passion fruit

Passiflora foetida L.—**amapola**, t'usku', tsyquitieco, pok'pok'

Passiflora incarnata L. [syn. *Granadilla incarnata* Medik., *Grenadilla incarnata* Medik., *Passiflora edulis* Sims var. *kerii* Masters, *Passiflora kerii* Spreng.]—true passionflower, passionflower, wild passion vine, maypop

Passiflora involucrata (Masters) A. Gentry [syn. *Passiflora quadriglandulosa* var. *involucrata* (Masters) Killip, *Passiflora vitifolia* var. *involucrata* Masters]—chontay huasca

Passiflora jorullensis H.B.K.—coanenepilli

Passiflora laurifolia L.

Passiflora quadrangularis L. [syn. *Passiflora macrocarpa* Masters]—tumbo, bate

Passiflora rubra L.—liane zombie (cf. **zombie poison**)

History

Most passionflowers are tropical plants native to Central and South America. In pre-Columbian times, many Indians used some species as a source of food (twelve to sixty species are edible) and as sedatives and medicines. When Spanish missionaries invaded the New World, they took *Passiflora* as a sign from God, seeing the unusual flowers as a symbol of the mystery and the passion of their savior. Among those who played an important role in promoting this view were the cloister student and artist Jacomo Bosio, the Jesuit J. B. Ferrari in Siena, Father Simone Parlasca, and Pope Paul V (Klock 1996, 13).

The color of the enchanting flower of *Passiflora amethystina* Mikan led to its being named after the amethyst, the sacred stone of Dionysos. (Photographed in Japan)

The English herbalist John Gerard may have been the first to report on the mysterious new plant (Meier 1995b, 116; Rätsch 1991a, 203*). In the eighteenth and nineteenth centuries, botanists helped spread many passionflower species across much of the globe (Meier 1995b, 115). Most species were described in the nineteenth century (Schneider 1974, 3:31*).

Today, passion fruits are regarded as one of the most prized exotic fruits in the world (Mollenhauer 1962). The genus is still awaiting comprehensive ethnopharmacological research, particularly with regard to its psychoactive usefulness (cf. Meier 1995b, 119).

Distribution

Almost all species of the genus *Passiflora* are indigenous to the tropical rain forests of the Americas, especially South America. *Passiflora incarnata* was originally found in the Caribbean region as well as in southeastern North America (Meier et al. 1994, 35). Only a few cold-resistant species (*P. caerulea* L., *P. incarnata* L., *P. lutea* L.) can survive outdoors in temperate zones. *P. caerulea* now grows wild in southern Europe (Italy and Greece) (Meier 1995b). Passion fruits are grown in Portugal and Spain. Many *Passiflora* species, such as the beautiful *P. amethystina*, have become established in Southeast Asia as ornamentals.

Cultivation

The passionflowers are becoming increasingly important as houseplants and ornamentals. All species can be grown from seed (see Klock 1996), which can be sown in very loose, airy potting soil throughout the year; in central Europe, however, the period from November to April is the best time for planting (time to germination: two to six weeks at 20 to 25°C). As houseplants, passion-flowers should be well watered between April and September and given fertilizer every fourteen days. In spring, the shoots should be cut back to a length of 10 to 15 cm (or pot up as needed).

The grenadilla, or passion fruit (*Passiflora edulis*).

One of the few passionflowers that can be cultivated in Europe: *Passiflora caerulea*. (Wild plant, photographed in Cyprus)

The juicy and vitamin-rich fruit of the maracuja (*Passiflora edulis*). In Brazil, the juice pressed from this fruit is used in the production of the psychoactive *vinho do jurema*.

Passiflora rosea, known as tumbo, photographed in the Andes of northern Peru.

Passiflora aff. *foetida* is commonly called *amapola*, “opium.” (Photographed at Tikal, Guatemala)

One of the many as yet undescribed tropical *Passiflora* species in the Amazonian rain forests.

Appearance

All *Passiflora* species are evergreen climbing vines or bushes with many-lobed leaves and unmistakable, bizarre flowers with three styles, some seventy-two filaments, and five anthers. The fruits are usually oval and, in many species, edible.

Psychoactive Material

—Passionflower herbage (leaves and stalks; *passiflorae herba*, *herba passiflorae*) from the stock plant *Passiflora incarnata* L.; *Passiflora caerulea* L. was formerly used as well but is now regarded as a counterfeit of the drug (Meier 1995b)

—Roots of *Passiflora involucrata*

—Fruit juice of *Passiflora edulis*

—Calyxes of *Passiflora foetida*

Preparation and Dosage

To make calmativ teas, the dried herbage of *Passiflora incarnata* is best combined with valerian roots (*Valeriana officinalis*), hop cones (*Humulus lupulus*), and St. John's wort (*Hypericum perforatum* L.) or with valerian roots, balm (*Melissa officinalis* L.), anise (*Pimpinella anisum* L.), and mint (*Mentha* sp.) (Meier 1995b, 124 f.). The recommended daily dosage of the dried herbage of *Passiflora incarnata* is 4 to 8 g; as a tea, 2.5 g per cup, taken three or four times daily (Meier 1995b, 122; Wichtl 1989). Tea can also be prepared using 15 g of passionflower herbage and 150 g of boiling water. To date, no interactions with other substances (negative synergies) are known (Meier et al. 1994, 46).

The herbage can be smoked alone or in **smoking blends** (overdoses are unknown).

In Mexico, the flowers of *Passiflora foetida* are known as **amapola**, “opium,” and are made into a tea that is used as an opium substitute (Argueta V. et al. 1994, 119*).

The roots of *Passiflora involucrata* are suitable for use in preparing **ayahuasca analogs**.

Passion-fruit juice is used together with *Mimosa tenuiflora* and probably *Pithecellobium* spp. to produce the ayahuasca-like drink known as *jurema*. Further study of this use is needed.

Ritual Use

In the region of Iquitos, the roots of the Amazonian species *Passiflora involucrata* are used as an **ayahuasca** additive “so that the visions become more intense” (Rob Montgomery, pers. comm.). Maracuja juice (*P. edulis* var. *edulis*) plays an imprecisely understood role in the little-studied Brazilian *jurema* cult, whose practices are similar to those surrounding ayahuasca.

Artifacts

The Brazilian *jurema* cult may possess artifacts that make reference to the passionflower.

Medicinal Use

In Amazonia, a tea of maracuja leaves (*Passiflora edulis*) is drunk as a sedative (Duke and Vasquez 1994, 130*). A tea made from the leaves of tumbo (*Passiflora quadrangularis*) is used as a narcotic and sedative. The Kubeo Indians say that a decoction of the leaves of *Passiflora laurifolia* has sleep-inducing effects (Schultes and Raffauf 1986, 269*). The Indians of the Caribbean and Central America also know of *Passiflora* species that they use as sedatives and sleeping agents.

In European folk medicine and phytotherapy, *Passiflora incarnata* is taken as a tea or as part of a combination preparation for states of nervous unrest (Meier 1995b, 122; Wichtl 1989). In homeopathy, a mother tincture (*Passiflora incarnata* hom. *HAB1*, *PFX*, *HPUS88*) is used for such purposes as calming and to promote sleep (Meier et al. 1995, 47).

Constituents

It was once thought that harmane alkaloids were the active constituents in *Passiflora incarnata* and other species (Löhdefink and Kating 1974; cf. **β -carbolines**, **harmine** and **harmaline**).²⁷ One can sometimes read in the literature that 100 g of dried *Passiflora incarnata* herbage contains approximately 10 mg of harmane alkaloids, but this amount is highly questionable (Meier 1995b, 120). It is possible that cinnamic acid derivatives and **coumarins** were mistaken for harmanes during the analysis (Meier et al. 1994, 38). Maltol (a ypyrone), once thought to be the main active constituent, is actually a by-product produced when the raw plant material is heated and cannot be responsible for the effects. The most recent research indicates that the C-glycosylflavones apigenine and luteoline are the main active constituents (Meier 1995b, 120; Meier 1995a; Meier et al. 1994).

The following compounds are present in *Passiflora incarnata*: vicenine-2, isoorientine-2''-O-glucoside, schaftoside, isoschaftoside, isoorientine, isovitexine-2''-O-glucoside, isovitexine, and swertisine. Orientine and vitexine are present only in trace amounts. Saponarine, which was thought to be a component as well, is absent (Meier 1995a). *Passiflora jorullensis* contains passicol, harmol, harmane, harmine, harmalol, and harmaline (Emboden 1979, 187*).

The mucilaginous pulp (mesocarp) of passion fruit (*Passiflora edulis*) consists primarily of 2 to 4% citric acid, relatively little ascorbic acid (only 20 to 50 mg per 100 g of pulp), carotenoids (0.5 to 2.5 mg per 100 g of pulp), starch, and more than two hundred aromatic substances (Meier 1995b, 116 ff.). There is no evidence indicating whether harmanes occur in the fruit.

The roots of *Passiflora involucrata* appear to be rich in **β -carbolines** with MAO-inhibiting properties. The chemistry of the flowers of *Passiflora foetida* has not yet been clarified (Argueta V. et al. 1994, 119*).

Effects

Maracuja juice increases the efficacy of *vinho do jurema* (see *Mimosa tenuiflora*), as it allegedly possesses MAO-inhibiting properties (cf. **ayahuasca analogs**).

Animal experiments have demonstrated that an aqueous extract of *Passiflora incarnata* both deepens and prolongs sleep. The neuropharmacological effects have been compared to those of *Cannabis sativa* (Speroni and Minghetti 1988). Although calmativ effects are often mentioned, there is no pharmacological evidence to support them. The effects appear to be more anxiolytic (Meier 1995b, 123).

When smoked, the herbage of *Passiflora incarnata* induces a marijuana-like “high” (Brown and Malone 1978, 11*). The effects are very subtle. It has been claimed that smoking *Passiflora* inhibits

MAO, so that orally administered **N,N-DMT** can be effective.

Smoking *Passiflora jorullensis* induces a state of euphoria that is said to be like that produced by ***Cannabis sativa*** (Emboden 1979, 187*). Whether the *Passiflora rubra* of the Dominican Republic is able to produce a zombielike state is unknown.

Commercial Forms and Regulations

The seeds of various species can be obtained in nurseries and flower shops (the blue crowned passionflower is frequently sold under the name *Passiflora caerulea*). Passion fruits are now found on fruit stands in much of the world. Tea mixtures and herbal tablets based upon *Passiflora incarnata* are available without restriction and can be purchased in pharmacies, herb shops, health food stores, et cetera.

The bizarre blossom of the passionflower (*Passiflora incarnata*) has long stimulated the human imagination. (Drawing by Sebastian Rätsch)

Luteoline

Apigenine

“This plant, which the Spaniards in the West Indies named *Granadilla* because of its similarity to the fruit of the pomegranate, is the same that the Virginians called *Maracoc*. The Spanish Friars first called it *Flos Passionis*, passion flower, because of an imagined conception, and reported that it was epitome of the passion story of Our Savior. The fruit, which thrives in the West Indies, is large and red and reminiscent of a pomegranate. But the husk is thinner, and although the flesh of the fruit is without taste, the juice is sour. The Indians as well as the Spaniards open the fruit in the manner of eggs and eagerly suck out the juice. The fruit is a mild laxative.”

JOHN GERARD *THE HERBALL* (1591)

Paullinia cupana Kunth ex H. B. K.

Guaraná Vine

Family

Sapindaceae (Soapberry Family); Subfamily Sapindoideae, Paullinieae Tribe

The young guaraná vine (*Paullinia cupana*) in the Amazonian rain forest.

Forms and Subspecies

The wild form is *Paullinia cupana* H.B.K. var. *typica* (Seitz 1994, 53). The cultivated form, *Paullinia cupana* H.B.K. ssp. [or var.] *sorbilis* (Mart.) Ducke, is often regarded as a subspecies or variety (Erickson et al. 1984, 273).

Synonyms

Paullinia cupana H.B.K.

Paullinia sorbilis Mart.

Paullinia sorbilis (L.) Mart.

Folk Names

Brasilianischer kakaobaum, Brazilian cocoa, camú-camu (Shipibo), cipo-guaraná, cupana, cupána, dschungeltee, guarana, guaraná, guaraña, guaranália, guaranáránke, guaranastrauch, guaranáuva, guaraná vine, guaranazeiro, naraná, naranajeiro, uabano, uaraná, uraná

History

The use of guaraná—which the Indians regard as a gift from the gods—is said to have been discovered by the Amazonian Satéré-Mawé tribe and to have a tradition dating back thousands of years (Carneiro M. 1989, 60f.*; Pavia 1995, 137*; Straten 1996, 62). A drink made of water and the

ground fruits of the guaraná vine was originally consumed by shamans so that they could acquire secret knowledge. Many Indians use guaraná drinks, which they call “elixirs of eternal youth,” as a hunting drug. The Amazonian Indians have known of the plant and its stimulating products for centuries.

In Europe, however, reports of the jungle vine did not appear until the mid-seventeenth century (Straten 1996, 60 f.). The plant became more well known through Alexander von Humboldt, who became acquainted with both the plant and the drink it yields during his travels from the Orinoco to the Rio Negro. The high caffeine content was detected in 1840 and has been confirmed numerous times (Berrédo Carneiro 1931). Today, guaraná is increasingly being exported to Europe, both as an agent of pleasure and for pharmaceutical processing (Schröder 1991, 108 f.*). Guaraná has become a popular coffee substitute (see *Coffea arabica*), and is now also known as a “techno drug” (cf. **herbal ecstasy**). It has also played a significant role in the development of **energy drinks**.

Around the world, stimulating drinks are now manufactured from guaraná seeds (*Paullinia cupana*).

Distribution

The natural range is in central Amazonia from the Rio Madeira to the Rio Tapajos and on the Rio Negro and the Orinoco. Wild stands occur only in these areas. Amazingly, these regions are also the only places where the plant has been successfully cultivated (Schöder 1991, 109*).

Cultivation

Guaraná can be grown either from viable seeds or from cuttings taken from prunings. The method of pollination, which has a very strong influence on the yield, was long unknown. It now appears that hundreds of insects are responsible (Esteves Gondim 1984).

Guaraná has now been cultivated successfully for years in the central Amazon region (Schultes 1979, 259). The primary area of cultivation, consisting of some fifteen thousand acres (six thousand hectares), is near Manaus (Erickson et al. 1984). One plant produces about 1 kg of seeds per harvest. It is astonishing that guaraná cultivation has not been commercially successful in any other part of the world. Apart from the Central Amazon region, the plant has been cultivated only in Sri Lanka, Uruguay, and Central America (Seitz 1994, 54).

Appearance

This woody, vinelike climber can grow over 12 meters long. It climbs up supporting trees by means of its spreading branches. The perennial underwood plant has a smooth, vertical stem and large, long leaves consisting of five ovate-oblong individual leaves. The white, scentless flowers are attached to short stalks and grow from the branch axis in bushy panicles. The three-chambered ovary usually contains a single developed seed that is about 1 cm in size, round, and embedded in a thin, dark brown seed coat. The seed is filled with two starchy cotyledons (Tschirch 1918). The flowers begin to

blossom when the rainy period ends. The fruits (guaraná clusters) mature some three months later (Seitz 1994, 54).

“The first description of guaraná was written in the year 1669 by the Jesuit missionary J. F. Betendorf, who spoke about the diuretic effects of the drink and its use for headaches, fever, and cramps. In the eighteenth century, interest in guaraná was the reason for searching for a trade route across central Brazil, from Mato Grosso across the source rivers of the Rio Tapajós to the Rio Maués. The merchants needed 9–10 months to journey back and forth by boat, which had to be pulled over land in some places, but the effort was obviously worthwhile. The Maué intensified the cultivation to meet the demand, and the Brazilians themselves built plantations.”

BRUNO WOLTERS

DROGEN, PFEILGIFT UND INDIANERMEDIZIN [DRUGS, ARROW POISONS, AND INDIAN MEDICINE] (1994, 154 f.*)

The guaraná vine can be easily confused with other species of the genus *Paullinia* (see ***Paullinia*** spp.).

Psychoactive Material

—Seeds

—Pasta guarana (pasta guaraná, pasta seminum paullinae, massa guaranae, guarana paste, guaraná paste)

Preparation and Dosage

The traditional method of preparing the seeds is to manufacture guaraná breads (also known as *bastão*):

The fruits are placed in water, allowing the outer hull to swell so that it can be more easily removed. The seeds are then lightly roasted so that the starch adheres the cotyledons together. The seeds that have been prepared in this way are then ground with the shells or pounded with a pestle. Mixed with manioc starch flour [*Manihot esculenta* Crantz] and perhaps also cacao [***Theobroma cacao***], it is kneaded with water to produce a doughy paste. This guarana paste, whose caffeine content can vary considerably depending upon the amounts of the admixtures, is dried in the sun or over a low fire for the domestic market in the form of rolls about a foot long and the width of a wrist. (Schröder 1991, 110*)

These loaves are easily transported. The Amazonian Indians use the ossified tongue (hyoid bone) of an Amazonian fish called *pirarucú* (*Arapaima gigas* Cuvier) to rasp off the amount they wish to use and drink the powder suspended in water.

For pharmaceutical and industrial processing, guaraná is prepared by mixing the dried, shelled, more or less strongly roasted and powdered seeds with water to produce a paste (Seitz 1994, 54).

One-half teaspoon of the prepared powder is often given as an average daily dosage. One gram of pharmaceutical guaraná paste represents a single dose (Seitz 1994, 56).

Ritual Use

According to the mythology of the Brazilian Tupí Indians, the guaraná plant had a shamanic origin. The shamaness Omniamasabé, who possessed a very comprehensive knowledge of the “real world that is hidden to humans,” was impregnated in the forest solitude by the snake god Mboy. Shortly thereafter, she gave birth to a son. Her jealous brothers enlisted a hostile shaman to kill the son. This shaman drank **ayahuasca** and transformed himself into an ara parrot. In this form, he searched out and killed the boy. As the tears of the mother poured over the body, it was transformed into the guaraná vine. Since that time, shamans eat the guaraná fruits so that they may be initiated into the

secrets of the knowledgeable shamaness Omniamasabé.

Most Amazonian Indians, including the Mundurucú, tell some version of the following origin myth:

A son born to a couple of the Maué tribe, so the story goes, was an exceptional child who spread happiness and good will wherever he went, a veritable angel. A jealous evil spirit resolved to eliminate the youngster. Despite close supervision by the tribe the child slipped out alone one day to collect fruit in the forest. The evil spirit, Iurupari, transformed himself into a snake that attacked and killed the child. When rescuers found him he was lying facing the sky, bearing a benevolent expression in death, eyes opened wide.

Soon thereafter a shattering bolt of lightning shook the earth, halting the lamentations of the assembled tribe. Enter the mother who gave a lengthy discourse on how she had received divine instructions to bury the excised eyes of the child. No one wanted to accept the gruesome task so a lottery was conducted, and the interment performed by the loser. Later a shrubby plant sprouted from the buried eyes. This was the first guaraná and its origin accounts for ripe fruit having the appearance of living eyes. (In Erickson et al. 1984, 280)

For the Indians, this story also explains the plant's abilities to help a person stay awake. The fruit's eyelike shape is interpreted as a kind of signature for mystical vision. Because of this, the plant has a certain significance as a shamanic plant and is ingested when diagnosing diseases (cf. Karlinger 1983, 128–32). For this reason, the Indians do not pick the guaraná berries until the first “eye” has opened (Seitz 1994, 54). Some Amazonian Indians also use guaraná for ritual fasts (Straten 1996, 143).

In recent years, guaraná has acquired a reputation in Europe as a “techno drug” (Walder 1995). Using copious amounts of guaraná makes it easier to dance through the night at techno parties, which have a distinct ritual character. In certain circles, guaraná is also used as a substitute for **cocaine**.

Artifacts

The Indians also use the guaraná paste to manufacture decorative articles. They shape it into figures of humans, animals, and plants, and even into relief pictures with depictions of village life. These sculptures are often decorated with colors that are produced from indigenous natural dyes [e.g., *Bixa orellana*] and minerals. The traditional value of these objects far exceeds their simple beauty. Because they are made from one of the Indians' most valuable medicines and foods, they acquire a spiritual, almost religious significance. (Straten 1996, 64)

Medicinal Use

Many Indians of the Amazon esteem guaraná as an aphrodisiac. In the region of the Peruvian Amazon, the subspecies *sorbilis* especially is regarded as an aphrodisiac (Rutter 1990*). Apart from this, the plant is used primarily as a remedy for intestinal diseases (Schröder 1991, 110*). Guaraná also finds use in folk medicine for treating menstrual pains, difficulties with digestion, conditions of weakness, diarrhea, and fever (Seitz 1994, 56).

In phytotherapy and alternative medicine, guaraná has been found to be effective primarily as an antidepressant, to treat “coffee addiction,” for migraines, and for chronic fatigue syndrome (CFS) (Straten 1996, 70, 155).

In homeopathy, a tincture of pure seeds, *Guarana hom. HAB34* or *Paullinia sorbilis hom. HPUS88*, is used to treat headaches and other afflictions (Schneider 1974, 3:33*; Seitz 1994, 57).

Constituents

Guaraná is the strongest of all **caffeine** drugs. It is some three times stronger than coffee (*Coffea arabica*) and eight times as potent as maté (*Ilex paraguariensis*).

The seeds contain approximately 5% caffeine, 3% fatty oil, 9% tannic acids, 8% resin, 10% starch, 50% fiber, minerals (potassium, sodium, magnesium, calcium), some protein, sugar, and water. The oil is sometimes attributed with “hallucinogenic” properties, for example, in the package inserts of commercial guaraná products that are sold on the techno scene.

The leaves contain 0.38% caffeine and up to 1.2% theobromine (cf. *Theobroma cacao*). All the other parts of the plant also contain traces of caffeine and other purines (Seitz 1994, 54).

The active constituents and concentrations change as the seeds are made into the paste. Cyanogenic glycosides are presumably produced during this process. The paste contains 3.6 to 5.8% caffeine, 0.03 to 0.17% theobromine, 0.02 to 0.06% theophylline, up to 12% tanning agents (proanthocyanidin, [+]-catechin, [–]-epicatechin), saponins, seed fat, minerals, and water. A portion of the caffeine occurs in a complex bond with the tanning agents. This complex was formerly referred to as guaranine (Seitz 1994, 55).

“On this occasion, I noticed that a missionary seldom undertakes a journey without taking along the prepared seeds of the cupana vine. This preparation requires great care. The Indians grind the seeds, mix them with manioc flour, wrap the mass in banana leaves, and allow this to ferment in the water until the mass has turned saffron yellow. This dough is dried in the sun, and after water has been poured over it, it is consumed in the morning instead of tea. The drink is bitter and strengthens the stomach, but I found the taste to be very unpleasant.”

ALEXANDER VON HUMBOLDT

REISE IN DIE AEQUINOCTIAL-GEENDEN DES NEUEN CONTINENTS [TRAVELS TO THE EQUINOCTIAL REGIONS OF THE NEW CONTINENT] (STUTTGART 1862, VOL. 5, P. 113)

To the Indians, the medicinal value of this plant [*Paullinia cupana*] and its ability to stimulate the brain and keep the body active and vital is nothing short of a miracle.”

MICHAEL VAN STRATEN *GUARANA*
(1996, 62)

Effects

Guaraná has potent stimulating effects due to the **caffeine** and the “guaranine.” However, the overall effects are distinctly different from those produced by coffee and other purine drugs. It is thought that the long duration of the stimulant effects (in contrast to the relatively short duration of the effects of coffee) is due to the complex binding of caffeine to the tanning agents. Guaraná also has an inhibiting effect upon sensations of hunger and thirst. It has been characterized as “a harmless, mild antidepressant” (Straten 1996, 11). There have been many reports of aphrodisiac effects (Miller 1988, 57*; Straten 1996, 61). Curiously, some people do not experience any effects or paradoxically become tired, even with high dosages.

Commercial Forms and Regulations

To protect its own economy and its monopoly status, Brazil does not allow the export of viable seeds (Schröder 1991, 109*). Apart from this, guaraná is subject to the various laws regulating foods.

Guaraná is the main ingredient in numerous manufactured products that are freely available (supermarkets, body shops, health food stores, gas stations, et cetera). Buzz Gum, a sugar-free chewing gum made with guaraná extract, is sold in the United States. Gumdrops containing guaraná extract as well as **caffeine** and taurine are sold in Switzerland. In Germany, tea bags containing guaraná and maté (*Ilex paraguariensis*) have recently become available in stores.

Paullinia spp.

Paullinia Species

Family

Sapindaceae (Soapberry Family); Subfamily Sapindoideae, Paullinieae Tribe

Several species of the genus *Paullinia* occur in the tropics of Central and South America. The genus encompasses some 150 to 200 species in all, some of which contain large quantities of **caffeine** (see ***Paullinia cupana***), while others (e.g., *Paullinia curruru* L.) have very toxic properties and have been used as fish poisons and to produce arrow poisons with curare-like effects (Blohm 1962, 67*; Millspaugh 1974, 167*; Schultes 1942, 314). Species in the very closely related genus *Serjania* also contain powerful fish poisons (Schultes 1942, 314).

Paullinia australis St.-Hil.

Indigenous to the forests of Brazil, this species is said to produce a toxic or psychoactive **honey** (Millspaugh 1974, 167*). The leaves and roots of Argentinean plants contain an alkaloid with sedative and narcotic properties (Schultes 1942, 314).

Paullinia carpopodea Camb.

In Brazil, the leaves of this species are used in folk medicine to treat pain. They may contain a narcotic or analgesic principle.

Paullinia emetica Schultes

The Karijona Indians of Colombia used a tea made from the leaves of this species medicinally and ritually as a potent emetic agent (Schultes 1977b, 119*). At the present, we can only conjecture as to whether the species also contains **caffeine** or has psychoactive properties.

Paullinia pinnata L. [syn. *Paullinia angusta* N.E. Br., *Paullinia nitida* Steud., *Paullinia pinnata* DC., *Serjania curassavica* Radlk.]—timbosipo, cururu apé, guaratimbo

In Amazonia, this evergreen climber is known as *sapo huasca* (*sapo* means “toad”!) and is purportedly used as an inebriant. The root cortex is said to contain a toxin (“timboine” or “timbol”) with narcotic properties (Duke and Vasquez 1994, 132*; Millspaugh 1974, 167*; Schultes 1942, 314).

In Paraguay, where the plant is known as *erejna*, the Ayoré Indians use *Paullinia pinnata* L. to treat rheumatism (Schmeda-Hirschmann 1993, 107*). The vine is called *bejuco de zarcillo* (“earring vine”) in Venezuela. The stalks and roots were used as fish poison and to commit suicide (Blohm 1962, 67*).

Few chemical studies of the plant have been conducted to date.

Paullinia yoco Schultes et Killip ex Schultes—yoco

This woody vine, which can grow to a very long length and can have a diameter of up to 12 cm, is found in southern Colombia (Putumayo) and Ecuador, where it is known as *yoco* or *yoko* (Schultes 1942). The Indians make a distinction among a number of forms: *yoco blanco*, *yoco colorado*, *huarmy yoco*, *taruco yoco*, *yagé yoco*, *canaguche yoco*, *verde yoco*, and others; however, these are not distinguished botanically (Schultes 1942; 1987, 527). The name *yagé yoco* suggests an association with *Banisteriopsis caapi* or a use of *yoco* as an additive in **ayahuasca**. The name *canaguche yoco*

indicates the addition of yoco to a type of **chicha** known as *chicha de canaguche*, which is fermented from the fruits of *Mauritia minor* Burret (cf. **palm wine**) (Schultes 1942, 312). The Kofán differentiate between two ecological forms with the names *to-to-oa-yoko*, “white yoco,” and *cu-i-yoko*. The first form is preferred because it contains more latex (Schultes 1981, 23*). The use of yoco was discovered only in the 1920s (Schultes 1942, 309). The Inga, Kofán, and Coreguaje use yoco as a daily morning stimulant. These Indians never go on hunting expeditions or journeys without taking a supply of pieces of the vine (Schultes 1942, 322).

The Mexican plant *aquiztli* (*Paullinia fuscescens* H.B.K.) was the first species in the caffeine-producing genus *Paullinia* to be described and illustrated. (From Hernández, 1942/46 [Orig. pub. 1615]*)

“Yoco is undoubtedly the most curious caffeine-rich plant that people have bent to their use. A forest liana of the westernmost Amazon of Columbia, Ecuador, and Peru, it is the only species the bark of which is employed in the preparation of a stimulant drink. The liana is the most important non-food plant in the life of numerous tribes of Indians; when a local supply of the wild source is exhausted, the natives find it necessary to abandon their home-site and re-locate in another area where the plant is found in greater abundance. It appears that the liana is rarely or never cultivated, probably because it is extremely slow growing.”

RICHARD EVANS SCHULTES

“A CAFFEINE DRINK PREPARED FROM BARK”

(1987, 527)

A milky latex that contains a very high level of **caffeine** flows through the bark. Yoco bark is drunk only in the form of a cold-water extract. The vine (epidermis, bark) is scraped, and the bark pieces and the caffeine-rich latex yield a mass that is then pressed in cold water. One dosage is prepared from 15 to 28 ounces (= 420 to 790 g) of scraped bark and a tree gourd (*jicara*) full of water (Schultes 1987). The effects are a powerful stimulation with tingling in the fingers. A general sensation of well-being and clear wakefulness manifests within a few minutes of consuming the drink. The appetite is profoundly and persistently suppressed. Most yoco users drink two *jicaras* in the morning right after rising and do not eat until the late afternoon (Schultes 1942, 323).

The bark is also added to the tobacco preparation known as *ambíl* (see *Nicotiana tabacum*) and is mixed with *Ilex guayusa*.

Yoco bark contains 2.73% **caffeine** (Rouhier and Perrot 1926). No other active constituents have been detected. The buds have also been found to contain caffeine (Schultes 1942, 313).

Pausinystalia yohimba (K. Schum.) Pierre ex Beille

Yohimbé Tree

Family

Rubiaceae (Coffee Family)

Forms and Subspecies

Presumably none

Synonyms

Corynanthe johimbe K. Schum.

Corynanthe yohimba K. Schum.

Corynanthe yohimbe K. Schum.

Pausinystalia macroceras Kennedy (non [Schum.] Pierre)

Pausinystalia johimbe (K. Schum.) Pierre ex Beille

Pausinystalia yohimbe Pierre

Folk Names

Johimbe, liebesbaum, lustholz, pau de cabinda (Portuguese), potenzbaum, potenzholz, potenzrinde, yohambine (Arabic), yohimba, yohimbe, yohimbé, yohimbébaum, yohimbehe, yohimbéhé (French), yohimbehon, yohimbene, yohimbe tree, yohimbé tree, yohumbe, yumbehoa

History

Since ancient times, the bark of this tree has been used in Africa as an aphrodisiac, especially among the Bantu peoples (Miller 1993, 70*). It is possible that the ancient Egyptians may have known about and even imported the bark through trade relations with western Africa. In Cameroon, this jungle tree has long been esteemed as an aphrodisiac and stimulant (Dalziel 1937).

The German chemist Spiegel isolated the alkaloid **yohimbine** from the bark in 1896, and the compound subsequently found use in Western medicine as a treatment for impotence and as a local anesthetic (Brown and Malone 1978, 20*; Schneider 1974, 3:34*). The tree was correctly botanically described in 1901 (Gilg and Schumann 1901, 94 f.). The bark is a source of alkaloids of pharmaceutical value (Oliver-Bever 1982, 39).

At the beginning of the twentieth century, yohimbé bark and yohimbine enjoyed great popularity in Germany as psychoactive aphrodisiacs. (Magazine advertisement, 1915)

Distribution

The tree occurs in the tropical forests of Nigeria and Cameroon and in the Congo (Hutchinson and Dalziel 1963, 112).

Cultivation

The plant can be propagated either from seeds or from cuttings. Details, however, are lacking.

Appearance

This evergreen tree, which can grow to a height of 30 meters, somewhat resembles an oak. It has oval, attenuated leaves (7 to 13 cm long) and bushy inflorescences and produces winged seeds. The light or gray-brown bark is 4 to 8 mm thick with both longitudinal and transverse fissures and is usually heavily overgrown with lichens.

The yohimbé tree is easily confused with *Pausinystalia macroceras* (K. Schum.) Pierre ex Beille and with some members of the genus *Corynanthe* (*Corynanthe* spp.).

Psychoactive Material

—Bark (cortex yohimbe, yohimbe cortex, yohimbehe cortex, yohimberinde, yohimbeherinde, potenzrinde, yohimbé bark)

The raw drug is apparently counterfeited with the bark of other *Pausinystalia* species and *Corynanthe* spp.:

It is interesting, by the way, that the natives in the French Congo used the bark of a tree that they called “endun” and that Pierre named “*Pausinystalia trillesii*” as an aphrodisiac. This bark also contains yohimbine; the tree itself probably belongs to the genus *Corynanthe*. (Hirschfeld and Linsert 1930, 172*)

Preparation and Dosage

Only the dried bark is used. It can be prepared as an extract in **alcohol** (tincture) or as a tea (cf. Geschwinde 1996, 146*).

To make tea, 6 teaspoons of yohimbe bark per person should be boiled with 500 mg of vitamin C for ten minutes and then sipped slowly (from Gottlieb 1974, 76*; Miller 1985, 117*).

The following ingredients can be used to decoct a tea for a “firm erection” (from Gottlieb 1974, 81*):

- 1 tablespoon yohimbe bark (cortex yohimbe)
- 1 teaspoon dita seeds (*Alstonia scholaris*), crushed
- 1 tablespoon cola nuts (*Cola spp.*), broken
- 1 tablespoon sarsaparilla bark (*Smilax spp.*)

The ingredients should be boiled in water for ten minutes and then sipped slowly.

The pharmaceutical industry uses yohimbé extracts to manufacture aphrodisiacs and medicines to treat impotence. These extracts are usually combined with **atropine**, *Turnera diffusa*, *Strychnos nux-vomica*, *Strychnos spp.*, *Liriosma ovata*, or other substances.

The bark is also used in aphrodisiac **smoking blends** (Brown and Malone 1978, 20*). In western Africa, it was or is still used as an additive to iboga (see *Tabernanthe iboga*).

A “stimulant for the sexual organs” consists of ten drops of a 1% solution (Boericke 1992, 803*). For more on dosages, see **yohimbine**.

Ritual Use

It is likely that yohimbé was once used in western Africa as an initiatory drink in fetish and ancestor cults and in initiations into secret societies. It has been conjectured that yohimbé was used together with *Tabernanthe iboga* in the *bieri* cults of the Fang. Unfortunately, no detailed evidence has come down to us (cf. *Alchornea spp.*).

Today, yohimbé is used chiefly in North America but also in Europe for sexual magical rituals that borrow from Indian Tantra and the techniques of various occultists (Aleister Crowley). Miller (1985, 117 ff.*) has recommended using yohimbé as a sacrament for pagan wedding ceremonies.

The coarsely chopped bark (cortex yohimbe) of the West African yohimbé tree (*Pausinystalia yohimba*) contains the potent aphrodisiac yohimbine as well as numerous other indole alkaloids.

Artifacts

See *Tabernanthe iboga*.

Medicinal Use

In Cameroon, yohimbé is used in folk medicine to treat impotence resulting from witchcraft (cf. Amrain 1907).

Preparations containing yohimbé are used in modern phytotherapy and in Western medicine to treat frigidity and impotence and are also used in veterinary medicine (Pahlow 1993, 484*). In

homeopathy, Yohimbinum is regarded as an alternative for *Nuphar lutea*. It

arouses the sexual organs, affects the central nervous system and the respiratory center. Is an aphrodisiac in physiological dosages, but is contraindicated for all acute and chronic inflammations of the abdominal organs. Homeopathically, it is said to be able to help with congestive conditions of the sexual organs. Causes hyperemia of the mammary glands and stimulates milk production. (Boericke 1992, 802*)

Constituents

The bark of the trunk of trees that are older than fifteen to twenty years contains 2 to 15% indole alkaloids: yohimbine (= corynine, quebrachine), β -yohimbine (= corynanthidine, isoyohimbine, mesoyohimbine, rauwolscine), β -yohimbine (= amsonine), yohimbinine, corynanthine (= rauhimbine), corynanthein, dihydrocorynanthein, alloyohimbine (= dihydroyohimbine), pseudoyohimbine, tetrahydromethylcorynanthein, and ajmalicine (Oliver-Bever 1982, 39; Paris and Letouzey 1960; Poisson 1964; Roth et al. 1994, 544*). The average yohimbine content in commercial material (cortex yohimbe) ranges from 1.67 to 3.4% (Roth et al. 1994, 545*). Apart from the alkaloids, the bark also contains tannic acid and a coloring agent (Pahlow 1993, 484*).

Yohimbine

“The warlike Masai of East Africa call their ultra-hard ritual drug ‘motoriki’ or simply ‘ol motori,’ the soup. It is cooked from the bark of the yohimbé tree together with the roots of *Acokanthera* [sp.; an Apocynaceae]—which also provide an arrow poison.

“Archaic drug rituals almost always include an animal sacrifice. Among the Masai, a bull is killed on such occasions; they catch its blood in the opened dewlap and mix it into the finished brew of bark and root pieces. The motoriki drink produces an epilepsy-like tetanus in which the Morani—the young Masai warriors—are visited by terrible sights in which they fight with demons and wild animals. The horror visions are so strong that the inebriated men must be watched over and held on to so that they will not injure themselves or others. And yet there are repeatedly deaths from people running amok or respiratory paralysis of the intoxicated. Whoever survives this inebriation will no longer fear anything.”

PETER LEIPPE

GEGENWELT RAUSCHGIFT: KULTUREN UND IHRE DROGEN [COUNTER-WORLD INEBRIANT: CULTURES AND THEIR DRUGS]

(1997, 21 f.*)

“In Africa, the black sorcerers have their disciples drink johimbe and iboga to produce the inebriation required to prepare them for the great fetishistic initiations. The candidate ingests a great quantity of iboga, whether in the natural state or as a decoction. Shortly thereafter, all of his nerves tense up in an extraordinary manner; an epileptic fit comes over him, while he unconsciously utters words that, when they are picked up by the initiated, have a prophetic meaning and demonstrate that the fetish dwells within them.”

ALEXANDRE ROUHIER

DIE HELLSEHEN HERVORRUFENDEN PflANZEN [THE PLANTS THAT INDUCE CLAIRVOYANCE] (1927 = 1986*)

Botanical illustration of the kinkel tree (*Pausinystalia macroceras*). In the Congo and Gabon, its bark is also called yohimbé, and it is used for aphrodisiac purposes.

Effects

Yohimbé bark is reputed to be hallucinogenic (Schultes and Farnsworth 1982, 189*). The psychoactive effects are due primarily to the main active constituent, **yohimbine** (Roth et al. 1994, 545*). Yohimbine has sympatholytic effects and local anesthetic effects like those of **cocaine**; it also has vasodilating effects, particularly upon the sex organs (Oliver-Bever 1982, 40). Yohimbine interacts with other psychopharmacological agents (Roth et al. 1994, 544*). Overdoses can be very unpleasant (Sacha Runa and Lady Sanna 1995). For information about psychoactivity, see **yohimbine**.

Preparations of the bark usually produce only mild or subtle effects.

Commercial Forms and Regulations

The bark (cortex yohimbe) is available without restriction, while the pure alkaloid requires a prescription. In the United States, pharmaceutical extracts of yohimbé bark, often in a tincture together with saw palmetto fruits (*Serenoa repens*; cf. **Turnera diffusa**, **palm wine**, **wine**), are offered in health food stores and are not subject to any restrictions.

Peganum harmala Linnaeus

Syrian Rue, Harmel

Family

Zygophyllaceae²⁷⁸ (Caltrop Family)

Forms and Subspecies

None

Synonyms

None

Folk Names

Aspand (Kurdish), besasa (Egypt, “plant of Bes”), churma, epnubu (Egypt), gandaku, haoma (Persian), harmal, harmale, harmalkraut, harmal rutbah (Arabic/Iraq), harmel, harmelkraut, harmelraute, hermel, hermelkraut, hermelraute, hom (Persian), kisankur, moly, mountain rue, pegano, pégano, peganon, sipand (Persian), steppenraute, Syrian rue, syrische raute, techepak (Ladakhi), tukhm-i-isfand, uzarih (Turkish), wilde raute

History

Syrian rue is likely an ancient ritual plant that was used for psychoactive purposes from an early date. It may have been the **haoma** of ancient Persia and was in any case later used as a substitute for it. The plant appears in the ancient literature (Dioscorides) under the name *peganon*. The name *peganon* (also *peganum*) may have been derived from that of Pegasus, the winged horse of ancient mythology that was begotten by Poseidon, the god of the sea, and the dying Medusa. The plant has also been interpreted as the legendary magical plant known as **moly**.

The seeds, which are used both medicinally and ritually, were imported from Persia to India by the Muslims at an early date (Hooper 1937, 148*). The plant was present in central Europe by the fifteenth century at the latest and was portrayed by the “fathers of botany.” In the Near East and North Africa, Syrian rue has retained its great significance as a ritual **incense** into the present day. In North America and central Europe, it is increasingly being used to produce **ayahuasca analogs**.

Distribution

Syrian rue is distributed from the eastern Mediterranean region over northern India (Rajasthan) and into Mongolia and Manchuria (Schultes 1970, 25*). It is common in Yemen and the Negev Desert. In southern Europe, the plant can occasionally be found on Cyprus and less frequently in Greece (Sfikas 1990, 140*).

Cultivation

Although Syrian rue thrives without problem in extreme desert climates, cultivation of the plant is often difficult. The plant almost never grows in central Europe. It is more likely that suitable soils and climates are found in southern Europe. In California, cultivation is relatively simple. There, the seeds are simply broadcast onto normal, moistened potting soil and gently pressed in. When there is

sufficient—but not too much—sunlight and the air is warm, some of the seeds will germinate. Each can be repotted as a seedling as soon as its root has become strong enough.

Growing larger quantities of Syrian rue requires considerable experience in and knowledge of gardening.

Appearance

This herbaceous perennial, which can grow as tall as 50 to 100 cm, has ramified roots and many thin stalks. The multifid leaves are opposite and have a fragile appearance. The white flowers have five petals and ten yellow pistils. The delicate, solitary flowers are at the ends of long stalks attached to the leaf axils. The trilobular fruit is round and acquires a reddish color as it matures. It contains numerous gray or almost black triangular seeds (up to 3 mm long).

The herbage begins to develop new shoots in February, and flowers appear in April. The plant is green in early summer and develops fruits in July. The herbage has a characteristic scent that some people find unpleasantly obtrusive.

An old illustration of Syrian rue. (Woodcut from the herbal of Matthioli, 1627)

Syrian rue (*Peganum harmala*), displaying a mature fruit.

The seeds of *Peganum harmala*, known as harmel or hermel, contain large amounts of **harmaline** and **harmine** and are thus very well suited for making ayahuasca analogs. (Photograph: Karl-Christian Lyncker)

“Wild rue. Some also say that the wild peganon is the plant that is known in Cappadocia and Asian Galatia as *moly*. It is a bush that develops several branches from one root, it has leaves much larger and more tender than the other peganon [= rue], and with a penetrating scent, a white flower, with little heads at the tip, larger than with cultivated peganon [= rue], usually consisting of three parts, in which is found a three-sided light yellow seed that is also used. The seed ripens in late autumn, and when finely ground with honey, wine, chicken bile, saffron, and fennel juice, it can be used to treat dull vision. Some also call the same *harmala*, the Syrians *besasa*, the Egyptians *epnubu*, the Africans *churma*, and the Cappadocians *moly*, because it has a great similarity to *moly*, as it has a black root and white flowers. It grows in hilly and fertile soil.”

DIOSCORIDES (3.46)

Psychoactive Material

—Seeds (semen harmalae, semen rutae silvestris, harmalae semen, harmalasamen, harmala seeds, harmel seeds)

Preparation and Dosage

Burning the dried seeds as a fumigant is by far the most common use of *Peganum harmala*. The seeds are simply thrown onto glowing wood or charcoals, sometimes in combination with other substances (cf. **incense**). The seeds also are used as an ingredient in **smoking blends**, e.g., with hashish (cf. *Cannabis indica*). In Ladakh, the seeds are toasted on a red-hot iron plate, very finely ground, and then smoked, either alone or mixed with tobacco (*Nicotiana tabacum*) (Navchoo and Buth 1990, 320*). An especially effective smoking mixture can be obtained from 15 g of seeds and the juice of a lemon. The ground seeds are boiled carefully in some water and the lemon juice until a paste results. Mixed with tobacco and smoked, this is said to produce inebriating and aphrodisiac effects.

In Pakistan, 5 to 10 g of unground seeds are ingested with water after a meal for internal purposes (Goodman and Ghafoor 1992, 25*). In Morocco, the seeds are added to wine (*Vitis vinifera*) to make harmel wine. The powdered seeds are taken as a **snuff** to produce a “clear mind” (Vries 1984*).

Up to 20 g of powdered seeds have been ingested for psychoactive purposes, but such a dosage can have severe toxic effects. “Over 4mg/kg (oral) of the two substances [**harmine** and **harma-line**] have hallucinogenic effects on humans” (Roth et al. 1994, 548*). Some 3 to 4 g of crushed seeds (approximately one teaspoonful) is effective as an MAO inhibitor for activating the DMT in **ayahuasca analogs**. (By the way, it is not necessary to swallow the seeds or, in gelatin capsules, the powder. This amount can be extracted in cold water, and the solution can be used.)

In recent years, many psychonauts have experimented with adventurous combinations of harmel seeds and other psychoactive substances (*Lophophora williamsii*, *Phalaris arundinacea*, *Psilocybe* spp., *Trichocereus pachanoi*, **mescaline**, LSD, et cetera) (DeKorne 1995*; Turner 1994*). Great care should be exercised when conducting such self-experiments. It is better to use too little than too much!

Ritual Use

If Syrian rue was in fact the original **haoma** plant, then its greatest ritual significance would have been in pre-Zoroastrian Persia. It is possible that the plant may also have been the secret inebriant used in the ancient mystery cult of Mithra.

Dioscorides noted that the late ancient Syrians knew the plant as *besasa*, a name that is usually interpreted to mean “plant of Bes.” Bes was a misshapen god of dwarf form and with the face of an old man who was especially beloved among the simple Egyptian people, for he was a protector spirit who turned away all evil. His image, in the form of small amulets, was affixed to head rests, beds, mirrors, and cosmetic jars. The small figures of Bes were fumigated with Syrian rue seeds to promote their apotropaic powers.

Syrian rue was a sacred plant in the ancient Orient. The Koran states, “Every root, every leaf of harmel, is watched over by an angel who waits for a person to come in search of healing.” For this reason, it is said that dervishes in Bucharra also esteem and ritually utilize harmel seeds for their inebriating effects.

Syrian rue seeds, in the form of small incense balls (*sepetan*), are still offered by burning great quantities during Nouruz (New Day), the ancient Iranian and now Islamized spring and new year’s festival (on March 21, the vernal equinox). The ascending smoke is distributed throughout the entire house to keep away all misfortune (Schlegel 1987). In Persia (Iran, Iraq), the seeds are scattered over glowing coals at weddings to ward off evil spirits and the evil eye. It is said that the smoke is also capable of dispelling epidemic diseases (Hooper 1937, 148*).

In Baluchistan (Pakistan), the seeds are used to neutralize the enchantments of a *jin* (jinn) and to banish all evil spirits in general. A person who has fallen under the spell of or has been possessed by a *jin* is urged to inhale as much as possible of the smoke rising from the crackling seeds on the charcoals. It is said that such a treatment usually results in a rapid improvement (Goodman and Ghafoor 1992, 25*). Harmel is also used as a fumigant in Turkey to counteract the effects of the evil eye.

In North Africa, Syrian rue has been regarded as a magical and medicinal panacea since ancient times. The seeds are used as **incense**, both alone and in combination with other substances. The seeds are scattered over charcoal to dispel evil spirits. The smoke is inhaled to treat headaches, the consequences of the evil eye, and venereal diseases. In Morocco, an incense of Syrian rue seeds, alum, and olibanum (*Boswellia sacra*) is burned during the wedding night to fan the flames of desire (vries 1985). Fumigations of harmel seeds and alum, performed to defend against demons, are said to produce inebriating effects.

In the Himalayas and neighboring regions, shamans use the seeds as a magical incense. The shamans of the Hunza, who live in what is now Pakistan, inhale the smoke to enter a clairvoyant trance. The shamans (*bitaiyo*) then enter into a close, lusty sexual contact with the divining fairies, who give them important information and the ability to heal (cf. *Juniperus recurva*).

Artifacts

It is possible that Syrian rue may have played a role in the development of the floral patterns and elements of Islamic art. If the plant was indeed used in the haoma cult or the Mithraic mysteries, it likely would have inspired numerous cult images.

In modern Iran, fruit capsules of *Peganum harmala* are strung together and attached to articles of clothing as protective amulets (*panja*).

Medicinal Use

Traditionally, Syrian rue seeds have been used primarily for gynecological purposes. In India, the seeds (*hurmur*, *lahouri*, *marmara*) are burned as an **incense** to ease the birthing process. In Indian folk

medicine, the seeds (*harmal*, *is-band*) are regarded as an aphrodisiac, an asthma remedy, and an agent for treating menstrual difficulties. In Pakistan, infertile women and women with severe labor or uterine pains are fumigated with the seeds; in addition, special pipes are used to blow the smoke directly into the vagina (Goodman and Ghafoor 1992, 24f.*; Hassan 1967). Ill people generally inhale the smoke for all manner of afflictions. A tea made with 5 to 10 g of seeds is drunk after a meal to control flatulence (Goodman and Ghafoor 1992, 54*). In Rajasthan, the smoke of glowing seeds is used as an antiseptic agent to fumigate wounds (Shah 1982, 301*).

In the folk medicine of Asia Minor and central Asia, preparations of Syrian rue are used as aphrodisiacs. In Persia, the seeds were regarded as a purifying medicine and an aphrodisiac (Hooper 1937, 148*), and are used in Iran today. The Bedouins of the Negev Desert use the plant to promote menstruation and to induce abortions (Bailey and Danin 1981; Shapira et al. 1989). The herbage is traditionally used to treat unusual skin disorders (El-Rifaie 1980). A decoction of the seeds is drunk for stomach ailments, heart problems, and sciatica. A strong decoction can act as a tranquilizer.

Constituents

The herbage and seeds contain the β -**carbolines** harmine, harmaline, and related bases, e.g., harmalol and harmidine (Al-Shamma et al. 1981; Degtyarev et al. 1984). Also present are quinazo-line alkaloids with a similar structure: (–)-vasicine, (±)-vasicine, vasicinone, pegaline, tetrahydroharman, and desoxyvasicinon. The alkaloid content of the seeds can vary between 2 and 6% (Roth et al. 1994, 548*). In addition to the β carbolines, Syrian rue herbage contains a pleasantly scented **essential oil** that, when used in massage oils, has a relaxing effect upon the musculature. Vitamin C and fatty acids are also present.

Effects

The seeds have antidepressive effects and stimulate the imagination. There are reports of dreamlike states following the ingestion of larger quantities. The alkaloids as well as the total extract of the seeds act as MAO inhibitors, i.e., they suppress the excretion of the endogenous enzyme monoamine oxydase (= MAO), which metabolizes certain endogenous neurotransmitters (serotonin) as well as foreign toxins. This makes it possible for certain substances (*N,N*-DMT, 5-MeO-DMT, β -**phenethylamines**) to be orally efficacious (cf. *Banisteriopsis caapi*, *ayahuasca*, *ayahuasca analogs*).

Studies conducted at the University of Kansas (Lawrence) have shown that the harmine present in Syrian rue seeds has antibiotic effects on microorganisms (microbes) (Al-Shamma et al. 1981; cf. also Harsh and Nag 1984). In animal studies, an extract of the stems and leaves has been demonstrated to have abortifacient and anti-fertility properties (Shapira et al. 1989).

It is possible that the β -carbolines may pass into the smoke and can thus potentiate the effects of other smoked substances (e.g., **THC**).

Harmine

Harmaline

Commercial Forms and Regulations

The seeds are sold freely and can be obtained from nurseries and sources specializing in ethnobotanical supplies. In California, Syrian rue is considered a noxious weed and may not be imported or sold. Apart from this, the plant is not subject to any restrictions.

“Harmel rue, Syrian rue, *Peganum harmala*. A plant of southern Europe and the Orient. All parts of it have a strong and unpleasant scent. The seed is three-sided and tastes very bitter. . . . According to Pseudo-Aristotle, this rue species was eaten in ancient times as a remedy against fascination. In modern Greece, women hang *Peganum* on their little ones’ heads as an amulet. On Cephalonia, little pieces of it are placed in children’s swaddling clothes.—In Morocco, the seeds are carried in amulet bags to protect against the evil eye and the dñûn. It is also used as a fumigant.—In Punjab, the seeds are mixed with bran and salt and burned to ward off the evil eye, the dñûn, and such things.”

SIEGFRIED SELIGMANN

DIE MAGISCHEN HEIL- UND SCHUTZMITTEL AUS DER BELEBTEN NATUR [THE MAGICAL HEALING AND PROTECTIVE AGENTS FROM THE ANIMATED NATURE]

(1996, 121f.*)

“The alkaloid-rich seeds (harmine and harmaline) [of Syrian rue] are used because of their sudoriferous effect to heal febrile diseases of a general nature. The seeds are roasted and the fumes are inhaled. They also serve as an anthelmintic. In addition, they are used to spicen foods. It is said that they are esteemed among the dervishes in Bucharâ for their inebriating effect.”

Pelecyphora aselliformis Ehrenberg

False Peyote, Peyotillo

Family

Cactaceae (Cactus Family)

Forms and Subspecies

None

Synonyms

None

Folk Names

Asselkaktus, falscher peyote, false peyote, hatchet cactus, peotillo, peyote (see *Lophophora williamsii*), peyote meco, peyotillo, piote

History

Indians of northern Mexico once used this relatively rare cactus in a similar manner to or as a substitute for peyote (see *Lophophora williamsii*).

The first botanical description of the psycho-active cactus was made by the Berlin physician and botanist Christian Gottfried Ehrenberg (1795– 1876). A powder of the cactus was formerly sold in Paris under the name *poudre de peyote*, “peyote powder.”

Distribution

This cactus occurs only in northern Mexico (San Luis Potosí) (Preston-Mafham 1995, 167*; Zander 1994, 422*).

Cultivation

The plant is propagated from seeds, which are planted in the same manner as those of *Lophophora williamsii*.

Appearance

This solitary cactus can grow to a height of 10 cm. It has a round form with lateral, flattened tubercles that are arranged in a spiral fashion and have scalelike pectinate spines. Because of this, the cactus sometimes resembles a deeply convoluted brain. The flowers are up to 3 cm across and are bright violet. The fruits are red pods.

Peyotillo can easily be confused with the closely related species *Pelecyphora strobiliformis* (Werderm.) Kreuz. [syn. *Ariocarpus strobiliformis* Werderm., *Encephalocarpus strobiliformis* (Werderm.) Berger; cf. *Ariocarpus fissuratus*], which is found in Nuevo León (Mexico) (Preston-Mafham 1995, 167*). Another very similar species is *Pelecyphora pseudopectinata* Backeb. [syn. *Neolloydia pseudopectinata* (Backeb.) Anderson, *Turbinicarpus pseudopectinatus* (Backeb.) Glass et Foster]; in Tamaulipas, this cactus is also called peyote (Díaz 1979, 90*). *Turbinicarpus valdezianus* (Moell.) Glass et Foster [syn. *Pelecyphora valdezianus* Moell.] is also quite similar, but it is smaller

(growing to a height of only 2.5 cm) and occurs in Coahuila (Preston-Mafham 1995, 194*).

The rare Mexican hatchet cactus (*Pelecyphora aselliformis*) produces peyote-like effects.

Psychoactive Material

—Fresh or dried cactus flesh (buttons)

Preparation and Dosage

The flesh of the cactus (the aboveground portion or the head) can be eaten fresh or dried. No information concerning dosages is known.

Ritual Use

Only as a peyote substitute (see *Lophophora williamsii*)

Artifacts

See *Lophophora williamsii*.

Medicinal Use

See *Lophophora williamsii*.

Constituents

The cactus contains hordenine, anhalidine, pellotine, 3-dimethyltrichocerine, some **mescaline**, *N*-methylmescaline, and other **β-phenethylamines** (Mata and McLaughlin 1982, 110*; Neal et al. 1972).

Effects

One cactus, eaten fresh, is said to produce peyote-like effects (cf. *Lophophora williamsii*). Although the effects are not quite as dramatic, they do include the typical visual changes and phenomena (William Emboden, pers. comm.).

Commercial Forms and Regulations

This rare cactus is almost never found in the international cactus trade. It may be possible to obtain seeds from ethnobotanical mail-order suppliers.

The rare and beautiful *Pelecyphora aselliformis* cactus was used as a peyote substitute in Mexico. (Copperplate engraving, colorized, from Jacques Brosse, *Great Voyage of Discovery*, 1764–1843)

Literature

Petroselinum crispum (Miller) Nyman ex A.W. Hill

Parsley

Family

Apiaceae (Umbelliferae) (Carrot Family); Subfamily Apioideae, Amminae Tribe

Forms and Subspecies

The species is divided into two subspecies (Frank 1994, 105):

Petroselinum crispum ssp. *crispum* (leaf parsley; has a smooth-leaved and a crisp-leaved form, as well as three chemotypes [see “Constituents”])

Petroselinum crispum ssp. *tuberosum* (Bernh. ex Rchb.) So (root parsley, parsley root)

Synonyms

Apium hortense E.H.L. Krause

Apium laetum Salisb.

Apium petroselinum L.

Apium romanum Zuccagni

Apium vulgare Druce

Carum petroselinum Benth. et Hook.

Helosciadium oppositifolium Reuss

Ligusticum levisticum Elsmann

Petroselinum hortense Hoffm.

Petroselinum macedonicum (Lonitzer) Bubani

Petroselinum petroselinum Karst.

Petroselinum sativum auct. non. Hoffm.

Petroselinum sativum Hoffm.

Petroselinum vulgare Kirschl.

Selinum petroselinum E.H.L. Krause

Sium oppositifolium Kit.

Wydleria portoricensis DC.

Folk Names

Apio ortense (Italian), apium, bittersilche, elixanter, gartenpetersilie, jaubert, maghdunes (Iraq), oxillatrum, parsley, perejil (Spanish), persil, peterchen, peterlein, peterling, peterselie (Dutch), petershiljen, petersilie, petersilienkraut, petersill, petersillig, petroselino, petrosella, pitar saleri (Hindi), prezzemolo, silk, tukhm-i-kalam (Persian)

History

It is possible that Dioscorides described parsley under the name *sison* as a seed that was savored in Syria (3.57). Whether the ancient Egyptians used the plant is a subject of debate (Germer 1985, 144 f.*). One of the earliest descriptions of parsley mentions a psychoactive property: “It produces seriousness in the mind of a person” (Hildegard von Bingen, *Physica* 1.68). It has been listed as a

medicine in all pharmacopoeias since the Middle Ages (Schneider 1974, 3:43*).

The chief significance of parsley is culinary; it is used as a kitchen spice, soup seasoning, and aromatic substance (including for alcoholic beverages; cf. **alcohol**). In the history of psychoactive substances, the plant is of only minor importance. It may have been an ingredient in **witches' ointments** and **theriac**. It was often used as a **beer** additive. Since the 1960s, the dried herbage has been smoked as a marijuana substitute (cf. ***Cannabis indica***). The root is sometimes used as an ingredient in **incense**, while parsley oil is used in the (illegal) manufacture of psychoactive **phenethylamines** of the MDA or MDMA type (see ***Myristica fragrans***, **herbal ecstasy**; Shulgin and Shulgin 1991*).

“Following the ingestion of a larger quantity of the essential oil [of parsley], first a central state of arousal, then inebriated states are possible (an effect of the hallucinogenic myristicin?).”

FRANZ-CHRISTIAN CZYGAN *PETERSILIENFRÜCHTE* [PARSLEY FRUITS]
(1989, 369)

“Parsley was already being planted in the gardens of German farmers during the early Middle Ages. . . . It plays a great, often shrouded role in folk eroticism. First, it is regarded as an aphrodisiac for the man because of its strong aroma. It is . . . attributed with powerful arousing effects.”

MAGNUS HIRSCHFELD AND RICHARD LINSERT
LIEBESMITTEL [APHRODISIACS] (1930, 156*)

Distribution

Parsley is thought to have originated in the Mediterranean region. As a result of cultivation, it is now found throughout the world and has become wild in some areas.

Cultivation

Parsley is very easily grown from seed. The seeds need only be broadcast onto a bed of good topsoil and watered.

Appearance

This biennial fragrant plant has pinnate, incised leaves, a smooth stalk, and a spindle- or turnip-shaped vertical root. The root of the subspecies *tuberosum* is substantially thicker and more bulbous than that of the rest of the species. The white umbel, which grows from the center of the branching stalk, does not appear until the second year. For this reason, most hobby gardeners are unfamiliar with flowering parsley. The flowering period is from June to July. The gray-brown, 2 to 3 mm long fruits mature on the ten- to twenty-flower pedicels, which are arranged on the umbel in a radial manner.

Parsley can be confused with the only other member of the genus, *Petroselinum segetum* (L.) Koch. It is also very similar to the toxic dog parsley (*Aethusa cynapium* L.) and poison hemlock (***Conium maculatum***) (Frank 1994, 106).

Wild parsley is said to be more psychoactive than garden parsley. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

Psychoactive Material

- Herbage (petroselini herba, folia petroselini, herba petroselini, parsley leaves), fresh or dried
- Seeds (semen petroselini, petroselini fructus)
- Parsley fruit oil (petroselinum aetheroleum e fructibus, oleum petroselini, parsley seed oil, grünes apiol, apiolum)
- Root (petroselini radix, radix petroselini, parsley root)

Parsley (*Petroselinum crispum*) is not normally associated with psychoactive substances. But it does contain powerful active constituents.

Preparation and Dosage

The subspecies *crispum* is used primarily for its herbage, while the subspecies *tuberosum* is used chiefly for its root.

A daily medicinal dose is regarded as 6 g of the dried herbage (Frank 1994, 115). For the ingestion of powdered parsley fruits, a therapeutic single dose is 1 g. For a cold- or hot-water extract, a daily dose is listed as 1 to 3 g of seeds crushed shortly before being steeped (112). A hot-water extract or infusion should be allowed to steep for five to ten minutes.

Parsley fruit oil is obtained by distilling the mature fruits. The composition of the oil varies depending on the chemical race (see “Constituents”). As a result, the different oils have correspondingly different applications and dosages. The oil of the apiol race is used to induce

abortions. For this purpose, either a single dose of up to 10.8 g or a daily dose of 1 g for one to two weeks is ingested (Frank 1994, 109). Only the oil of the myristicin race can be used for psychoactive purposes (cf. *Myristica fragrans*). Unfortunately, no reliable information regarding dosages is available.

Ritual Use

Parsley herbage played a magical and apotropaic role in the customs of central Europe:

In Moravia, the plant makes the influence of witches upon cows ineffective if it is sown between the 24th and the 26th of June. In many communities, a wreath of parsley is placed on a child's head on its first birthday, for it has then survived the most dangerous time. According to a widely held superstition, pulling a parsley root from the ground will bring death to that person who was thought of when it was planted. In Galacia, the Ruthenian bride carries bread and parsley on the way to the church so as to ward off evil spirits. Garlic and parsley are tied to the linen cloth under which a woman in labor lies in order to protect her from magic. (Schöpf 1986, 124*)

Artifacts

None

Medicinal Use

Parsley herbage is used in folk medicine to purify the blood and to treat diseases of the urinary tract. In homeopathy, both an essence of the fresh herbage—*Petroselinum*—*Petersilie* (*Petroselinum crispum* hom. *HAB1*, *Petroselinum sativum* hom. *HPUS88*)—and a tincture made from the mature fruits—*Petroselinum e seminibus*—are used (Schneider 1974, 3:43*).

Constituents

The entire plant contains an **essential oil** consisting of myristicin, *p*-apiol (= parsley camphor), monoterpenes, and sesquiterpenes. The seeds contain the highest concentration of essential oil (2 to 6%; average 2.7%) (Czygan 1989, 268; Fühner 1943, 240*; Roth et al. 1994, 552*). Three chemotypes (chemical races) have been distinguished on the basis of the principal constituents of the essential oil of the mature fruits (Frank 1994, 106; Warncke 1992):

- Myristicin race, with 49 to 77% myristicin, 0 to 3% apiol, and 1 to 23% allyltetramethoxybenzol
- Apiol race, with 58 to 80% apiol, 9 to 30% myristicin, and up to 6% allyltetramethoxybenzol
- Allyltetramethoxybenzol race, with 50 to 60% allyltetramethoxybenzol, 26 to 37% myristicin, and traces of apiol

The essential oil of the root of the subspecies *tuberosum* is composed chiefly of apiol (principal constituent), β -pinene, and myristicin but has traces of elemicine, limonene, bisabolene, sesquiphellandrene, and germacrene-A (Czygan 1989, 370 f.; Frank 1994, 116). The herbage contains flavones (apiine) and furanocoumarin (cf. **coumarins**). The fruits are rich in a fatty oil (petroselinic acid). The roots contain polyacetylene and furanocoumarin. Parsley herbage has a high vitamin C content (165 mg per 100 g) and also contains nicotine amide and considerable potassium (1%).

Effects

The essential oil of the apiol race has powerful abortive effects (Fühner 1943, 240*) and also can

induce coma (Frank 1994, 109). The essential oil of the myristicin race has primarily psychoactive and inebriating effects comparable to those of *Myristica fragrans* (Czygan 1989, 369).

Commercial Forms and Regulations

Fresh parsley is one of the most commonly sold herb seasonings. The dried herbage, the seeds, and the dried root (chopped drug) can be procured in herb shops and pharmacies (without restriction). The seeds can also be obtained in flower shops.

In the drug culture, the word *parsley* is a pseudonym for marijuana. This is not inappropriate, as the plant does contain inebriating essential oils. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Myristicin

Apiol

Allyltetramethoxybenzol

Family

Gramineae: Poaceae (Grass Family)

Forms and Subspecies

Several varieties and cultivars have been described, including *Phalaris arundinacea* var. β *picta* L. (from North America), known as bent grass. The widespread cultivar *Phalaris arundinacea* cv. Turkey Red produces primarily **5-MeO-DMT** (Appleseed 1995, 37).

Synonyms

Balclutha arundinacea (L.) Dumort.

Phalaroides arundinacea (L.) Rauschert

Typhoides arundinacea (L.) Moench

Folk Names

Bentgrass, canarygrass, canary grass, glanzgras, militz, phalaridos, randgräs, reed canarygrass, reed canary grass, reed grass, rohrglanzgras

History

Reed canary grass was known even in ancient times. It cannot be determined whether this or another species (e.g., *Phalaris aquatica* L. or *Phalaris canariensis* L.) is the *phalaridos* described by Dioscorides. A number of grasses appear in herbals from the early modern period. The fact that *Phalaris* is psychoactive was discovered during phytochemical studies of the grasses for agricultural purposes. For several years, closet shamans have been experimenting with possibilities for using this and other grasses for psychoactive purposes (cf. *Arundo donax*, *Phalaris* spp., *Phragmites australis*).

Distribution

The grass is found in Eurasia, North Africa, and North America. Thick stands grow on the banks of rivers and lakes and in wet meadows, often in reed fields and large sedge swamps (so-called phragmitetea).

The common reed canary grass *Phalaris arundinacea* is found throughout the world. Depending upon its location, it can exhibit variously high concentrations of tryptamines.

Phalaris arundinacea var. *picta*, a variety of reed canary grass that was bred for ornamental purposes.

The variety of reed canary grass known as *Phalaris arundinacea* cv. Turkey Red contains especially high concentrations of DMT.

Cultivation

The grass can be grown from seed or propagated by root cuttings (Appleseed 1995). The seeds need only be broadcast onto the ground. The grass prefers nutrient-rich, acid soils and must be near water

or watered frequently.

Appearance

The perennial grass develops gray-green stalks that can grow up to 2 meters in height and can branch. The long, wide leaves have rough edges and are attached to the stalks. The panicle can take on a light green or red-violet hue. The spikelets bear a single flower. The flowering period is from June to August (Christiansen and Hancke 1993, 74 f.*). Large specimens can be confused with small forms of *Phragmites australis*.

Psychoactive Material

—Leaves

Preparation and Dosage

While the dried grass can be smoked, smoking almost never yields any effects. An extract obtained from the leaves is more suitable for smoking. It can be produced in the following manner: The dried leaves are finely chopped or powdered and, preferably, freeze-dried (or frozen and unfrozen several times). The material prepared in this fashion is placed in a blender with water and minced into a mush that is made acidic by the addition of an acid (e.g., acetic acid) and lightly simmered. The material is then boiled down until a tarlike mass remains. This mass can then be dissolved in alcohol (or a mixture of ethanol and water). The resulting solution is then impregnated into material suitable for smoking (e.g., damiana herbage; cf. *Turnera diffusa*). After being dried, the preparation should be quite potent (cf. DeKorne 1994, 127 ff.*).

Reed canary grass is increasingly being used to produce **ayahuasca analogs**. To date, however, there are very few detailed reports about optimal dosages, and definitive information about the races or strains of the grass to use is also lacking (Appleseed 1993).

A combination of 125 mg of an extract of *Peganum harmala* seeds and 50 mg of *Phalaris* extract produced unequivocal psychedelic effects “accompanied by strong waves of nausea” (DeKorne 1994, 98*). A combination of 60 g fresh weight of *Phalaris* and 3 g of *Peganum harmala* produced strong toxic effects (Festi and Samorini 1994).

Ritual Use

To date, we know of no traditional use of *Phalaris arundinacea* as a psychoactive substance. However, the Roman poet Ovid (43 B.C.E.–17 C.E.) described a shamanic transformation that was induced by (an unfortunately unidentified) “grass.” In the story of Glaucus, a fisher from Anthedon in Boeotia, Glaucus himself described his wondrous metamorphosis into a sea god:

I sought the cause if any God had brought this same abowt,
Or else sum jewce of herb. And as I so did musing stand,
What herb (quoth I) hath such a powre? And gathering with my hand
The grasse, I bote it with my toothe. My throte had scarcely yit
Well swallowed downe the uncouth jewce, when like an agew fit
I felt myne inwards soodeinly to shake, and with the same,
A love of other nature in my brest with violence came.
And long I could it not resist, but sayd: Deere land, adeew,
For never shall I haunt thee more. And with that woord I threw
My bodye in the sea. The Goddes thereof receyving mee,
Vouchsawed in theyr order mee installed for too bee,
Desyring old Oceanus and Thetis for theyr sake,
The rest of my mortalitie away from mee to take.
They hallowed mee, and having sayd nyne tymes the holy ryme
That purgeth all prophanednesse, they charged mee that tyme

To put my brestbulk underneathe a hunred streames. Anon
The brookes from sundry coastes and all the Seas did ryde uppon
My head. From whence as soone as I returned, by and by
I felt my self farre otherwyse through all my limbes, than I
Had beene before. And in my mynd I was another man.
Thus farre of all that mee befell make just report I can.
Thus farre I beare in mynd. The rest my mynd perceyved not.
Then first of all this hory greene gray grisild beard I got,
And this same bush of heare which all along the seas I sweepe,
And theis same myghty shoulders, and theis grayish armes, and feete
Confounded into finned fish.

(OVID, *METAMORPHOSES* 13.1099–24; IN NIMS 1965, 348–49)

Perhaps the “grass” was *Phalaris arundinacea*, and a preparation was known in ancient times that would have been suitable in rituals for animal transformation.

Gramine

Artifacts

None

Medicinal Use

Dioscorides noted that the “crushed plant, treated with water or wine to make a juice, has the power to have good effects on bladder disorders” (3.149).

Constituents

The entire grass contains **indole alkaloids**, the composition of which can vary greatly depending upon race, strain, location, time of collection, et cetera (Marten 1973; Ostrem 1987). ***N,N*-DMT**, **MMT**, and **5-MeO-DMT** are usually present (Matum et al. 1979). The grass also can have high concentrations of gramine, a very toxic alkaloid (Appleseed 1995).

Effects

Smoking a suitable preparation can produce effects like those produced by ***N,N*-DMT**. While some of the **ayahuasca analogs** that have been tested to date have indeed yielded ayahuasca-like effects, many of the reports describe unpleasant experiences (cf. Festi and Samorini 1994).

Commercial Forms and Regulations

The seeds are available through ethnobotanical specialty sources.

“An extremely potent smokable form of DMT can be extracted from the reed canary grass (*Phalaris arundinacea*). . . . *Phalaris* DMT is something brand new—derived from one of the ayahuasca analog plants, it is a natural form of DMT and 5-MeO-DMT which can be grown by anyone anywhere on the planet outside of the polar regions. It has no somatic side effects (nausea, vomiting), nor is it dependent for its extraction on complicated laboratory procedures, equipment or knowledge; hence it isn’t necessary to rely upon a profit-oriented monopoly of dealers to obtain. It comes on fast, is too intense, and subsides rapidly: just like the way we live our lives.”

JIM DEKORNE *PSYCHEDELIC SHAMANISM* (1994, 103, 105)

A copperplate engraving of *Phalaris* grass, from the German edition of Dioscorides (1610).

Phalaris spp.

Canary Grasses

Family

Gramineae: Poaceae (Grass Family)

Following a comprehensive revision of the genus *Phalaris*, a total of twenty-two species is now accepted. The greatest number of species (eleven) are found in the Mediterranean region, where they are part of the indigenous flora. Four species are native to the American Southwest (Baldini 1995). Like ***Phalaris arundinacea***, many species exhibit considerable variability. The various species appear to have different chemotypes and chemical races. For this reason, experimenting with unknown types of *Phalaris* without previously analyzing their constituents can be extremely dangerous. Many grasses contain gramine, a very toxic alkaloid.

***Phalaris aquatica* L. [syn. *Phalaris bulbosa* auct. non. L., *Phalaris commutata* Roem. et Schult., *Phalaris nodosa* Murray, *Phalaris tuberosa* L.]—water canary grass**

Originally from the Mediterranean region, this species is now found throughout the world. *Phalaris aquatica* is very common in Australia, where it is despised in sheep pastures as a poisonous grass (McBarron 1991, 17). This species is thought to contain the highest concentrations of ***N,N*-DMT** in the genus (Baxter and Slaytor 1972; Mack et al. 1988). Whether the Aborigines used this grass in any way is unknown. There also is no evidence to determine whether the grass was present in Australia before the arrival of the Europeans or whether it was introduced along with the cattle and sheep. There are several varieties (e.g., var. *australia*, var. *uneta*), some of which represent chemical races. Some sorts or strains contain primarily ***N,N*-DMT**, while in others **5-MeO-DMT** predominates (Mack and Slaytor 1979; Mulvena and Slaytor 1982, 1983). This grass is being increasingly tested for use in developing **ayahuasca analogs**.

***Phalaris* spp.—cane canary grass**

Ancient Egyptian graves have yielded grave garlands into which pieces or entire stalks (including panicles) of *Phalaris* species were worked (Germer 1985, 219*). It is possible that psychoactive tryptamines may be present in a number of *Phalaris* species.

This early modern illustration of a canary grass may represent the DMT-rich species *Phalaris aquatica*. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

The grass *Phalaris aquatica* (= *Phalaris tuberosa*) is rich in DMT and other tryptamines.

Many *Phalaris* species have not been chemically investigated to date. There are strong indications, however, that many members of the genus contain psychoactive constituents. (A *Phalaris* species, photographed in Crete)

The common canary grass (*Phalaris canariensis*) is known primarily as a source of bird food. This species also contains alkaloids.

Phragmites australis (Cav.) Trinius ex Steudel

Reed

Family

Gramineae: Poaceae (Grass Family)

Forms and Subspecies

At least two subspecies have been described (Germer 1985, 205*):

Phragmites australis ssp. *altissimus* (Benth.) Clayton *Phragmites australis* ssp. *stenophyllus* (Boiss.) Bor.

Synonyms

Arundo isiac Del.

Arundo phragmites L.

Arundo vulgaris Lam.

Phragmites communis L.

Phragmites communis Trin.

Phragmites communis var. *isiacus* (Del.) Coss. et DR.

Folk Names

Calamus vallis, canna sepiaria, carrizo, carrizo de panocha, common reed, ‘eqpe’w (Chumash), gemeines rohr, gemeines schilfrohr, harundo, ‘iqpew, lók’aa’ (Navajo, “tube”), kalamos, phragmites (Greek), rancül, reed, reedgrass, ried, rohr, schelef, schilf, schilfrohr, topo, xapij

History

In ancient Egypt, reeds were used for a number of purposes, especially as a source of materials (Germer 1985, 205*). The plant was described by Theophrastus, Dioscorides, and Pliny. Apart from its use as a fermenting agent, no traditional psychoactive use of the plant has been documented to date.

Over time, reeds have been used for a wide variety of purposes, including as roofing material, as a source of cellulose, and in the manufacture of arrows, cane mats, and musical instruments (Aichele and Hofmann 1991, 120*; cf. *Arundo donax*). The plant has even been used as a source of nourishment. The seeds have been made into porridge, the young shoots are a good vegetable, and the sweet pith can be used to make fermented beverages (**beer**) (Bremness 1995, 202*; Timbrook 1990, 246*).

Distribution

The reed is the largest grass in central Europe, where it is often encountered along the shores of lakes (in the water) in so-called reed fields. The grass can grow on land, but only where the water table is close to the surface and does not subside for any length of time, e.g., in sedge meadows and fens (Christiansen and Hancke 1993, 89*). The common reed is now found throughout the world.

Cultivation

The plant is propagated primarily vegetatively. The grass can be easily grown from a piece of the root (rhizome). Reeds prefer marshy soil and require a great deal of nutrient-rich water. They are well suited for use as ornamentals in garden ponds. However, they do not tolerate acidic water (Christiansen and Hancke 1993, 89*).

Appearance

This perennial marsh grass develops a thick, creeping, branching rhizome from which runners grow into the swampy subsurface. The canes can grow from 1 to 3 meters tall. The leaves have rough margins and can attain a length of 40 to 50 cm and a width of 1 to 2 cm. The very large, 15 to 40 cm long panicle is multiflorous and develops four- to six-flowered dark violet spikelets. The flowering period is from July to September (Christiansen and Hancke 1993, 88*). The seeds do not ripen until the winter, when the plant also loses its leaves. The panicle then usually turns light white in color. The new shoots begin to appear in early summer and grow rather slowly. The subspecies *altissimus* can grow to a height of at least 5 meters. In the tropics, the reed can attain a height of up to 10 meters and is then easily confused with *Arundo donax* (Aichele and Hofmann 1991, 120*). The reed can be easily distinguished from *Arundo donax* by the fact that its panicle hangs only to one side (Germer 1985, 205*).

Psychoactive Material

—Root (reed root, radix arundinis vulgaris)

Preparation and Dosage

The fresh or dried rootstock (20 to 50 g) is boiled for at least fifteen minutes, combined with 3 g of *Peganum harmala* seeds, and drunk as an **ayahuasca analog**. Exercise care when determining dosages!

Ritual Use

To the Navajo, the reed is a sacred plant of ritual significance. According to the Navajo creation myth, the reed saved humanity (i.e., the Navajo) during the Great Flood. The Navajo received the reed from a holy person. Humans, animals, and insects climbed into the magical reed, which immediately grew up to the sky. So that it would be able to grow straight up, a holy person took a feather and attached it to the ascending reed, like the feathers on an arrow. For this reason, the reed still has a flower that flutters like a feather in the wind. The shaft of the reed is used to make prayer poles for all ceremonies and healing rituals (Mayes and Lacy 1989, 101 f.*).

The Serí Indians of northern Mexico used fragments of the reed to smoke wild tobacco species (see *Nicotiana* spp.).
