The cosmopolitan reed (*Phragmites australis*) contains potent psychoactive substances.

“I boiled 45 g of roots of *Phragmites australis* for 15 minutes to make a tea. I then ingested a normal dose of *Peganum harmala*, 3 g. It was the most exceptional and pristine experience of my life and definitely the most powerful trip with an ayahuasca analog that I had had to that point. Very visual, with awe-inspiring insights into myself and the world. God, what a day! Six hours full of mind-shattering insights and revelations. Unbelievable sensations of intense beauty. Visions of golden worlds beyond any conception. . . . I was emotionally deeply moved by the exquisiteness and beauty of the experience. . . . There was no nausea or other side effects.”

ANONYMOUS “*PHRAGMITES AUSTRALIS*” (1995, 39)

Artifacts

The reed is depicted in numerous works of art from ancient Egypt, e.g., in the wall paintings at Medinet Habu and Amarna. A hieroglyph (j) was derived from the characteristic flower panicle (Germer 1985, 205 f.*).

The Navajo make the stalks into prayer poles, and many cultures use them to make arrow shafts.

Medicinal Use

In late ancient times, the finely ground root was mixed with onions to prepare a wrap or plant poultice for removing thorns and splinters. “Mixed [with] vinegar, it soothes dislocations and hip pains” (Dioscorides 1.114). In Europe, the herbage was once used as a diuretic (Schneider 1974, 3:54*). An infusion of the roots is used in folk medicine for the same purpose (Aichele and Hofmann 1991, 120*); it can also be used to treat mucus obstruction, coughing, lung pains, and hiccups (Bremness 1995, 202*).

The Navajo use a tea as an emetic agent to treat certain stomach and skin problems (Mayes and Lacy 1989, 101*).

Constituents

The rootstock contains *N,N*-DMT, 5-MeO-DMT, **bufotenine**, and gramine (Wassel et al. 1985).

Effects

Dioscorides stated that the flower tufts of *Phragmites australis*—like those of *Arundo donax*—cause

deafness if they get into the ear (1.114).

Reports about the psychoactive effects of *Phragmites australis* are based almost exclusively on experiences with **ayahuasca analogs** that are composed of the root extract, lemon juice, and *Peganum harmala* seeds. Unpleasant side effects (nausea, vomiting, diarrhea) are usually mentioned (Eros 1995).

Commercial Forms and Regulations

None

The common reed (*Phragmites australis*) is the largest naturally occurring true grass in central Europe. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Phytolacca acinosa Roxburgh

Pokeweed, Shang Lu

Family

Phytolaccaceae (Pokeweed Family)

Forms and Subspecies

The Chinese make a distinction between a form with white flowers and a white root, which they regard as harmless and edible, and a form with red flowers and a reddish root, which is considered dangerous, toxic, and hallucinogenic (Li 1978, 21*). The edible type is presumably the variety *esculenta* Maxim., which formerly was regarded as a distinct species (see “Synonyms”).

Synonyms

Phytolacca esculenta Van Houtte

Folk Names

Cancer-root, Chinese pokeweed, chinesische kermesbeere, dpa’-bo dkar-po, dpa’-bo ser-po (Tibetan), fu, Indian poke, jaringo, jaringo sag (Nepali), juniper, kermesbeerspinat, pokeweed, shang lu, shang-lu, sweet belladonna, tibetische kermesbeere, white pokeberry, yellow pokeberry

History

The edible variety (var. *esculenta*) is mentioned in the ancient *Shih Ching*, the Book of Songs (ca. 1000–500 B.C.E.), under the name *fu* (Keng 1974, 402*). The leaves have long been eaten as a vegetable (Li 1978, 21*). The plant is still in use in traditional Chinese and Tibetan medicine. The genus *Phytolacca* is now quite well known pharmacologically and chemically (Woo 1978). The psychoactivity of the plant is debated.

Distribution

In the Himalayas, the plant occurs at altitudes between 2,000 and 3,000 meters (Polunin and Stainton 1985, 342*). It is found in Tibet, China, Korea, Japan, and India and has become naturalized in some parts of Europe (e.g., Greece). The plant also may be found in many European botanical gardens.

Cultivation

The plant is propagated from seeds, which should be pregerminated and planted in good topsoil. This perennial is quite easy to grow in central Europe. The aboveground herbage dies back after the fruiting period. The root sends forth new shoots the following spring.

Appearance

This bushy, heavily ramified plant can grow to a height of about 1 meter. It has large, oblong, attenuated leaves that can grow as long as 26 cm. The stems are normally light green in color but may also be violet. The terminal flowers grow in clusters. The flowers are whitish, while the ripe berries are dark violet to black. The plant flowers in June and the fruits mature by August. The racemes sometimes bear fruits and flowers simultaneously. The plant has a turnip-shaped root tuber.

Shang lu is easily confused with American pokeberry (*Phytolacca americana* L. [syn. *Phytolacca decandra* L.]). North American Indians of the Pacific Southwest allegedly used this species as a narcotic (Emboden 1986, 164*).²⁷⁹

In contrast to *Phytolacca americana*, *Phytolacca acinosa* has vertical upright inflorescences and infructescences; in the American relative, both of these lean to the side.

The closely related species *Rivina humilis* L. (Phytolaccaceae), which is known as *coralillo*, *colorines*, or *hierba mora*,²⁸⁰ is said to be identical to the Aztec narcotic *amatlaxiotl* (Díaz 1979, 93*).

Psychoactive Material

—Root

Preparation and Dosage

Both the manner(s) in which the root should be prepared for psychoactive use and the dosage that should be used have not come down to us. It is possible that the root was used as an additive in the production of **sake**, for the few sources do mention a “brewed” preparation.

In Nepal, the young, tender leaves and stalks are cooked and eaten as vegetables (Malla 1982, 193). This use is the source of the German name for the leaves, *kermesbeerspinat* (“kermes berry spinach”).

Ritual Use

In ancient China, the root was placed into the same category as ginseng (***Panax ginseng***) and mandrake (***Mandragora officinarum***). The root also was used as a substitute for belladonna root (***Atropa belladonna***) (Emboden 1986, 164*).

T’ao Hung-ching reported that the plant “is used by the Taoists. When it is boiled or brewed and consumed, it is good for lower abdominal parasites and to see spirits” (Li 1979, 22*). Su Sung wrote, “In olden times, it was used a great deal by the magicians [= shamans]” (Li 1979, 22*). Su Ching provides more precise information:

There are two forms of this medicine, one red and one white. The white kind is used in the healing arts. The red kind can be used to conjure spirits; it is very toxic. Otherwise, it can be used only externally for inflammations. If eaten, it is very terrible: it causes bloody stools. It can be lethal. It causes one to see spirits. (Li 1979, 22*)

Unfortunately, nothing more is known about any shamanic or alchemical use of the plant.

The typical infructescence of pokeweed (*Phytolacca acinosa*), the root of which was used in ancient China for psychoactive purposes.

The flower of American pokeweed (*Phytolacca americana*), a plant that Indians used for many purposes, including as a narcotic.

“Plant [*Phytolacca acinosa*] said to have narcotic properties, and produces a bitter toxic substance. The leaves make an excellent pot-herb if well-boiled.”

OLEG POLUNIN AND ADAM STANTON
FLOWERS OF THE HIMALAYA (1985, 342*)

Artifacts

The plant is depicted on Tibetan medicine thangkas (Aris 1992, 79, 235*).

Medicinal Use

In traditional Chinese medicine, the roots of shang lu (*Phytolacca acinosa* Roxb. var. *esculenta* Maxim.) are used to treat tumors, edema, and bronchitis (Yeung et al. 1987; Yi 1992). In Asian folk medicine, the roots are especially esteemed for their anti-inflammatory and antirheumatic effects.

In Tibetan medicine, the roots are attributed with cooling qualities. They are utilized as an antidote, to treat chronic fever, and to treat the pain of wounds. Nepalese Sherpas use a paste made from the roots as a potent purgative to treat food poisoning (Bhattarai 1989, 51*).

Constituents

The roots of *Phytolacca acinosa* Roxb. var. *esculenta* Maxim. have been found to contain various saponins (esculentoside-I, esculentoside-N, phytolaccagenin derivatives) (Yi 1992). The triterpenes phytolaccagenin and acinospesigenin have been detected in the leaves (Spengel and Schaffner 1990). The fruits have yielded acids of the 28,30-dicarboxy-oleanene type and its ester (Spengel et al. 1992). The triterpenoids acinosolic acid, phytolaccagenin (empirical formula $C_{31}H_{40}O_7$), phytolaccagenic acid, esculentic acid, jaligonic acid, phytolaccagenin-A, and acinosolic acids A and B have also been identified (Harkar et al. 1984).

Proteins with abortifacient effects occur in the roots, leaves, and seeds (Yeung et al. 1987).

The species *Phytolacca bogotensis* H.B.K., which is toxic to cattle, has been found to contain cyanoglycosides (Schultes 1977b, 111*).

Effects

Apart from the ancient Chinese sources, according to which the use of shang lu “enables one to see spirits” (i.e., is hallucinogenic), there are no reports of psychoactive experiences.

Sedative effects are possible, as other species in the genus are used for narcotic purposes. The Kofán Indians of Colombia produce a fish poison from the leaves of *Phytolacca rivinoides* Kunth et Bouché and the leaves of a *Phyllanthus* species (Schultes 1977b, 112*).

The saponins (triterpene aglycones) that are present in the roots of the genus have immune-enhancing, anti-inflammatory, and molluscicide effects (Parkhurst et al. 1990; Yi 1992).

Commercial Forms and Regulations

Because the bush is highly regarded as a beautiful ornamental, its seeds are occasionally available from seed suppliers and flower shops.

Shang lu (*Phytolacca acinosa*), a Chinese magical and medicinal plant that is related to pokeweed (*Phytolacca americana*), as depicted in the herbal *Chêng-lei pên-ts'ao* (1249 C.E.).

“The [shang lu] flowers—Ch’ anghau’ —are esteemed for treating apoplexy. The root is so poisonous that it is normally used only externally.”

Piper auritum H.B.K.

Gold Pepper

Family

Piperaceae (Pepper Family); Pipereae Tribe

Forms and Subspecies

It is possible that there are varieties, forms, or subspecies that may be distinguished on the basis of their leaves. However, the taxonomy of the neotropical *Piper* species is quite confusing.

Synonyms

Piper auritum Kunth

Piper umbellatum L.

Piper sanctum (Miq.) Schl. may also be a synonym; Martínez 1987 (page 1188) lists practically the same Mexican names for the two species.

Folk Names

Acoyo, acuya, acuyo, aguiyu, alahan, bakanil a iits' (Huastec), cordoncillo, cordoncillo blanco, corriemineto, coyoquelite, gold pepper, goldpfeffer, hierba anís (“anise herb”), hierba de Santa María (Spanish, “the herb of Saint Mary”),²⁸¹ hierba santa, hinojo sabalero, ho’ben (Lacandon, “the herb of the five”), hoja de anís, hoja de cáncer, hoja santa (Mexico, “sacred leaf”), homequelite, ixmaculan, jaco, jinan (Totonac), maculan, ma’haw, ma’jóo, mak’ulan, mecaxóchitl (Nahuatl), momo, mumun, mumun te’ (Tzeltal), omequelite, omequil-it-dos quelite, Santa María,²⁸² tlampa, tlanepa, tlanepaqueelite, tlanipa, totzoay, tzon tzko ntoko, wo, woo, xalcuahuitl, xmaculan (Mayan/ Quintana Roo), x-mak-ulam, xmak’ulan, x’obel (Mayan/San Antonio [Belize]), yerba santa

History

Gold pepper is an ancient traditional Mayan remedy that was mentioned as a medicinal plant in the few sources from the colonial period (e.g., the Motul dictionary and the *Relación de las cosas de Yucatán*) (Roys 1976, 263*). In contemporary Mexico, the primary use of the plant is as a seasoning; fish and other seafood are wrapped in the large, aromatic leaves and braised (Bye and Lianres 1983, 6*; Cioro 1982, 143*).

In Panama, the leaves were or still are used to catch fish. Apparently, their scent attracts a food fish known as *sábalo pipwu* (Gupta et al. 1985).

In Brazil, the leaves were used in the industrial production of raw safrole for the international market (Rob Montgomery, pers. comm.).

Distribution

Gold pepper is found from Mexico through Central America and into South America. It is very common among the tropical flora of Mexico (Chiapas), Belize, Panama, and Brazil and has been carried into other tropical areas.

Cultivation

The plant is most easily propagated through cuttings (approximately 15 to 20 cm long) taken from the lower stems. In tropical areas, it can very easily go wild and can displace other pepper plants (e.g., *Piper methysticum*), thereby causing some ecological damage (e.g., in Hawaii).

Appearance

This evergreen perennial bush, which can grow to a height of 4 to 5 meters, develops branched green stems that do not lignify on their lower ends until quite late. The leaves are opposite, oval, and tapered at the end and project straight out from the stem or droop slightly. The green-white, very thin inflorescences extend straight up and can attain a length of more than 10 cm.

Gold pepper is easily confused with the very similar species *Piper sanctum* (possibly a synonym), which is also known as *hoja santa* and is also rich in safrole (Martínez 1994, 185*). However, *Piper sanctum* grows to a height of only 1.5 meters and does not occur in the southeastern lowlands (Argueta et al. 1994, 813*).

The closely related and similar, but generally smaller, species *Piper amalago* L. (see *Piper spp.*) also contains safrole and is used ethnobotanically in very similar ways (Arvigo and Balick 1994, 64 f.*). Some Maya regard this species as the “female” counterpart of the “male” gold pepper.

Gold pepper is almost identical in appearance to *Piper methysticum*; most laymen can distinguish the two species only by the scent of the leaves.

Psychoactive Material

- Fresh leaves
- Dried leaves
- Essential oil

Preparation and Dosage

Shade-dried leaves may be smoked by themselves or in combination with other herbs (see **smoking blends**). Fresh leaves are added to **alcohol** (*aguardiente* = sugarcane alcohol, mescal; see *Agave spp.*) (Argueta et al. 1994, 49*).

The **essential oil**, which is easily obtained through steam distillation (Gupta et al. 1985), is suitable as a precursor for the synthesis of amphetamine derivatives (e.g., MDMA; cf. **herbal ecstasy**).

An orally administered dose of 9 g/kg of plant extract did not have any lethal effects upon rats. When administered via injection, the LD₅₀ is calculated as 2g/kg (Argueta et al. 1994, 50*).

The tropical gold pepper (*Piper auritum*) can be recognized by its very large leaves, its perpendicular flowers, and the strong safrole scent of its leaves and young shoots. (Wild plant, photographed in Belize)

“*Maculan* or *Ix-maculan*: Certain bushes or roses, the leaves of which are roasted over the fire and placed onto chronic inflammations as a remedy.”

MOTUL DICTIONARY (SIXTEENTH CENTURY)

Ritual Use

Today in Belize, the large leaves are smoked, most likely as a marijuana substitute (cf. *Cannabis indica*) and for hedonistic purposes. To date, we know of no traditional rituals in which gold pepper has been used for its psychoactive properties.

The natives of the West Indies (or Mexico) are said to have once used *Piper plantagineum* Schlecht., a species found throughout the Caribbean region, as a narcotic in a manner similar to the way kavakava (*Piper methysticum*) is used. It is possible that this species is synonymous with *Piper auritum*. Unfortunately, almost nothing is known about it.

Artifacts

None

Medicinal Use

In Belize (San Antonio, Cayo District), the large, fresh leaves are heated over a wood fire and laid over painful areas of the back, especially around the small of the back. The Yucatec Maya of Quintana Roo use the leaves as a stimulant, as an analgesic, and to treat asthma, bronchitis, dyspnea, weak digestion, stomachaches, head colds, erysipelas, fever, gout, rheumatism, and wounds (Cioro 1982, 143*; Roys 1976, 263*). In Mexican folk medicine, the leaves are used for ethnogynecological purposes. A tea made from the leaves and mixed with **honey** is used to treat scorpion stings. Juice pressed from the leaves is ingested to relieve asthma, coughing, and bronchitis (Argueta et al. 1994, 49*).

The fresh leaf buds and young shoots can be eaten as mild stimulants. When eaten, a mild numbness is produced in the mouth that feels very similar to the anesthesia of the mucous membranes that is caused by *Piper methysticum*.

Constituents

The leaves contain 0.47 to 0.58% **essential oil** (Martínez 1994, 185*). The essential oil is also present in the stalks, although in much lower concentrations (Oscar and Poveda 1983).

The essential oil has a characteristic safrole or sassafras scent and consists of up to 70% safrole; also present are some forty other substances, including α -thujene, α -pinene, camphene, sabinene, β -pinene, myrcene, β -phellandrene, carene, α -terpinene, limonene, 1,8-cineole, γ -terpinene, β -phellandrene, *cis*-sabinene hydrate, nonanon-2, *r*-cymenene, terpinolene, linalool, camphor, borneol, *r*-cymene-8-ol, bornylacetate, eugenol, D-elemene, α -cubenene, muurolene, α -copaene, β bourbonene, paraffin, β -caryophyllene, humulene, myristicin, β -bisabolene, elemicine, D-cadinene, cadina-1,4-dien, spathulenole, β -caryophyllene oxide, and *n*-hexadecane (Gupta et al. 1985; Argueta et al. 1994, 49*).

The leaves have been found to also contain the flavonoid 3'-hydroxy-4',7-dimethoxyflavone, β sitosterol, and the **diterpene** *trans*-phytol. Various phenoles are also present in the leaves (Ampofo et al. 1987). The roots contain isoquinoline alkaloids, phenylpropenoids, and safrole (Argueta et al. 1994, 49*; Hansel et al. 1975; Nair et al. 1989).

Safrole

Effects

The pharmacological effects of the leaves are clearly the result of their high safrole content (cf. *Sassafras albidum*).

Commercial Forms and Regulations

Although the plant is not subject to any regulations, it is not available as a living plant or as dried raw plant material. Because it is a precursor for the synthesis of MDMA and closely related amphetamine derivatives, safrole is subject to registration (cf. **herbal ecstasy**). In some areas, trade in safrole or in preparations with a high safrole content is regulated or even prohibited.

Piper betle Linnaeus

Betel Pepper

Family

Piperaceae (Pepper Family); Pipereae Tribe

Forms and Subspecies

The two most frequently cultivated and utilized varieties differ from one another primarily in their concentrations of **essential oil** and oleoresins:

Piper betle L. var. *bangla*: 5.9% oleoresin, 1.6% essential oil

Piper betle L. var. *metha-thakpala*: 4.9% oleoresin, 2.4% essential oil

Numerous cultivars are distinguished in Sri Lanka: ‘Rata Bulath-vel’, ‘Siribo Bulath’, ‘Naga Walli-Bulath’ (with spotted leaves), ‘Getatodu-Bulath’, ‘Mala-Bulath’, ‘Gal-Bulath’, and ‘Dalu-Kotu-Bulath’ (Macmillan 1991, 427*).

Synonyms

Piper malamiris L. l.c.p.p.

Piper pinguispicum C. DC. et Koord.

Piper siriboa L.

Folk Names

Beatelvine, betel, bétel, betele, betel-leaf, betel pepper, betelpfeffer, betel vine, betle, betre (Malay, “single leaf”), bettele, bettele-pfeffer, bu, buio, bulath (Singalese), bulath-vel, buru, daun syry (Malay), fu-liu, fu-liu-t’êng (ancient Chinese), ikmo (Philippines), liu, mô-lû, nagavalli (Sanskrit), paan, pan, pelu (Thai), pu, sirih, tambul (Sanskrit), tambula (Sanskrit), tembul, veth-thile

History

In Southeast Asia and India, the use of betel leaves must be very ancient (cf. *Areca catechu*, **betel quids**). The plant is mentioned in early Sanskrit texts.

The first European representation of the betel leaf (although entirely inaccurate) can be found on a copperplate engraving from the *Delle navigationi e viaggi* of Giovanni Battista Ramusio (1485–1557), published in Venice in 1553. The first botanically correct representation was published in Paris in 1758 in *Histoire générale des voyages*, by Antoine-François Prévost.

Today, betel pepper (fresh betel leaves) is one of the most important articles of trade in Southeast Asia and in all areas in which large numbers of Indians or Tamils have settled.

Distribution

Betel pepper is indigenous to the Indo-Malayan region but is now grown in all of southern and Southeast Asia and even in the Seychelles and in Mauritius, Madagascar, and eastern Africa. It appears to have originated in central or eastern Malaysia. Some authors have suggested that the plant is originally from Java (Gupta 1991, 79*).

Cultivation

Propagation is performed almost exclusively with cuttings taken from the stem (10 to 20 cm in length). They are either placed in water until they develop roots or placed in moist cultivation beds. The plant requires moist and humus-rich soil and a semishaded location (Macmillan 1991, 427*).

In the tropics, the leaves of this evergreen plant can be harvested throughout the year. They normally are picked in the early morning.

Appearance

Betel pepper is a climbing half-shrub that bears shiny, light green, heart-shaped leaves (up to 18 cm in length). The sheen of the leaves is a reliable characteristic for distinguishing this species from other species of *Piper*, with which it can easily be confused (cf. ***Piper* spp.**). The “buds” (spikes) hang on the leafstalks like long, light-colored threads. The male spikes are cylindrical; the female grow to a length of only 4 cm. The fruit is a spherical drupe about 6 mm in diameter.

Psychoactive Material

—Betel leaves (folia piperis betle, piperis betle folium, betel pepper leaves)

Only fresh leaves are suitable for making **betel quids**; dried leaves can be used for medicinal purposes. The leaves are pressed after they are collected.

Occasionally the “buds” (= spikes) are also used for betel quids.

Preparation and Dosage

Fresh, undamaged leaves that have not begun to dry are used almost exclusively for psychoactive preparations. A normal dosage is one leaf per **betel quid**. A tea can be brewed from fresh or dried leaves. Again, one leaf is used per dosage.

Ritual Use

In India, all of life is ritually associated with the betel pepper. When a parcel of land is being prepared for cultivating betel pepper, a goat is first sacrificed while special mantras are recited. The head of the goat is buried in one corner of the future betel field (*paan mara*), the four hoofs are buried in the four cardinal directions, and the blood, mixed with earth, is distributed along the borders of the field as a landmark. Then a number of *shobhanjana* (*Moringa oleifera*) trees are planted. The betel vines will later grow up the branches of these fast-growing trees. Rows of mandara trees (*Erythrina indica*; see ***Erythrina* spp.**) are planted along the margins of the field as windbreaks. Anyone who enters the field must perform a gesture of veneration, for the field is regarded as a temple and is revered accordingly (Gupta 1991, 77 f.*).

Betel leaves are regarded as sacred and are among the more important offerings that can be made to Shiva, to whom all inebriating plants are sacred (cf. ***Aconitum ferox*, *Cannabis indica*, *Datura metel*, *Strychnos nux-vomica***). Myths describe how the betel vine first grew only in heaven. Shiva asked the plant to go to the people on the earth. At first the vine refused because it was afraid that it would not be sufficiently respected and venerated. Shiva promised the plant that its leaves would be

used with respect in all ceremonies. When he had convinced the plant, it came down from heaven to the earth. For this reason, it is considered good manners to offer guests a few betel leaves (with or without areca nuts; cf. *Areca catechu*). Betel leaves are also used for sprinkling sacred water during every ceremony. When the leaves are combined with cloves, castoreum, salt, and red, black, white, and yellow colors, they are considered a sure agent for banishing demons (Gupta 1991, 78 f.*).

For more on ritual uses, see **betel quids**.

Artifacts

The heart-shaped leaves have been depicted in Indian art since ancient times and are often used as an ornamental decoration on objects for making or consuming **betel quids**.

Medicinal Use

In the folk medicine of southern and Southeast Asia, betel leaves are chewed or eaten to treat coughing, inflammations of the mucous membranes, diphtheria, inflammations of the middle ear, and all types of stomach ailments. In India, the leaves are also used to treat snakebites and as an aphrodisiac (Gupta 1991, 79*).

In Southeast Asia, the roots and inflorescences are used in cases of weak digestion (Macmillan 1991, 424*); the same custom is found in the Seychelles and in other places with an Indian population. In the Seychelles, the leaves are “chewed in order to stay healthy. Seven leaves, finely chopped and placed on wounds, promote healing. A compress is also said to be effective against varicose veins” (Müller-Ebeling and Rätsch 1989, 29*).

Constituents

The leaves contain 0.2 to 2.6% **essential oil** with phenolic constituents (eugenol, isoeugenol, allylpyrocatechol, chavicol, carvacrol) as well as nonphenolic substances (cineole, cadinene, and α -caryophyllene) (Roth et al. 1994, 569*). Also present are safrole, anethol, hentricontane, pentatriacontane, β - and γ -sitosterol, stearic acid, and triacontol. The pungent substance piperine, present in most *Piper* species, has not been detected in the betel pepper.

A team of Chinese researchers isolated and clarified neolignans (methylnpiperbetol, piperol A, piperol B, crotepoxyde) from the stems (and leaves) (Yin et al. 1991). Betel pepper flowers contain large amounts of essential oil, primarily with eugenol and isoeugenol.

Effects

The leaves have stimulant, antibiotic, digestion-promoting, and antifatulence effects (Roth et al. 1994, 569*). They have a clear stimulating and awakening effect and open the perception. The effects appear to be synergistically potentiated by the other ingredients in **betel quids**.

The essential oil has anthelmintic properties (Ali and Mehta 1970) and appears to have anti-mutagenic and cancer-inhibiting effects. As a result, the betel leaf is an important health-promoting component of the betel quid. Pharmacological investigations of aqueous leaf extracts of Indonesian plants carried out at the Center for Research for Traditional Medicine (Airlangga University, Surabaya) have demonstrated that they stimulate phagocytosis, thereby strengthening the body's immune system (Sutarjadi et al. 1991). On the other hand, the neolignan crotepoxyde is said to have pronounced cytotoxic effects (Yin et al. 1991).

Commercial Forms and Regulations

Because betel leaves are internationally recognized as not being an “addictive drug” or “narcotic,” the plant is not subject to any laws regarding medicines or similar regulations but is classified as a

foodstuff (the laws regulating such products may apply). In Switzerland, the fresh leaves are available in shops selling Indian articles.

The betel pepper (*Piper betle*) develops aesthetically perfect heart-shaped leaves, which are used to make betel quids.

One of the first botanical illustrations of the betel pepper. (Copperplate engraving from Antoine-François Prévost, *Histoire générale des voyages*, Paris 1758)

Eugenol

“I would like to add that the scent of this [betel] leaf, when chewed, is reminiscent of that of our mugwort. It produces a breath that incites sensuous pleasure to a high degree, and the number of those who chew the leaf is very large. It simultaneously restores and strengthens, so that it incites anew to the joys of Venus.”

Piper methysticum Forster f.

Kava

Family

Piperaceae (Pepper Family)

Forms and Subspecies

There are numerous cultivars that can be distinguished on the basis of morphological and chemical differences. Botanically, however, few of these have been described as varieties (Hölzl et al. 1993, 201).

In contrast, the Polynesians differentiate among a large number of varieties. In Fiji, six are counted; they differ from one another in the height, length, and thickness of the knots on their stems and the color (from green to purple). *Yagona leka*, which is stocky but develops the best aroma, is particularly esteemed. On the island of Tahiti, fourteen varieties were once recognized and differed from one another solely in their inebriating qualities (Lewin 1886, 6). In Hawaii, a particular distinction is made with regard to the variety known by the name *black awa*, the stems of which are nearly black; in addition, the following forms are also named: *apu*, *kau la'au*, *ke'oke'o*, *kuaea* (= *nene*), *kumakua*, *liwa*, *makea*, *mamaka*, *mamienie*, *mo'i*, *mokilana*, *papa*, *papa ele'ele*, and *papa kea* (Singh 1992, 20). Twenty-one varieties are recognized on the Marquesas Islands and five in Papua New Guinea, and Vanuatu has been reported to have seventy-two different cultivars (Lebot and Cabalion 1988). The existence of such variety may be the reason for the rather different experiences with kava drinks in the different regions. Recently, completely new and previously unknown varieties are said to have been discovered on Vanuatu (Kilham 1996).

Folk Names

Agona, angona, angooner, ava, ava-ava, awa, 'awa (Hawaiian), awa-awa, cáva, gea, gi, intoxicating pepper, kava, kava-kava, kawa, kawa-kawa, kawa pepper, kawapfeffer, malohu, maluk, meruk, milik, poivre enivrant, rauschpfeffer, sakau, wati, yagona, yakona, yangona, yaona, yaqona, yaquona

The Polynesian word *awa* or *kava* means “bitter,” “pungent,” “sour,” or “sourish”; *yangona* (and its derivatives) means “drink” as well as “bitter” and, thus, “bitter drink” (Singh 1992, 15). In most cases, the names given to the plant and to the drink prepared from it are identical. *Piper methysticum* does not grow on Rennel Island (southern Solomon Islands), and no drink made from the plant is used there. However, a drink made there from coconuts (*Cocos nucifera*) is called, strangely enough, *kava kava ngang*i (Singh 1992, 16).

History

Kava is the most important psychoactive agent in Oceania (Lebot et al. 1992). On most of the islands of Polynesia, the use and cultivation of the plant appears to have spread along with the settlement of the islands. Both the plant and kava drinking have also spread into many of the islands of Melanesia (Singh 1992, 15). It has been conjectured that Polynesians colonized Easter Island (Rapa Nui) in the third or fourth century because a chief was “led” there by a kava-induced vision (Ripinsky-Naxon 1989, 221*).

The ethnologist R. W. Williamson has worked out strong resemblances between the Vedic **soma** ritual and the Polynesian kava ceremonies and has conjectured that at least the ritual of kava spread from India to Oceania. There, the kava pepper was used as a substitute for the Indian soma plant (Williamson 1939). Another ethnologist has argued that Polynesia was originally settled by two cultures, which on the basis of their “drug” consumption he called the betel people and the kava people. Even today, the areas in which betel is chewed and those in which kava is preferred can be geographically clearly distinguished (Churchill 1916). The custom of chewing **betel quids** only rarely overlaps with that of drinking kava.

The first Europeans to become acquainted with kava were Captain James Cook (1727–1779) and his fellow travelers. In 1777, Johann Georg Forster (1754–1794), who accompanied Cook, provided the first botanical description of the plant and the associated ceremony (Vonarburg 1996, 57). The report of Cook’s journey (1784) noted that “when several of the members of the ship’s crew partook of the drink, it was observed that it induced an effect like that of a strong dose of an alcoholic drink or even more a stupefaction such as produced by opium [cf. *Papaver somniferum*]. The effects of kava have also been compared to those of wild lettuce [cf. *Lactuca virosa*] and those of hashish [cf. *Cannabis indica*]” (Lewin 1886, 44).

Many islanders used or use kava as an everyday beverage, just as tea (*Camellia sinensis*) or coffee (*Coffea arabica*) is consumed in other parts of the world (Gajdusek 1967; Lewin 1886, 18). There are official kava bars in Fiji and on other islands.

On many South Sea islands, the **alcohol** that was introduced by missionaries has supplanted the use of kava and caused substantial devastation to the indigenous cultures. Fortunately, this situation has seen some reversal in recent decades, as an increase in ethnic identity has given new life to traditional values. As a result, large amounts of kava are once again being consumed in many places, and this has helped to successfully counteract the growth of alcoholism.

Of all of the psychoactive plants that have been introduced into Australia, kava appears to have acquired the greatest significance among the Aborigines. Since 1980, kava drinking has been part of the culture of the Northern Territory (Lebot et al. 1992, 72, 199–202). Some Aborigines use it to treat alcoholism, while others drink such high overdoses of kava that new problems have arisen (Prescott and McCall 1988; Singh 1992, 17).

Kava was first used therapeutically in Europe around 1820. It was initially used primarily in the treatment of venereal diseases (Lewin 1886, 17).

The first pharmacognostic and pharmacological studies were carried out at the close of the nineteenth and the beginning of the twentieth centuries (Lewin 1886; Penaud 1908). Today, kava is a popular “natural tranquilizer” (Vonarburg 1996, 61).

“This folia bettele, which grows throughout India and snakes up both wild and good trees like the pepper or cubeb fruit, is smeared with the already frequently mentioned areca fruit or pynan, together with a little shell lime, and is chewed and eaten by both the great and the common man as a necessity of all necessities; it produces a pleasantly scented breath and cleanses the mouth and the gums of all scorbutic blood. Likewise, it is also laid onto injuries like our plantain or plantago, which makes them thoroughly healthy and they quickly heal.”

GEORGE MEISTER *DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER* [THE ORIENTAL-INDIAN ART

Botanical illustration of the inebriating pepper (*Piper methysticum*). (From De Lessert, *Icones selectae plantarum*, 3:89 [1837])

“Queen Elizabeth of England and the members of her family are always offered kava as greeting when they visit Fiji and they always drink it!”

YADHU N. SINGH “KAVA”
(1992, 28)

Distribution

The original home of kava is unknown; it is occasionally found in New Guinea and on the New Hebrides. Wild plants are unknown, although stands of plants that have become wild are encountered from place to place. Since all of the cultivars are sterile, the plant can have spread only through human activity. It may have developed from *Piper wichmannii* C. DC.

Prehistoric Polynesians brought the plant to Hawaii (= Sandwich Islands) at a very early date. Once there, it spread quickly (Krauss 1981, 2*).

The plant does not occur in New Zealand (cf. *Macropiper excelsum*) or on Easter Island (Whistler 1992a, 185).

Cultivation

The plant is propagated from cuttings (approximately 15 to 20 cm long) taken from the lower stems or from young stems separated from the rootstock (also called a stump) when the root is harvested. The new plant develops shoots after a short growth period. The plant grows into a substantial shrub and is ready to be harvested after five to six years at the most. Kava plantations are fertilized almost exclusively with ash from wood and are well tended:

The cultivation of kava requires great care, skill, and diligence. The soil is often subjected to treatment with the rake for this purpose, freed of weeds and fertilized with lime from shells and coral. . . . In areas where the plant is still cultivated, it is a question of honor for every family to grow good kava. Before the arrival of the missionaries, the kava fields were divided into three parts. The best was given to the gods that can cause harm—it was taboo, i.e., sacrosanct, the

second to the atuas, the gods of sleep, and the third was the family's portion. . . . It was preferred to locate the plantations in places that were raised, on cliffs, and dry. But when there was no other way, one could also find the plants in lower and wetter valleys at the margins of rivers. The plants that develop here do not taste as well and are less aromatic than the former. The plantations are reminiscent of young fig plantations. (Lewin 1886, 13)

The most important commercial areas for growing kava are now found in Samoa, Fiji, and Vanuatu.

Appearance

This bushy, evergreen shrub usually grows to a height of about 2 meters, although it can grow to a height of more than 5 meters. The light green, alternate, heart-shaped leaves can grow as long as 30 cm. The greenish white male inflorescences can attain a length of up to 6 cm and form in spikes attached at the leaf axils; female flowers are unknown (Whistler 1992a, 185). The fruits are said to form one-seeded berries (Lewin 1886). The juicy root (stump) can grow very large, develop multiple branches, and weigh from 2 to 10 kilos.

Piper methysticum is easily confused with similar *Piper* species (e.g., *Piper tutuilae* C. DC.), which are also called *kava* or *ava* (Uhe 1974, 23*).

The closely related species *Piper puberulum* (Benth.) Benth. var. *glabrum* (C. DC.) A.C. Sm. [syn. *Macropiper puberulum* Benth., *Piper macgillivrayi* C. DC. ex Seem.], which is very common in Tonga, is similar in appearance (although it has red inflorescences) and is known as *kavakava'uli* or *kavakava'ulie*, and on Niue even as *kavakava*, but it is not used for psychoactive purposes (Weiner 1971, 443; Whistler 1992b, 73 f.; Whistler 1992a, 169). Another quite similar species is *Piper latifolium* Forst. (also known as bastard kava; Lewin 1886, 8), which grows on the Marquesas. On the Society Islands, *P. latifolium* is known as *avavahai*. Any psychoactive use of this plant is unknown (Steinmetz 1973, 6).

The kava plant is so similar to the American species ***Piper auritum*** that almost the only way to distinguish the two species is by the scent of their leaves. Steinmetz reported a Caribbean species that is also very similar (*Piper plantagineum* Schlecht.) and that the natives of the West Indies or Mexico allegedly once used in a similar manner to kava (Steinmetz 1973, 6).

A variety of inebriating pepper (*Piper methysticum*) that has dark stems is known as the black awa form. (Photographed on Oahu, Hawaii)

The large rootstocks of the Oceanian inebriating pepper (*Piper methysticum*) are used in both fresh and dried form to prepare the tonic, stimulating, and inebriating kava drink.

Kava, the inebriating pepper (*Piper methysticum*), is Oceania's most important psychoactive plant. (Photographed in Hawaii)

“Here is Awa for you, you gods,
 look down upon this family with friendliness,
 let it thrive and increase
 and let us all remain healthy;
 let our plantations, our fruits become good;
 give us nourishment in abundance.
 Here is Awa for you, you war gods!
 Let a strong race grow up for you in this land.
 Here is Awa for you, you wind gods!
 Do not come to this land, but go over the ocean to another.”
 PRAYER AT A KAVA LIBATION (SAMOA) IN *ÜBER PIPER METHYSTICUM (KAWA)*
 (LEWIN 1886, 28)

Psychoactive Material

—Root (rhizome, kava-kava rhizome, kava-kava rootstock, kava pepper root, piperis methystici rhizoma, radix kava-kava, rhizoma kava-kava, rhizoma kavae, waka); usually the peeled stump that has been freed of small roots

The dried plant material must be stored away from light. The stump loses some 60% of its moisture as it dries. The kava from Vanuatu is especially high in quality.

—Fresh leaves

—Fresh or dried stems (lewana)

Preparation and Dosage

The freshly dug root is freed of its small secondary roots, peeled and chopped, and then prepared while either fresh or dried. Kavains (kavapyrones) are not easily soluble in water but do dissolve well in alcohol. For this reason, it is best to prepare an alcohol tincture of the stump. In the pharmaceutical industry, the dried root is used to obtain alcohol/water or acetone extracts with 94% ethanol and 1% ethylmethylketone. The yield, or kavapyrone content, is greatest in a pure alcohol extract (31.6 to 35.4%) and makes up some 30% in alcohol/water mixtures (cf. Hölzl et al. 1993, 203). Sixty to 120 mg of kavapyrones is listed as a medicinal dosage (the amount can vary considerably depending upon the preparation); in clinical studies, 200 to 300 mg were administered daily for a period of several days. In spite of the daily use by countless numbers of Polynesians, the pharmaceutical literature warns against using the plant for a period exceeding three months. Pregnant women and people with endogenous psychoses should also avoid kava (Hölzl et al. 1993, 210).

The traditional production of the refreshing and inebriating kava drink (also known as *ava*, *kavakava*, *sakau*, *wati*, *viti grog*, and *fiji grog*) is identical on almost all of the islands. Normally, the fresh roots are peeled and then chewed by young men (less frequently by girls or young women) for about ten minutes and insalivated. This process can increase the volume of the root pieces considerably. The chewed material is then mixed with water in special sacred vessels (kava bowls, *tanoo*, *kanoa*) made from the hard wood of *vesi* (*Intsia bijuga* [Colebr.] O. Ktze. [syn. *Afzelia bijuga* A. Gray]; Leguminosae [Caesalpiniaceae]) and “fermented” shortly before use. (In the early literature, one could occasionally read that the drink was allowed to “ferment”; this information, however, appears to be based on an error; Lewin 1886, 24.) The resulting milky drink is filtered through a sieve made from the inner bark of *Hibiscus tiliaceus* L. (*vau*, *fau*) or from coconut fibers (*Cocos nucifera*) and poured into drinking bowls. The drink is consumed only while fresh, as it becomes flat and unappetizing if allowed to stand for too long (Steinmetz 1973, 13 ff.).

The finished kava drink has a dark, sometimes brown, yellow, or gray cloudy color and a characteristic taste that can differ in aroma but may also be soaplike, very bitter, or astringent. The drink induces an anesthesia on the surface of the mouth similar to that produced by coca (cf. *Erythroxylum coca*).

In Fiji, the kava drink was once prepared not by chewing (*mama*) the root but by grating it with large mushroom corals (a practice that presumably was also found in other places) (Ford 1967, 165). In Hawaii, kava was made using coconut milk (cf. *Cocos nucifera*) instead of water (Krauss 1981, 2*). In addition, Hawaiian Huna sorcerers (*kahunas*) would boil a poisonous drink from roots collected on days of heavy rain together with the leaves of *Tephrosia piscatoria* [syn. *Theoprosia purpurea*] *Daphne indica*, and a *Lagenaria* species (Kepler 1983; McBride 1988; cf. also Singh 1992, 15).

Typically, each person drinks one to four coco nut shells’ worth of kava drink (= 0.5 to 2.0 liters) at the kava ceremonies. Many Polynesians drink a couple of bowls of freshly prepared kava every day. Some “enthusiastic kava drinkers consume the drink 6 to 8 times a day” (Lewin 1886, 19).

The old notion that kava acquires its inebriating or psychoactive effects only after it has been “fermented” (insalivated) has been clearly refuted (Schmidt 1994, 376 f.). However, the insalivation does appear to enable the kavapyrones (which do not easily dissolve in water) to release in the emulsion and thus be absorbed when the fresh beverage is consumed.

The inebriating (psychoactive) effects become apparent only after the consumption of several liters: “A certain numbness appears only after the ingestion of some 9 liters of the kava drink” (Vonarburg 1996, 58). Chronic consumption of very high doses (13 liters per day, corresponding to approximately 310 to 440 g of dried rootstock) can lead to toxic effects (rash, hair loss, yellow coloration of the skin, reddening of the eyes, loss of appetite, et cetera) (Hölzl et al. 1993, 211). Daily dosages of 4 liters or less will not induce these symptoms or will do so only extremely rarely.

The traditional methods of preparation use some 100 g of dried plant material per 100 ml of water, corresponding to about 70 mg of kavapyrones, oftentimes more (Hölzl et al. 1993, 203). The lethal dosage for humans is unknown. In mice, the LD₅₀ is 1,500 mg of kavapyrones per kilogram of body weight (Hölzl et al. 1993, 212).

The inebriating effects of kava can also result from or be potentiated by various additives:
But kava can also be used alone and without any preparation. A piece of the fresh rootstock about as long and as thick as a finger is a good dosage for inducing psychoactive effects. It should be chewed well and then swallowed. The effects of kava appear to be potentiated by the addition of *Cannabis*.

A tonic can be prepared by emulsifying equal parts of ground kava root and lecithin in a blender. Kava roots are sometimes used as an ingredient in **betel quids**. It is possible that kava roots and honey may be used to brew a **mead** whose effects are more inebriating than those of a cold-water extract of chewed roots. Whether the inebriating beverage known as **keu** was indeed made from *Piper methysticum*, as has been suggested, is unknown.

In the Society Islands, juice from the root of *Piper tristachyon* was formerly used to “ferment” an inebriating beverage known as *ava ava* (von Reis Altschul 1975, 45*).

Kava Additives			
Other substances are occasionally added to the kava drink (Holmes 1967, 107; Lewin 1886, 23; Singh 1992, 23):			
Chili pods	<i>Capsicum</i> spp.	Polynesia	
Kava leaves	<i>Piper methysticum</i>	New Guinea	
Coconut milk	<i>Cocos nucifera</i>	Hawaii	
Thorn apple seeds	<i>Datura metel</i>	Fiji	
Yagoyagona extract	<i>Piper puberulum</i>	Fiji	

Ritual Use

The traditional ritual uses of kava include the kava ceremonies as well as the use of the plant for magical purposes. The more original kava ceremonies are especially well documented in the ethnographic literature and still exist, in the same or at least a similar form, in Fiji, Samoa, and Vanuatu (Lebot et al. 1992; Singh 1992).

Kava ceremonies range from formal to informal in nature. They can function as a greeting for guests, as a part of tribal deliberations, and as a part of the relaxing, social drinking rounds that take place in the evenings. The basic pattern of the ceremonies is always the same. First, the drink is prepared, accompanied by prayers and songs. Then the participants sit either in two groups, one facing the other, or in a circle. The priest, chief, politician, or host distributes equal portions of the drink to all of the participants. The ceremony, which is usually accompanied by collective singing, ends after a number of rounds. At the conclusion, the location at which the ceremony has taken place, the temple, and the ceremonial objects are all cleansed. Sometimes dancing accompanies the ceremony (Singh 1992).

In some places, only men are allowed to take part in the kava ceremonies, while on other islands everyone can drink. The women of Tonga once had their own drinking societies (Lewin 1886, 20). Some initiation ceremonies, such as the initiation of girls into the sacred hula dances, also involve kava. On Niue, it was once only the priests who drank kava, which they did to obtain visions (Singh 1992, 16).

Any person who saw the shark-shaped sea god Sekatoa in the water would have to ceremonially purify himself with a kava drink (Singh 1992, 28).

At their ceremonies or libations, the Samoans—through their chief—ask the gods for health, long life, a good harvest, and success in war. In Samoa, the largest roots are called *lupesina* (“great respect”); they are presented as gifts to people of respect but are not consumed (Cox and O’Rourke 1987, 454).

Kava roots were or are placed as offerings in temples and shrines or hung together with small branches of *Waltheria americana*. Kava roots also are placed on the graves of deceased family members as a last farewell. Perhaps this should be seen in the context of certain mythological traditions, according to which the first kava plant grew upon the grave of a Tongan leper. On the Marquesas Islands, it is believed that the plant was born as a child of the god Atea, who provides food, sends the rain, is the lord of the farmers, and was transformed into the inebriating plant. One story told in Tonga describes how the cooked daughter of the host was placed before the great chief Loua during a feast. When he smelled the roast, he had the well-done flesh buried. The first kava plant grew from the grave. In Vanuatu, it is said that an old man observed a rabbit chewing on a kava root. After watching this on several occasions, he tried the root himself and invented the kava drink (Singh 1992, 18 f.).

On the islands of Vanuatu and other islands of the South Pacific, kava is used in magic, especially magic intended to harm others (Singh 1992, 29). The practice is known as *elioro* in Vanuatu and is used to send out disease or death to a specific person. The sorcerer buries a “deadly object”—usually a kava root upon which incantations have been uttered or a blood-filled bamboo tube—at a spot where it is assumed that the intended victim will pass by. By passing or, even better, walking over the spot, the unsuspecting victim assimilates the harmful magic and then becomes ill or dies (Ludvigson 1985, 56). In contrast, in Hawaii kava is regarded as a means for removing magic (Singh 1992, 15).

Artifacts

The majority of the artifacts associated with kava are those used in its preparation and consumption (shells, bowls, mortars, drinking vessels).

The large, round wooden bowls used in preparing kava frequently feature carved legs (often depictions of people). Strings made of coconut fiber are used to attach cowrie shells (*Cypraea moneta* L., *Cypraea annulus* L.) to the kava bowls of the chiefs for magical protection. In Samoa, the *wa ni tanoa*, “king’s vessel,” was sometimes decorated with the renowned gold cowrie (*Cypraea aurantium* Gmelin), the symbol of the ruler’s office (Ford 1967, 166, 167).

The drinking vessels of Fiji (*m’bilo*, *bilo ni yagona*, *ipu’ava*, ‘*apu ‘awa*) are made from halves of coconut shells (*Cocos nucifera*) to which strings of coconut fibers are sometimes attached. The resinous remnants of the drink impart a glasslike finish to these coconut shells after they have been used enough times. This layer is sometimes scraped off and ingested as an especially potent form of kava (Lewin 1886, 27; Singh 1992, 26). In Tonga, banana leaves are woven together to make single-use kava cups. On the Hawaiian and other Polynesian islands, ritual kava-drinking vessels are made from calabash gourds (*Lagenaria* spp.) (Dodge 1995).

In Fiji and Samoa, there are numerous kava songs that are sung at ceremonies, when greeting people, when making kava, and on other occasions. Some of these songs have been published in ethnomusical recordings (e.g., *Unique Fiji: The Nakamakama Villagers in Meke and Songs*, Olympic Records no. OL-6159, 1979). One psychedelic rock band from England took its name—Kava Kava—from that of the inebriating plant. The plant can also be seen in the paintings of some Hawaiian and Polynesian artists.

Medicinal Use

In Samoa, kava is regarded as an aphrodisiac, tonic, and stimulant. The rootstock is used to treat gonorrhea and elephantiasis (Uhe 1974, 23*; Weiner 1971, 443). The plant is widely used as an internal and external analgesic (Whistler 1992a, 186).

In Hawaii, restless and feverish children are given in the morning and in the evening kava roots that their mothers have prechewed (Krauss 1981, 2*). In Tonga, an infusion of crushed yellow (semiwilted) leaves is administered to crying children as a calmativ (Weiner 1971, 443). In New Caledonia, the fresh leaves are chewed for bronchitis (Weiner 1971, 443); in Tonga, the fresh leaves are rubbed onto the stings of giant centipedes, insects, and poisonous fish (Whistler 1992b, 73). In Oceania, kava is used as an antidote for poisoning by **strychnine** or ***Strychnos nuxvomica*** (Pfeiffer et al. 1967, 155; Schmidt 1994, 474), a traditional use whose effectiveness has been pharmacologically verified (Singh 1992, 39).

In Papua New Guinea, great quantities of kava are chewed and swallowed to induce a kind of numbness for painful tattooing procedures (Steinmetz 1973, 23).

In Western phytotherapy, kava preparations are used to treat states of nervous anxiety, tension, and restlessness (Hölzl et al. 1993, 210; Schmidt 1994) and—according to the claims of certain pill manufacturers—to increase concentration and performance (Hänsel and Woelck 1995). Preparations in which kava is combined with St. John’s wort (*Hypericum perforatum* L.) are used as mild antidepressants (cf. Becker 1994, 3*). The essence or mother tincture (Piper methysticum hom. *HAB34*, Piper methysticum hom. *HPUS88*) is used in homeopathy for such conditions as states of excitation and exhaustion (Hölzl et al. 1993, 212).

One English band from the early 1990s took its name, Kava Kava, from that of the inebriating pepper of the South Seas. The band’s music incorporated both psychedelic and funk influences. However, the CD booklet does not tell us whether the band members were inspired by kava or by more traditional European psychedelics. (CD cover 1995, Delerium Records)

“Kava was so intimately intertwined with the social, religious, and political life of the South Sea islanders, and was the accompanist of every peaceful or hostile undertaking of the individual or the group, for every joyful or sorrowful event of these people, that it is no wonder that the first discoverers of these islands mentioned the plant and its use, sometimes in quite considerable detail. In addition, the magicians and physicians of the natives held it up as a medicine because it not only induced euphoria soon after it was drunk but also was able to induce even painlessness.”

LOUIS LEWIN

ÜBER PIPER METHYSTICUM (*KAWA*) (1886, 15)

Constituents

Kavalactones (= kava pyrones, kavapyrones, α pyrones, kavains) occur in all parts of the plant, usually totaling a concentration of over 5%, with 1.8% kavain, 1.2% methysticin (= kavahine, kavakin,

kavatin, kanakin), 1% demethoxy-yangonin, 1% yangonin, 0.6% dihydrokavain, 0.5% dihydromethysticin, and traces of dihydrokavain-5-ol, 11,12-dimethoxyhydrokavain, 11-hydroxy-12-methoxykavain, 11-methoxy-nor-yangonin, 11-methoxy-yangonin, and the two ethylketones cinnamoylacetone and methylendioxy-3,4-cinnamoylidenacetone (Schulgin 1973; Young et al. 1966). The plant has been found to contain amides (2-methoxy cinnamic acid pyrrolidide, cinnamic acid pyrrolidide), chalcones (flavokavin A and B), and free and aromatic acids (anisic acid, benzoic acid, capronic acid, hydroxy cinnamic acid, and derivatives) (Hölzl et al. 1993, 202; Klohs 1967). A pale yellow **essential oil** has also been described (Lewin 1886, 30).

The leaves contain 0.71% transient piper-methysticin (an alkaloid); this compound is found in the stems in lower concentrations but not in the roots (Cox and O'Rourke 1987, 454). Dihydrokavain, dihydromethysticin, and yangonin are present in the stems. Trace amounts of the substance cepharadione A were discovered in the roots (according to the DAB supplemental volume 6). This substance is also found in other *Piper* species (***Piper* spp.**) (Jaggy and Achenbach 1992).

Kavapyrones are chemically related to longistylines (cf. ***Lonchocarpus violaceus*, balche'**).

Effects

Potent psychoactive effects of the local drink have been reported particularly for Pohnpei (Ponape) (Hambruch 1917; Thurnwald 1908). It is said that after several rounds, the participants in the drinking ritual leave their bodies and are able to glide over the tropical island world in a disembodied state and journey to the heavens, to the home of the kava plant. They experience sensations of fraternization and unity with their environment as well as erotic visions. These and similar statements in the older literature, according to which kava may have hallucinogenic effects, have been cast in serious doubt by many authors who have had numerous experiences of their own (Cox and O'Rourke 1987, 454). The legendary hallucinogenic effect has occasionally been attributed to the additives that may be used (in particular ***Datura metel***; see above).

Frequent mention is made of euphoric effects that begin shortly after the consumption of larger amounts and subside some two to three hours later (Roth et al. 1994, 572*). There is general agreement among both the authors and the kava consumers alike that the drink quenches thirst better than **beer**, has mild stimulating and invigorating effects that revitalize the body after strenuous exertion, clears the head, and stimulates the appetite. In contrast, the aphrodisiac or anaphrodisiac effects are the subject of debate (Lewin 1886; Steinmetz 1973). "Too, *kava* is a means of maintaining or enhancing intimacy" (Gregory 1995, 44). Louis Lewin summarized the reported psychoactive effects in the following way:

Following not too large amounts, a sensation of happy lightheartedness, comfort, and satisfaction appears without any physical or mental excitation. At first, speaking is easy and free and the vision and hearing are more acute for finer impressions. The agent reveals a calming power. The drinkers never become angry, mad, quarrelsome, or paralyzed as with alcohol, which the Fiji Islanders also especially esteem as an advantage of this beverage. The natives and the whites regard it as a sedative in cases of accidents. Both consciousness and the rational faculties remain intact. When somewhat larger quantities are consumed, then the limbs become limp; the muscle power no longer appears to be under the jurisdiction and control of the will; walking becomes slower and more unsteady; the people appear as if half-drunk; one feels the need to lie down. The eye sees objects that are present but does not want to and cannot fix upon them on command, just as the ear perceives without being able or willing to give an account of that which is being heard. An overpowering tiredness and a need to sleep that controls every sensation becomes apparent in the drinker; he becomes somnolent and finally falls asleep. Some

Europeans have observed this power of kava to lame the senses and ultimately lead to sleep, which is like magic, on their own selves. Often, it merely produces a torpid/somnolent state accompanied by disconnected dreams and, according to some reports, by erotic visions as well. (Lewin 1886, 44 f.)

Numerous pharmacological studies have demonstrated that the psychoactive effects of kava are due to the kavapyrones; moreover, they are not caused by one isolated substance but instead appear to be due to the mixture (Meyer 1967, 140). In experiments with mice, extracts have produced strong sedative effects (Hölzl et al. 1993, 203):

Like meprobamat or benzodiazepine [cf. **diazepam**], the kavapyrones are capable of lowering the excitability of the limbic system, whereby the inhibition of the activity of the limbic system is regarded as an expression of a suppression of emotional excitability and an improvement in the mood. (Hölzl et al. 1993, 204)

Muscle-relaxing, antispasmodic, analgesic, local anesthetic, and nerve-protecting effects have all been pharmacologically demonstrated. The kavapyrones also cause a prolongation or deepening of anesthesia (induced, e.g., by chloroform, ether, laughing gas, or barbiturates), for which methysticin has the strongest synergistic effects. Kava extracts have antagonistic effects on dopamine, apomorphine, and amphetamine (cf. **ephedrine**) (Hölzl et al. 1993, 205; Meyer 1976). Kava also potentiates the effects of **alcohol** (e.g., the duration of sleep following inebriation; cf. Zubke 1997). The local anesthetic effects are very similar to those of **cocaine**, procaine, and lidocaine, and the duration of effects is similar (Hölzl et al. 1993, 206; Meyer and May 1964; Singh 1992, 40). There is some evidence suggesting that the kavapyrones bind to the GABA and/or benzodiazepine receptors ([*3H*]-GABA bond, [*3H*]-diazepam bond), thereby exhibiting an affinity similar to that of **muscimol** and **diazepam** (Hölzl et al. 1992). Human pharmacological studies on healthy subjects using 210 mg or even 300 to 600 mg of kavapyrones per day have demonstrated that the quality of sleep is improved, anxiety states are dissipated, and information processing in the brain is improved, while reaction times are unaffected (Hölzl et al. 1993, 207; Hänsel and Kammerer 1996). Often the desired effects do not become apparent until after several days of regular consumption (Schmidt 1994, 376). In rare instances, kava use may result in mild allergic reactions. However, “there are no indications of physical and/or psychological dependency” (Hölzl et al. 1993, 210).

It has frequently been reported that kava can induce marijuana-like effects (cf. ***Cannabis indica***), but that these effects are very subtle and are perceived only following repeated ingestion of the substance (Miller 1985, 59*; Zubke 1997).

Kavain

Methysticin

Commercial Forms and Regulations

Kava, both raw and in its various preparations, is available without restriction throughout the world (even in herb shops, health food stores, supermarkets, et cetera). Many South Pacific islands have bars in which no alcohol is served but various preparations of kava are.

Numerous preparations and products (capsules, tablets, coated tablets, solutions, tinctures) are available in European and Western markets, including capsules containing kava extracts and the oil of St. John's wort (*Hypericum perforatum* L.; cf. Becker 1994*) for treating stress and capsules with extracts of kava and valerian (*Valeriana officinalis*) for relaxation. Each of the Antares® 120 tablets contains 120 mg of kavapyrones; these thus have one of the highest concentrations of all commercial forms (Schmidt 1994, 376). Each capsule of the psychopharmacological agent known as Neuronika contains 200 mg of kavain (cf. Kretschmer 1970). Many products contain only 10 mg of kavapyrones in each pill.

A very early illustration of the production of kava. (Woodcut from *Captain Cook's Three Famous Voyages around the World*)

“The wonder drug of Polynesia represents an enrichment of our treasure of phytotherapeutic medicines. Its use for difficult states of unrest and anxiety is not a task for self-medication. For many of modern man's disturbances of health (‘nervous sleep disturbance, stress-related tension’), it is certainly worth trying this medicinal plant, which is to be preferred over the quick use of the benzodiazepines [cf. **diazepam**].”

MICHAEL SCHMIDT *KAVA-KAVA*
(1994, 377)

“During a time of hunger and need, the Tui Tonga (king of Tonga) wanted to visit his subjects on the island of Eua and sent his messengers to the chief of the island to announce the impending visit. The chief and his wife were put in a difficult position because they lacked all that they needed for the festive greeting in honor of the divine Tui Tonga. After grappling between their hearts and their duty for days and nights, the no-longer-young couple decided to offer Tui Tonga their only child, a beautiful little girl. The beautiful child was dead when Tui Tonga arrived, the parents were grieving beyond all measure, and the entire island was grieving with them. The king was overcome by the events and deeply moved by the faithfulness of his subjects. Tui Tonga bade the mourners to place the dead child in the ground, and as he departed he promised that he would provide them with consolation during the year. Exactly one year to the day later, a plant

that no one had ever seen before grew above the head of the victim. The chief called it ‘kava,’ and a new plant shot forth from the foot end and was given the name *do* (sugarcane). So did kava come to the earth as a mild relief for grieving souls, and *do*, the sweet sugarcane, was given to us to counteract the bitterness of memory that can poison and exhaust the body.”

WALTER HURNI “KAVA—GESCHENK DER GÖTTER” [KAVA—GIFT OF THE GODS] (1997, 66)

Piper spp.

Pepper Species

Family

Piperaceae (Pepper Family); Pipereae Tribe

The genus *Piper* includes some 1,000 to 1,200 species, many of which are ethnobotanically significant (Hölzl et al. 1993, 191; Schultes and Raffauf 1990, 364*). Half of all *Piper* species occur in the American tropics. These include epiphytic plants, climbers, half-shrubs, and small trees. A large number of **essential oils** occur in the genus, so many leaves, inflorescences, and fruits are highly aromatic and have therefore attracted cultural attention. Some *Piper* species are said to have psychoactive, and others aphrodisiac, effects. Safrole and asarone have been identified in various species (such as *Piper divaricatum* Meyer, *P. manassausense*, *P. futokadsura*, and *P. sarmentosum*) (Avella et al. 1994). *Piper abutiloides* Kunth, *Piper cincinnatoris* Yuncker, and *Piper lindbergii* C. DC., which are used in Brazilian folk medicine as analgesics, are pharmacologically active (Costa et al. 1989). It has even been suggested that the common black pepper (*Piper nigrum* L.) is capable of inducing hallucinogenic effects (Schultes and Hofmann 1980, 368*).

The so-called red pepper comes not from a *Piper* species but from the Peruvian pepper tree (*Schinus molle* L.; cf. Norman 1991, 53*). In South America, it is used to aid in the fermentation of **chicha** and also as a **beer** additive.

Piper amalago L. [syn. *Piper medium* Jacq.]—amalago pepper

The leaves of this bush, which is indigenous to Central America (southern Mexico, Belize), are smaller and narrower than those of *Piper auritum*, but the plant is otherwise quite similar in appearance. When rubbed, its leaves smell strongly of the **essential oil** safrole. It may be possible to use this pepper species for psychoactive purposes. The Maya, who call the plant *yaaxpehelche*, regard it as the “younger sibling” or “female” counterpart of *Piper auritum*.

Piper angustifolium Ruiz et Pavón—matico pepper

It is not known whether this American pepper species has psychoactive effects by itself. Because of the disinfectant properties of its fresh leaves, the plant is also known as soldier’s herb. Its leaves and inflorescences are an ingredient in various Aztec cacao recipes (see *Theobroma cacao*) and have a mild stimulating effect because of the **essential oil** that is present (Rätsch 1991a, 185*). Some authors regard *Piper angustifolium* as a synonym for *Piper elongatum*, which is also known as matico pepper.

Many wild pepper species, such as the Central American *Piper amalago*, contain stimulating and inebriating essential oils. (Wild plant, photographed in Belize)

***Piper cubeba* L. [syn. *Cubeba officinalis* Miq. (or Raf.)]—cubeb pepper**

This climbing shrub, which is indigenous to the Sunda Islands and eastern Asia, grows preferentially on *Erythrina indica* [syn. *E. variegata*] (cf. ***Erythrina* spp.**) and is the source of the fruit that is sold under the names *cubeb*, *kubeb*, *cubeb pepper*, *pimenta cubeba*, and *fructus cubebae* (Macmillan 1991, 415*; Norman 1991, 54*). The fruits contain 10 to 20% **essential oil**, 2.5% cubebin ($C_{20}H_{20}O_6$), and amorphous cubeb acid. Large doses of the essential oil can induce irritation in the urinary tract as well as headaches, which is why one of the fruit's folk names is dizzy corns. Such typical CNS symptoms as anxiety states and delirium have also been reported. Two grams has been given as a well-tolerated single dosage, while the daily dosage should not exceed 10 g (Roth et al. 1994, 570*). Hildegard von Bingen described the psychoactive effects as well as an anaphrodisiac effect that is difficult to understand:

The cubeb is warm, and this warmth in itself is of the proper mixture, and it is also dry. And when someone eats cubeb, then any unseemly desires that are within him are moderated. But it also makes his spirits cheerful and his reason and knowledge pure, for the useful and moderate warmth of the cubeb extinguishes the unseemly flames of desire in which the stinking and slimy liquids are hidden, and it makes the spirit of man and his reason illuminatingly clear. (*Physica* 1.26)

Cubeb is used in folk medicine in cases of weakness of memory and to increase the sexual appetite (aphrodisiac) (Gottlieb 1974, 26 f.*; Hölzl et al. 1993, 196). In Yemen, where they are known as *kebâb*, the fruits are regarded as an aphrodisiac and nerve tonic (Fleurentin and Pelt 1982, 92 f.*). In former times, cubeb was often used as a spice. Today, it is used only in Asian cuisine (e.g., as an ingredient in curries). It is one of the primary ingredients in the Moroccan spice mixture *ras el hanout*, which also contains cardamom (*Elettaria cardamomum*), nutmeg fruits and flowers (***Myristica fragrans***), galanga (*Alpinia* sp.; cf. ***Kaempferia galanga***), long pepper (*Piper longum*), cinnamon (*Cinnamomum verum*), cloves (*Syzygium aroma-ticum*), ginger (***Zingiber officinale***), rose buds (*Rosa* sp.), lavender flowers (*Lavandula angustifolia* Mill.), Spanish fly (*Cantharides*), ash berries (*Fraxinus* sp.?), paradise corns (*Amomum melegueta*), black pepper (*Piper nigrum*), peanuts (*Arachis hypogaea* L.), turmeric (*Curcuma longa*), cassia (*Cinnamomum cassia*), fennel seeds (*Nigella sativa*), monk's pepper (*Vitex agnus-castus*), belladonna (***Atropa belladonna***), and violet root (*Viola odorata* L.) (Norman 1991, 96 f.*). The consumption of large quantities of this spice mixture is said to produce psychoactive and aphrodisiac effects. Cubeb pepper is also an ingredient in **Oriental joy pills** and was once used as an additive to wine (see ***Vitis vinifera***).

Red pepper is obtained not from a *Piper* species but from the American tree *Schinus molle* L. (From Hernández, 1942/46 [Orig. pub. 1615]*)

The fruits of the aphrodisiac cubeb pepper (*Piper cubeba*).

In India, the long pepper (*Piper longum*) is renowned as an aphrodisiac.

Botanical illustration of the aphrodisiac cubeb pepper. (Engraving from Pereira *De Beginnselen der Materia Medica en der Therapie*, 1849)

“On Cubeb: The Javanese, because they attribute many good virtues to this fruit, are protective of it, and so that it cannot be reproduced by any nation, it is said that they lay it in warm water before they trade it, which makes it incapable of developing. Apart from this, they swallow these and eat them for all kinds of ailments, like fever, cold stomach, and such things. In addition, when soaked in wine and then drunk, it is said to help strengthen the work of Venus.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]

(1677, CH. 9, P. 18*)

***Piper elongatum* Vahl [syn. *Artanthe elongata* (Vahl) Miq., *Piper angustifolium* Ruíz et Pavón, *Piper purpurascens* D. Dietr., *Steggensia elongata* (Vahl) Kunth]—matico pepper**

The matico or soldiers’ pepper comes from the Central and South American tropics and has a long history of use as a medicine and as an agent of pleasure. The leaves contain 0.3 to 6% **essential oil**, in which asarone and parsley apiol are present alongside the primary component, dillapiol (cf. *Acorus calamus*, *Petroselinum crispum*). Matico pepper is used in Panama as an aphrodisiac and stimulant (Hölzl et al. 1993, 198). In Mexico, it is one of the traditional spices for cacao (see *Theobroma cacao*). It is possible that mild psychoactive effects can result from the consumption of high doses of the leaves.

***Piper interitum* Trelease—tetsi pepper**

The Kulina Indians of Peru use the leaves and roots of *Piper interitum*, which they call *tetsi*, to produce a **snuff** used as a substitute for tobacco snuff (cf. *Nicotiana tabacum*) that is alleged to have psychoactive properties (Schultes 1978b, 227*; Schultes and Raffauf 1990, 365 f.*).

***Piper longum* L. [syn. *Chavica roxburgii* Miq., *Chavica sarmentosa* (Roxb.) Miq., *Piper latifolium* Hunter, *Piper sarmentosum* Roxb.]—long pepper, pippali**

In Asia and Arabia, the unripe fruits of the long pepper are used as a spice, an aphrodisiac, and a medicine (Fleurentin and Pelt 1982, 92 f.*; Rätsch 1995). They contain approximately 1% **essential oil** with sesquiterpene hydrocarbons and *p*-cymene, dihydrocarveol, terpinols, and α -thujene as well as

amides (piperidine and others). The drug has vasodilatory properties (Hölzl et al. 1993, 200). In Asia, long pepper has been used as a spice for much longer than black pepper (Norman 1991, 52*). While black pepper has been regarded as an aphrodisiac in Europe since ancient times, long pepper has an even greater reputation. Long pepper is a principal ingredient in numerous recipes for the aphrodisiac preparations used in tantric rituals (cf. **Oriental joy pills**). It is regarded as an “inciter” in Ayurvedic medicine. Its qualities are pungent, heating, and sweet, which is why it strengthens the functions of the genital system and is said to provide the organs of desire with a warming energy (Lad and Frawley 1987, 249*). The Ananga-Ranga, an ancient Indian book on the art of the love, lists a tantric “secret agent”—possibly with psychoactive effects—that awakens the lingam (= phallus) to life:

Take a few corns of black pepper [*Piper nigrum*], seeds of the thorn apple [*Datura metel*], one pod of pinpalli (*Piper longum*, which yields the pepper that works slowly, or betel powder [*Areca catechu*]) with lodhra peel or *Morinda citrifolia*, which is used for dyeing; rub this with light honey and [rub it on the lingam]. This agent is unsurpassable. (Johann Wolfgang von Goethes, Ananga-Ranga 1985, 65)

The spice mixture *trikatu*, “three spices,” which is widely known in India, consists of equal parts of long pepper, black pepper, and dried pieces of gingerroot (*Zingiber officinale*). This mixture is considered to be the most important Ayurvedic stimulant. *Trikatu* is a rejuvenator for *agni*, the inner fire. At the same time, it is important as an agent that is taken together with other medicines; its stimulating effects potentiate or improve the assimilation of all kinds of active substances.

The common pepper (*Piper nigrum*, fresh fruits) has also been attributed with psychoactive and even hallucinogenic effects.

***Piper plantagineum* Schlecht.**

This Caribbean species was once allegedly used in the West Indies (Mexico) in a similar manner to *Piper methysticum*; it may be identical to *Piper auritum*.

***Piper* sp.—sryboea**

In his book *Der Orientalisch-Indianische Kunstund Lustgärtner* [The Oriental-Indian Art and Pleasure Gardener] (1677), George Meister, who traveled to the East Indies, described a species of *Piper* that was used in a similar manner to or as a substitute for betel pepper (*Piper betle*):

On Foliis Sryboae. These run lengthwise up the trees in the same way as folia bettele or pepper. The fruit is almost that of a long pepper species, pungent taste, looking like the so-called aments that hang on the hazel nuts in the spring, but somewhat thicker and longer, almost a span in length. These are cut from one another and eaten along with filled bettele leaves and the fruit areca [cf. *Areca catechu*]. In addition, they also take the flower, known as canange, which has yellow petals, with this, so that it has not just a pleasant scent but also a good taste. (Ch. 9, 20)

Unfortunately, the species of pepper described here as an additive to **betel quids** cannot be determined with certainty. The “canange flower” is very likely the blossom of the ylang-ylang tree (*Cananga odorata*; cf. **essential oils**).

***Piper* spp.—masho-hara**

The Tanimuka and Yucuna Indians of the Río Miritiparaná (Amazonia) boil the very aromatic leaves of one *Piper* species to prepare a drink that is said to invigorate the elderly (Schultes 1993, 135*). Other species of *Piper* that are also known as *masho-hara* or *yauardi-hena* are used as ritual **snuffs** in Amazonia. The Muinane from the region of La Pedrera make a snuff from the dried leaves of a *Piper* species and tobacco (*Nicotiana tabacum*). Shamans chew or smoke various *Piper* species to track down cases of witchcraft. The Canelo use a *Piper* species that they call *guayusa* (cf. *Ilex guayusa*) as a stimulant (Schultes and Raffauf 1990, 367 f.*). One *Piper* species endemic to Papua New Guinea that has not yet been botanically described contains kavalactones (cf. **keu**).

The pepper species (*Piper* sp.) known in Aztec as *mecaxochitl*, “cord flower,” is used as an additive to Indian cacao drinks. (From Hernández, 1942/46 [Orig. pub. 1615]*)

The infructescences of the long pepper (*Piper longum*) and black pepper (*Piper nigrum*) have been used as spices, stimulants, and aphrodisiacs. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Psidium guajava Linnaeus

Guajava Tree, Guava

Family

Myrtaceae (Myrtle Family)

Forms and Subspecies

There are a number of wild forms and cultivars, which differ primarily in the size of their fruits (Lutterodt and Maleque 1988, 219).

Synonyms

Psidium guajava Raddi

Psidium pomiferum L.

Psidium pyrifera L.

Folk Names

Aci'huit, äh pichib, al-pil-ca (Chontal), arazá, a'sihui't (Totonac), asiuit, asiwit, bec (Huastec), bek, bijui (Zapotec), bimpish (Shipibo-Conibo), bui, ca'aru (Coya), carú, chak-pichi (Mayan, "red guava"), chalcócotl (Aztec), coloc, cuympatan, djambubaum, enandi (Tarascan), gouyave, guabesbaum, guáibasim (Mayo), guajavabaum, guajava tree, guajave, guajave-apfel, guava,²⁸³ guave, guavenbaum, guayaba, guayaba dulce, guayaba manzana, guayaba perulera, guayabilla, guayabilla cimarrona, guayabo, guayabo colorado, guayabo del monte, guayabo de venado, guayabo morada, guayavabaum, guyav, huayabo, jaljocote pichi, jalocote, jukoin papoxtik, julú, kautonga, kolok, kuava, ku'ava, kuawa (Hawaiian), kuma (Siona), lacow (Huave), mo'eyi (Cuitlatec), ngoaba (Fang), ñi-joh (Chinantec), nulu (Cuna), pachi', palo de guayabo blanco, pata (Tzotzil), patan, pehui (Zapotec), pichi, pichi' (Mayan), pichib, pici, pitchcuy, pocs-cuy (Zoque), pojosh (Popoluca), posh-keip (Mixe), potoj, potos, pox (Mixe), poxr, puitá, sacpichi, sahuintu, saiyú, sumbadán (Zoque), tuava, tzon t kichi (Amuzgo), ushca-arú (Tepehuano), vayeavaxi-te (Huichol), vî papalagi, xalácotl (Nahuatl), xalcolotl, xalcócotl, xaxokotl, xaxucotl (Náhuatl), xoxococuabítl (Aztec), yagahuií (Zapotec)

The fruits of the guava tree are rich in vitamins. In contrast, the narcotic principle is found in the leaves. (Copperplate engraving from Meister, *Der Orientalisch-Indianische Kunst- und Lustgärtner* [The Oriental-Indian Art and Pleasure Gardener], 1677)

History

The plant was originally native from Mexico to Brazil but is now grown throughout the world as a tropical economic plant (Anzeneder et al. 1993, 59*). In Peru, it was already in cultivation by the eighth century B.C.E. (Root 1996, 105*). The first report about the guava tree is contained in *Relación de las cosas de Yucatán*, written by the Franciscan monk Diego de Landa (1524–1579). One of the earliest botanical descriptions of the tree as well as a copperplate engraving of the fruits were provided by the East Indies traveler George Meister (1677). The chewing of the leaves as a narcotic and diarrhea medicine is well known in the tropics. In contrast, the psychoactive use of the leaves was only recently discovered in Ghana (Lutterodt and Maleque 1988, 220).

Distribution

The guava tree is apparently originally from Mexico but is now found in all of the tropical zones from Mexico to Peru (Dressler 1953, 154*). It also is planted in other parts of South America (Brazil, Paraguay, Argentina), where it sometimes occurs as a wild or feral plant (Santos Biloni 1990, 222*). It prefers a distinctly tropical climate and has spread throughout the world (Africa, Oceania, Southeast Asia, India).

Cultivation

Propagation occurs through cuttings or seeds. In nature, the seeds are spread by birds, bats, rodents, and humans. The seeds contained in the fruits pass through the digestive tract without harm and are excreted “well fertilized” (Lutterodt and Maleque 1988, 219).

Appearance

The small, gnarled evergreen tree, which does not grow much taller than 10 meters, has squamous bark and opposite elliptical leaves (5 to 15 cm long, 3 to 6 cm wide). The large white flowers have five petals and have a large number of stamens (up to 275). The fruits (approximately 7.5 cm in length) are initially green but turn yellow and exude a fruity aroma as they mature. The fruits of the wild form contain a great number of seeds and only a little pulp. This situation is reversed in cultivated fruit trees, which develop only a few seeds while producing a great deal of pulp (Lutterodt and Maleque 1988, 219 f.).

The guava tree is easily confused with *Psidium acutangulum* DC., which also is called *guayaba* and cultivated for its edible fruits (Vickers and Plowman 1984, 24*).

Psychoactive Material

—Leaves (djambu leaves, djambu folium, folia djambu)

—Bark

—Root cortex

Preparation and Dosage

The fresh leaves are chewed or drunk as a decoction as needed. Overdoses do not appear to occur.

In Southeast Asia, and especially in China, a narcotic *Psidium* drug is obtained in a very unusual manner. The fresh leaves are fed to insects (walking sticks, praying mantises, especially *Heptapteryx dilata*) as their exclusive food. The dung the insects excrete is collected, kneaded into small balls, dried, and stored in an airtight container. When needed, some of these balls are dissolved in hot water and drunk. The wine-colored drink is said to have a “pleasant taste” (Lutterodt 1992, 156).

The tropical fruit tree *Psidium guajava* has leaves that produce narcotic effects.

Quercetin

Ritual Use

Use of the leaves as a psychoactive substance was first observed among the Ga tribes who live near the coast in Ghana. They chew the fresh leaves. It has not been reported whether ritual customs (e.g., communal chewing as a socially integrative element, magical acts, healing ceremonies) are associated with this use. The Ga say that the chewed leaves exert a depressing effect upon the central nervous system that is useful in cases of sleeplessness, and that the leaves also suppress the effects of **alcohol** (Lutterodt and Maleque 1988, 220).

In the Philippines, the bark is chewed in **betel quids** as a substitute for areca nuts (*Areca catechu*) (Hartwich 1911, 529*).

Artifacts

None

Medicinal Use

In many traditional medicine systems, the leaves are used as an analgesic, a neuroleptic, and an agent for treating diarrhea (including that caused by cholera) (Lutterodt 1992, 151). However, folk medical knowledge of the beneficial effects of the leaves as a diarrhea medicine (which have been pharmacologically confirmed) is not as widespread as one might assume (Lutterodt 1992, 155).

In Hawaii, the fresh young leaves are chewed and swallowed to treat diarrhea (Krauss 1981, 24*). An infusion of the leaves is used for the same purpose in Trinidad (Wong 1976, 133*).

The Yucatec Maya drink a decoction made from the bark or the leaves to treat diarrhea (Pulido S. and Serralta P. 1993, 46*). In Belize, a tea made from the leaves is gargled to treat mouth sores and bleeding gums. A decoction of nine leaves and nine young fruits (boiled for twenty minutes) is drunk three times daily before meals in cases of diarrhea, dysentery, upset stomach, and colds (Arvigo and Balick 1994, 121*).

In South America, teas made from the leaves are drunk to treat digestive disorders (Anzeneder et al. 1993, 59*). In Chile and Peru, the leaves are chewed to strengthen the teeth (Schultes 1980, 110*). In Panama, the leaves are chewed for toothaches (Lutterodt and Maleque 1988, 220).

The Fang of central Africa use the leaves to make an anthelmintic juice (Akendengué 1992, 169*). In Samoa, the leaves are used as a cough medicine and as an antidote for all types of poisonings (Uhe 1974, 22*).

Constituents

The leaves contain some 10% tannin, β -sitosterol, maslenic acid, guaijavolic acid, essential oil (chiefly caryophyllene, along with β -bisabolene, aromadendrene, β -selinene, nerolidiol, caryophyllene oxide, sel-11-en-4a-ol, and eugenol), triterpenoids (oleanolic, ursolic, crategolic, and guaijavolic acids),²⁸⁴ a quercetin derivative, guaijaverin (= 3- α -l-arabopyranoside), and several unidentified substances (Argueta et al. 1994, 711*; Lutterodt and Maleque 1988, 220; Wong 1976, 133*). The glycoside quercetin²⁸⁵ and its derivative (quercetin-3-arabinoside) are regarded as the primary active constituents (responsible for the narcotic effects) (Lutterodt and Maleque 1988, 229).

In an earlier study, guava leaves were found to contain the polyphenols quercetin, guaijaverin, leucocyanidin, and amritsosite (Seshadri and Vashishta 1965). Opiates (**opium alkaloids**) and cannabinoids (cf. **THC**) have not been detected (Lutterodt 1992, 152).

The fruit contains large amounts of vitamins (A, B, C), about two to three times as much as an orange (Arvigo and Balick 1994, 121*).

Effects

Animal experiments using a leaf extract demonstrated a distinct morphinelike effect as a result of inhibition of acetylcholine release (cf. **morphine**). This effect was likely produced by the quercetin contained in the leaves (Lutterodt 1989 and 1992, 152). The active constituent does not appear to bind to the opioid receptors and is not thought to have any “addictive potential” (Lutterodt and Maleque 1988, 225). Toxic effects and overdoses are unknown (Argueta et al. 1994, 711*).

A hot-water extract of dried leaves has antibacterial effects upon *Sarcina lutea*, *Staphylococcus aureus*, and *Mycobacterium phlei*. An aqueous extract of the fresh leaves has fungicidal effects (Arvigo and Balick 1994, 121*).

Commercial Forms and Regulations

Guava leaves are sometimes found as ingredients in tea mixtures (stomach teas) sold in pharmacies (Pahlow 1993, 437*).

Whether the psychedelic underground duo Ween named their debut album *Pure Guava* for the narcotic effects of guava leaves or used the fruits as a symbol for other substances is something the listener must decide. (CD cover 1992, Electra Records)

“Xalxocotl—Guajava-apple The Xalxocotl tree has thin foliage, sparse foliage. Its wood is brown-red on the surface. Its branches fall off. Its fruit is pale, dark yellow, delicate, very delicate, grainy. Its heart is like sand. They are round; it is sweet-sour. It makes one belch, makes one’s teeth dull, increases the flow of saliva. My teeth are dull. My saliva is flowing. I am becoming sour. My teeth are dull.”

Psychotria viridis Ruíz et Pavón

Chacrana

Family

Rubiaceae (Coffee Family)

Forms and Subspecies

It is possible for white thorns (domatia) to develop along the central nerve on the underside of some chacruna leaves. South American *ayahuasqueros* distinguish different forms of the plant on the basis of the number of these thorns. Plants with three thorns per leaf are considered to be particularly potent, medicinal, and well suited for the production of **ayahuasca**. A form with nine thorns is regarded as the highest quality.

Synonyms

Psychotria psychotriaefolia (Seem.) Standley may be a synonym (cf. ***Psychotria* spp.**).

Folk Names

Amirucapanga, cahua (Shipibo-Conibo), chacrona, chacruna, chagropanga, chalipanga, horóva (Campa), kawa (Cashinahua/Sharanahua), oprito (Kofán, “heavenly people”), sami ruca

History

It is not known when the use of chacruna in Amazonia first began. It is presumably as old as the use of ***Banisteriopsis caapi*** and **ayahuasca**. But it was only in the 1960s that the American ethno-botanist Homer Pinkley (a student of Schultes) first observed and described the psychoactive use of the plant among the Kofán Indians of Colombia, who use it as an ayahuasca additive (Pinkley 1969). Linnaeus, who provided the first botanical description of the genus *Psychotria*, derived the name of the genus from *Psychotrophum* (Patrick Browne), a term that had already been circulating in the literature. Unfortunately, he did not provide any reason for this action. It is quite possible that the genus name means that it “influences the psyche” (cf. Pinkley 1969).

Distribution

The tropical bush is at home primarily in the undisturbed forests of the Amazon lowlands but has spread from Colombia to Bolivia and into eastern Brazil as a result of extensive cultivation. It is said to occur also north of the Amazon region and into Central America (Pinkley 1969, 535). Today, there are also plantations in Hawaii and northern California.

Cultivation

The plant is difficult to propagate from seed. The seeds can require sixty days to germinate. Sometimes, only one seed in a hundred will germinate. In contrast, cultivation from cuttings is much easier and more successful. A small branch needs only to be set in the ground and watered thoroughly. Plants can be grown even from a branch piece having only two leaves, and it is possible for individual leaves and leaf pieces to develop into plants. It has been claimed that a young plant once developed from a piece of leaf that was accidentally covered with soil. The plant requires moist,

humus-rich soil. It can survive an occasional flooding of its location, as occurs in Amazonia (Pinkley 1969).

Appearance

The evergreen bush can grow into a small tree with a very woody trunk, but in cultivation it is usually maintained at a height of 2 to 3 meters. It has long, narrow, ovate leaves that are light green to dark green in color and whose upper side is shiny. The flowers have greenish white petals and are attached to long stalks. The red berry fruits contain several small ovate-oval retuse seeds (approximately 4 mm in length). The convex side is streaked with three parallel grooves with irregular edges.

Psychotria viridis is easily confused with other *Psychotria* species. *Psychotria psychotriaefolia* in particular is very similar in appearance and may in fact be a synonym (see ***Psychotria spp.***).

Psychoactive Material

—Leaves

Preparation and Dosage

The leaves must be collected in the morning and are used both fresh and dried to manufacture **ayahuasca** and **ayahuasca analogs**. The dried leaves are coffee brown in color. The leaves also can be used to produce an extract that thickens to a tarlike mass and can be smoked.

As little as 1 ml of the juice pressed from the fresh leaves is said to contain some 100 mg of **N,NDMT** (cf. Russo 1997, 6).

Ritual Use

See **ayahuasca**.

Artifacts

See **ayahuasca** (“Ayahuasca Music—A Discography,” on page 711).

Medicinal Use

The Machiguenga use juice that has been freshly pressed from the leaves of *Psychotria viridis* or another *Psychotria* species (***Psychotria spp.***) as eyedrops for treating migraine headaches (Russo 1997, 5). While *Psychotria viridis* does have a reputation as a medicinal plant, such use has been little studied to date (see also **ayahuasca**).

Constituents

The leaves contain 0.1 to 0.61% **N,N-DMT** along with traces of MMT and MTHC (= 2-methyltetrahydro- β -carboline). The DMT content is typically around 0.3%. *Psychotria* leaves appear to contain the highest concentrations of DMT in the early morning, which is why they should be collected at that time (Dennis McKenna, pers. comm.).

Effects

The Kofán Indians say that by mixing *Psychotria viridis* leaves into their yagé (= ayahuasca; cf. ***Banisteriopsis caapi***), they are able to see the *opríto*, the small “heavenly people” that bear the same name as the plant (Pinkley 1969, 535). When used as an ayahuasca additive, the leaves manifest typical DMT effects (see **ayahuasca**).

Commercial Forms and Regulations

The dried leaves are occasionally available from sources specializing in ethnobotanical products. The legal situation with respect to the raw plant material has not been clarified.

A large-leaved variety of the DMT-containing plant *Psychotria viridis*.

A small-leaved type of *Psychotria viridis*.

“*Psychotria* L. (Rubiaceae), derived from ψῆξ (soul, life) and τρεῖν (nourish, maintain); according to P. Browne, the seeds of *Ps.* herbacea are used on Jamaica to produce a pleasant, coffeelike drink. Linnaeus contracted the name *Psychotrophum* that Browne had originally coined.”

Psychotria spp.

Wild Coffee, Psychotria Species

Family

Rubiaceae (Coffee Family)

Most of the approximately 1,200 to 1,400 *Psychotria* species that have been described are found in the tropical zones of Central and South America, although a few species occur in the rain forests of Malaysia and in New Caledonia (Standley 1930). In the Caribbean, the seeds of some species, e.g. *Psychotria nervosa*, are referred to as wild coffee and drunk as a coffee substitute (cf. *Coffea arabica*). The fruits of many *Psychotria* species (*P. involucrata* Swartz, *P. nudiceps* Standley) are regarded as poisonous (Schultes 1969, 158; 1985). **N,N-DMT** has been demonstrated to be present in several species. Some contain the alkaloid psychotridine, and others indoles (Lajis et al. 1993). Some species (*Psychotria poeppigiana* Muell. Arg., *Psychotria ulviformes* Sterm.) appear to contain opium-like constituents (Elisabetsky et al. 1995, 78). The Yucatec Maya regard the Central American species *Psychotria acuminata* Benth. (*ix-anal*) and *Psychotria tenuifolia* Sw. (*x'anal*) as “male” and “female” counterparts and use them to treat nervousness and sleeplessness (Arvigo and Balick 1994, 45, 105*). In Europe, *Psychotria emetica* (L. fil.) Mutis, the Peruvian vomit plant, was known in particular as a counterfeit for ipecac (*Cephaelis ipecacuanha* [Brot.] Tussac [syn. *Psychotria ipecacuanha* (Brot.) Stokes]) (Rätsch 1991a, 136 f.*; Schneider 1974, 3:135 f.*). The vomit-inducing substance emetine is said to occur in numerous *Psychotria* species (Fisher 1973, 231).

Psychotria brachypoda (Muell. Arg.) Britton

This *Psychotria* is used traditionally as a pain medicine. The species contains active constituents with opium-like, analgesic effects (Elisabetsky et al. 1995).

Psychotria carthaginensis Jacquin—**sameruca**

According to information provided by the Colombian Makuna Indians, eating the fruit of this bush will induce perceptual alterations that can persist for days, nausea, weakness, and fever (Schultes 1969, 158). The leaves, which contain some **N,N-DMT**, are used as an ayahuasca additive (Schultes 1985, 118).

Psychotria colorata (Willd. ex R. et S.) Muell. Arg.

This bush is known as *perpétua do mato* in the Brazilian Amazon, where it is used in folk medicine to treat ear and lower abdominal pain. The Caboclos produce eardrops by heating the flowers in banana leaves on hot ashes. A decoction of the roots and fruits is drunk to treat abdominal pains. The leaves and flowers have been found to contain alkaloids with opium-like effects whose structures have not yet been determined (Elisabetsky et al. 1995).

Psychotria poeppigiana Muell. Arg.—**oreja del diablo** (Spanish, “devil’s ear”)

In Amazonia (Ecuador), the nectar of this species is used as a traditional ear medicine. The leaves are rich in **N,N-DMT** and are evidently well suited for use as an ayahuasca additive (**ayahuasca analogs**) (Rob Montgomery, pers. comm.). In the Putumayo region of Colombia, the roots are used to treat

lung ailments (Schultes 1985, 119; Schultes and Raffauf 1990, 395*).

Among the Ka'apor, *Psychotria poeppigiana* Muell. Arg. is called *yawaru-ka'a*, “black jaguar plant,” or *tapi'i-ka'a*, “tapir plant” (Balée 1994, 303*). These names suggest that the plant may be used for shamanic purposes (animal transformation).

***Psychotria psychotriaefolia* (Seem.) Standley**

In the Colombian Putumayo region, the leaves of this species are used together with *Banisteriopsis caapi* to produce **ayahuasca**. In Ecuador, both the leaves and the fruits are used for this purpose (Schultes 1969, 158). The addition of this plant to the mixture is said to deepen and prolong the visions. The leaves contain **N,N-DMT**. The Kofán Indians call the plant *oprto*. They use this same name to refer to the “heavenly people” that they contact while under the influence of **ayahuasca** (164). This species may be synonymous with *Psychotria viridis*.

Psychotria nervosa is also known as wild coffee. However, nothing is known about any possible psychoactivity.

Some *Psychotria* species develop very striking flowers and fruits. (A *Psychotria* species, photographed in Chiapas, Mexico.)

***Psychotria* spp.**

Among the many members of the genus *Psychotria*, there are certainly other species that contain **N,N-DMT** and may be suitable for use as ayahuasca additives. We already know of some as yet undescribed members of the genus that are used to make **ayahuasca** and are often called by the name *chacrana*.

While the leaves of *Psychotria poeppigiana* are not traditionally used in the production of ayahuasca, they do contain high concentrations of DMT.

“*Psychotria carthaginensis* has also been reportedly used as an *ayahuasca* admixture, and preliminary studies likewise detected DMT in leaves of this species. . . . Various unidentified species of *Psychotria* are also used as *ayahuasca* admixtures by Peruvian Sharanahua and Cashinahua Indians. *Psychotria* leaves called *pishikawa* and *batsikawa* were added to *ayahuasca* by Sharanahua of the upper Río Purús region . . . , and the latter was said to be inferior. . . . *Nai kawa* was thought to be *P. alba*, *P. carthaginensis*, *P. horizontalis* or *P. marginata*. Clearly, more detailed taxonomic and ethnobotanical studies are needed to clarify the identity of these *Psychotria* species. A number of species of the genus are used ethnomedicinally throughout Amazonia.”

JONATHAN OTT *AYAHUASCA ANALOGUES* (1994, 25*)

Rhynchosia pyramidalis (Lam.) Urban

Bird’s Eyes

Family

Leguminosae: Papilionideae (Legume Family); Subfamily Fabodeae

Forms and Subspecies

The genus consists of some three hundred species that are found in the tropical and subtropical regions of both hemispheres (Schultes and Hofmann 1980, 338*).

Synonyms

- Dolicholus phaseoloides* Sw.
- Rhynchosia phaseoloides* (Sw.) DC.

Folk Names

Äh mo’ ak’ (Lacandon, “ara parrot vine”), antipusi, atecuixtle, atecuxtli, bejuco culebra, bird’s eyes, casanpulgas, chanate pusi, cha’pak’ (Mayan), colorín chiquito, colorincito, colorines (cf. *Erythrina americana*), coralito, frijol de chintlatlahua, frijolillo, guarecitas, gun-ma-muy-tio-ña (Chinantec), krebssaugenbohne, liucaí-nofal (Chontal), negritos, ojitos de picho (Spanish, “little eyes of the dove”), ojo de cangrejo (Spanish, “crab’s eye”), ojo de chanate (Mexico, “eye of the thrush [*Cassidix mexicanus*]”), ojo de culebra (Spanish, “eye of the snake”), ojo de pajarito (Spanish, “eye of the little bird”), ojo de zanate (Mexico, “eye of the thrush [*Cassidix mexicanus*]”), pega palo, peonía, perico, peyote (see *Lophophora williamsii*), pipilzintli, piule, pulguitas, puren-sapicho, saltipús, senecuilche (see *Heimia salicifolia*), shasham wupu’är (Pima), sinicuiche, xenecuilche

“I was still living in the unformed world when the hermaphroditic animals rose in the heavy atmosphere of the depths of the dark waters —when fingers, fins, and wings were still a single thing, when eyes without heads swam around like mollusks between steers with human faces and snakes with dog’s paws.”

GUSTAVE FLAUBERT

LA TENTATION DE SAINT ANTOINE [THE TEMPTATION OF SAINT ANTHONY]

(1979, 122*)

History

The Aztecs may have used the striking seeds of this plant for ritual purposes (Schultes and Hofmann 1980, 340*). The red-black seeds, which are known by the name *piule* (Santesson 1938), were or are used ritually in the village of San Pedro Nexapa, on the slopes of Popocatepetl (Mexico) (Wasson and Wasson 1957, 306 f.). In Mexico, the name *piule* has been used as a catchall term for psycho-active plants since the twentieth century (Martínez 1987, 757*; cf. *Psilocybe mexicana*, *Turbina corymbosa*). The word *piule* may have been derived from the Nahuatl *peyotl* (= *Lophophora williamsii*). Accordingly, *piuleros* are those people who use a psychoactive substance (*piule*) to divine and/or heal (Santesson 1937a, 1937b). Some species, e.g., *Rhynchosia longeracemosa* Mart. et Gal., are now also known by the name *peyote* (Schultes 1966, 296*).

Distribution

This climber is found throughout the tropical and warm regions of Mexico and on many islands of the Caribbean (Cuba) (von Reis and Lipp 1982, 139*). It usually grows at the edge of forests and in clearings. It is frequently found in fallow milpas (slash-and-burn gardens).

Cultivation

The seeds are best pregerminated in a mixture of soil and moss. The seedlings must be planted in topsoil and watered well as soon as the seeds have opened and the young shoots have become visible (Grubber 1991, 56*). The plant requires a moist, warm climate and in northern zones can thus be grown only as a houseplant.

Appearance

The vine, which can grow to a length of several meters, has the typical leaves of the Legume Family, in which three leaves sit upon each stalk. The greenish flowers are arranged in long racemes. The bean-shaped seedpods are constricted between the two small, red-black, almost spherical hard seeds (4 to 6 mm long).

The kidney-shaped seeds of the closely related *Rhynchosia longeracemosa* are “mottled light- and dark-brown” (Schultes and Hofmann 1992, 55*).

Rhynchosia pyramidalis is often confused with *Abrus precatorius* L. (jequirity, rosary pea), which is widely feared as a poisonous plant. It too produces red-black seeds, although they are somewhat larger (6 to 7 mm long). Jequirity can be recognized by its smaller, pinnate leaves. The seeds of *Abrus precatorius* contain abrin, a lectin mixture that is unstable when heated and one of the most potent of all known toxins, along with several alkaloids (Ghosal and Dutta 1971; Nwodo 1991; Nwodo and Alumanah 1991; Roth et al. 1994, 83 f.*). In Mexico, the seeds of *Abrus precatorius* are known as *colorines* (see *Erythrina* spp.). They are associated with the mescal bean cult (see *Sophora secundiflora*); ashes from the leaves are used as a coca additive (see *Erythroxylum coca*).

Psychoactive Material

—Seeds (semina rhynchosiae phaseoloides, bird’s eyes, *colorines*)

—Stalks

Preparation and Dosage

In entheogenic rituals in the high valleys of Mexico, twelve untreated seeds were ingested with six pairs of *Psilocybe aztecorum* per person (Wasson and Wasson 1957, 306).

Ritual Use

To date, the only description that is available pertains to the ritual use of the seeds in connection with the ingestion of mushrooms. The ingestion of the seeds is presumably more symbolic in meaning, for the red-black seeds represent bodiless, free-floating eyes, a symbol of psychedelic and prophetic vision.

The Zapotec of Miahuatlan are said to have used the seeds of the closely related species *Rhynchosia minima* (L.) DC. [syn. *Dolicholus minimus*] in magical rituals (Díaz 1979, 87*).

Artifacts

The small, durable seeds are made into amulets and chains (cf. *Erythrina americana*, *Erythrina* spp., *Sophora secundiflora*).

Wall paintings at Teopantitla (near Teotihuacán) allegedly show the seeds falling out of the hand of the rain god Tláloc (D. McKenna 1995, 102*). The red-black coloration is said to be an indication of the seeds’ hallucinogenic use (Schultes 1970c; Schultes and Hofmann 1980, 340*).

Medicinal Use

The seeds are regarded as a narcotic and poison in Mexican folk medicine (Jiu 1996, 254*). The Yucatec Maya use the root along with other herbs to produce a medicine to treat pellagra²⁸⁶ (Pullido S. and Serralta P. 1993, 37*). The Pima of northern Mexico grind the seeds on a mortar and strew the powder into the eyes of those who are suffering from the “evil eye” (Pennington 1973, 223*).

In the Dominican Republic, the stalks are used to prepare an aphrodisiac drink (Díaz 1979, 87*).

Constituents

The chemistry of the constituents has not yet been clarified. Reports about the alkaloids are contradictory (Santesson 1937a). The seeds apparently contain alkaloids similar to those in *Sophora secundiflora* and *Erythrina* spp. (D. McKenna 1995, 102*). The root may possibly contain niacin or nicotine amide, for it is used in the Yucatán as a folk medicine to treat pellagra (maidism). Whether the flavonol rhynchosin (Adinarayana et al. 1980) occurs in the plant is unknown.

Effects

In Mexico, it is commonly believed that the seeds cause “imbecility” or “madness” (Díaz 1979, 87*; Jiu 1996, 254*). There are as yet no reports of actual psychoactive effects. An extract of the seeds is said to have curare-like activity (Schultes and Hofmann 1980, 340*).

Commercial Forms and Regulations

The seeds are sometimes available through the international seed trade. Mexican Indians sometimes sell necklaces with beads of *Rhynchosia* seeds.

The bird's eyes vine (*Rhynchosia*) in bloom. (Photographed in Palenque, Mexico)

The seeds of *Rhynchosia* resemble those of the poisonous jequirity (*Abrus precatorius* L.) to the smallest detail.

An Indian necklace made from the seeds of *Abrus precatorius*. Because the toxic alkaloids are supposedly absorbed through the skin, many tourists fear wearing such chains. Experience, however, has shown that the wearing of such a necklace will not result in any effects. Jequirity seeds contain the alkaloid abrin, which is lethal at a dosage of 0.01 mg/kg. This notwithstanding, particularly courageous Plains Indians appear to have used the seeds as “red medicine” for vision quests.

“Just one single seed [of jequirity, *Abrus precatorius*]—which must however be chewed thoroughly before swallowing—can produce lethal effects in humans. Cattle and goats are more resistant, but 60– 120 g of seeds can also kill a horse.

A case of poisoning proceeds in the following sequence: First, stomach pains become noticeable, the urge to vomit appears, the patient falls into a coma, and the circulation collapses so that the patient dies. . . . In some tropical countries, the unripe seeds are used to murder a person; they are formed into sharp needles that are then stabbed into the victim. Because the toxin can directly enter the bloodstream in this manner, it is usually lethal. . . . In some places, the seeds are used to produce decorative objects. They are used, for example, to make necklaces, chains, and also rosaries.”

Salvia divinorum Epling et Játiva-M.

Ska María Pastora

Family

Labiatae (Lamiaceae; Mint Family); Subfamily Nepetoideae, Salviae Tribe, Salviinae Subtribe, Dusenostachys Section

Forms and Subspecies

Only clones or races of varying bitter taste are known. The Wasson clone is very bitter and is derived from plants collected in 1962; the “palatable clone,” which has hardly any bitter taste, was collected in Llano de Arnica, Oaxaca, by the American ethnobotanist Bret Blosser (Ott 1996, 33).

Synonyms

None

Folk Names

Aztekensalbei, blätter der hirtin, diviner’s sage, foglie della pastora, hierba de la pastora, hierba de la virgen, hoja de la pastora (Spanish, “leaf of the shepherdess”), hojas de adivinación, hojas de maría pastora, la hembra, leaves of the Mary shepherdess, mazatekischer salbei, pipiltzitzintli, sage of the seers, salvia, salvia of the seers, ska maría pastora, ska pastora (Mazatec, “leaf of the shepherdess”), wahrsagesalbei, yerba de maría, yerba maría, zaubersalbei

History

The Aztecs knew and used a plant they called **pipiltzintzintli** (literally “the noblest little prince”) in entheogenic rituals in a manner very similar to the ways in which they used mushrooms (*Psilocybe spp.*). A number of authors have suggested that this plant was *Salvia divinorum* (Wasson 1962; Ott 1995, 1996).²⁸⁷

Gordon Wasson discovered the plant and its divinatory use in 1962. That same year, the plant was first botanically described by Carl Epling and Carlos D. Játiva-M., botanists from UCLA. In the 1960s, Albert Hofmann was unable to discover any active constituents in an initial analysis of juice pressed from the plant (Hofmann 1979, 151–68*; 1990). The chemistry and pharmacology was not clarified until the 1980s and 1990s, when **salvinorin A** was discovered (Ortega et al. 1982; Valdés 1994; Valdés et al. 1987; Siebert 1994).

Distribution

Salvia divinorum is endemic to the Mazatec region of the Sierra Madre Oriental in the Mexican state of Oaxaca. Apart from this, the plant is found only as a cultigen among “neo-shamans” and in botanical gardens. It occurs naturally in tropical rain and cloud forests at altitudes between 300 and 1,800 meters (Reisfield 1993). Because of its small original range, the plant is one of the rarest of all natural entheogens. It is now grown by plant enthusiasts around the world.

Cultivation

Propagation is performed with cuttings or layers/shoots. All leaves except the topmost pair are

removed from an 8 to 12 cm long branch tip, which is then placed in water. The cutting should develop roots in about two weeks. It can be planted in soil after about four weeks. *Salvia divinorum* requires a great deal of water and prefers high to very high humidity. If the edges of the leaves turn brown, this is a sure sign that the air is too dry. As a shade plant, it does not tolerate any direct sunlight, prefers dark soil, and needs copious amounts of water, i.e., it should be watered almost every day. Although the plant is sensitive to cold, cultivated *Salvia divinorum* can survive a mild frost.

Methods for cultivating the plant from seed are currently being investigated (cf. Reisfield 1993).

Appearance

The evergreen plant is an herbaceous perennial that can grow to over 1 meter in height. Its most characteristic feature is its completely four-sided, sometimes even square stem, which can grow as thick as 2 cm. Its edges are angular. Both the opposite leaves and the side branches develop from nodes on the stem. The light to dark green leaves are entirely covered in fine hairs and attain a length of over 20 cm and a width of some 10 cm. The leaves are lanceolate and tapered at both ends. The paniced inflorescences appear at the ends of the stalks and look exactly like those of *Coleus blumei*. The campanulate calyxes are bluish or purple in color, while the petals are always white (Reisfield 1993; cf. Brand 1994, 540). In Mexico, the plant blossoms between October and March but primarily in January. In cultivation, the plant seldom flowers, and fruits almost never develop. Recently, however, one clone has been discovered that develops fruits and seeds more frequently. A hummingbird has been observed as a pollinator (Reisfield 1993). The seeds germinate and begin to develop, but with our current gardening techniques, they all eventually die.

Salvia divinorum can be confused with a similar, closely related Central American species, *Salvia cyanea* Lamb. ex Benth. (Epling et Játiva-M. 1962; Mayer 1977, 777).

Psychoactive Material

—Fresh or dried leaves (salvia divinorum leaves, folia salviae divinorum, divination leaf)

Preparation and Dosage

The Mazatec take thirteen pairs of fresh leaves (twenty-six leaves in all) and roll them into a kind of cigar (quid) that they place in the mouth and suck on or chew while retaining it in the mouth. The juice is not swallowed, as the active constituents can be absorbed only through the mucous membranes of the mouth. At least six fresh leaves are needed to prepare one quid (threshold dosage), while more distinct effects will occur with eight to ten leaves. When consumed in the form of a quid, the effects appear after almost exactly ten minutes and persist for some forty-five minutes. The dried leaves are best smoked by themselves. Here, as little as half an average-sized leaf (two or three deep inhalations) can be sufficient to elicit profound psychoactive effects. Usually, however, one or two leaves are smoked. The dried leaves can be soaked in a *Salvia divinorum* tincture, after which they should again be allowed to dry.

Dried *Salvia divinorum* leaves are becoming popular as an ingredient in **smoking blends** and even in the manufacture of psychoactive **incense** (Valdés 1994).

Tinctures are prepared from fresh or dried leaves by using an ethanol-water mixture (60% alcohol). The tincture can be either used to impregnate dried leaves, thereby potentiating their effects, or applied sublingually. Dosages appear to vary considerably in their effects among individuals. In addition, several experiments seem to be needed before the effects become apparent. Looking back, however, one realizes that there were noticeable effects before.

For information concerning the use and dosage of the primary constituent, see “Constituents” and also the discussion of **salvinorin A** (cf. also Ott 1995; Siebert 1994; Valdés 1994).

Ritual Use

The shamans and shamanesses of the Mazatec of Oaxaca use *Salvia divinorum* in divinatory and healing rituals, usually as a substitute for the preferred psychoactive mushrooms (cf. *Psilocybe mexicana*, *Psilocybe* spp.). Only a few shamans prefer to use this *Salvia*. The ritual use is very similar to that of the mushrooms (Hofmann 1990).

Salvia divinorum rituals almost always take place at night in complete darkness and silence. Either the healer is alone with the patient or other patients as well as healthy participants are present. Before the shaman and perhaps other people chew and suck the leaves in the form of a quid, the leaves are fumigated with copal (cf. **incense**) while prayers are spoken and the quids are consecrated to the higher powers. After chewing the leaves, the participants lie down and try not to make any sound. Both sounds and sources of light will greatly disturb the visionary experience. Because the effects of the leaves are much shorter in duration than those of the mushrooms, *Salvia* rituals rarely last more than one or two hours. If the visions are sufficiently pronounced, the shaman will have identified the cause of the illness or some other problem. He then reports to the patient, provides appropriate advice, and ends the nocturnal meeting (Hofmann 1990; Mayer 1977; Ott 1995; Valdés et al. 1987; Wasson 1962).

In Mazatec folk taxonomy, *Salvia divinorum* is related to two species of *Coleus*. *Salvia* is *la hembra* (“the mother”), *Coleus pumila* (a species introduced from Europe) is *el macho* (“the father”), and *Coleus blumei* is both *el nene* (“the child”) and *el ahijado* (“the godchild”) (Wasson 1962, 79). It is this relationship that is responsible for the psychoactive reputation of *Coleus*.

In the region of Puebla, a similar and botanically as yet unidentified species of *Salvia* known as *xiwit* is cultivated for use in treating the folk ailment *susto* (“fright”) and in rituals. The ritual is said to be very similar to that practiced by the Mazatec (Díaz 1979, 91*).

The “sage of the seers” (*Salvia divinorum*), from the Mazatec region of Oaxaca, is known only from cultivation.

“Under the direction of Maria Sabina, one of the children, a girl of about ten years of age, prepared the pressed juice of five pairs of fresh leaves of *hojas de la pastora* for me. I wanted to make up the experience with this drug, which I had missed in San José Tenango. The drink is said to be especially powerful when it is prepared by an innocent child. The cup with the pressed juice was also fumigated and Maria Sabina and Don Aurelio spoke over it before it was handed to me. . . . Probably as an effect of the *hojas*, I found myself for a time in a state of increased sensitivity and intense experience that was not accompanied by any hallucinations.”

ALBERT HOFMANN *LSD—MEIN SORGENKIND* [LSD – MY PROBLEM CHILD]
(1979, 164 f.*)

Artifacts

The botanist William Emboden has suggested that certain floral elements in the Mayan hieroglyphic manuscripts may represent *Salvia divinorum* (cf. *Nymphaea ampla*). This interpretation is difficult to imagine, for the plant is entirely unknown in the Yucatán Peninsula.

The American artist Brigid C. Meier has produced several paintings inspired by her own *Salvia divinorum* visions.

A riotous novel titled *Nice Guys Finish Dead* (Debin 1992) features *Salvia divinorum* and a “super drug” called NICE made from the plant.

Medicinal Use

Indians use nonpsychoactive preparations to treat defecation and urination disorders, headaches, rheumatism, and anemia and to reinvigorate the infirm, the aged, and the dying (Brand 1994, 541; Valdés 1994, 277).

Constituents

The leaves contain the neoclerodan **diterpenes salvinorin A** and salvinorin B (= divinorin A and divinorin B) as well as two other similar substances whose composition has not been completely determined (Brand 1994, 540; Siebert 1994; Valdés 1994). The main active constituent is **salvinorin A**, which can induce extreme effects in dosages as small as 150 to 500 [μ]g (Siebert 1994, Zubke 1997).

Loliolide,²⁸⁸ a substance known from *Lolium perenne* L. (cf. *Lolium temulentum*), has also been detected (Valdés 1986).

Neither an **essential oil** nor thujone, which is known to occur in other *Salvia* species, has been discovered to date (Ott 1996, 35).

Effects

Most people who have ingested *Salvia divinorum* in the form of a quid or tincture or by smoking have reported very bizarre and unusual psychoactive effects that are difficult to compare to the known effects of euphoric or psychedelic substances. Space is often perceived as curved, and surging and rolling body sensations or out-of-body experiences are frequently described as typical.

Daniel Siebert has summarized the phenomenology of the effects of *Salvia divinorum* in the following way:

Certain themes are common to many of the visions and sensations described. The following is a listing of some of the more common themes:

1. Becoming objects (yellow plaid French fries, fresh paint, a drawer, a pant leg, a Ferris wheel, etc.).
2. Visions of various two dimensional surfaces, films and membranes.
3. Revisiting places from the past, especially childhood.
4. Loss of the body and/or identity.
5. Various sensations of motion, or being pulled or twisted by forces of some kind.
6. Uncontrollable hysterical laughter.
7. Overlapping realities. The perception that one is in several locations at once.

(SIEBERT 1994, 55)

These effects are strongly reminiscent of those that are experienced at subanesthetic dosages (50 to 100 mg) of ketamine (Ketanest®) (Bolle 1988; Jansen 1996).²⁸⁹

Commercial Forms and Regulations

Living plants are increasingly available from sources specializing in ethnobotanical products, especially in North America and Europe. The plant is not regulated in any way.

“When I wish to heal a sick person during the time in which there are no mushrooms, then I must turn to the leaves of the pastora. When

you rub and eat them, they work like the *nienn*. Of course, the pastora is not as powerful as the mushrooms.”

Sassafras officinale Th. Nees et Eberm.

Sassafras officinalis Nees et Eberm.

Sassafras sassafras (L.) Karst.

Sassafras variifolium (Salisbury) O. Kuntze

Sassafras variifolium (Salisbury) O. Kuntze var. *albidum* (Nutt.) Fern.

Folk Names

Ague tree, cinnamon wood, fenchelholz, fenchelholzbaum, laurus sassafras, nelkenzimtbaum, pavane, saloop, sassafrasbaum, sassafras tree, sassafrax, sassafrax tree, saxifrax, sommerlorbeer

History

North American Indians were already drinking a tea of sassafras root cortex in pre-Columbian times for stimulant, tonic, and medicinal purposes. In 1582, sassafras wood was included in lists of German medicines under the names *lignum pauamum*, *lignum floridum*, and *sassafrasbaum* (Schneider 1974, 3:230*).

The name *sassafras* is apparently a corruption of the Spanish word for the genus *Saxifraga*, which the Spanish botanist Monardes coined in the sixteenth century. Even into the twentieth century, a sassafras tea with milk and sugar known as saloop was sold on many London street corners in the early mornings (Grieve 1982, 715*).

During the American Civil War, the root cortex was used as a substitute for Chinese tea (*Camellia sinensis*) (Havard 1896, 45*). Until recently, it was also used in the United States as a flavoring agent in root beer, a nonalcoholic soft drink (Bremness 1995, 83*). In the southern states, dried, young leaves are used as a spice in gumbo, a Creole dish.

This illustration of a Mexican plant called *sasafrás*, presumably the oldest illustration of a plant of this name, may represent *Elaphrium pubescens* Schlecht. (From Hernández, 1942/46 [Orig. pub. 1615]*)

Distribution

Entire forests of the tree are occasionally found along the Atlantic Coast from northern Florida to Canada. The variety *albidum* occurs from Maine west to Michigan and Illinois and south to Virginia and Arkansas. The variety *molle* is found from Maine to New York; in Illinois, Iowa, and Kansas; and as far south as Florida and Texas (Zander 1994, 500*).

Cultivation

The tree can be propagated from ripe seeds that have not yet dried, from cuttings, or from root scions. The tree thrives in almost all types of soil but does best in good topsoil. It requires a temperate climate (Grubber 1991, 58 f.*).

The plant is cultivated for pharmaceutical purposes primarily in the states of New Jersey, Pennsylvania, and North Carolina and reportedly in northern Mexico and Taiwan as well (Bertram and Abel 1994, 611).

Appearance

This deciduous tree, which can grow as tall as 30 meters, bears foliage that is green in summer and golden red in autumn. The thick bark is deeply furrowed and has a different structure in each of the two varieties. The clusters of small yellow flowers appear before the new leaves. The small blue fruits (pea-sized drupes) are attached to red stalks.

The sassafras tree is particularly recognizable by the shape of its leaves. The tree develops three different forms of leaves, each of which appears on a separate branch. The smallest form is oval, while the somewhat larger form is oval with an indentation (two-lobed). The largest and most frequent (three-lobed) form is deeply digital with two indentations. The tree also can be identified by the typical scent of safrole, which is exuded when the leaves are rubbed or crushed.

The sassafras tree can be confused with the other two members of the genus, *Sassafras tzumu* (Hemsl.) Hemsl. and *Sassafras randaiensis* (Hay.) Rehd. (Bertram and Abel 1994, 610).

Psychoactive Material

- Root pith (sassafras lignum, lignum sassafras, sassafras wood, lignum pavanum, fenchelholz)
- Essential oil**, obtained from the root pith through steam distillation (sassafras oil, sassafras aetheroleum, oleum sassafras, sassafrasöl, fenchelholzöl, essence de sassafras)
- Root cortex (= root bark; sassafras radix, sassafras cortex, fenchelholzrinde)

This leaf shape is characteristic of the sassafras tree (*Sassafras albidum* var. *albidum*).

This illustration of the American sassafras tree may in fact be the earliest European representation of the plant. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

The very aromatic root cortex can be obtained from the living tree without killing it. A hole is dug to reveal a piece of the root (no more than one third). The root cortex is then carefully removed. Care must be taken not to damage the inner cortex so the tree is able to regrow the root cortex that has been removed (Grubber 1991, 59*).

Other Species of Sassafras

Other trees are also known as sassafras in North America: *Magnolia virginiana* is known as swamp sassafras, *Massoja aromatica* is called *Sassafras goesianum*, and *Umbellularia californica* is known as California sassafras (Grieve 1982, 716*).

The tree *Mespilodaphne sassafras* Meister is called Brazilian sassafras and is also used as a counterfeit for true sassafras wood (Bertram and Abel 1994, 615).

The **essential oil** obtained from *Ocotea cymbarum* H.B.K. (Lauraceae) is permitted to be sold under the name *sassafras oil* or *Brazilian sassafras oil* (Bertram and Abel 1994, 611).

In Australia, the name *sassafras* is applied to trees from the Family Monimiaceae that “smell of sassafras” and also contain safrole: *Atherosperma moschatum* Labill (southern sassafras, black sassafras) and *Doryphora sassafras* Endl. (real sassafras, yellow sassafras, canary sassafras). Both trees are used to produce a “bush tea” with stimulant and tonic properties. In addition to the essential oil, the bark of *Doryphora* also contains the alkaloid dryphorine (Cribb 1984, 172, 174*).

Preparation and Dosage

Sassafras formerly was used as an additive to **beer** and to perfume tobacco (*Nicotiana tabacum*) (Schneider 1974, 3:231*).

To prepare as a tea (called sassafras tea or saloop), add 30 g of chopped root cortex to 0.5 liter of boiling water. A normal dosage for a blood depurative tea is regarded as 2.5 g of chopped root (sassafras wood). Pour boiling water over this amount and strain after ten minutes (Wichtl 1989). As a single dose, 5 g of sassafras wood can be ingested (Bertram and Abel 1994, 617).

One or two drops of sassafras oil, dissolved in **alcohol**, can be taken several times daily as a medicinal dosage. The *EB6* lists 0.1 g as a single dosage (Bertram and Abel 1994, 612). A good starting dosage for aphrodisiac and psychoactive purposes is regarded as 100 to 200 mg of the oil (Gottlieb 1973, 45*). This dosage should be increased only with great care, as overdoses can result in kidney irritation (Pahlow 1993, 418*). One teaspoon of sassafras oil can induce “vomiting, dilated pupils, stupor and collapse” (Grieve 1982, 716*). The safrole present in the oil is regarded as carcinogenic (Bertram and Abel 1994, 612 f.). In former times, sassafras oil was often mixed with opium (cf. *Papaver somniferum*) when the latter was administered to children in order to cover up its horribly bitter taste. For medicinal use, sassafras oil was usually mixed with *Guaiacum* spp. and sarsaparilla (*Smilax regellii* Kill. et C.V. Morton) (Grieve 1982, 716*).

In Louisiana, filé (dried, powdered young sassafras leaves) are used to bind soups and to prepare gumbo (Bremness 1995, 83*).

Ritual Use

To date, no ritual use of sassafras, especially for psychoactive purposes, has been documented. The use of sassafras oil as an inebriant did not become well known until MDMA was made illegal (cf. **herbal ecstasy**).

Artifacts

Gumbo (Atlantic Records, 1972), an album from Dr. John, the Night Tripper (the “high priest of voodoo rock”), is named after the Creole dish gumbo, which is prepared with sassafras leaves. Whether the ingestion of copious amounts of sassafras leaves contributed to the hallucinations immortalized on the album is unknown.

Medicinal Use

In Europe, sassafras is regarded as a panacea (Schneider 1974, 3:230*). Sassafras oil was administered internally in folk medicine to treat physical and mental debility, gout, menstrual complaints, urine retention, and inflammations of the urethra and bladder. It was applied externally to soothe the pains of rheumatism and insect stings (Bertram and Abel 1994, 612). The oil was used internally to alleviate the cramps and pains associated with menstruation (Grieve 1982, 716*). It also was used to induce abortions, and it should be avoided when pregnancy is desired (Bertram and Abel 1994, 612).

In central Europe, teas made from the leaves or the root cortex were especially popular as a blood depurative (Bremness 1995, 83*; Wichtl 1989, 425).

The mother tincture (Sassafras hom. *HAB34*, Sassafras officinale hom. *HPUS88*), obtained by extracting the dried root cortex in 90% ethyl alcohol, is used in homeopathic medicine (Bertram and Abel 1994, 617).

Constituents

The root cortex typically contains between 6 and 9% **essential oil** whose primary constituent is safrole (approximately 80%). Also present are safrole camphor (= camphor/D-camphor; cf. *Cinnamomum camphora*), tannins (sassafrid), red tannic acid (an orange dye), resin, wax, mucilage, sugar, and sitosterol (Bertram and Abel 1994, 611; Grieve 1982, 715*). A recent study has provided further knowledge of the composition of the essential oil; it is 85% safrole, 3.25% camphor, and 1.1% methyleugenol. Each of the other components—including estragol, eugenol, elemicine, myristicin (cf. *Myristica fragrans*), 5-methoxyeugenol, and apiol—make up less than 1% of the mixture (Kamden and Gage 1995). According to a different analysis, the essential oil obtained through steam distillation of the root cortex consisted of 90% safrole, with the remaining 10% composed of 30% 5-methoxyeugenol, 18% asarone, 5% camphor, 7% coniferaldehyde, 11% piperonylacrolein, and traces of apiol, l-menthone, α -phellandrene, β -phellandrene, thujone, anethol, caryophyllene, copaene, elemicine, eugenol, myristicin, α -pinene, and syringaldehyde (Sethi et al. 1976).

The root cortex also contains alkaloids (aporphine and benzyloquinoline derivatives, boldine, isoboldine, norboldine, cinnamolaurin, norcinnamolaurin, reticuline) (Bertram and Abel 1994, 614; Chowdhury et al. 1976; Wichtl 1989, 425).

The root pith consists of some 1 to 2% essential oil (of which approximately 80% is safrole). The seeds are 60% fatty oil with linoleic and oleic acids (Bertram and Abel 1994, 611, 616).

Effects

There are few reports of psychoactive effects resulting from use of the tea: “Large dosages have stimulating and sudoriferous effects” (Schuldes 1995, 69*). Ingestion of high dosages of sassafras oil results in profound stimulation, erotic excitation, perceptual changes, and particularly a more profound sensitivity in the emotional domain. The effects are sometimes described as MDMA-like and empathogenic (cf. *Myristica fragrans*). Higher dosages also can result in unpleasant side effects (cold sweats, cramping of the chewing muscles, nervousness, unease).

Commercial Forms and Regulations

Sassafras oil has been illegal in the United States since 1960, when it was claimed that it was carcinogenic (Kamden and Gage 1995). Because sassafras oil is a suitable precursor for the illegal manufacture of MDMA, it is now a controlled substance worldwide and is almost never sold, even in small amounts. Even the raw plant material (root wood, root cortex) has practically disappeared from the market. In the United States, and especially in the southern states, the only product still available is

powdered sassafras leaves, which are sold as gumbo filé.

Safrole

This bark, whose structure is typical for *Sassafras albidum* var. *albidum*, contains an essential oil that smells of safrole.

The bark of *Sassafras albidum* var. *molle* has a very different structure.

“Sassafras may have been the first tree to be brought to Europe from the Americas.”

Sceletium tortuosum (Linnaeus) N.E. Br.

Kougoed

The South African Hottentots (Khoikhoi) once chewed a variety of plants known as channa, kanna, or kougoed—including *Sceletium tortuosum*—as agents of pleasure and inebriation. (Copperplate engraving from Meister, *Der Orientalisch-Indianische Kunst- und Lustgärtner*, 1677) [The Oriental-Indian Art and Pleasure Gardener]

Family

Aizoaceae (Ice Plant Family) (Mesembryanthemaceae); Subfamily Mesembryanthemoideae (cf. Bittrich 1986)

Forms and Subspecies

None

Synonyms

Mesembryanthemum tortuosum L.

Folk Names

Canna, canna-root, channa, gunna, kanna, kauwgoed, kauwgood, kon (“quid”), kou, kougoed, tortuose fig-marygold

History

Some three hundred years ago, it was reported that the Hottentots (Khoikhoi) of southern Africa chewed, sniffed, or smoked an inebriant that was said to be known as **kanna** or channa (Schleiffer 1979, 39 ff.*). The enthusiasm with which the Hottentots smoked was noted by all the early travelers to the region. Unfortunately, most of them neglected to provide any information about the botanical source of the “tobacco” (e.g., Meister 1677, 31 f.*). And so it was not until the end of the nineteenth

century that it was suggested that the inebriant must have come from ***Mesembryanthemum* spp.**, for these species were then still known by the name *kanna* in South Africa. The effects that were experienced at that time, however, were not nearly as dramatic and inebriating as had been hoped (Meiring 1898). Around the same time, Carl Hartwich was already suggesting that the species in question was *Mesembryanthemum tortuosum* (1911, 810*), which (following a taxonomic revision) is now known as *Sceletium tortuosum*. However, the first ethnobotanical evidence of the psychoactive use of *Sceletium tortuosum* as kougoed was obtained only a few years ago (Smith et al. 1996).

Distribution

The plant occurs only in South Africa, in the so-called kanna land. *Sceletium tortuosum* and other species (*Sceletium strictum*) have become rare in South Africa and are increasingly difficult to find (Smith et al. 1996, 128).

Cultivation

Propagation occurs through the seeds, which must be treated in the same manner as cactus seeds. The best method is to scatter them onto cactus or succulent soil, press them down slightly, and water (Schwantes 1953). Both the cultivation and care are similar to that for the Cactaceae, which is the most closely related family.

Appearance

This herbaceous plant, which resembles a leaf succulent, can grow as tall as 30 cm. It develops fleshy roots, a smooth and fleshy stalk, and low-growing branches that spread laterally. The thick, angular, fleshy leaves do not have stalks but are attached directly to the branches. The pale yellow flowers are 3 to 4 cm across and are attached to the ends of the branches. The plant produces angular-shaped fruits with small seeds.

Kougoed is easily confused with other members of the genus *Sceletium* (as well as with ***Mesembryanthemum* spp.**). Those species that not only look similar but also have similar effects and contain the same active constituent (mesembrine) were presumably also referred to as kougoed and used in the same manner (Arndt and Kruger 1970; Jeffs et al. 1970, 1974; D. McKenna 1995, 101*):

Sceletium anatomicum (Haw.) L. Bolus [syn. *Mesembryanthemum anatomicum* Haw.]

Sceletium expansum (L.) L. Bolus [syn. *Mesembryanthemum expansum* L.]

Sceletium joubertii L. Bolus²⁹⁰

Sceletium namaquense L. Bolus

Sceletium strictum L. Bolus

Psychoactive Material

—Entire plant with root

Preparation and Dosage

The method for preparing kougoed has only recently been discovered and described in great detail. The plant material—which should be collected in October, when the plant is most potent—is harvested, crushed between two rocks, and allowed to “ferment” for a few days in a closed container. At one time animal skins or hemp bags were used for this purpose, but plastic bags are now used in their place. The first step entails setting the bag containing the plant material in the sun. During the day, the plant will exude its juice, which condenses on the plastic and is later reabsorbed by the plant material. During the night, the material cools. After two or three days, the bag is opened and the

contents are stirred well. Then the bag is sealed and placed outside again. On the eighth day after this procedure was started, the kougoed is taken from the bag and spread out to dry in the sun. It can be used as soon as it has dried. According to informants, the fresh leaves do not have any potency; only the “fermented” plant is psychoactive. The kougoed is now either chopped or powdered. This process presumably helps to substantially reduce the high content of oxalic acid that is characteristic of the genera *Sceletium* and *Mesembryanthemum*. Oxalic acid can produce severe irritation and allergies. A more hurried method involves simply toasting a fresh plant on glowing charcoals until it has completely dried and then powdering the result (Smith et al. 1996, 126).

The powder usually is taken orally with some **alcohol** and held in the mouth for about ten minutes. The saliva that collects can be swallowed. Two grams of the powder produces a “tranquil mellowness” in about thirty minutes; approximately 5 g of the powder is a dosage sufficient to relieve anxiety, and higher dosages can lead to more profound effects (euphoria, visions) (Smith et al. 1996, 126 f.).

The chopped plant material can be smoked alone or in combination with ***Cannabis sativa*** (cf. **smoking blends**). The finely ground powder purportedly also can be sniffed, either alone or mixed with tobacco (cf. **snuffs**).

This and other species were used as psycho-active additives to **beer** or to induce fermentation (Smith et al. 1996, 127).

Ritual Use

The South African Bushmen (San) use the same name for *Sceletium tortuosum* as they do for the eland antelope (*Taurotragus oryx* Pallas): *kanna*. The eland is regarded as the “trance animal” par excellence; since prehistoric times, it has played a central role as a magical ally in many ceremonies and was closely associated both with the rain-makers and with divination, healing, and the communal trance dances (Lewis-Williams 1981). Kanna appears to have been used as part of these rituals (cf. also ***Ferraria glutinosa***).

The Hottentots (Khoikhoi) apparently chewed *Sceletium* for their ritual and healing dances or smoked it together with *dagga* (***Cannabis sativa***). They also use the name *kanna* for the magical eland antelope (Smith et al. 1996, 120).

In contemporary South Africa, kougoed is now used primarily as an agent of pleasure; it is used as a party drug in the same way that *Cannabis sativa* is used in Western society.

A cultivated South African kougoed (*Sceletium tortuosum*).

“And so it should be known how these clean mountain nymphs [the Hottentot women] are so unashamed that they even pass their maiden water in the presence of Europeans and are even accustomed to answering the call of nature Because they are also excellent lovers of the noble weed nicotianae or tobacco [a presumed reference to kougoed], then these brave women probably show to a curious, lewd lover everything that he asks of them before a pipe of tobacco.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]

(1677, CH. 4, P. 4*)

Mesembrine

Artifacts

It is possible that a great deal of the rock art of South Africa, some of which appears to be extremely visionary, was inspired by kougoed (Lewis-Williams 1981).

Medicinal Use

The natives of Namaqualand and Queenstown (southern Africa) drink a tea made from the leaves as an analgesic and to suppress hunger (Smith et al. 1996, 128).

Constituents

The leaves and stalks of the plant contain 0.3 to 0.86% mesembrine (empirical formula $C_{17}H_{23}NO_3$), along with some mesembrinine and tortuosamine (Smith et al. 1996). The leaves appear to also contain oxalic acid (Frohne and Jensen 1992, 125*). It is possible that tryptamines may occur in the plant as well. Methyltryptamine (MMT) and *N,N*-DMT have been detected in a *Delosperma* species, a close relative from the same family (Smith et al. 1996, 124).

Effects

The South African users describe the important effects of small dosages of kougoed as relief from anxiety and stress, deepening of social contact, increase in self-confidence, and dissolution of inhibitions and feelings of inferiority. “Some reported euphoria as well as a feeling of meditative tranquility. Several users felt that the relaxation induced by ‘kougoed’ enabled one to focus on inner thoughts and feelings, if one wished, or to concentrate on the beauty of nature. Some informants reported heightened sensation of skin to fine touch, as well as sexual arousal” (Smith et al. 1996, 127f.).

Higher dosages, especially when combined with *Cannabis sativa* and **alcohol** (whiskey), produce mild visions. Chewing kougoed shortly after smoking *Cannabis* can considerably potentiate the effects of the hemp. Kougoed suppresses both the effects of tobacco (*Nicotiana tabacum*) and the desire for **nicotine**.

Scelletium tortuosum, as shown in an eighteenth-century woodcut.

Commercial Forms and Regulations

Seeds of *Scelletium tortuosum* and other *Scelletium* species—usually under the synonym *Mesembryanthemum*—are occasionally available through flower shops and ethnobotanical specialty sources. Living members of the genus are sometimes offered by cactus dealers and shops.

Scopolia carniolica Jacques

Scopolia

“Skopolie, indigenous to Carinthia and Ukraine, cultivated in gardens by the Lithuanians in eastern Prussia as ‘crazy root.’ The root serves them as a medicine to treat paralysis agitans [= Parkinson’s disease]; also as an erotic inebriant, applied locally, as an abortifacient.”

HERMANN FÜHNER *MEDIZINISCHE TOXIKOLOGIE* [MEDICAL TOXICOLOGY]

(1943, 195*)

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Hyoscyameae Tribe, Hyoscyaminae Subtribe

Forms and Subspecies

Three to five species are now accepted botanically in the genus (D’Arcy 1991, 79*; Lu 1986, 6*). A number of varieties of *Scopolia carniolica* have been described:

Scopolia carniolica Jacq. var. *brevifolia* Dun.

Scopolia carniolica Jacq. var. *carniolica*

Scopolia carniolica Jacq. var. *concolor* Dun.

Scopolia carniolica Jacq. var. *hladnikiana* (Fleischm.) Fiori

Scopolia carniolica Jacq. var. *longifolia* Dun.

A new form that has pure yellow flowers and is found only in Slovenia (Hladnikov) has recently been described (Dakshobler 1996):

Scopolia carniolica Jacq. forma *hladnikiana*

Synonyms

Hyoscyamus scopolia L.

Scopolia hladnikiana Fleischm.

Scopolia longifolia Dun.

Scopolina atropoides Schultes

Scopolina hladnikiana Freyer

Scopolina viridiflora Freyer

Folk Names

Altsitzerkraut, deewa sales, durna rope (Lithuanian, “crazy root”), glockenbilsenkraut, gotteskraut, krainer tollkraut, matragun (Romanian),²⁹¹ mauda, maulda, pikt-rope (“evil root”),²⁹² pometis ropes (“pometis root”), Russian belladonna, scopolia (Italian), scopolie, skopolia, skopolie, toll-kraut, tollrübe, volčič, walkenbaum

History

It is uncertain whether scopolia was known to the authors of antiquity. The “sleeping strychnos” (*Strychnos hypnoticos*) of Dioscorides (cf. ***Solanum* spp.**) has sometimes been interpreted as a *Scopolia* species (Fühner 1919, 223). The genus was named for the naturalist Antonio Scopoli (1723–1788), who was the first to study and describe the flora of Slovenia (Festi 1996, 35). In Slovenia, the plant may once have been used to prepare **witches’ ointments**. In eastern Prussia, the root of the plant was used as a folk inebriant and aphrodisiac. It is said that women would use it to persuade young men to become their willing lovers. Sometimes some of the root was added to a person’s coffee (***Coffea arabica***) as a practical joke so that others could amuse themselves on the seemingly nonsensical behavior of the inebriated victim (Fühner 1919).

In the history of pharmaceuticals, *Scopolia* has played only a minor role as a substitute or counterfeit for belladonna root (***Atropa belladonna***) and belladonna leaves (Schneider 1974, 3:240*). Today, the plant is used in the industrial manufacture of L-hyoscyamine and **atropine** (Wagner 1985, 172*).

Distribution

The plant occurs wild in the Alps, the Carpathian Mountains, and the Caucasus Mountains (Gelencir 1983, 217). It also grows in southeastern Europe (Slovenia), Lithuania, Latvia, and the Ukraine.

Cultivation

Cultivation is very simple. In spring, the seeds are sown into seedbeds to germinate. Later, the seedlings can be transplanted to the desired location. The plant does not tolerate a great deal of exposure to the sun (Festi 1996, 36), preferring dark, humid forests and calciferous humus soil. In Lithuania and Latvia, it has long been planted in gardens for use as a medicinal plant.

Appearance

This annual plant, which is typically 30 to 60 cm in height but can grow as tall as 80 cm, develops a fleshy, spindle-shaped root. The dull green leaves resemble those of the belladonna plant (***Atropa belladonna***)—hence the name *Russian belladonna*.

The small, pendulous, campanulate flowers are purple to pale yellow in color and are similar in shape to henbane flowers (***Hyoscyamus albus***)—hence the German name *glockenbilsenkraut* (“bell henbane”). The plant flowers from April to June. The fruit develops a capsule with a double partition and many small seeds.

Scopolia is easily confused with Chinese scopolia (*Scopolia carniolicoides* C.W. Wu et C. Chen) and Japanese scopolia (*Scopolia japonica* Maxim.). *Scopolia anomala* (Link et Otto) Airy Shaw [syn. *Scopolia lurida* Dun.], which is native to Nepal and Sikkim, is about twice as large as the European scopolia (Weinert 1972).

Psychoactive Material

—Root (rhizoma scopoliae, scopoliae radix, scopolia root, glockenbilsenkrautwurzel, europäische scopoliaawurzel)

—Herbage (herba et radix scopoliae carniolicae)

Preparation and Dosage

The fresh root, when boiled and grated, can be eaten as a mush or taken in coffee (***Coffea arabica***). It also is added to **beer** or brewed with it in order to potentiate its effects (Fühner 1919, 224).

The root and the rootstock (scopoliae radix et rhizoma) are used. The root is dug up, dried, and

used exactly as the belladonna root. Taste, color, and appearance are exactly like bella-donna. Many plant collectors confuse the bell henbane with belladonna [*Atropa bella-donna*], which is why one always finds scopolia mixed into belladonna, especially when the belladonna is from the Carpathians. (Gelencir 1983, 217)

The dried herbage, collected while the plant is in flower, can be smoked alone or in **smoking blends**.

Scopolia (*Scopolia carniolica*) was used in eastern Europe much like the mandrake.

The Asian scopolia *Scopolia anomala* also has psychoactive properties.

“White thorn apple [*Datura metel* var. *alba*] and black scopolia [*Scopolia anomala*] heighten the sex drive, and together with henbane [*Hyoscyamus niger* var. *chinensis*], they alleviate illnesses caused by tiny little animals.”

“*DER BLAUE BERYLL*” (ARIS 1992, 67*)

“The incident occurred at the end of March 1901 in the church village of Lappienen, in the district of Niederung [eastern Prussia]. . . . Here, some women added a decoction of scopolia to a man’s afternoon coffee, supposedly as a joke. According to his own testimony, he developed a severe headache and a terrible burning soon after drinking the coffee. His tongue became completely rigid, and for a time he did not know where he was. Taken home, he lay in bed for a while and then vomited, whereupon the pains let up. But he remained lying in bed for three weeks, and during this time he suffered from severe headaches. A witness who took him home described his behavior in the

following terms: ‘Immediately after consuming the coffee, he complained of internal pains and talked all kinds of nonsense. On the way home, he acted like a madman: he ran, fell, claimed to see people, wood, a saw, and all manner of things. After arriving home, he did not recognize his wife, thought she was a young girl, lay down in bed, jumped back up, and was ill for quite a while.’

HERMANN FÜHNER “SCOPOLIAWURZEL ALS GIFT UND HEILMITTEL BEI LITAUEN UND LETTEN” [SCOPOLIA ROOT AS POISON AND MEDICINE AMONG THE LITHUANIANS AND LATVIANS] (1919, 225)

Ritual Use

In eastern Prussia, Lithuania, and the Balkans, scopolia formerly was collected and used in magic in the same manner as mandrake (*Mandragora officinarum*). In the early twentieth century, only rudiments of this ritual use were still being practiced (Fühner 1919).

Artifacts

See *Mandragora officinarum*.

Scopolia anomala is depicted on Tibetan medical thangkas (Aris 1992, 67*).

Medicinal Use

Scopolia carniolica was used in eastern European folk medicine in the same manner as *Mandragora officinarum* (Schneider 1974, 3:240*). In Lithuania, the plant was used to treat rheumatism, gout, toothaches, colic, and Parkinson’s disease; as a sedative for children and an aphrodisiac; and to induce abortions (Fühner 1919, 224).

In homeopathy, the essence obtained from the fresh-blooming herbage is known as Hyoscyamus scopolia and is used in accordance with the medical description (Schneider 1974, 3:240*).

Constituents

The entire plant contains hallucinogenic **tropane alkaloids** (Evans 1979, 249*). The total alkaloid content averages around 0.5% but can range from 0.3 to 0.8% (Fühner 1919, 223; Roth et al. 1994, 648*). The dried leaves contain 0.19% hyoscyamine and 0.13% **scopolamine** (Scholten et al. 1989). The root contains approximately 0.5% scopolamine (Gelencir 1983, 218). Also present are the alkaloids cuscohygrine, tropine, and 3αtigloyloxytropine. Chemotaxonomically, *Scopolia* is thus closely related to henbane (*Hyoscyamus spp.*) (Evans 1979, 249*; Zito and Leary 1966). The alkaloid content of the dried roots can be as high as 1% (Wagner 1985, 172*).

In addition to the alkaloids, the entire plant also contains the **coumarins** scopoline and **scopoletin** as well as chlorogenic acid (Roth et al. 1994, 648*).

Effects

Few documents describing the actual effects of scopolia are available (Festi 1996). Depending upon dosages, all preparations are capable of producing psychoactive effects that are very similar to those produced by henbane. Low doses induce aphrodisiac sensations, whereas “larger quantities of the root are inebriating and produce a condition associated with unpredictable, comic actions” (Fühner 1919, 224). High doses have been observed to produce delirium, loss of awareness of reality, coma, severe pupillary dilation, headache, disturbances of coordination, and other symptoms typical of an overdose of *Atropa belladonna*.

Smoking the leaves produces only very mild psychoactive effects that are comparable with those resulting from smoking *Hyoscyamus niger* or *Datura stramonium*.

Commercial Forms and Regulations

The herbage and roots can sometimes be found in eastern European herb shops. The seeds are occasionally available from ethnobotanical specialty sources.

Solandra spp.

Cup of Gold

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solandreae Tribe (formerly Datureae Tribe)

Species

Ten to twelve species are currently botanically recognized as belonging to the genus *Solandra* (D'Arcy 1991, 79*; Bärtels 1993, 207*; Schultes and Farnsworth 1982, 166*). However, the taxonomy of the genus is rather confusing or, as Schultes (1979b, 150*) expressed it, “very poorly understood.”

The species of ethnopharmacological significance are:

Solandra brevicalyx Standl.—kieli, kieri, kiéri

Solandra guerrerensis Martinez—huipatlí, hueypatlí, tecomaxochitl²⁹³

Solandra guttata D. Don ex Lindley (possibly identical to *Solandra brevicalyx*; Furst 1995, 55)

Solandra nitida Zucc. [syn. *Solandra maxima* P.S. Green, *Solandra hartwegii* N.E. Brown, *Swartzia nitida* Zucc.]—cutaquatzitziqui, copa de oro

To nonbotanists, these four species are difficult if not impossible to distinguish (Morton 1995, 20*). The Indians regard them as equivalent.

The following species, which occur in Mexico and are rich in alkaloids (Evans et al. 1972), have not been ethnobotanically described or investigated to date:

Solandra grandiflora Sw.

Solandra hirsuta Dun.

Solandra macrantha Dun.

Synonyms

Datura maxima Sessé et Mociña (= *Solandra* sp.)

Datura sarmentosa Lam. (= *Solandra grandiflora* Sw.)

Datura scandens Velloso (= *Solandra* sp.)

Solandra herbacea Mordant de Launay is a synonym for *Datura ceratocaula* (see ***Datura* spp.**).

Folk Names

In Mexico, these folk names are used for all of the species in the genus (cf. Martínez 1966): arbol del viento, bolsa de Judas (Spanish, “bag of Judas”), bolute, chalice vine, copa de oro (Spanish, “cup of gold”), cup of gold, cútacua (Tarascan), cutaquatzitziqui, floripondio del monte (Spanish, “angel’s trumpet of the forest”), goldkelch, hueipatlí, hueypatlí, hueytíaca, itzucuatiziqui, k’äni bāk’el (Lacandon, “yellow bone/scent”), kieli, kiéli, kieri, kiéri (Huichol, “tree of the wind”), lipa-catu-hue (Chontal), ndari (Zapotec), perilla, tecomaxochitl (Aztec, “offering drink plant”), tetona, tima’ wits

(Huastec, “jicara decorated gourd flower”), tree of the wind, windbaum, wind tree, xochitecómatl (Nahuatl).

History

It is not known how ancient the ritual use of the potently hallucinogenic cup of gold in Mexico is, but it may have originated in prehistoric times. The Aztec plant *tecomaxochitl*, which is very likely to be interpreted as a *Solandra* species, was first described by Hernandez in the early colonial period. Maximino Martínez was the first to discuss the psychoactive use of *Solandra* species (1966). It is possible that the *Solandra* shamanism (also known as *kiéli* shamanism) of central Mexico may be older than the peyote cult, which arose in northern Mexico (cf. *Lophophora williamsii*) (Furst 1995).

The genus was named for the Swede D. C. Solander (1736–1786), a student of Linnaeus and a companion on the journeys of Captain Cook. To date, the ethnobotany of the genus has been only poorly studied, as the plants are often associated with witchcraft and harmful magic and their uses are consequently kept secret and suppressed. The plant (and its associated uses) was earlier often confused with *Datura innoxia*. The Huichol refer to *Solandra brevicalyx* as the “true” *kiéli*, and to *Datura innoxia* as *kiélitsha*, “bad *kiéli*” (Knab 1977, 81).

The flower of the cup of gold (*Solandra brevicalyx*) exudes a delicious perfume.

The large cup of gold (*Solandra nitida*), cultivated by numerous Mexican Indians, develops very large flowers. (Photographed in Naha', Chiapas, Mexico)

The pendulous flower of *Solandra guttata*.

“Among the Huichol, *Solandra* is closely associated with sorcery. An individual is initiated into the secrets of the plant and of sorcery by an older shaman, but only after he himself has become a shaman. *Kiéri* is also associated with the wind. The Huichol fear strong winds and whirlwinds as bringer of illness and other misfortunes. The one most feared is called *Tawekáme*, the term also used for drunkard. This type of wind, which is said to make one drunk, is directly associated not only with *Kiéri* as plant but with his personification as *Kiéri*. *Kiéri* in general is feared, it being believed that just the pollen from *Kiéri* flowers can make birds and insects faint and bees lose their sense of direction. Even the fragrance alone can intoxicate people. . . . Indeed, as mentioned above, the psychotropic properties of *Kiéri* are feared, so much so that if any use is made of them today, it is sub-rosa, lest the user reveal himself to be a sorcerer.”

PETER T. FURST “THE DRUNKARD KIÉRI” (1995, 52, 58)

Distribution

The genus *Solandra* is indigenous to Mexico (Schultes and Farnsworth 1982, 166*). Most of the species occur in central Mexico. The genus is represented to the south as far as the rain forests of Chiapas (Martínez 1966). Several species have spread into the Caribbean and to South America (Peru) (Furst 1995, 51).

Cultivation

Propagation is easily performed with cuttings. A piece of the stem (if possible from the end of the branch) approximately 20 cm long is placed in water. The plant can be placed in the ground as soon as its roots have started to develop. *Solandra* must be well watered and does not tolerate frost. In the rain forest, often all that is needed is to place a piece of the stem in the ground. Shoots will then quickly appear.

Solanda grandiflora and *Solandra nitida* are the most commonly cultivated species for garden and ornamental use (Bärtels 1993, 207*).

Appearance

The perennial, heavily branching, fast-growing climber develops oblong-elliptic leaves that are up to 15 cm in length and tapered at the end. The solitary, terminal, chalice-shaped yellow flowers exude a sweet scent, usually in the evening, that is intoxicating, delicious, and very fine. This scent is

comparable to the perfume of *Brugmansia suaveolens* or *Brugmansia* x *insignis*. Because almost all of the plants are the product of cultivation, they only very rarely form fruits (spherical berries enclosed by the calyx). The flower of *Solandra nitida* can attain a length of 20 cm. Its fruits, known as *papaturra*, can weigh as much as 1 kg (Bärtels 1993, 207*).

Solandra species can be confused with the tropical dogbane *Allamandra cathartica* L., a potent laxative (Blohm 1962, 79 f.*).

Psychoactive Material

—Flowers

—Stalks

—Leaves

Preparation and Dosage

A tea can be made from the stalks (Schultes and Farnsworth 1982, 166*). The fresh stalks can be pressed to obtain a juice; “the shoot juice of *Solandra maxima* [= *S. nitida*] is an inebriant of the Mexican Indians” (Bremness 1995, 29*). Unfortunately, no information is available concerning dosages.

The fresh leaves (of *Solandra brevicalyx*) can be crushed and administered as an anal suppository or given as a decoction in the form of an **enema** (Knab 1977, 85). The dried flowers and leaves can be smoked alone or as a part of **smoking blends**.

A medicinal dosage is regarded as the tea prepared from one fresh flower (Yasumoto 1996, 247).

In colonial Mexico, Indians used the cup of gold to add zest to their cacao drinks (cf. *Theobroma cacao*) (Heffern 1974, 101*).

Ritual Use

The cup of gold is only rarely used as a shamanic trance drug, and the ethnographic reports are correspondingly few. The Huastec are said to still ingest the flowers of *Solandra nitida* ritually and to place the scented flowers on altars as an offering (Alcorn 1984, 320, 793*). The Mixtec also are reported to traditionally ingest *Solandra* as a hallucinogen for divination (Avila B. 1992*).

The most well-known use of the “plant of the gods” known as *kiéli* or *kiéri* occurs among the Huichol Indians who now live in the Mexican state of Jalisco. One of the plants they use has been botanically identified as *Solandra brevicalyx* (Knab 1977, 86). In the mythology of the Huichol, the plant was originally a god: Kiéli Tewiali, the god of wind and of magic. At the beginning of the world, he was born of the union of the cosmic serpent and the rain. Later, for the use and the blessing of humankind, he transformed himself into the enchantingly scented plant the “tree of the wind.” An entire cycle of myths relates to this theme (Furst and Myerhoff 1966).²⁹⁴ The *Solandra* is often identified with Kiéritáwe, the “drunken Kiéri” (Furst 1989; Yasumoto 1996).

This divine plant is regarded as very powerful and mighty and thus can be used for all types of magic (“kiéli shamanism”), including for dark purposes (harmful magic, death magic). Shamans-to-be must complete a five-year training period before they are allowed to use this potent magical plant. The leaves, which only experienced shamans (*mara’akame*) may remove from the tree, are later used as magical weapons for healing illnesses caused by magic or foreign, perfidious shamans (Knab 1977).

The divine plant must not be disturbed or offended lest one be punished with madness or death. The gifts offered to the plant are similar to those offered to the peyote (*Lophophora williamsii*): ceremonial pipes, tortillas, a homemade tequila known as *túche* (cf. *Agave* spp.), tobacco gourds (cf. *Nicotiana rustica*), coins, yarn paintings, jewelry, bead necklaces, et cetera. The Huichol sometimes

approach the plant and offer it prayers, e.g., before they undertake a journey or make a pilgrimage to Wirikuta, the land of the peyote. They also ask it for fertility, improvements in singing ability, and artistic creativity (Knab 1977, 83).

Shamans are able to receive sacred knowledge from the “tree of the wind.” The Huichol artist José Bautista Corrillo provided the following explanation of such a ritual of knowledge portrayed in one of his yarn paintings:

Kauyumari, the leader of the shamans in the shape of a deer, eats Kiéri, the tree of the wind, to learn about the legends of the past and the art of healing. He passes this knowledge on to the shaman who asks Kiéri to teach him everything while he sings throughout the entire night. The puma, who was once the fire, and the wolf, who was once a shaman, help the shaman to understand the teachings. (1996)

The plant is apparently used only extremely rarely as a hallucinogen. The leaves seem to be preferred for this purpose, although the fruits (which develop only infrequently) and the roots are thought to be more potent (Knab 1977, 85). It is said that the plant is able to help a person fly (Furst 1995, 53). Sometimes the hallucinogenic use of *Solandra* is regarded as a sure sign of sorcery, witchcraft, and black magic (Knab 1977, 85; Furst 1995). On the other hand, some Huichol say that this plant opens their mind for the “highest levels of enlightenment.”

Some Huichol say that people are not allowed to ingest the plant but may only be exposed to its scent. Even the scent is capable of inducing trance, and the Huichol use it as a spiritual guide into mystical domains (Valadez 1992, 103 f.). They climb a steep mountain, upon which a *kiéli* plant is growing, for this purpose. They must fast (no food or beverages, including water) both before and while they are climbing, and they spend the night near the scented plant, inhaling its perfume and showing the bush their respect and attention (Meier 1996). While they sleep, they hope to receive meaningful visionary dreams in which they will be able to find messages.

Artifacts

Kiéri is sometimes depicted in the visionary yarn paintings of many Huichol artists (Valadez 1992). Although the plant can appear in varying degrees of abstraction, it usually is shown in a quite realistic and botanically correct manner (yellow flowers, leaf arrangement).

Many floral elements in the pre-Columbian wall paintings at Teotihuacán may symbolize *Solandra* vines (cf. *Turbina corymbosa*). Some of the illustrations resemble the typical iconography of the plant in modern Huichol yarn paintings (cf. *Lophophora williamsii*).

Medicinal Use

In Mexico, the cup of gold is used in folk medicine primarily as a love drink and aphrodisiac. Warnings against overdoses are common: one can dry out and die from an excessive sex drive. The Huastec use the rainwater or dew that has collected in the buds of *Solandra nitida* as eye-drops to improve sight (Alcorn 1984, 793*). A tea made from the flowers is drunk to treat coughing (Yasumoto 1996, 247).

Constituents

All of the Mexican species of *Solandra* contain potently hallucinogenic **tropane alkaloids**. The primary alkaloids are **atropine**, noratropine, and (–)-hyoscyamine (originally described as “solandrine”); the secondary alkaloids are littorine, hyoscyne, norhyoscyne, tigloidine, 3 α -tigloyloxytropane, 3 α -acetoxytropine, valtropine, norhyoscyamine, tropine, nortropine, χ -tropine,

and cuscohygrine (Evans et al. 1972; Schultes and Farnsworth 1982, 166*). According to another source, scopolamine is the primary alkaloid, present at a concentration of 0.1 to 0.2% (Díaz 1979, 84*). The stalks of *Solandra guttata* have been found to contain norhyoscyne. *Solandra* is chemotaxonomically closely related to the genera *Datura* and *Duboisia* (Evans 1979, 245*).

Most *Solandra* species contain approximately 0.15% alkaloids (Schultes 1979b, 150*). The highest concentration of alkaloids (calculated as **atropine**) was found in the roots of *Solandra grandiflora* (0.64%). The roots generally exhibit the highest alkaloid concentrations (Evans et al. 1972). However, in *Solandra nitida*, the alkaloid concentration is clearly highest in the fruits (Morton 1995, 20*).

Effects

The Huichol compare the visions produced by *Solandra brevicalyx* with the effects of *Lophophora williamsii* but warn against the former because they may frighten a person “to death” (Knab 1977).

In Mexico, *Solandra nitida* Zucc. (Perilla) is regarded as poisonous (Jiu 1966, 256*). A tea made from one flower induced a “toxic psychosis” in an adult, who required thirty-six hours to make a complete recovery (Morton 1995, 20*). Internal administration of *Solandra* preparations can lead to severe hallucinations, delirium, delusions, et cetera. The spectrum of effects is very similar to that of *Brugmansia sanguinea*.

An illustration of the shamanic *kiéle* ritual, together with the corresponding *Solandra* plants, on a yarn painting by the Huichol artist José Bautista Corillo (1996).

The illustration to the left shows the *kiéle* plant (*Solandra* sp.) on a Huichol yarn painting; the blooming shrubs to the right are from wall paintings at Teotihuacán and may represent *Solandra* bushes. (From Rätsch 1994)

Smoking the flowers and/or leaves produces effects that are more subtle but still clearly psychoactive and aphrodisiac and generally very similar to the effects produced by smoking other night-shades (*Brugmansia*, *Datura*, *Latua pubiflora*).

It has been said that merely inhaling the scent can produce entheogenic states (Meier 1996). The Lacandon say that the scent has erotic effects and awakens sexual desire.

Commercial Forms and Regulations

Solandra species are not subject to any legal restrictions. In North America, young plants are occasionally available in nurseries.

JORIS-KARL HUYSMANS *TIEF UNTEN* [DEEP BELOW] (1972, 186)

Solanum spp.

Nightshade Species

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solaneae Tribe, Solaninae Subtribe

Some one thousand to two thousand species are currently recognized in the genus *Solanum* (D'Arcy 1991, 79*; Schultes and Raffauf 1991, 43*; Teuscher 1994, 734). Many *Solanum* species are edible and are used as sources of food (eggplant, potato, kangaroo berry). A number of species have a long tradition of use as folk medicines. A few species are used as additives for coca chewing (see *Erythroxylum coca*). Some appear to be psycho-active or to be used for psychoactive purposes. At the turn of the twentieth century, the Zuni Indians were still using *Solanum elaeagnifolium* Cav. as a sedative **snuff** (von Reis and Lipp 1982, 271*).

Several members of the genus contain **tropane alkaloids** (Schultes and Raffauf 1991, 43*) and myricetin derivatives, substances that also are found in such plants as *Ledum palustre* (Kumari et al. 1984). The roots of many species have been found to contain steroidal alkaloids and sapogenins (Ripperger 1995).

The Peruvian nightshade (*Solanum hispidum*), shown here with flowers and fruits, is found throughout South America.

Solanum dulcamara L. [syn. *Dulcamara flexuosa* Moench, *Solanum laxum* Royle, *Solanum lyratum* Thunb., *Solanum scandes* Lamk.]—**bittersweet nightshade**

This nightshade has been interpreted to be the “sleeping strychnos” (cf. *Strychnos nux-vomica*) of Dioscorides (Schneider 1974, 3:274*). In ancient times, the root cortex was drunk in **wine** as a sleeping agent.

The Germanic tribes used the plant as a narcotic and referred to it and *Solanum nigrum* as “night harm.” Night harm is an illness induced by an elfish demon (nocturnal nightmare demon) during the night while one is sleeping and can be healed using *Solanum dulcamara*. The illness “should be fought off by the embodiment of another magically powerful elfish demon in the plant, i.e., the nocturnal unrest of the ill person is soothed by means of a narcotic agent” (Höfler 1990, 96*).

Bittersweet nightshade “was regarded as an elfen plant and is still known as alp [= elf] vine. It was placed in children’s cradles to ward off enchantment and was placed around the necks of cattle to ward off ‘hunsch,’ or wheezing. Humans generally appear to have an aversion to this plant, for it has been called sow’s vine, stinking devil, dog berry, choke plant, etc.; it is also regarded as a symbol for a treacherous person” (Perger 1864, 182*). During the Middle Ages, the berries were strung onto

cords to make amulets or talismans that were worn around the neck to ward off evil gossip. The plant also played a role in other magical customs: “to initiate a vengeful magic, place the name of an enemy on the dry stem and lay this before the door of that person, [and] the berries can be used as a magical aid for all transformative magic, especially lycanthropic magic” (Magister Botanicus 1995, 193*). It may have been an ingredient in **witches’ ointments**.

In Mexico, where the plant is known as *dulcamara* or *jazmincillo*, it is used in folk medicine as a sedative and narcotic agent. Mexican plant material has been found to contain solanine derivatives and **tropane alkaloids** (Díaz 1979, 85*).

The herbage contains between 0.3 and 3.0% and the roots approximately 1.4% steroid alkaloid glycosides. The alkaloid content of the fruits declines as they ripen, and ripe fruits are almost completely devoid of alkaloids (Teuscher 1994, 737). The alkaloid content and composition can exhibit considerable variation (Máthé and Máthé 1979). There may be chemical races with psychoactive properties.

***Solanum hirtum* Vahl**

This neotropical nightshade species is known in Mayan as *put balam*, “papaya of the jaguar.” To the Maya, the jaguar is the most important and most powerful shamanic animal (cf. *Nymphaea ampla*). It is possible that this plant was or is still associated with shamanic practices.²⁹⁵ Chewing the fresh leaves produces a narcotic and stimulating effect. The fruits also are used medicinally to treat angina (Pulido S. and Serralta P. 1993, 62*). In Mexico, the very similar species *Solanum rostratum* Dunal is known locally as *hierba del sapo*, “plant of the toads” (Martínez 1994, 434*).

***Solanum hypomalacophyllum* Bitter ex Pittier**

This plant, which is known as *borrachera* in Venezuela, may contain **tropane alkaloids** (Schultes 1983a, 271*). Steroid alkaloids (solaphyllidin, solamaladin) and a steroid sapogenin (andesgenin) have been isolated from the plant (González et al. 1975; Schultes and Raffauf 1991, 44*). Whether the plant has psychoactive effects and has been used for this purpose is unknown, although possible. Why else would it be known as *borrachera*, “inebriator”?

***Solanum leptopodum* Van Heurck et Muell. Arg.**

The Secoya Indians call this bush *oyo-ha’-o*, “bat leaf,” and use the leaves for washings to treat and calm crying children. It may exert a sedative effect (Schultes and Raffauf 1991, 44 f.*).

***Solanum ligustrinum* Lodd.—natre**

This bush is used in Chilean folk medicine to treat fever. It has mild analgesic properties and is known by the interesting name of *hierba de chavalongo*, usually translated as “typhus fever plant” (Hoffmann et al. 1992, 154*). But the similarity between this name and that of the still unidentified **cabalonga**, the psychoactive magical plant of the northern Andes region, is almost too striking. More detailed investigations into the ethnobotany of this plant would likely yield some very interesting findings. The plant is known to contain several alkaloids (natrine, huevine) as well as solanine (Hoffmann et al. 1992, 156*).

***Solanum mammosum* L.**

In South America, the powdered fruits of this species are used as a cockroach poison. The plant reputedly is used in Colombia to “satisfy children,” i.e., as a sedative narcotic (Schultes 1978a, 193*).

The fruits of *Solanum dulcamara* have a bittersweet taste.

The bittersweet nightshade (*Solanum dulcamara*) in bloom.

The leaves of the tropical nightshade species *Solanum hirtum*, known in the Yucatán as “papaya of the jaguar,” have narcotic effects. (Wild plant, photographed near Chichen Itzá, Yucatán, Mexico)

The black nightshade (*Solanum nigrum*) occurs in a number of varieties and forms throughout the world. (Wild plant, photographed in Hamburg)

Originally from South America, the potato (*Solanum tuberosum*) has been found to contain trace amounts of a natural sedative agent.

Early illustration of the “garden nightshade,” either *Solanum nigrum* or *Solanum dulcamara*. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

“In the empire of Ethiopia, the ‘criminal telepath’ was an established institution until at least the time of the Second World War. Usually an as yet untouched boy, such a person was known as a *lebaschà* (concentrating searcher). He was called upon when a theft occurred. The *lebaschà* was required to imbibe a drink that contained the leaves of nightshade plants along with other things, there are also reports of

drug smoking. The lebaschà then enter an inebriated kind of state and follow ‘the scent’ to all of the places that might be connected with the theft, and would ultimately find the object and the person who had stolen it.”

WERNER F. BONIN *NATURVÖLKER UND IHRE ÜBERSINNlichen FÄHIGKEITEN* [NATURE PEOPLE AND THEIR EXTRASENSORY ABILITIES] (1986, 49)

***Solanum nigrum* L. [syn. *Solanum americanum* Mill., *Solanum caribaeum* Dun., *Solanum nodiflorum* Dun.; for other synonyms see Teuscher 1994, 744]—black nightshade**

This nightshade has been interpreted as the “garden strychnos” (cf. *Strychnos nux-vomica*) of Dioscorides (Schneider 1974, 3:274*). It has often been attributed with psychoactive properties: “the nightshade was a true Germanic narcotic” (Höfler 1990, 96*). The plant was one of the ingredients in **witches’ ointments**.

In Mexico, where the American variety of the black nightshade is known as *chichiquilitl* or *hierba mora*, the plant is used in folk medicine as a local analgesic, a sedative, and a stimulant and to treat Parkinson’s disease and epilepsy (Díaz 1979, 85*). The plant is called *yocoyoco* in Venezuela, a name strikingly reminiscent of that of *Paullinia yoco* (see *Paullinia* spp.) (Blohm 1962, 97*). In Chile, the black nightshade is used as an antidote for overdoses of *Latua pubiflora*. The herbage contains chiefly solanine as well as related alkaloids. The unripe fruits can contain as much as 1.6% alkaloids, whereas ripe fruits are usually devoid of alkaloids (Teuscher 1994, 744). Further research is needed to determine whether the plant can be used for psychoactive purposes.

***Solanum subinerme* Jacq.—gujaco**

The Witoto Indians add the ripe fruits of *gujaco* or *ujaca*, as they call the species, to their cassava **beer** to impart to it a special taste. It is not clear whether this affects only the taste or whether the fruits also contribute to the psychoactive effects (Schultes and Raffauf 1991, 46*).

***Solanum topiro* Humb. et Bonpl. [syn. *Solanum sessiliflorum* Dun.]—de-twa’**

The Taiwano Indians dry and crush the small seeds from the edible fruits and add the powder to coca leaves when the oral mucosa have become irritated from too-frequent coca chewing (cf. *Erythroxylum coca*). The mixture is said to provide relief (Schultes 1978a, 194*; Schultes and Raffauf 1991, 46*).

***Solanum tuberosum* L.—potato**

The potato is one of humankind’s most important food plants. It originated in Peru, where there are numerous sorts, and is now planted worldwide. In the culture of inebriation, it is used both as a fermenting agent for **chicha** and **beer** and in the distillation of vodka (**alcohol**). The roots contain solanidine (Ripperger 1995). Recently, the potato was found to contain a “natural Valium” (see **diazepam**). Using very accurate methods of analysis, “traces of substances were found in the tubers that inhibit the binding of benzodiazepine to benzodiazepine receptors in the rat brain. To date, 8 of these have been identified as benzodiazepine derivatives, including diazepam and lormetazepam” (Teuscher 1994, 747). However, it is unlikely that one would notice any effects of these substances from eating potatoes, as one would probably need to consume an entire bushel for the effects to manifest.

***Solanum verbascifolium* L.**

This plant, which has a pantropical distribution, is known as *toonpaap* (“hot tail”). The shamans of the Yucatec Maya (southern Mexico) appear to make use of the plant, although no precise information is available (Garza 1990, 189*). The Mayan name seems to suggest an aphrodisiac use of the plant.

***Solanum villosum* Mill. [syn. *Solanum nodiflorum* Jacq.]—witch’s tomato**

This species is very closely related to the black nightshade (Heiser et al. 1979). The plant is known as *tomate de la bruja* (“witch’s tomato”) in Spain, where it allegedly was once used for psychoactive purposes (J. M. Fericgla, pers. comm.; Fericgla 1996*). It may have been one of the ingredients in **witches’ ointments**.

“Dulcamara. (Stipites.)

One of the most excellent agents of the practice of the poor, powerful, and inexpensive. It is one of the most effective remedies for chronic rheumatism, catarrh, for beginning catarrhal and tubercular phthisis (the most common of them all), for chronic skin diseases, for whooping cough. The dosage is 2 to 4 drams daily, not as an infusion but rather as a decoction, because only the boiling brings out the power sufficiently.—The same thing is true of the extract that has been said about the plant.”

C. W. HUFELAND *ARMEN-PHARMAKOPÖE* [PHARMACOPOEIA OF THE POOR] (VIENNA; 1830, 19)

Sophora secundiflora (Gómez-Ortega) Lagasca ex DC.

Mescal Bean

Family

Leguminosae (Legume Family); Subfamily Lotoideae (Papilionoideae), Sophoreae Tribe

Forms and Subspecies

A form that occurs in Texas has exclusively yellow seeds; it has been described (Rudd 1968, 528) under the name *Sophora secundiflora* (Ort.) Lag. f. *xanthosoma* Render.

Synonyms

Agastianis secundiflora (Gómez-Ortega) Raf.

Broussonetia secundiflora Groussonetia

Calia erythrosperma Berlandier in Mier-Terán

Cladrastis secundiflora (Gómez-Ortega) Raf. ex Jacks.

Dermatophyllum speciosum Scheele

Sophora sempervirens Engelm. in A. Gray

Sophora speciosa (Scheele) Benth.

Virgilia secundiflora (Gómez-Ortega) Cav.

Folk Names

Big drunk bean, chilicote, colorín, colorines, coral bean tree, coral bean, frijolillo (Spanish, “little bean”), frijolillo of Texas, frijolito, frijolillo, k’awnk’odl (Comanche), mescal bean, meskalbohne, mountain laurel,²⁹⁶ patiol, patol, red bean, red medicine, schnurbaum, Texas mountain laurel

History

In Texas, mescal beans have been found together with *Ungnadia speciosa* in archaeological contexts (ritual caves) that extend into strata dating as far back as eight thousand years (Adovasio and Fry 1976*). Mescal beans appear together with *Ungnadia* and peyote (*Lophophora williamsii*) in more recent layers. In the American Southwest, the use of the beans for ornamental purposes has been documented for eight thousand years (Merrill 1977).

Some anthropologists have assumed that the mescal bean cult (mescalism) represents a precursor to the peyote cult (peyotism). The mescal bean cult disappeared because the effects of the peyote cactus are much more pleasant and visionary (Campbell 1958; Howard 1957, 1960; La Barre 1957).

The use of the name *mescal* for this plant and its seeds has resulted in considerable confusion in both the ethnographic and the ethnobotanical literature. The name *mescal* is used in Mexico for an alcoholic beverage made from *Agave* spp., while *mescalito* is used in northern Mexico to refer to peyote, peyote buttons, and the peyote spirit. There also is the Mescalero Apache tribe, who were responsible for carrying the peyote cult into North America. The confusion is increased by the fact that necklaces of mescal beans have been used as ritual objects in both the historical and the modern peyote cult (cf. *Lophophora williamsii*).

In northern Mexico, mescal beans are used interchangeably with the seeds of *Erythrina flabelliformis* (Merrill 1977).

Distribution

The tree is found from Texas and New Mexico south into central Mexico (Rudd 1968, 528).

Cultivation

Propagation occurs from seeds, which should be pregerminated for best results. It also can be propagated from cuttings taken from the green wood (Grubber 1991, 49*). The bush requires a dry, warm climate.

Appearance

The shrub or small tree can attain a height of up to 12 meters. It has evergreen pinnate leaves with seven to eleven leaflets. The scented violet flowers are some 3 cm in length and form pendulous clusters. The siliquose, constricted fruits contain the actual mescal beans (seeds). The beans are 0.8 to 2 cm long and 0.5 to 1.5 cm wide. Although they are usually red, seeds that are dark red, light red, orange, and yellow also occur.

Mescal beans are difficult to distinguish from the similarly red seeds of *Erythrina flabelliformis* (cf. *Erythrina* spp.) and are often confused with them.

The closely related and similar species *Sophora conzatti* Standl. and *Sophora purpusii* Brandeg. are found in Mexico, where they too are known as *frijolillo* (Rudd 1968, 525 ff.).

Psychoactive Material

—Seeds (beans, mescal beans, meskal beans, colorines)

Preparation and Dosage

No more than a quarter of a bean is roasted on a fire until it turns yellow and then ground, chewed, and swallowed (Gottlieb 1973, 35*).

The Mescalero Apache add the seeds to the **beer** (*tiswin*, *tulbai*) they make from maize (*Zea mays*) in order to potentiate its effects (Bye 1979b, 38*).

Half of a bean is said to be sufficient to induce a state of delirium that can persist for two to three days (Havard 1896, 39*). In former times, up to 3 mg of cytisine (a component alkaloid) per day was used as a respiratory stimulant (Brown and Malone 1978, 9*).

It has been said that in the early twentieth century, Chinese immigrants in Oklahoma mixed mescal beans with sugar, vanilla, and musk to produce an aphrodisiac candy known as “red beans from China” (Reko 1938, 137*).^{[297](#)}

Ritual Use

During the colonial period, the Coahuilteco Indians of southern Texas and northern Mexico were known to alternate eating mescal beans (the source calls them *frixolillo*) and eating peyote in their communal rituals (Merrill 1977). The Indians of San Antonio (Texas) formerly used the beans as a ritual inebriant (Havard 1896, 39*). Several Plains tribes also consumed the seeds.

The seeds were a common component of amulets. The seeds were stored in small leather medicine bags or carried on a person’s body. Some of the Plains tribes had mescal bean secret societies, the members of which presumably used the beans in their vision quests. Unfortunately, we have few details about such use due to the secrecy that surrounded these groups (Merrill 1977).

Artifacts

Numerous necklaces of mescal beans are known and have been ethnographically described for North America. Ethnographic objects made with mescal beans have been documented for the following

tribes: Apache, Arapaho, Arikara, Blackfoot, Caddo, Cheyenne, Coahuilteco, Comanche, Crow, Delaware, Hidatsa, Iowa, Kansa, Kickapoo, Kiowa, Kiowa-Apache, Mandan, Missouri, Ojibwa, Omaha, Osage, Oto, Pawnee, Ponca, Prairie Potawatomi, Pueblos, Sauk and Fox, Shawnee, Shoshone, northern Ute, Sioux, Tonkawa, Wichita, and Winnebago (Merrill 1977). Necklaces of mescal beans are still worn at peyote ceremonies today.

The red-black seeds of *Abrus precatorius* L. have also been found among the paraphernalia of the mescal bean secret societies and in several medicine bundles of the Iowa and Omaha (cf. *Rhynchosia pyramidalis*).

A prehistoric medicine bundle containing seven mescal beans and the herbage of an *Ephedra* species (*Ephedra* spp.) was discovered in southwestern Texas (Merrill 1977, 68). In general, the prehistoric art style (Pecos River style) of this region has been associated with the mescal cult (Wellmann 1981, 94*).

The mescal bean tree (*Sophora secundiflora*) is indigenous to Texas.

The seedpods and seeds of the mescal bean (*Sophora secundiflora*).

Medicinal Use

The northern Mexican Kickapoo Indians use the seeds to treat ear ailments. They prepare a decoction from one ground seed and some tobacco (*Nicotiana* spp.), which is then dripped into the ear canal. A cold-water extract of crushed seeds is used as an ear wash. Ear drops also are produced by boiling a bean with a branch of juniper (*Juniperus* sp.) (Latorre and Latorre 1977, 352*).

Constituents

Mescal beans contain the alkaloids **cytisine** (= baptitoxine, sophorine, ulexine, laburnine, cyti-tone), *N*-methylcytisine, and sparteine (Keller 1975; Merrill 1977). Quinolizidine alkaloids have also been

identified: *epi*-lupinine, Δ 5-dihydrolupanine, anagyrine, and thermopsine (Hatfield et al. 1977). At 0.25%, cytisine is the primary active constituent.

Effects

Depending upon the dosage, the seeds exhibit first psychoactive and then powerful toxic effects. The sequence of effects begins with a reddening of the face and inebriation and includes spasms, muscular rigidity, headache, nausea, vomiting, defecation, fainting, delirium, and, at the end, death. The reddening of the face is an effect that has been reported often (Howard 1957, 76).

Whether mescal beans are hallucinogenic remains an open question (Schultes and Hofmann 1992, 57*). To date, only a single case of poisoning has been reported in the toxicological literature (Hatfield et al. 1977, 374).

Commercial Forms and Regulations

Mescal beans are occasionally available on the international seed market.

Sophora tomentosa, which is related to the mescal bean, also contains efficacious alkaloids. The seeds of the plant were once used as an inebriating beer additive.

Cytisine

“Those who have been poisoned or intoxicated with Sophora powder find themselves in a mildly sedated state (as if ‘cheered up’) without, however, exhibiting any disturbances in their intelligence. About one-half hour after ingesting the (raw, typically powdered) beans, they manifest a striking hypersensitivity of the skin. Every touch is perceived as a ‘tickling’ (hence the name ‘laughing intoxication’), a gentle caress of the mouth provokes a flow of saliva, touching the umbilical region produces involuntary urination or wet dreams.”

VICTOR A. REKO *MAGISCHE GIFTE* [MAGICAL POISONS]
(1938, 135*)

Strychnos nux-vomica Linnaeus

Poison Nut

A botanical illustration of the flowers and fruits of the poison nut tree. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

In Germany, the seeds of the poison nut tree (*Strychnos nux-vomica*) were once known as “crows’ eyes” (*krähenaugen*). (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The seeds of the poison nut tree (*Strychnos nux-vomica*) contain strychnine.

Family

Loganiaceae (Logania Family, Strychnos Family); Subfamily Strychneae

Forms and Subspecies

None

Synonyms

Strychnos colubrina Wight

Strychnos lucida R. Br.

Strychnos spireana Dop

Strychnos vomica St. Lag.

Folk Names

Azaraki, brauntaler, brechnußbaum, cilibucha, fuluz mahi (Persian), gemeines krähenaug, goda kaduru, kajara, kanchurai, krähenauglein, krähenaug(e), krähenaugenbaum, kuchila (Hindi), kuchla, kuchla of India, kuchûlah, noce vomica, noix vomique, nux vomica, nux-vomica tree, poison nut, poison nut tree, Quaker buttons, rvotnyi orech (Russian), strychninbaum, strychnine, strychnine plant, visamusti

History

Probably the first person to describe the poison nut was Theophrastus, who discussed it under the name *strychnós manikós*, “strychnos that makes manic.” It was once thought that this name referred to the thorn apple (cf. ***Datura stramonium***), an interpretation that is now considered highly doubtful (Marzell 1922, 171*; Schneider 1974, 3:294*). The “sleeping strychnos” of Dioscorides is now interpreted as *Solanum dulcamara*, and the “garden strychnos” as *Solanum nigrum* (cf. ***Solanum spp.***). Many very early Persian sources mention the poison nut as an agent that can induce paralysis (Hooper 1937, 175*). In Europe, the plant first became well known in the fifteenth century.

Distribution

The tree, which probably originated in the dry forests of Sri Lanka (Macmillan 1991, 416*), is native to India and Burma (Myanmar) but has now spread into all the tropical areas of the Indian Ocean and Southeast Asia (Bremness 1995, 131*). It is most commonly encountered in dry forests.

Cultivation

Propagation occurs through seeds or cuttings. The tree prefers sandy soils and a tropical but dry and

hot climate. The seeds are collected primarily between August and November (Macmillan 1991, 417*). The most important areas of cultivation are in Southeast Asia, India, Pakistan, and tropical Africa (Teuscher 1994, 829).

Appearance

The projecting, shrublike tree can reach a height of up to 25 meters; the trunk can have a circumference of as much as 3 meters. The smooth, shiny, oval leaves are opposite and have five nerves. The greenish white umbels produce yellow fruits with gray, disk-shaped seeds that display a silky sheen through fine small hairs.

The poison nut tree is easily confused with the similar species *Strychnos nux-blanda* A.W. Hill. The latter, however, has larger flowers and fruits (Teuscher 1994, 829).

Psychoactive Material

—Ripe, dry seeds (brechnuß, krähenaugen, strychni semen, nux metella, nux vomica, semen nucis vomicae, semen strychni)

Preparation and Dosage

After the fruits have been collected, the seeds are extracted and dried in the sun. The seeds must be stored in a cool, airtight location that is protected from the light. When seeds are stored properly, the raw constituents should remain stable for a long time. The seeds are used to produce extracts and tinctures for pharmaceutical purposes (Teuscher 1994, 832). To make Ayurvedic medicines, the seeds are boiled in milk or cow urine (this is known as the *sodhna* technique).

The largest therapeutic individual dosage is given as 0.1 g of dried poison nut (with a standardized alkaloid content of 2.4 to 2.6%); the largest total daily dosage is 0.2 g (Teuscher 1994, 836). The dosage of pure strychnine should never exceed 5 mg. In the “drug culture,” strychnine is used as an adulterant to “stretch” **cocaine** and heroin (Teuscher 1994, 836).

Theophrastus described some rather drastic dosages (which should not be imitated!):

If someone is simply playing a joke and wants to make the biggest fool out of oneself, you take one dram [app. 3.4 g] of it, but 2 drams if he wants to become crazy and experience apparitions; persistent madness can be produced by three drams. Four drams are required to cause death.

In ancient times, the root (1 dram) was drunk in **wine** for psychoactive purposes. Poison nuts are an ingredient in bhang or *majun* (see ***Cannabis indica***), **Oriental joy pills**, and similar aphrodisiacs. In Persia, an aphrodisiac tea was made from poison nuts, hemp (***Cannabis indica***), and poppy leaves (***Papaver somniferum***) (Most 1843, 570 f.*).

Ritual Use

It is only as an ingredient in other psychoactive products that poison nuts have acquired any ritual significance (cf. ***Cannabis indica***, ***Vitis vinifera***, **Oriental joy pills**, **wine**).

Artifacts

In India, poison nuts are used in amulets for magically protecting the house and farm (Jain 1991, 172*).

Medicinal Use

The Ayurvedic medical system regards the seed as a tonic and stimulant (Macmillan 1991, 417*) and

especially as an aphrodisiac. In Indian folk medicine, the juice of the root cortex, along with cow's milk, is applied externally to treat snakebite (Bhandary et al. 1995, 154*). The bark also is used there to treat cholera. In Nepal, the seeds are used for palsy and rabies (Bremness 1995, 131*). In Iran, the seeds were still being used as a tonic in the twentieth century (Hooper 1937, 175*).

In Europe, poison nut seed was once seen as a remedy for the black death (Schneider 1974, 3:295*) and was long regarded as an “agent for strengthening the nerves” (Bremness 1995, 29*). The seeds are used in folk medicine to treat migraines, nervousness, and depression (Teuscher 1994, 835). Homeopathic preparations of poison nuts (*Strychnos nux-vomica* hom. *HAB1*, *Nux vomica* hom. *PFX*, *Angustura spuria* hom. *HAB34*) are used in accordance with the medical description to treat such ailments as ill moods, headaches, and nervous overstimulation (Teuscher 1994, 832). *Nux-vomica* D6 is said to be a good, dependable treatment for a hangover, even when accompanied by a severe headache (Olaf Rippe, pers. comm.). Combination preparations are also available (see *Claviceps purpurea*).

Constituents

The bark, the roots, and especially the seeds contain the **indole alkaloids strychnine** and brucine, as well as colubrine, pseudostrychnine, vomicine, and strychnicine (Bisset and Choudhury 1974).

The seeds contain an average of 2 to 3% alkaloids but, less frequently, can contain as little as 0.25% or as much as 5.3%. The strychnine content lies between 1.1 and 1.5% but can sometimes reach 2.3%. Also present are 1.1 to 2.1% brucine as well as the secondary alkaloids (comprising a total of no more than 1%) 12-hydroxystrychnine, 15-hydroxystrychnine, α -colubrine, β -colubrine, icajine, 11-methoxyicajine, novacine, vomicine, pseudostrychnine, pseudobrucine, pseudo- α -colubrine, pseudo- β -colubrine, *N*-methyl-sec-pseudo- β -colubrine, and isostrychnine (Teuscher 1994, 831).

The flesh and the shell of the fruit contain essentially the same alkaloids as the seeds. In addition, the alkaloid 4-hydroxystrychnine has been demonstrated to be present. The iridoids loganaine and secologanaine have been detected as well (Bisset and Choudhury 1974).

The total alkaloid content of the leaves can range from 0.3 to 8.0% (Teuscher 1994, 829). The flowers also contain alkaloids. The bitter fruit pulp, which is sometimes characterized as edible, contains only 0.35% alkaloids.

The stem cortex contains up to 9.9% alkaloids, and the root cortex as much as 18%. The wood of the roots can contain as much as 1.8%, the bark of the branches up to 6.8%, the wood of the branches up to 1.4%, and the wood of the trunk only 0.3% alkaloids. Strychnine is always the primary alkaloid (Teuscher 1994, 829). The root cortex of a sample from Sri Lanka was found to contain a new alkaloid, which was named protostrychnine (Baser et al. 1979).

Effects

The effects of poison nuts are almost always the result of their **strychnine** content. With the exception of 12-hydroxystrychnine, none of the alkaloids exhibits any notable pharmacological activity. Strychnine and 12-hydroxystrychnine are specific antagonists of the neurotransmitter glycine and bind to the same receptors as glycine does. This results in a stimulation of the central nervous system. “The perception of sensory impressions is potentiated, differences in color and brightness are perceived better, the visual field becomes larger, and the sense of taste is improved” (Teuscher 1994, 835). Poison nuts have erotic/psychoactive effects similar to those produced by *Pausinystalia yohimba*, which is due primarily to the sharpening of sensory perception (vision, sense of smell, sense of taste). In addition, it is possible that men may experience “strong erections” (Roth et al. 1994, 684*).

Overdoses can result in ego dissolution associated with anxiety and severe spasms while remaining

fully conscious and ultimately to death through respiratory paralysis. As little as 0.75 to 3 g can be lethal (Teuscher 1994, 836 f.).

Strychnine

Brucine

“In extracts and in powder form, the crows’ eyes are occasionally used internally; but they always demand great care when they are used. Because of the narcotic properties, they must be stored using the necessary precautions.”

DULK

IN *KOMMENTAR ZUR PREUBISCHEN PHARMAKOPÖE* [COMMENTARY ON THE PRUSSIAN PHARMACOPOEIA] 1839

“The strychnos manikos, which some persons call persion [‘round fruit’], others thryon [a plant from the magical gardens of Colchis], anhydron [‘removed from water’], pentadryon [‘five clusters’], enoron, orthogyion. . . . The root, in the amount of 1 dram drunk in wine, has the power to create not unpleasant imaginary images, 2 drams drunk persists for up to three days, 4 drams drunk can even kill. The antidote for this is honey mead, amply drunk and vomited up again.”

DIOSCORIDES

DE MATERIA MEDICA

(4.74)

In India and Southeast Asia, the powdered seeds of *Syzygium cumini* (L.) Skeels [syn. *Myrtus cumini* L., *Eugenia cumini* (L.) Druce, *Eugenia jambolana* Lam., *Syzygium jambolana* (Lam.) DC.] are used as an antidote for overdoses of poison nuts (Macmillan 1991, 417*). In Oceania, ***Piper methysticum*** appears to have been used with success as an antidote. In ancient times, **mead** was considered an antidote. There have been reports of using curare to treat strychnine poisoning (Roth et al. 1994, 684*).

Commercial Forms and Regulations

Poison nuts (which are almost never available through retail sources) require a physician’s prescription and can be obtained only from a pharmacy. The mother tincture as well as homeopathic dilutions up to and including D3 also require a prescription (Teuscher 1994, 838).

Strychnos spp.

Strychnos Species

Family

Loganiaceae (Logania Family, *Strychnos* Family); Subfamily Strychneae

The genus *Strychnos* is represented in both the Old and the New World by some two hundred species (Neuwinger 1994, 517*). Generally speaking, it can be said that the Old World species contain alkaloids of the **strychnine** type, while New World species contain substances from the curarine group (Macmillan 1991, 432*). Several New World *Strychnos* species were or still are used to produce curare and similar arrow poisons (Bauer 1965). In addition, several species are used for ethno-medicinal purposes. *Strychnos potatorum* L. f. is used in Ayurvedic medicine to treat hallucinations. Many New World species contain **indole alkaloids**, primarily in their bark. Norharman (see **harmaline and harmine**) was found in an extract of *Strychnos barnhartiana* leaves (Quetin-Leclercq et al. 1990). The mysterious **cabalonga** has been interpreted as a species from the genus *Strychnos* (*Strychnos cabalonga* hort. Lind.). Many species contain strychnine, which is why they are used as aphrodisiacs and also are potential sources of the raw materials for psychoactive substances.

Strychnos icaja L. (= *Strychnos ikaja*) [syn. *Strychnos dewevrei* Gilg, *Strychnos dundusanensis* De Wildeman, *Strychnos kipapa* Gilg, *Strychnos mildbraedii* Gilg, *Strychnos pusilliflora* S. Moore,

Strychnos venulosa Hutchinson et M.B. Moss]—**ikaja, bondes root**

Known variously as *bondo*, *mbundu*, *mbondo*, or *icaja* (Fang), this plant is a 20- to 100-meter-long vine that can climb as high as 40 meters. Of all the African *Strychnos* species used to make hunting poison, this is the most important (Neuwinger 1994, 519*). In central Africa, it was used to make arrow poisons (Macmillan 1991, 432*). The red root cortex was boiled to obtain the poison. The plant is considered sacred because it was used in trials by ordeal. An accused person was given the plant to eat. If he survived he was considered innocent. In the Congo, “the macerate of the root is used in palm wine for very painful gastrointestinal complaints and broken bones. In low dosages, it is said to have diuretic and inebriating effects” (Neuwinger 1994, 521*). In Zaire, ashes of the root are used to treat insanity. The plant contains primarily **strychnine** as well as the related alkaloids icajine, vomicine, and novacine (Neuwinger 1994, 521 ff.*; Ohiri et al. 1983, 177). The missionary Alexander Le Roy (1854–1938) reported the following about this species:

Bwiti, which is the great fetish of the land, has its initiates in the area of Sette Cama [central Africa] and in other places. To be accepted into the secret society, the aspirant must first chew certain roots and drink a decoction of the bark of a tree which is known to botanists as *Strychnos icaja*. It does not take long for him to fall into a deep sleep and completely lose consciousness. Then a vine [*Ipomoea* spp.] is tied around his neck. Three days later, when he begins to recover, a magician will ask him to look into a piece of glass that is attached to the belly of *Bwiti*. He will see certain figures therein, about which he must report. If he says the correct things, he will be accepted; if not, this is taken as a sign that the fetish does not wish to reveal itself to him. (Le Roy 1922, 222)

“The rhinoceros bird is said to have such an immunity to strychnos seeds that they are his favorite food. . . . The poisonous seeds of *Strychnos cabalonga* are supposedly also eaten by several mammals, such as *Dasyprocta agouti*.”

LOUIS LEWIN *GIFTE UND VERGIFTUNGEN* [POISONS AND POISONINGS] (1992, 792f.*)

This report is illuminating for a number of reasons. First, it provides evidence that the Bwiti cult was found in central Africa as well as West Africa; second, the Bwiti cult, which is now a syncretic, neomessianic movement, is characterized as a pure, typically African fetish cult (cf. Thiel et al. 1986); third, it establishes the use of *Strychnos icaja* as a psychoactive substance; and fourth, it supports the theory that *Strychnos icaja* is used as an iboga substitute (cf. ***Tabernanthe iboga***). Of further interest is the description of how the aspirant is bound with a vine, another plant that can be included in the circle of psychoactive plants.

***Strychnos ignatii* Bergius [syn. *Ignatia amara* L. f., *Ignatia philippinensis* Blume, *Ignatiana philippinica* Lour., *Strychnos balansae* A.W. Hill, *Strychnos beccarii* Gilg, *Strychnos blay-hitam* Dragendorff, *Strychnos cuspidata* A.W. Hill, *Strychnos hainanensis* Merr. et Chun., *Strychnos krabiensis* A.W. Hill, *Strychnos lanceolaris* Miq., *Strychnos ovalifolia* Wall. ex G. Don, *Strychnos philippensis* Blanco, *Strychnos pseudo-tieuté* A.W. Hill, *Strychnos tieuté* Lesch]—Ignatius bean**

This creeping climber, which is also known as bitter fever nut and Saint-Ignatius’s-bean, originated on the Sunda Islands and in the Philippines but is now found throughout Southeast Asia. In Malaysia, the Ignatius bean is regarded as *upas radja*, “royal poison,” and was used both as an arrow poison and to commit murder (Lewin 1920, 556*). Reports of the plant’s psychoactive properties had already appeared by the early modern period: “The Ignatius bean has a very energetic action upon the nervous system . . . acting in the very same manner as the poison nut [***Strchynos nux-vomica***]” (Meissner in Schneider 1974, 3:297*).

Today, the Ignatius bean is used by the pharmaceutical industry as a source of **strychnine**. It is used in folk medicine as an aphrodisiac and tonic. It also has acquired a certain significance in homeopathy (*Strychnos ignatii* hom. *HAB1*). Ignatius beans require a prescription and may be obtained only from a pharmacy. Homeopathic preparations (mother tincture up to and including D3) also require a prescription.

The seeds (*faba febrifuga*, *faba indica*, *faba sancti ignatii*, *fabae St. Ignatii*, *semen ignatii*, *ignatii semen*, Ignatius beans) contain 2.5 to 4% alkaloids (sometimes as much as 5.6%), of which some 45 to 60% is **strychnine**. Brucine, caffeic acid, and chlorogenic acid are also present. The therapeutic single dosage is given as 0.1 g and the total daily dosage as 0.3 g (Roth et al. 1994, 682*).

An aphrodisiac with psychoactive effects (single dosage) consists of 12.5 mg of yohimbé extract (***Pausinystalia yohimba***), 12.5 mg of Ignatius bean extract, 0.3 mg of **atropine** methonitrate, and 3.3 mg of **ephedrine** HCL (formerly registered as the medicine Tonaton®, to treat hypotonia of the bladder).

***Strychnos usambarensis* Gilg [syn. *Strychnos cooperi* Hutchinson et M.B. Moss, *Strychnos distichophylla* Gilg, *Strychnos micans* S. Moore]—little monkey orange, umuhoko**

This species is one of the three most common members of the genus *Strychnos* in Africa. A tree form that can grow from 3 to 15 meters in height is found throughout eastern and southern Africa. A climbing bush form that can attain a length of over 70 meters (!) occurs in Zaire, the Congo, and West Africa. The Banyambo hunters of Rwanda use the roots and leaves of the tree form to make an arrow poison with curare-like effects (due to the presence of the alkaloids curarine, calebasin, dihydrotoxiferin, and afrocurarine). The leaves have been found to contain sixteen indole alkaloids of the usambarane type. Considerable amounts of harmane have been found in the stem bark of both

forms (Quetin-Leclercq et al. 1991). It is possible that the bark of this *Strychnos* species may have psychoactive uses (cf. **ayahuasca analogs**).

The Ignatius bean (*Strychnos ignatii*) contains the potent substance strychnine. (Photograph: Karl-Christian Lyncker)

Tabernaemontana spp.

Tabernaemontana Species

The Indians refer to this *Tabernaemontana* species from southern Mexico as *u nek'tsimin*, “the genitals of the tapir.” (Photographed in Yaxchilan, Chiapas, Mexico)

A *Tabernaemontana* species, showing the typical flower of the genus.

One *Tabernaemontana* species common in Belize is called “dog testicles” because of its fruit. (Wild plant, photographed in Belize)

Family

Apocynaceae (Dogbane Family); Subfamily Plumerioideae, Tabernaemontaneae Tribe, Tabernaemontaninae Subtribe

Synonyms

Ervatamia spp.

Peschiera spp.

Folk Names

Throughout the world, the suggestive appearance of the fruits of many *Tabernaemontana* species has led to them being named for the genitals of various mammals: dog’s testicles, u nek’ pek’ (“the testicles of the dog”), u nek’ tsimin (“the testicles of the tapir”), äh toon tsimin (“the penis of the tapir”), et cetera.

History

The genus *Tabernaemontana* is composed of some 120 tropical and several subtropical species (Sierra et al. 1991). Most occur in tropical rain forests, especially in Central and South America and in Africa (Schultes 1979). In Africa, many species are used for ethnomedicinal purposes (Omino and Kokwaro 1993*).

Linnaeus developed the genus name to honor the naturalist and “father of botany” Jakob Theodor, called Tabernaemontanus (1522–1590). Phytochemical studies of the genus have only recently taken place. **Indole alkaloids** dominate; several species have been found to contain **ibogaine** and voacangine (cf. *Tabernanthe iboga*, *Voacanga* spp.). As a result, this genus is of special interest in the search for new psychoactive plants. Several species with psychoactive effects and uses have already become known.

Appearance

Most species in the genus are bushy shrubs, shrubby herbs, climbers, or small trees. They have evergreen, lanceolate, more or less tapered leaves that frequently have a leathery upper surface. The pentacuspitate flowers often grow in clusters from the leaf axils. The fruits are always symmetrically bipartite with a more or less conspicuous constriction; they often appear remarkably similar to the scrotums of higher mammals. Some fruits turn luminously red as they ripen. The presence of whitish or yellowish latex in the bark is a characteristic of the genus.

Tabernaemontana coffeoides Bojer ex DC.

This plant is used in Madagascar as a stimulant. It contains voacangine and other alkaloids. Voacangine can be transformed in vitro to **ibogaine** (Ott 1993, 401*).

Tabernaemontana crassa Bentham

This midsize tree is from the rain forests of West Africa, where the local populace uses it for various folk medicinal purposes. The latex is applied externally to treat wounds and fleshworms. An extract of the leaves is ingested for fever. One especially popular application involves using the leaves as a local anesthetic, e.g., in the treatment of dislocations and broken bones (Agwu and Akah 1990).

Whether the plant was or is also used for psychoactive purposes (as a narcotic) is still unknown.

***Tabernaemontana dichotoma* Roxburgh ex Wallich—divi kaduru**

In India, the root and stem cortex of this species are used in folk medicine to treat wounds as well as snakebites and centipede bites (Perera et al. 1985, 2097). The bark is also regarded in India as a drug that can induce delirium—that is, have psychoactive effects (Ott 1993, 401*; Perera et al. 1983). In Sri Lanka, *divi kaduru* is regarded as a “forbidden fruit” and included in the same folk taxonomic category as *Strychnos nux-vomica* (*goda kaduru*); *kaduru* means “poisonous.” Muslims call the fruit “the forbidden fruit of the Garden of Eden,” while Europeans living in Sri Lanka call it “Eve’s apple.” The seeds are said to have potent narcotic and hallucinogenic effects, and folk healers consider them the equal of the seeds of *Datura metel* (Perera et al. 1984, 233 f.). The bark has been found to contain twenty-two alkaloids of the **ibogaine** type, including the stimulating vobasine and ibogamine (Perera et al. 1985).

***Tabernaemontana heterophylla* Vahl.—sanango**

The Tukano Indians of the Brazilian Amazon give old people who are becoming slow and forgetful a tea made from the leaves twice a day for two weeks (Schultes 1993, 132*). *Sanango*, a word that essentially means “memory,” is a name given to a number of Amazonian plants (Schultes 1979, 186). Whether this species is psychoactive or merely a brain tonic is an open question. It is possible that the leaves are used as an **ayahuasca** additive.

***Tabernaemontana muricata* Link ex Roemer et Schultes**

The leaves and white flowers are dried in the sun and used as a stimulating additive to **chicha** made from *Manihot esculenta*. Such chicha is said to be especially good for the elderly. The leaves and flowers contain alkaloids (Schultes 1979, 186).

***Tabernaemontana pandacaqui* Poir. [syn. *Ervatamia pandacaqui* (Poir.) Pichon, *Tabernaemontana wallichiana* Steub.]**

The root of this species, which is common in Thailand, is used in folk medicine to treat fever, pain, and dysentery. Pharmacological studies have demonstrated that an alcohol extract of the root, stem, leaves, and flowers has potent analgesic effects (Taesotikul et al. 1989b). To date, nothing is known about any psychoactive effects upon humans. The root has been found to contain 3S-hydroxyvoacangine, an **indole alkaloid** of the voacangine type that also occurs in *Voacanga* spp. Alkaloids of the **ibogaine** type are also present (Sierra et al. 1991).

***Tabernaemontana rimulosa* Woodson ex Schultes**

In Venezuela, a few leaves of this species, boiled in milk, are drunk as a sleeping agent (Schultes 1979, 186).

***Tabernaemontana sananho* Ruíz et Pavón—sanango**

In Amazonia, the *sanango* tree, which can grow as tall as 5 meters, is regarded as a cure-all; the leaves, the root, and the latex-rich bark are all used in folk medicine (Schultes 1979, 187 ff.). The leaves of the tree are used psychoactively as an additive to **ayahuasca** and also are combined with *Virola* spp. to produce an orally efficacious hallucinogen. The plant is also called *uch pa huasca sanango* and is known as a “memory plant,” a reference to the fact that its inclusion in a psychoactive preparation causes a person to better remember the experiences he or she has had while under the influence of that preparation. It is added to **ayahuasca** so that a person can, afterward, more clearly

recall the visions he or she saw.

The raw drug of *Tabernaemontana sananho* consists of stem pieces.

Dried leaves, flowers, and fruits of *Tabernaemontana sananho*.

In Ecuador, the plant is known as *sikta* and is available in raw form (short branch pieces) at local markets.

The Jíbaro drip the freshly pressed juice into the nostrils of their dogs so that they may be better able to locate prey. The plant is also known as *yacu zanango*.²⁹⁸

It is rich in alkaloids (Schultes 1983a, 270*).

***Tabernaemontana tetrastachys* H.B.K.—uchusanango, saticu**

The Makuna Indians call this plant *beé-e-ge* and use its latex as stimulating eyedrops (cf. *Tabernanthe iboga*). A few drops is said to dispel tiredness and sleep (Schultes 1979, 189).

Constituents

Indole alkaloids are common in the Family Apocynaceae. To date, the approximately 120 species of the family have been found to contain 256 alkaloids, of which many are **ibogaine** analogs. Several species even contain pure ibogaine. Many *Tabernaemontana* species contain high concentrations of indole alkaloids, primarily tabernanthine, ibogaine, and ibogamine alkaloids (Achenbach and Raffelsberger 1980; van Beek et al. 1984). Other species, e.g., *Tabernaemontana campestris* (Rizz.) Leeuwenberg [syn. *Peschiera campestris* (Rizz.) Rizz.], contain voacangine, the main active constituent in **Voacanga spp.**, and similar alkaloids (Gower et al. 1986). Biochemical studies have shown that the genus's production of indoles is open to influence and can be modified (Dagnino et al. 1992). Many of the alkaloids have stimulant effects (van Beek et al. 1984).

Relatives

Some of the species that were originally assigned to the genus *Tabernaemontana* are now viewed as belonging to a genus of their own, *Pandaca*. **Indole alkaloids** of the ibogaine type also occur in the genus *Pandaca*.

Tabernaemontana van heurkii Muell. Arg. now bears the botanically valid name *Peschiera van heurkii* (Muell. Arg.) L. Allorge. The leaves and the stem bark contain twenty indole alkaloids, some of which have antibacterial properties (Muñoz et al. 1994).

Tabernanthe iboga Baill.

Iboga Shrub

Family

Apocynaceae (Dogbane Family); Subfamily Plumerioideae, Tabernaemontaneae Tribe

Forms and Subspecies

The synonyms are occasionally defined as distinct species. These may, however, merely represent varieties, forms, races, et cetera. The natives of Gabon make a distinction between two varieties on the basis of the shapes of the fruit (Brenneisen 1994, 890). The ethnographic literature sometimes distinguishes two varieties (Fernandez 1982):

Tabernanthe iboga var. *iboga* (iboga vrai, mabasoka)

Tabernanthe iboga var. *mannii* (ñoké)

Synonyms

Iboga vateriana J. Br. et K. Schum.

Tabernanthe albiflora Stapf

Tabernanthe bocca Stapf

Tabernanthe mannii Stapf

Tabernanthe pubescens Pichon

Tabernanthe subsessilis Stapf

Tabernanthe tenuiflora Stapf

Tabernanthes eboka (incorrect spelling in the literature, e.g., Fernandez 1966, 46)

Folk Names

Abona, abonete, aboua, ahua (Pahuin), bocca, boccawurzel, boga, botola, bugensongo (Ngala), dibuga, dibugi, difuma (Eshira), eboga (Fang), eboga bush, ebôga, ébogé, eboghe, eboka (“miracle wood”), elahu (Mongo), eroga, gbana (Gbaya), gifuma, iboa, ibo’a, iboga (Galwa-Mpongwe/Miene), ibogakraut, ibogain-pflanze, iboga shrub, ibogastrauch, iboga typique (Congo), iboga vrai, ibogawortel (Dutch), ibogawurzel, ikuke (Mongo), inado a ebengabanga (Tshiluba), inaolo a ikakusa (Turumbu), inkomi (Mono), isangola, leboka, liboko (Vili/Yoombe), libuga, libuka, lofondja, lopundja, mabasoka, mbasaoka, mbasoka (Mitsogo), mbondo (Aka Pygmy), meboa (Bakwele), minkolongo (Fang), moabi, mungondo (Eshira), ñoké, nyokä (Mitsogo), obona, obuété, pandu (Mongo), sese (Fang), wunderholz

History

According to legend, the iboga bush arose from a person, just like many other psychoactive plants. According to the mythology of the West African Fang:

Zame ye Mebege [the last of the creator gods] gave us Eboka. One day . . . he saw . . . the Pygmy Bitamu, high in an Atanga tree, gathering its fruit. He made him fall. He died, and Zame brought his spirit to him. Zame cut off the little fingers and the little toes of the cadaver of the Pygmy and

planted them in various parts of the forest. They grew into the Eboka bush. (Schultes and Hofmann 1992, 112)

For many West African tribes, the plant became a “bridge to the ancestors,” an instrument of initiation to the true world, a fetish in which the personal god dwells. The wisdom of the original ancestor, the Pygmy plant expert Bitamu, is embodied in the plant, and his sacrifice established the plant cult. The ingestion of iboga causes one to travel through time. Iboga is a sacrament and a symbol of the power of the forest (the Fang say that “Bwiti is a religion of the trees”).

In West Africa, iboga has been used in fetish cults and in magic since ancient times (Bisset 1989, 21; Pope 1969). In the Congo, its psycho-active effects have been used to enable mediums to be possessed by fetishes (Schleiffer 1979, 49*). Hunters chewed the root so that they could stay awake and retain their strength during long hunting expeditions. It is said that the iboga root gives one the power to remain immobile for two full days while hunting the coveted lion trophies (Bouquet 1969).

Botanical illustration of the West African iboga shrub (*Tabernanthe iboga*). (From Landrin, *Bull. Sc. Pharmacol.* 11, 1905)

Iboga found its greatest significance in the reformatory cults that developed around the beginning of the twentieth century from the ancestor cults (*bieri*) of the Neo-Bantu peoples (Fang) and became known as Bwiti (Fernandez 1964; 1966, 44). Administrators in Gabon tried several times to suppress the Bwiti cult, sometimes using such spurious arguments as “Bwiti is a cult of cannibals and ritual murderers” (Schleiffer 1979, 54*). But Bwiti has remained vital in northern Gabon even into the present day and is, in fact, steadily gaining in popularity. The first white person ever to be initiated into the Bwiti cult and to undergo and survive the effects of the iboga root was the Italian ethnobotanist Giorgio Samorini (1993, 1996b).

The first report about the plant and its stimulant and aphrodisiac effects appeared in 1864 (Schultes 1970, 35*). The bush was botanically described in 1889 by Henri E. Baillon (1827– 1895). The primary constituent of the plant, **ibogaine**, was isolated in 1901; pharmacological investigations of this substance have been conducted primarily in France.

Distribution

This tropical plant is found in Gabon and the surrounding areas of the Congo and from Cameroon to Angola. It also is planted in many parts of West Africa. It is a typical shade-loving underwood plant

that thrives at altitudes from sea level to 1,500 meters. The plant is often encountered along rivers and in marshy areas (Vonk and Leeuwenberg 1989, 11).

Cultivation

Propagation usually occurs with root segments taken from the rootstock or from scions. Propagation from seed is very difficult, as the seeds remain viable only if they have not completely dried.

Tabernanthe iboga can be crossed with *Tabernanthe elliptica*. Even natural hybrids occur (Vonk and Leeuwenberg 1989, 12 f.). The so-called Kisantu hybrid was described under the name *Daturicarpa elliptica* x *Tabernanthe iboga*, but it may have been better interpreted as *Tabernanthe elliptica* x *Tabernaemontana* (*Pterotabera*) *inconspicua* (Bisset 1989, 24; Massiot et al. 1988).

Appearance

The evergreen, branching shrub can attain a height of 1.5 to, more rarely, 2 meters. The opposite, lanceolate leaves can grow 10 to 15 cm in length. The shrub develops strong, heavily branching roots that have a brownish rind and yellowish wood. The tiny yellow flowers have a corona 5 to 10 mm in length and often appear in clusters. The pendulous, orange-yellow fruits are ovoid and pointed at the end (18 to 24 mm long). The plant produces a white latex with a powerful scent. In the tropics, the shrub flowers from March to June/July (and sometimes even longer). The fruits ripen at the beginning of the dry period. Both flowers and fruits can appear simultaneously.

The iboga shrub can be easily confused with other members of the genus *Tabernanthe*. Following the last taxonomic revision of the genus, however, this confusion should be limited to the very similar *Tabernanthe elliptica* (Stapf) Leeuwenberg [syn. *Daturicarpa elliptica* Stapf, *Daturicarpa firmula* Stapf, *Daturicarpa lanceolata* Stapf]. *Tabernanthe elliptica* distinguishes itself by its copious white latex. The iboga shrub can also be confused with several *Tabernaemontana* species (*Tabernaemontana* spp.), regarded as its closest relatives (Vonk and Leeuwenberg 1989, 3).

Psychoactive Material

- Root (tabernanthe radix, tabernanthewurzel, boccawurzel, ibogawurzel, iboga root)
- Root cortex (tabernanthe radicis cortex, tabernanthewurzelrinde, tabernanthe root cortex)
- Leaves (tabernanthe folium, tabernantheblatt, tabernanthe leaves)

The West African iboga shrub (*Tabernanthe iboga*)

The tiny flowers of the iboga shrub (*Tabernanthe iboga*)

Preparation and Dosage

In Gabon, the roots are harvested from living plants. A small hole is dug in the ground near the rootstock. Part of the root is removed, but enough of the rootstock is left in the ground that the plant can remain alive and develop new roots.

The root or root cortex is dried and rasped or ground. The extremely bitter, repulsive-tasting root is either eaten and washed down with water or, less frequently, made into a tea.

In the Congo, an aphrodisiac wine is made by steeping the fresh or dried root in **palm wine** for a few hours and then removing it (Bouquet 1969, 67).

A heaping teaspoon of the root powder acts as a stimulant and produces an agreeable state of euphoria (Samorini 1993, 6). Six to 10 g of the dried root powder induces visions and psychedelic hallucinations. For initiation into the Bwiti cult, one eats 50 to 100 g, and sometimes probably even more (200 g).

A dosage corresponding to 2 to 10 mg per kilogram of body weight (calculated as ibogaine) produces a non-amphetamine-like stimulation of the central nervous system. With an amount corresponding to 40 mg of ibogaine per kilogram, the serotonin receptors are occupied, resulting in LSD-like effects (Brenneisen 1994, 892).

The bark and bark juice were used together with *Parquetina* and/or *Strophanthus* species to make arrow poisons (Bisset 1989, 21).

The fruits are edible and do not produce any psychoactive effects (Fernandez 1982, 474). Although leaf extracts contain different alkaloids, they are said to be more pharmacologically active (Bisset 1989, 25).

Iboga roots were or are sometimes prepared together with other plants, only a few of which have been botanically identified (see the table below) (Emboden 1979, 73; Schultes 1970, 36*).

Psychoactive Eyedrops?

During Bwiti initiation, eyedrops (*ibama*, *ebama*) are sometimes dripped into the initiates' eyes so that they may receive more profound or clearer visions. It is possible that some of the eyedrop preparations may be psychoactive or have synergistic effects with iboga (Samorini 1996c). We have no precise recipes, but some of the ingredients are known:

Costus lucanusianus J. Braun et K. Schum. (Zingiberaceae), *Amorphophallus maculatus* N.E. Br. (Araceae), *Afromomum sanguineum* K. Schum. (Zingiberaceae), *Euphorbia hermentiana* Lem (Euphorbiaceae), *Mimosa pigra* L. (Leguminosae; cf. ***Mimosa* spp.**), *Buchholzia macrophylla* Pax (Capparidaceae), ***Elaeophorbia drupifera*** Stapf (Euphorbiaceae), and the juice of a large millipede (Fernandez 1972, 242 f.; Samorini 1996c).

"The souls fish the pool of *eboka* to make us fertile. There is a mirror in the pool that reflects heaven and earth, and that is the one that god sees. The wind of creation will enable trees to spring from the ground, but not people, for their spiritual sources are in the water of

creation—in the pool of *eboka*. For this reason, death has an inconsistency for us. The religion of *eboka* is like the rattan palm, although thorny, it offers a sweet repast to the wanderer. God, the source of all wisdom, has hidden himself and is as hidden as the heart of a palm, but we of the Bwiti cult learn directly from him.”

BWITI SERMON BY EKANG ENGONO IN “UNBELIEVABLY SUBTLE WORDS” (FERNANDEZ 1966, 64)

Iboga Additives

“Soon the day will begin
the chief has left us
in the beginning, a rope came from the heavens
from our father Nzambe
Humans increased their numbers
And the earth received fertilizing rain
No one can pass the place
where the harp player sits
Except for the primordial ancestors,
who know all things
The heart of the new initiate
is full of bitterness
That of the old is full of wisdom
The young initiate is divided
By the light of the sun and of the moon.”

TEXT OF THE BWITI RITUAL OF THE METSOGO

Ritual Use

According to information provided by the Fang, the iboga plant was originally discovered in the rain forest by the Pygmies. The Apinji and Metsogo, who established the foundation of the initiatory use, learned the secret of the consciousness-expanding root from these small rain-forest people. Sometime around 1890, the Fang adopted the ancestor ritual (*bieri*) from them and fused it with Christian concepts and customs to produce the syncretic Bwiti cult (Samorini 1993). In the process, the iboga plant was occasionally identified with the cult god Bwiti himself (Fernandez 1966, 62 f.). In any case, iboga is regarded as the true tree of knowledge that came directly from the Garden of Eden so that people could use it to recognize God and the world and, initiated into paradisiacal secrets, to spend their life on the earth in joy (Samorini 1993). The Bwiti cult has certain parallels to the North American peyote cult (see *Lophophora williamsii*) and the Brazilian Santo Daime cult (see *ayahuasca*), both of which have members ingest a psychoactive substance as a sacrament in a syncretic ritual. The Bwiti cult is first and foremost a rite of initiation:

The story of Bwiti is 150 years long; it arised from the influence of Christendom over the traditional cults in which *iboga* was used, widespread among different tribes of Gabon and of the

neighboring countries. The Bwiti is differentiated in numerous sects, each one constituted by different communities, and the differences among them are particularly due to the degree of absorption of the christian symbols and practices. In all the sects *iboga* is used as the “true sacrament,” in opposition to the ineffective christian host. . . . [T]he *ngoze*, or bwitist masses, are performed during three consecutive nights (from Thursday night to Saturday night), during which the faithful eat a “modest” quantity of powdered root of *iboga*, giving up to dances and songs until the coming of daybreak. . . . [T]he *tobe si* [is] the initiation rite, celebrated each time a person decides to enter into the religious community. In this case, the novice has to eat a huge quantity of *iboga*, comparable to hundreds of dosis as those used during the *ngoze*: a quantity that progressively carry him to a deep and long state of coma, during which his soul makes a trip into the “other world,” while his body lies on the ground, watched by the officiants. Still today, sometimes someone does not awake from the state of unconsciousness, and dies” (Samorini 1995, 105)

The various cult communities, each of which is composed of around fifty people, usually have a temple³⁰⁰ (*abein*) that is used for initiations as well as special holidays (Easter, Christmas) and the weekly nocturnal masses. Before giving his sermon, the priest of the Bwiti cult will lie, under the influence of *iboga*, in a grave dug into the ground. He remains there until he has found the words for his sermon (*nkobo akyunge*, literally “amazing words”). He usually will lie for hours in the grave, coming out after midnight to proclaim his “amazing words” (Fernandez 1966, 46).

A ritual use of *iboga* root (often in combination with 50 µg of LSD) in ritual circles known as “vision circles” has developed in Europe and the United States as well. The ritual structure borrows from that of Indian mushroom circles (cf. *Psilocybe mexicana*) and peyote meetings (cf. *Lophophora williamsii*). Sometimes the vision circle will follow a psychedelic medicine wheel. Here, the participants who sit in the south will ingest *Trichocereus pachanoi*, those in the east *Psilocybe spp.*, those in the west *ayahuasca*, and the participants in the north *iboga* root (Westerhout 1996).

Artifacts

In West Africa, the tradition of making and venerating fetishes for ancestor cults is very ancient and one of the characteristic features of the culture (Koloss 1980). The Fang were already carving anthropomorphic ancestor figures by the end of the nineteenth century. These were used as fetishes in the *bieri* cult and would later find use in the Bwiti cult as well.

A variety of paraphernalia is used in the *iboga* cult. The harp is especially important; it is made with great care and is played during the ritual (Swiderski 1970). The music and the texts that are sung with the harp represent the most important cultural artifacts of the Bwiti cult (Grebert 1928). The singer and harp player of the cult community sings Bwiti songs to accompany the soul of the initiate. For example:

So was the beginning. Spirit of earth, spirit of the sky. The place that we traverse. Father Zame, who is the gatekeeper. I come to a new land that is the cemetery. . . . Lightning and Thunder. Sun and Moon. Heaven and Earth. They are all of them twins. They are life and death. They are all twins. The yawning hole of the grave and the new life, they are all twins. . . . Joy, full of joy the ancestors greet you and hear the news. The anxious life of the born is at an end, at an end, at an end. And now come the disciples of death. I go to the dead. . . . Everything is pure, pure. Everything new, new. Everything is light, light. I have seen the dead and I am not afraid! (from Fernandez 1982)

Medicinal Use

Iboga root is used in West African folk medicine as a stimulant, tonic, and aphrodisiac; in cases of nervous weakness; and to treat fever and high blood pressure. Because of its anesthetic properties, it also is used for toothaches (Brennesien 1994, 892). The Metsogo also use iboga roots to divine and diagnose the causes of illness (Prins 1987). In the Congo, iboga is used to treat the tropical sleeping sickness (Hirschfeld and Linsert 1930, 202*).

The Fang use these fetishes, carved from wood, in the West African iboga cult.

The French in equatorial Africa once praised an iboga extract called *lambarence* as a cure-all and recommended it especially in the treatment of neurasthenia and syphilis (Miller 1985, 50*).

In homeopathic medicine, a mother tincture and various dilutions (*Tabernanthe iboga* hom.) obtained from the fresh root are used in accordance with the medical description.

Constituents

The dried root cortex can contain a total of up to 6% monoterpene **indole alkaloids** (Brennesien 1994, 892; Schultes 1970, 36*). The alkaloid concentration in the entire root is about 1% (Roth et al. 1994, 688*). The alkaloids can be divided into three types: the ibogaine type (**ibogaine**, tabernanthine, ibogamine, gabonine, ibogaline, et cetera), the voacangine type (voacangine, catharanthine, voacryptine, et cetera), and the voaphylline type (voaphylline) (Brennesien 1994, 890). The main active constituent is ibogaine. Voacangine can be regarded as another important component (cf. ***Voacanga* spp.**). The alkaloid mixture varies depending upon the race, location, et cetera. Many of the iboga alkaloids also occur in ***Tabernae-montana* spp.**

The seeds contain the alkaloids (–)-catharanthine, (+)-voaphylline, and (–)-coronaridine (Roth et al.

1994, 688*).

The form indigenous to Zaire, which was previously described under the name *Tabernanthe pubescens*, has been found to contain the following alkaloids: coronaridine, voaphylline, tetrahydroalstonine, voaphylline hydroxyindolenine, 11-hydroxytabersonine, ibogamine, ibogaine, ibogaline, iboxygaine, voacangine, voacangine hydroxyindoleine, voacristine, 3,6-oxido-iboxygaine, 10-hydroxycoronaridine, 10-hydroxyheyneanine, and 3,6-oxidoibogaine (Mulamba et al. 1981).

Effects

The Fang describe the visions that follow the ingestion of iboga as “wending through the forest.” They experience carrying the entire wondrous world of the forest within themselves. Reports of visionary encounters with the ancestors are typical (Fernandez 1982, 476 ff.).

Although only a few white people have had the opportunity to use iboga root, their reports are also constant in some respects. They describe powerful yet peaceful visions and especially contact with deceased family members, unknown people, and animals (“ancestors” in the broadest sense). The following represents a typical report of an iboga experience:

A white light rose up from within me. First as an infinitely small point. The point grew in spite of all mathematical definitions. It became larger, but did not form a circle. . . . It became a triangle, or more precisely, a three-cornered crystal that glowed white. I knew that it was the center of the eternal circle. Its three crystalline faces were the past, the present, and the future. All three aspects of time were one, they touched one another and together they created the world. I had the cosmic jewel before me. Indeed, the etymology of *cosmos* is jewel. The Buddha also holds a magical jewel, from whose brilliance the world arises, in his enlightened hand. Many ochre brown layers lay around the three-cornered crystal. Each one housed another one. All of the layers penetrated into every direction. Every layer was a stage in the development of the universe, in the evolution of life, in the unfolding of consciousness. Every sequence of layers, whether it was that of the past, the present, or the future, transcended into the infinite. There the layers met once more. The infinite was the extreme outer limit of the crystal, and it lay precisely in its center. I saw a culture that is beyond all cultures and yet is inherent to all cultures. I saw gods that are beyond all known gods and yet are contained in all gods. I saw rows of ancestors, all of which are beyond humans and yet have effects upon them even into the present time. I saw the archetypes. They danced in rings around one another in all units of consciousness and led them securely through the universe. *Maya* is not the appearance of things. *Maya* is the masks of the archetypes. We need *Maya*, otherwise we would no longer understand the world. There was no stop to this swirl of insight, one face followed the next. And yet all of the faces remained in existence. I had never remembered faces so well before. Since then, they have never disappeared. I can remember everything clearly, nothing has gotten confused.

The extract of the root has a potent stimulating effect upon the brain that is not comparable to the stimulation produced by amphetamines (cf. **ephedrine**) (Bert et al. 1988). The effects of the root are also different from those of isolated or pure ibogaine, because the other alkaloids exhibit an affinity to certain receptors or represent antagonists (e.g., tabernanthine has an antagonistic activity toward benzodiazepine and GABA receptors).

Commercial Forms and Regulations

The plant is (still) legal, although there have been attempts to schedule the constituent **ibogaine** under current drug laws. The mother tincture of the root can be obtained in France and Switzerland.

Dilutions (D3 and higher) can be purchased in the United States. Plant material is only rarely available outside of West Africa. Iboga roots are sometimes offered by ethnobotanical specialty sources, but the material is often counterfeit.

Ibogaine

Voacangine

Voaphylline

“For this reason God left the *iboga*, so that men would see their bodies as God had made them, as He himself has hidden inside them. Therefore brothers take the *iboga*, the *iboga* plant that God gave to Adam and Eve, Obola and Biome.”

Tagetes spp.

Marigolds

Family

Compositae: Asteraceae (Aster Family); Helecieae Tribe

Species of Ethnobotanical Significance

Tagetes erecta L.—cempoalxóchitl, flor de los muertos (the subspecies *Tagetes erecta nana* is primarily used for cultivation purposes; *Tagetes erecta* hybrids)

Tagetes lucida Cav.—yauhtli

Tagetes minuta L. [syn.

Tagetes glandulifera Schrank]—wild marigold

Tagetes patula L.—French marigold

Tagetes pusilla H.B.K. [syn. *Tagetes filifolia* Lag., *T. congesta* Hook et Arn., *T. multifida* DC.]—pampa anis

Folk Names

Most of these names are used for all species of *Tagetes*: anisillo, belbop (Nepali), cempoal, cempoalxóchitl, flor de los muertos (Spanish, “flower of the dead”), flor de tierradentro (Spanish, “flower of the underworld”), gainda, gendha, hierba anis, hierba de nubes (Spanish, “herb of the clouds”), marigold, marygold, pericirituela de muerto (Spanish, “rose of the dead”), sammethblume, Santa María,^{[301](#)} sempolxochitl, stinkende hofart (Switzerland), studentenblume, tagète, yerbanis

“To dispel evil spirits, the Garinagu prepare a mixture of orange peels and marigolds. At burials, the helpers wash their hands in a water to which the flowers were added. The priests at the ceremonies of the Maya wash their hands and faces with a decoction of the leaves so that they will be better able to invoke the spirits.”

ROSITA ARVIGO AND MICHAEL BALICK

DIE MEDIZIN DER REGENWALDES [THE MEDICINE OF THE RAIN FOREST]

(1994, 147*)

Macuilxochitl (“five flowers”), a manifestation of Xochipilli, the Aztec god of inebriating plants (*Florentine Codex*, book 1; sixteenth century). One *Tagetes* species bore his name.

The typical flower of *Tagetes erecta*.

Tagetes erecta with filled flowers.

An interesting type of *Tagetes* aff. *erecta* from Nepal.

The fresh herbage of *Tagetes lucida* has a very pleasant scent.

History

Tagetes species were bred and cultivated in pre-Columbian Mexico. They were first described in the Aztec Badianus manuscript of 1552 (Emmart 1940*). The Aztec name for those *Tagetes* species that were used as ritual incense is *yyauhtli* (also written *yyahitl*); the word is derived from *ujana*, “to offer incense in sacrifices” (Siegel et al. 1977, 20). The Spanish physician Fernando Hernandez wrote in his colonial-period work that *Tagetes* stimulates sexual desire and relieves the insane.

Most *Tagetes* species (especially *T. erecta* and *T. patula*) quickly spread throughout the world as ornamental plants. In India and Nepal, they even took on ritual significance as flowers for offering to the goddess Bhagwati and to Shiva (Majupuria and Joshi 1988, 221*). *Tagetes* has also acquired a certain significance as “American saffron,” used to counterfeit the considerably more expensive true saffron (see *Crocus sativus*).

Distribution

All species of *Tagetes* originated in the Americas, where they occur from the North American Southwest to Argentina (Ferraro 1955). The main area of distribution and the area in which the greatest variety can be found is in southern Mexico (Neher 1968, 317). *Tagetes lucida* is very common in Nayarit and Jalisco at altitudes of up to 2,100 meters (Siegel et al. 1977, 20). *Tagetes erecta* is originally from Mexico (Dressler 1953, 147 f.*).

The diminutive *Tagetes minuta*.

One of the many cultivated sorts of *Tagetes* aff. *patula*.

Illustration of the variety of *Tagetes erecta* known as *cempoalxóchitl* (b) in the Aztec-language work of Fra Bernardino de Sahagun. (Paso y Troncoso edition)

Illustration of the variety of *Tagetes erecta* known as *macuilxochitl* (a) in the Aztec-language work of Fra Bernardino de Sahagun (Paso y Troncoso edition); *macuilxochitl* is the flower of Xochipilli.

Cultivation

All *Tagetes* species are easy to grow from seed. The seeds are scattered onto the ground in March or April and covered only lightly with soil.

Appearance

Most of the species discussed here are available in numerous cultivated forms and strains (Kaplan 1960). They are often difficult to distinguish from one another. This difficulty is compounded by the fact that most plants have double flowers (Graf 1992, 330*). The plants, which grow from 20 to 50 cm in height, almost always have yellow flowers that either have five distinct petals or are filled to some degree, and most have pinnate leaves. All *Tagetes* species exude a strong, sometimes pungently “medicinal” scent.

Psychoactive Material

—Flowering herbage

Preparation and Dosage

The herbage can be infused, boiled, or ground to produce a paste. Bundles of fresh or dried flowering herbage of *Tagetes lucida* are sold in markets in Mexico; these may be used as a spice for preparing food (the aromatic herbage is used to flavor maize dishes), as a remedy, or as a ritual plant (Bye and Linares 1983, 6 f.*).

Two to three cups of an aromatic tea (infusion of one bundle) made from *Tagetes lucida* are sufficient to produce potent stimulant effects (Neher 1968, 321).

The leaves of *Tagetes pusilla*, which is known in southern Peru as *pampa anis* (“prairie anis”), are heated until they turn to ash and then added to coca quids (see *Erythroxylum coca*).³⁰²

In Lesotho (Africa), the leaves of *Tagetes minuta* are burned to ash and then finely ground with tobacco leaves (*Nicotiana tabacum*), an *Aloe* species, maize cobs, and millet stalks (*Sorghum* spp.) to produce a (medicinal?) **snuff** (Neher 1968, 320).

Unfortunately, no information is available concerning precise dosages.

Ritual Use

The Mexican Indians have attributed *Tagetes* species with magical properties since pre-Columbian times. One variety of *Tagetes erecta* with filled flowers is known in Aztec as *macuilxochitl* (according

to Sahagun). *Macuilxochitl* (also spelled *macuilsuchitl*), “five flower,” is a manifestation of Xochipilli, the god of psychoactive plants (Nicholson 1967*). The Maya used this flower as an additive to the sacred balche’ drink. It is said that contemporary Mayan shamans still use the plant they call *xpuhuc* (*tagetes lucida*) as an inebriant (Ott 1993, 402*). The Mixe of Oaxaca drink a tea made from nine flowers for divination (Lipp 1991*).

In Mexico, the flowers of *Tagetes erecta* and *Tagetes patula* are known as *flores del muerto*, “flowers of the dead.” They are offered to the dead the night of the All Saints’ Day festival (November 1). The blossoms of these species are also used as flower offerings in many Hindu ceremonies in India and Nepal.

The Aztecs referred to *Tagetes lucida* as *yauhtli*, “plant of the clouds.” They would sprinkle a powder of the plant into the faces of war prisoners who were to be burned as sacrifices so that they would be sedated during their ordeal. Even today, many Mexican Indians burn the dried herbage of *Tagetes lucida* as an **incense** on their house altars or at public ceremonies (Neher 1968, 322).

The Huichol Indians of the Sierra Madre (Mexico) call *Tagetes lucida* either *tumutsáli* or, more rarely, *yahutli*. They smoke the dried herbage alone or mixed with equal parts of the leaves of *Nicotiana rustica*. Although *Tagetes* is also smoked recreationally, the mixture does have a ceremonial character. The leaves and flowers are smoked in cigarettes made from corn husks. The **smoking blend** is often smoked in combination with the ingestion of peyote (*Lophophora williamsii*), *tesquino* or *nawa* (maize **beer**), or homemade *cí* or *soter* (cactus liquor; cf. **alcohol**). These combinations are said to produce lively hallucinations. Bundles of the dried herbage are placed as offerings in temples, administrative buildings, and sacred sites (Siegel et al. 1977, 20).³⁰³

“Yellow flowers open wide;
It is our mother, she with the masked face.
You, who have come from
Tamoancan.
Yellow are your flowers.”

AZTEC PRAYER IN *LA LITERATURA DE LOS AZTECOS*
(A. GARIBAY, 1971)

A number of herbs are used in Mexican *brujería* (“witchcraft”) for *limpias*, “purifications,” to dispel diseases. *Tagetes lucida* and *Tagetes erecta* are among these.

Artifacts

Representations of flowers having five petals are often found in pre-Columbian art. It is possible that some of these are depictions of *Tagetes* species. The Museo Carlos Pellicer Camara (Villahermosa, Tabasco) has on display a cylindrical polychrome ceramic vessel from the Classic Mayan period (300–900 C.E.) that depicts a yellow flower whose form and color suggest that it may represent *Tagetes lucida*.

In Mexican folk art, a wide variety of skulls, skeletons, et cetera, are produced for such purposes as the All Saints’ Day festivals. These objects of wood, papier-mâché, or sugar are sometimes decorated with painted *Tagetes* flowers.

The album *IN Mixkoakali* (Cadamac Records, 1996), by the Mexican music group Tribu, includes “Sempoalxochitl,” a piece played with pre-Columbian instruments that is dedicated to the “flower of twenty scents” (*Tagetes erecta*).

Medicinal Use

The Aztecs used all species of *Tagetes* for medicinal purposes, e.g., to treat hiccups and diarrhea.

People who had been struck by lightning were treated with extracts of *Tagetes lucida*.

Today, the fresh herbage of *Tagetes lucida* is made into a tea that is drunk for abdominal pains (Bye and Linares 1983, 8*). In Mexico, it is believed that the herbage promotes lactation (Jiu 1966, 252*). It is also used as a bath additive to treat rheumatism (Siegel et al. 1977, 20).

In Uttar Pradesh (India), juice that has been freshly pressed from *Tagetes erecta* leaves is administered to treat eczema (Siddiqui et al. 1989, 482*).

In Mexico, the crushed leaves or the juice that has been pressed from the herbage of *Tagetes erecta* is mixed with water or wine (pulque; cf. **Agave spp.**) and drunk as an aphrodisiac (Neher 1968, 318). A tea of the plant is used as a stimulant.

In Argentina, a decoction of the leaves of *Tagetes minuta* L. is drunk for coughs (Filipov 1994, 186*). It is also a well-known insect repellent.

Constituents

All *Tagetes* species contain potently aromatic essential oils. *Tagetes lucida* and *Tagetes erecta* contain salvinorin-like substances (see **salvinorin A**) whose structures have not yet been fully clarified. Also present are thiophene compounds, e.g., α -terthienyl (Roth et al. 1994, 689*). Benzofurans are present in *Tagetes patula* (Sütfeld et al. 1985).

The fresh, flowering herbage of *Tagetes minuta* contains mono- and sesquiterpenes (carvone, linalool, tagetone) as well as ocimenone. (5*E*)-ocimenone has been found to have lethal effects upon the larvae of the mosquito species *Aedes aegypti* (Maradufu et al. 1978).

Effects

Research is still needed to clarify the mechanism of activity of *Tagetes* species. When the eyes are closed, the Huichol **smoking blend** is said to be able to produce images and visions similar to those produced by peyote (*Lophophora williamsii*) (Siegel et al. 1977, 20 f.).

Commercial Forms and Regulations

The seeds of many *Tagetes* species, breeds, and cultivars as well as living plants can be obtained from any well-stocked flower store or nursery.

Tanaecium nocturnum (Barb.-Rodr.) Bureau et K. Schum.

Koribo

Family

Bignoniaceae (Bignonia Family)

Forms and Subspecies

None

Synonyms

None

Folk Names

Huangana huasca, hutkih (Lacandon),³⁰⁴ koribo, koribó, koriboranke, pum-ap, puu thotho moki (Yanomamö), samedu-ap

History

It was only in the 1970s that any information about the ethnomedicinal and ritual uses of this plant by the Indians of the Americas became known.

Distribution

The tropical plant occurs in Amazonia, the West Indies, Central America, and southern Mexico (Yucatán).

Cultivation

The Paumarí Indians occasionally use cuttings to propagate the plant. This method is quite new, as the Paumarí were originally a nomadic tribe that has now been made sedentary (Prance et al. 1977, 131 f.). The plant presumably can be grown rather easily from seed.

Appearance

This climbing bush has cordate leaves and long, trumpet-shaped white flowers that curl up in the sun. In the evenings, the flowers exude a delicious scent, like that of almond oil.

The plant is easily confused with the white vine (*Ipomoea alba* L.; cf. *Ipomoea* spp.).

The closely related Colombian species *Tanaecium exitiosum* Dun. is dangerous to cattle. In Venezuela, a comparable species (*Tanaecium crucigerum* Seemann) is known, astonishingly enough, as *borrachera* (Blohm 1962, 97*)—the same name that is given to many other psychoactive plants (e.g., *Brugmansia* spp., *Iochromoa fuchsioides*, *Pernettya* spp., et cetera).

Psychoactive Material

—Leaves and stems

—Root cortex

Preparation and Dosage

The green leaves are roasted, mixed with tobacco (*Nicotiana tabacum*), and ground for use as a **snuff** (Prance 1978, 72).

Ritual Use

The Paumarí (= Ija'ari) on the Purus River use the leaves to prepare a snuff known as *koribón-nafuni* that is used only in rituals. Only men use this snuff. Shamans snuff it when treating special cases, e.g., to extract magical objects (grasshoppers, pieces of wood, bones) from a patient's body. They also snuff it to enter a trance state as part of a ritual to protect children that is carried out whenever a child is learning to eat a new kind of food (e.g., an animal). This ritual is accompanied by sacred songs and begins with the snuffing of *koribo*. Men use bird bones to snuff the powder during puberty rites for girls (Prance et al. 1977, 131). Although women never use the snuff, they may use a tea that they prepare from the root cortex (two teaspoons per person) (Prance 1978, 72).

The Lacandon, who live in the rain forest of southern Mexico, use the latex of the stem of the plant, which they call *hutkih*, as a vulcanizing agent during the ritual manufacture of caoutchouc (rubber) figures known as *tulis k'ik'*, "full blood." These are offered to the gods and also are used in magical rites (Bruce 1974; Rätsch 1985, 128*).

Artifacts

None (apart from the rubber figures of the Lacandon)

Medicinal Use

The Karitiana Indians of Porto Velho (Brazil) mix the leaves with the leaves of a Leguminosae to treat diarrhea (Prance et al. 1977, 134). The Chocó Indians use the plant as an aphrodisiac. The Wayãpi Indians (Guyana) boil the bark and/or stems and use the decoction to bathe diseased areas. The Palikur make a decoction of the leaves and stalks that they use to bathe the head to treat migraines. The Brazilian Yanomamö (Yanomami) boil the leaves and rub the juice they press from them onto itchy areas of the skin (Milliken and Albert 1996, 18, 19).

The Colombian Creoles believe that the plant is efficacious in treating lung ailments. They also use leaf extracts to remove lice and fleas from their pets (Duke and Vasquez 1994, 165 f.*).

The flowers of the tropical climber *Tanaecium nocturnum* open only at night and exude a scent like that of almonds. (Photographed in South America)

Constituents

The leaves contain high concentrations of hydro-cyanic acid (HCN), which explains why they smell like bitter almonds (Duke and Vasquez 1994, 166*). They also contain toxic cyanoglycosides. Apart from this, the chemistry is essentially unknown. The cyanoglycosides appear to be destroyed when the leaves are roasted (D. McKenna 1995, 101*). Roasting the leaves also breaks down the hydrocyanic acid.

Effects

The **snuff** is said to induce somnambulant states entailing drowsiness, disturbances of concentration, and a clouding of consciousness (Müller 1995, 197*). The tea also produces “an inability to concentrate and reduces awareness” (Prance et al. 1977, 131). The Indians, on the other hand, describe the effects as identical to those of the *kawabó* snuff that is made from *Virola elongata* (Benth.) Warb. (see ***Virola* spp.**) (Prance et al. 1977, 134).

Theobroma cacao Linnaeus

Cacao Tree

Family

Sterculiaceae (Cocoa Family); Byttnerieae Tribe

Forms and Subspecies

Like all cultivated plants with a long history, *Theobroma* is a quite variable plant, especially with regard to the color, shape, and size of its fruits and the seeds (Baumann and Seitz 1994, 943). A number of subspecies, varieties, and forms have been described:

Theobroma cacao ssp. *cacao* (L.) Cuatr.—criollo

Theobroma cacao ssp. *sphaerocarpum* (Chevalier) Cuatr.—forastero, calabacillo, amelonado

Theobroma cacao var. *catonga*

Theobroma cacao f. *lacandonense* Cuatr.—balamte’ “jaguar tree”) (a wild form)

Theobroma cacao f. *leiocarpum* (Bernoulli) Ducke—porcelaine java criollo, cacao calabacillo

Theobroma cacao f. *pentagonum* (Bernoulli) Cuatr.—alligator cacao, cacao lagarto

The form *lacandonense* is a semi-climbing wild shrub with relatively small fruits that occurs in the primary forest of the Selva Lacandona (Chiapas, Mexico). The form is regarded as the natural precursor of the cultivated cacao tree (Baumann and Seitz 1994, 943).

On commercial plantations, a distinction is made between essentially only two cultivated sorts: *forastero* and *criollo*. The former is planted chiefly in Brazil and Africa, the latter in Central America. A number of hybrids have been produced from the two, and these are named after the places where they are cultivated, viz., Guayaquil, Caracas, Bahia, and Accra.

This cacao tree (*Theobroma cacao*) is covered with an abundance of red fruits.

History

The cacao tree was cultivated in Central America some four thousand years ago. There, it was venerated as a food of the gods and was consumed during rituals and offered to the gods. Linnaeus took this fact into consideration when he named the tropical plant *Theobroma cacao*. *Theobroma* means “gods’ food,” and *cacao* is a word borrowed from the Mayan language that refers to the tree, its fruit, and the drink prepared from the fruit. The word *chocolate* is derived from the Aztec *xocolatl*, a name for the beverage. Solid chocolate appears to have been a Swiss invention.

The Aztec held cacao beans in high regard. They used them as food, stimulants, medicine, and even currency (especially for paying prostitutes). They were revered as a food of the gods. The psychoactive effects of cacao were described in the Aztec-language texts of Bernardino de Sahagun (Ott 1985).

The conquistador Hernán Cortés brought the first cacao beans to Europe, where they were initially used almost exclusively in the production of love drinks. The first book about cacao, titled *Libro en el cual se trata del chocolate* [Book on the Preparation of Cacao], was published in New Spain (Mexico) in 1609. In 1639, a book appeared in Europe in which it was claimed that the sea god Neptune had brought chocolate from the New World to Europe (Morton 1986, 10, 14). Today, cocoa for drinking and the various kinds of chocolate are among the most commonly consumed foods and/or agents of pleasure in the world.

Distribution

The wild form of the plant is known only in southern Mexico. The cultivated cacao tree had spread

into all of the tropical rain forests of the Americas by prehistoric times. Today, there also are large occurrences of the plant in Africa and Southeast Asia, where it is grown as a crop.

Cultivation

Cacao is propagated from fresh seeds, which are pregerminated in plantations and allowed to develop into small trees before being planted into the ground. This tropical tree grows only in the tropics in areas that receive at least 130 cm of precipitation per year. The cacao tree is a shade-loving plant that does not tolerate exposure to direct sunlight. Because of this, modern cacao plantations plant groves of bananas (known as “cocoa mothers”) next to the young trees (Morton 1986, 57–58). The first harvest occurs after the eighth year, and thereafter a rich harvest can be obtained at least twice a year.

In ancient Nicaragua, cacao farmers were required to abstain from sex for thirteen days before planting the seeds so that they would not make the god of chocolate (= moon god) angry, thereby protecting their harvest.

Appearance

This evergreen tree can attain a height of around 15 meters and can live for some sixty years. The tiny white, pink, or violet flowers grow directly from the trunk or the thicker primary branches, often at the same time as the pods (fruits), which hang from the trunk on short stems. A single tree can develop approximately one hundred thousand flowers annually. The pods are initially green and then turn yellow, red, or purple as they mature.

Psychoactive Material

- Cacao beans (cacao semen, avellanae mexicanae, faba cacao, fabae mexicanae, nuclei cacao, semen cacao, semen cacao tostum, semen theobromae, theobromatis semen, kakaosamen, cocoa beans)
- Cocoa shells (cacao cortex, cortex cacao, cortex cacao tostus, testae cacao, kakaotee)
- Cocoa butter (cacao oleum, butyrum cacao, oleum cacao, oleum theobromatis, kakao fett)
- Fresh fruit pulp (for brewing **beer** or **chicha**)

Preparation and Dosage

The Indians prepared a cacao mixture from roasted and ground cacao beans, cornmeal (cf. ***Zea mays***), honey (from wild bees), vanilla, allspice, and chili pods. In former times, a variety of spices (cinnamon/canella, vanilla, almonds, pistachios, musk, nutmeg [cf. ***Myristica fragrans***], cloves, allspice, anise) usually were added to the cocoa as well.

The Spanish conquistador Hernán Cortés is said to have brought the following cacao recipe to Spain in 1528 (from Montignac 1996, 27):

The flowers and fruits of the cacao tree grow directly from the trunk.

The ripe cacao fruit (*Theobroma cacao*).

The seeds of the cacao fruit are known as cacao beans.

700 g cacao
750 g white sugar
56 g (= 2 ounces) “cinnamon” (canella, perhaps *Canella winterana*)³⁰⁶
14 Mexican peppercorns (*Capsicum* spp.)
14 g “spice cloves” (*Pimenta dioica*)
3 vanilla pods
1 handful “anise” (probably *Tagetes lucida*)
1 hazelnut
musk, gray amber, and orange blossom water

One important ingredient in the traditional Indian preparation was the cacao flowers, which came from *Quararibea funebris* and not *Theobroma cacao*. Today, the cacao drink prepared with *Quararibea* flowers is called *tejate* (West 1992, 106). Generally speaking, cacao appears to have served an important function as a vehicle for administering other psychoactive plants and fungi (Ott 1985).

In the seventeenth and eighteenth centuries, a *succolade* made from powdered cacao beans, sugar, and **wine** was drunk in Germany, sometimes heavily fortified with cardamom (cf. **essential oils**) and saffron (***Crocus sativus***) (Root 1996, 364*).

At the beginning of the twentieth century, invigorating drinks made of cacao and ***Catha edulis*** were made in London and sold as Catha-Cocoa Milk. Preparations of cacao and ***Cola* spp.** or ***Coffea arabica*** are now popular. In Switzerland, a special chocolate with powdered ***Psilocybe semilanceata*** is being manufactured clandestinely.

Cacao shells can be brewed to make a tea. A normal dosage is 2 to 4 g per cup of water (Baumann and Seitz 1994, 946).

To date, no incidents of overdosing on cacao are known.

Ritual Use

Numerous archaeological finds demonstrate that the ritual use of cacao—as an offering, incense, or inebriant—must be very ancient in Mesoamerica. Among the prehistoric Toltecs, a cacao branch was placed in the hand of every person who made a public smoke offering to the gods as a sign of his religious respect.

The Aztecs viewed the cacao tree as a gift from their peace-loving god Quetzalcoatl (“feathered serpent”). An Aztec text from the early colonial period provides a precise description of the tree and of the drink, which could be inebriating:

Cacaoaquavitl—Cacao Tree

It has broad branches. It is simply a round tree. Its fruit is like the ears of dried maize, like an ear of green maize. Its name is “cacao ear.” Some are reddish brown, some whitish brown, some bluish brown. Its heart, that which is inside it, its filled insides, is like an ear of maize. The name of this when it grows is *cacao*. This is edible, is drinkable.

This cacao, when much is drunk, when one consumes much of it, especially that which is green, which is tender, makes one drunk, has an effect upon one, makes one ill, makes one confused. If a normal amount is drunk, it makes one happy, refreshes one, comforts one, strengthens one. Thus it is said: “I take cacao. I moisten my lips. I refresh myself.” (Sahagun, 11)

Aztec Additives to Cacao
(from Dressler 1953, 149*; Heffern 1974*; Navarro 1992, 124*; Ott 1993*; Reents-Budet 1994, 77–79; supplemented)

Aztec Name	Botanical Name	Active Constituent
cacahuaxochitl	<i>Quararibea funebris</i> (Llave) St. (see <i>Quararibea</i> spp.)

tlacoxiloxochitl	<i>Calliandra anomala</i>	alkaloids

The so-called cacao flowers come from the rare tree *Quararibea funebris* and are used to flavor cacao.

Matipo (*Piper angustifolium*) is used to flavor traditional Aztec cacao.

“Quetzalcoatl ruled in Tula. Abundance and happiness were complete. No one paid money for food, nor for the things that were necessary for life. The gourds were so large and fat that a man could barely carry them under his arm. The ears of maize were as large and full as the grip of the stone that was used to grind maize and cacao. . . . Even jewels and gold were given without one having to give anything in return, in such abundance were they present. Cacao thrived magnificently. Cacao plants could be seen everywhere. All of the inhabitants of Tula were rich and happy, they suffered from no need, nothing was missing from their houses.”

AZTEC TEXT
IN *LITERATURA DEL MÉXICO ANTIGUO* (M. LEON-PORTILLA 1958)

The Aztecs ingested cacao or chocolate together with entheogenic mushrooms (*Psilocybe* spp.) in associated rituals, a practice that is still found among numerous tribes today (West 1992, 106).

The Yucatec Maya venerate a black god named Ek Chuah (= God M, presumably identical to Yacatecuhtli, the long-nosed Aztec god of merchants) as the cacao god. Cacao farmers held a festival in his honor during the month of Muan in the old Mayan calendar. During travel, incense (consisting perhaps of cacao beans and copal) was offered to effect a safe return. Ek Chuah was frequently depicted on incense vessels. The glyph of the god’s name was a free-floating eye (Taube 1992, 88 ff.). The Maya and Lacandon use freshly whipped cacao as a ritual additive to **balche’**.

The shamans of the Cuna Indians of Panama (Darien) also use cacao beans as a ritual **incense**. The healers use it in their diagnoses. First, a clay incense vessel with two handles on its sides is filled with glowing charcoal. The shaman then scatters cacao beans onto the charcoal and peers into the ascending smoke. The shaman reads the patient’s illness in the behavior and structure of the smoke. Cacao beans are burned as incense at almost every Cuna ritual occasion and tribal ceremony. The cacao smoke also finds medicinal use. The beans are mixed with chili pods (*Capsicum frutescens* L.; see *Capsicum* spp.) and then burned; this pungent smoke is said to promote healing for all types of fever diseases, including malaria (Duke 1975, 293*).

Artifacts

The Maya of the Classic Period (300–900 C.E.) left behind a rich trove of ritual drinking vessels. These polychrome ceramics are artistically decorated with hieroglyphic texts and varied depictions of visionary experiences and ritual activities. Many of the hieroglyphic texts found on such drinking vessels have now been deciphered. The owner of the vessel is frequently named, and the text then notes that “the vessel [was used] for cacao freshly picked from the tree,” indicating that these drinking vessels were directly associated with the ritual ingestion of cacao (MacLeod and Reents-Budet 1994). The hieroglyph for cacao is a stylized monkey head.

Cacao fruits are frequently depicted in Aztec and related art. The tree, its fruits, and the drink prepared from the fruits are often depicted in the illustrated manuscripts of numerous Meso-american peoples.

In the 1960s, an American psychedelic band took the name Chocolate Watch Band. Its music, however, was probably influenced by other types of drugs.

Medicinal Use

In ancient America, cacao was esteemed as a tonic and aphrodisiac. In Indian folk medicine, cacao is drunk to treat diarrhea and scorpion stings. Cuna women drink a decoction of the fruit pulp as a pregnancy tonic. Listless children are given a tea made from the leaves, and fresh, young leaves are applied externally as an antiseptic agent (Duke 1975, 293*). In Peru, cacao is drunk primarily as a diuretic and in cases of kidney infections (Chavez V. 1977, 322*).

In homeopathy, the mother tincture obtained by macerating the roasted seeds (Cacao hom. *HPUS88*) occasionally finds use (Baumann and Seitz 1994, 946).

The debate as to whether chocolate is harmful or beneficial to health continues today (Fuller 1994). A recently published book written by a physician argues that chocolate is very healthful for people:

Today, there is a moral obligation to disseminate its extraordinary nutritional properties everywhere, which together with its preventive effects especially in the area of cholesterol make it a beneficial and wholesome food source that should be used frequently and which, in the proper amounts, is to be recommended as a regular component of the diet. (Montignac 1996, 198)

Constituents

Cacao beans contain 18% protein, 56% lipids (fat), 13.5% carbohydrates, 1.45% theobromine, 0.05% **caffeine**, and 5% tannin (Montignac 1996, 203). Theobromine is also found in *Ilex cassine* and *Ilex guayusa*. Also present is theophylline, a compound with a similar structure, and β phenethylamine, tyramine, tryptamine, serotonin, and catechin tanning agents (especially in the shell). Dried and roasted cocoa shells can contain up to 0.02% caffeine and 0.4 to 1.3% theobromine (Baumann and Seitz 1994, 946).

The leaves also contain the methylxanthines theobromine and caffeine. The concentrations vary depending upon the source but typically comprise less than 1% of the dry weight. They also contain chlorogenic acid and rutoside (Baumann and Seitz 1994, 944).

It has recently been discovered that cacao also contains anandamides (see **THC**).

An early modern illustration of the cacao bean. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Theobromine

Effects

The psychoactive effects described in the Aztec sources may be due to the cacao additives or to a synergism with the added substances. I have found the traditionally prepared Indian drink to be very stimulating and euphoric. These effects are not necessarily to be expected with commercial cocoa.

Chocolate is popularly referred to as “brain nourishment” or “nerve food.” Moderate to high use clearly leads to an improvement in mood and other beneficial effects. This is attributed to the theobromine but may also result from the anandamide (cf. **THC**). Theobromine can apparently produce a kind of dependency (a so-called chocolate addiction).

It is unlikely that the smoke produced by burning cacao beans will have any pharmacological effects.

Commercial Forms and Regulations

Cacao is subject only to the laws governing foods and is freely available. Internationally, the *criollo* variety is especially prized, as it is regarded as superior in quality. In Europe, it is sometimes sold under the name *Mayan chocolate*.

“O happie money [= cocoa beans], which provides the human race with a delightful and useful drink and exempts its immune possessor from the Tartaric plague of avarice, since it cannot be buried and cannot be stored for long!”

PETRUS MARTYR

IN *DIE MENSCHLICHEN GENUßMITTEL* [THE HUMAN AGENTS OF PLEASURE]

(HARTWICH 1911, 336*)

“Chocolate is divine, we all know that—divine as in delicious, delectable . . . a-a-ahhh. But chocolate really *is* divine—divine as in heaven-born. It came on this earth as the gift of a god. And earthly incarnations of divinity—emperors, kings, princesses—have always made it their own before passing it down to the rest of humanity. Today it still suggests luxury, opulence, and pleasure.”

MARCIA AND FREDERIC MORTON *CHOCOLATE*

(1986, 1)

Harvesting the flowers of the cacao flower tree (*Quararibea funebris*), which was added to cacao as an aromatic and possibly psychoactive spice. Other *Quararibea* species were used for psychoactive purposes (**espingo**) in Peru or were added to **ayahuasca** in Amazonia. (Colonial-period illustration from the Paso y Tronco edition of Sahagun)

Theobroma spp.

Wild Cacao

Family

Sterculiaceae (Cocoa Family); Byttnerieae Tribe

The genus *Theobroma* consists of some twenty neotropical, i.e., American, species. Several species of wild cacao that occur in the tropics of Central and South America have ethnopharmacological significance. To date, there have been few chemo-taxonomic studies of the genus. For example, the presence of **caffeine** and theobromine has been demonstrated only for *Theobroma cacao* (Baumann and Seitz 1994, 942).

Theobroma bicolor Humb. et Bonpl.

This Central American cacao species is known in Mayan as *kakaw*, *xaw*, or *balamte*’ (“jaguar tree”). In other parts of Mexico, it is called *cacao blanco*, *cacao malacayo*, *pataste*, or *pataxte* (Hernández 1987, 1228*). The Maya used it as a **balche**’ additive. In Mexico, its fruits are used as a substitute for the cultivated cacao (*Theobroma cacao*). It is grown in plantations in the state of Guerrero, where the fruit juice is used to prepare a soft drink as well as a fermented, winelike beverage.

Theobroma grandiflorum (Willd. ex Spreng.) Schum.—cupuassú

The wild cacao species known as *cupuassú* occurs in the area of Manaus (Amazonia) and is esteemed especially for its fruits, which are rounder and flatter than those of *Theobroma cacao* (de Aguiar and Lleras 1983). The abundant fruit juice is used to make fermented drinks (cacao **wine**). The leaves are used to manufacture alkaline plant ashes for **snuffs** and coca quids (see *Erythroxylum coca*). This species of cacao contains neither caffeine nor theobromine; its only active constituent is the purine alkaloid theacrine (Baumann and Seitz 1994, 942).

Theobroma subincanum Martius—cacahuillo

A number of Amazonian tribes burn the bark of this cacao species and add the resulting ashes to **snuffs**, especially those from *Virola* spp. or tobacco (cf. *Nicotiana tabacum*) (Schultes 1978a, 187*). The powdered inner bark, mixed with tobacco, is said to be used as a hallucinogen (Duke and Vasquez 1994, 169*).

It has been suggested that *Theobroma cacao* may have been derived through the cultivation of this Amazonian species (Baumann and Seitz 1994, 942).

Literature

This unidentified Mexican plant, known in Aztec as *cacahuaxochitl*, “cacao flower/plant,” was used to flavor cacao. (From Hernández, 1942/46 [Orig. pub. 1615]*)

Wild cacao (*Theobroma bicolor*)

In Peru, the ashes of the leaves of a *Theobroma* species are used as an alkaline additive to coca. The black mass (*llipta de cacao*) has a pungent taste.

Trichocereus pachanoi Britton et Rose

San Pedro Cactus

Family

Cactaceae (Cactus Family); Cereus Subdivision

Forms and Subspecies

The Indians make a distinction between two forms of the cactus, a “male” (with long spines) and a “female” (with short or even no spines). These forms do not have botanical names.

Synonyms

Cereus peruvianus nom. nud.

Cereus giganteus

Echinopsis pachanoi (Britt. et Rose) Friedr. et Rowl. (cf. *Echinopsis* spp.)

Folk Names

Achuma, agua-colla, aguacolla, aguacolla-cactus alucinógena, cardo, cimarrón, cimora blanca, cuchuma, gigantón, huachuma, huachumo, huando hermoso, kachum, rauschgiftkactus, sampetro, San Pedro, San Pedro cactus, San-Pedro-kactus, San Pedrillo, símora

History

The San Pedro cactus was in use at the very beginning of Andean civilization (Burger 1992); it was the *materia prima* of the shamans of that time (Giese 1989a, 225). In Peru, the central Andes region, and neighboring desert areas, the cactus has been used ritually for at least two thousand years (Cabieses 1983). The oldest archaeological evidence of its ritual use was found in the early layers of the formative period of Chavín (Joralemon and Douglas 1993, 185). San Pedro was used both as a sacral drug and as a shamanic medicine (Andritzky 1989*; Donnan and Douglas 1977). The cactus has been cultivated on the Peruvian coast since 200 B.C.E. to 600 C.E. (Early Intermediate period) (Davis 1983, 368).

Amazingly, there are very few reports about the Indian use that date to the colonial period. Moreover, the Inquisition (which apparently did know about it) did not persecute the use of the cactus (Andritzky 1987*).

No one knows precisely how an Indian sacred plant received the name of a Catholic saint (Saint Peter). The cactus probably was associated with rain cults and pagan rain gods. Since San Pedro is the patron saint of rain, it seems likely that the cactus obtained its name as a result (perhaps in an attempt to save it from the pharmacratic Inquisition). In addition, Saint Peter is the keeper of the keys to heaven (cf. *Nicotiana rustica*).

A flowering *Trichocereus pachanoi*.

Distribution

The San Pedro cactus is originally from Peru, where it is found at altitudes between 2,000 and 3,000 meters (Giese 1989a; Polia and Bianchi 1991). It also is cultivated in many other parts of the Andes, e.g., Ecuador and Peru. The cactus can be found in most botanical gardens and cactus nurseries around the world. It thrives in both dry regions and moist zones.

Cultivation

The cactus can be grown from its tiny seeds or propagated from cuttings. The latter approach requires simply placing a piece of the cactus in the ground. One or two new stalks will grow from the place where the cactus was cut.

Today, large numbers of *Trichocereus pachanoi* are planted in particular in California, not only for decorative purposes but primarily for use as entheogens. The cactus thrives in the Californian climate and grows quickly when watered daily. Because it is not a desert inhabitant but comes from the moist-warm, rain-rich areas of the Andes, the cactus is accustomed to receiving large amounts of water. My own experiments with cultivation have demonstrated that with regular watering (daily!), one can almost watch the cactus shoot up from the ground.³⁰⁷ At the same time, it is modest in its needs and can survive for months without water. Pieces cut from the cactus can survive for months or even years and can develop lateral shoots even without food and water. Anyone who plants this cactus at home will be impressed with its unbelievable vitality.

Trichocereus pachanoi is well suited for grafting with other cacti, e.g., peyote (*Lophophora williamsii*). The tip of the San Pedro cactus should be cut flat and the head of the other cactus placed on the cut surface and tied to it for a few days. However, the cactus that has been grafted onto San Pedro will not contain any **mescaline** unless it is a species that itself produces mescaline.

A mythical snail being with a cactus, which may represent a *Trichocereus* species. (Painting on a Mochica pottery vessel, Chimú,

Appearance

The almost spineless columnar cactus can grow as tall as 6 meters (Britton and Rose 1963, 2:134 ff.*). It has several ribs—usually six, but often seven or eight, sometimes as many as twelve, and in very rare cases (or not at all?) only four (the Indians consider a four-ribbed cactus to be especially powerful, as it symbolizes the four cardinal points). The beautiful white flowers appear only at night. The very delicious red fruits, which are almost the size of a child's head, only very rarely develop.

Psychoactive Material

—Slices of the fresh cactus

—Powdered rind

The fresh cactus slices are sold at “witches' markets” in Peru (Anzeneder et al. 1993, 79*).

Preparation and Dosage

The San Pedro drink is prepared from fresh cactus stalks or pieces. The chopped stalks are boiled for a few hours in ample water (often with other plants added). The decoction is then poured off and boiled again for several hours until only about half of the original volume remains (Davis 1983; Dobkin de Rios 1968). Some *curanderos* (“healers”) boil four thin stalks in 20 liters of water for seven hours (Sharon 1980, 66).

Usually, a piece of cactus approximately 25 cm long and 5 to 8 cm thick is sliced and boiled per person. Some lemon or lime juice may be added to improve the dissolution of the mescaline. A technique using a pressure cooker has also been developed (Torres and Torres 1996).

Traditional *curanderos* fortify the San Pedro drink with leaves of the angel's trumpet known as *misha* (***Brugmansia* spp.**; Giese 1989b, 225) as well as with other plants. Some of these, such as *hornamo* and *condorillo*, have not yet been botanically identified with accuracy (Polia M. 1988*; Polia and Bianchi 1991, 66; Sharon 1980, 66). These plants clearly alter the qualities of the San Pedro drink (Dobkin de Rios 1968, 191; Giese 1989a, 228 ff.).

To harvest, the stalks are cut off some 5 to 10 cm above the ground. The remaining stumps will develop shoots again in just a short time. The stalks are cut into manageable pieces some 30 to 40 cm long. The ribs are then cut apart. The skin or rind is cut away at the place where the green coloration of the flesh disappears. The fresh skin is placed in the sun to dry. After a few hours, the pieces of skin will begin to roll up, and they should then be placed so that the inside faces the sun. The drying process can last from two to six days, depending on the amount of solar radiation. After the cactus skins have dried thoroughly, they are ground. This can be done with a mortar and pestle (very arduous), a Mexican metate (grinding stone), a coffee mill, or a professional device from a drug store for pulverizing raw drugs (i.e., raw plant material). The more finely the cactus material is ground, the more effective is the absorption of the mescaline. Because the cactus tastes extremely or even disgustingly bitter, many Californians pour the powder into gelatin capsules that hold 1 g each. This practice makes it easier to ingest the powder and also makes it easy to determine the dosage. The powder should be stored in a dry, dark location. Because mescaline is a relatively stable compound, the powder will remain active for a long time if stored properly. If the powder is dissolved in milk, water, apple juice, tea, or some other liquid, it should be consumed as quickly as possible, as otherwise it will congeal into a disgusting mass.

Ritual Use

In pre-Hispanic times, the cactus played a ritual role in oracles, sexual magic, and shamanism (Andritsky 1989; Burger 1992; Dobkin de Rios 1982). Although the ritual use appears to date back to very ancient times, no precise pre-Columbian rituals have been documented. Dobkin de Rios (1985) has suggested that the renowned earth drawings on the Nazca plain may represent a kind of sacred cartography (or visionary map) that Moche shamans used for their out-of-body flights.

Today, Peruvian *curanderos* still ingest the sacred cactus during their nocturnal *mesa* rituals and also give it to the other participants. The *mesa* (Spanish, “table”) is an altar with numerous objects (sticks, shells, ceramics, images of saints, et cetera) whose structure dates back to pre-Hispanic times and represents a visionary map (Giese 1989a, 1989b; Joralemon 1985, 21; Joralemon and Sharon 1993, 167; Villoldo 1984). The drink is consumed primarily by shamans so that they can recognize the cause of an illness during their nocturnal ceremonies. Less frequently, the patient and other people who are present may also receive some of the drink. Prior to this, however, they must “drink” an alcohol extract of tobacco (*Nicotiana rustica*) through the nose from a snail or seashell to purify themselves and protect themselves from negative powers.

The San Pedro cactus (*Trichocereus pachanoi*) has only a few soft, short spines. It is one of the most important shamanic plants of Peru.

A monstrous form of *Trichocereus pachanoi*.

The dried powder of the rind of *Trichocereus pachanoi* contains mescaline. It is light green in color and tastes extremely bitter.

The *Pernettya* species known as *toro-maique* is a fortifying additive to the San Pedro drink.

The use of the San Pedro drink among Peruvian folk healers is no longer truly shamanic but has taken on a more symbolic form. At the *mesa* rituals, the dosage that is now usually taken is not large enough to elicit psychoactive effects:

Based on my observations of numerous *mesa* rituals in Lima and Huancabamba, the *achuma* drink does not have a hallucinogenic effect. Even in the *curandero* and his helpers (*rastreadores*), no signs of an altered state of consciousness could be noticed. According to their statements, the

achuma strengthens the visionary/diagnostic sensitivity, animates the objects on the *mesa*, and allows the souls of the patients to “blossom.” But true hallucinogenic visions were not reported at any *mesa*. (Andritzky 1989, vol. 1, 113 f.*)

Artifacts

There are numerous pre-Columbian artifacts from Nazca and from the Moche-Chimu period that depict columnar cacti that look exactly like *Trichocereus pachanoi* (and less like other species) (Dobkin de Rios 1977a*, 1980). An image engraved in a stele showing the oracle god of Chavín holding a cactus in his hand is particularly well known (Burger 1992; Cordy-Collins 1977, 1980; Mulvany de Peñaloza 1984*). The flowering cactus is also depicted on two-thousand-year-old shamanic textiles of the Chavín culture, although in an idealized form (with only four ribs). And while Peruvian shamans today still claim that four-ribbed cacti are the most potent, no such specimens have ever been observed in nature (Cordy-Collins 1982*). Many Mochican stirrup vessels have representations of cacti, either in three-dimensional relief or as drawings, that are clearly indicative of shamanic associations (Bourget 1990; Cordy-Collins 1977; Donnan and Sharon 1977; Kutscher 1997*; Sharon 1972, 1980, 1982). One especially interesting object is a vessel on which the magical cactus is shown growing out of a deer, i.e., here a connection is made between a cervine and a plant that contains mescaline, a connection that is also made in the Huichol peyote cult (see *Lophophora williamsii*). A Mochica vessel with an image of an erotic scene shows a woman on her back and a man who is in the act of penetrating her while holding a slice of San Pedro in his hand (Furst 1996*).

The American artist Donna Torres has produced several paintings that were inspired by experiences with San Pedro. The Chilean museum illustrator and artist José Pérez de Arce Antoncich produced a lithograph, *Hume Adentro*, after his own first experience with the San Pedro cactus (signed copies are available at the National Museum for Pre-Columbian Cultures in Santiago de Chile).

A Peruvian postage stamp features a drawing of *Trichocereus pachanoi* in flower.

Medicinal Use

The cactus is used primarily by shamans in psychedelic rituals. In Peruvian folk medicine, preparations of the cactus flesh are used in a limited degree as aphrodisiacs and tonics (Dobkin de Rios 1968).

At the present time, the cactus does not find any use in homeopathic or Western medicine.

Constituents

The dried extract of *Trichocereus pachanoi* is said to contain 2% mescaline (Cabieses 1983, 138; Polia and Bianchi 1991, 66). Information in the literature about the concentrations of active ingredients often varies. According to Gottlieb (1978, 45*), 1 kg of fresh cactus contains 1.2 g of **mescaline**. The fresh cactus is said to have a mescaline content of 0.12% (Polia and Bianchi 1991, 66). Freeze-dried material has been found to have a mescaline content of 0.33% (Brown and Malone 1978, 14*). DeKorne (1994, 88*) has stated that 100 g of dried material contains 300 mg of mescaline. More recent chromatographic methods (HPLC) have achieved very precise results indicating that the mescaline content in six different samples of *Trichocereus pachanoi* ranged from 1.09 to 23.75 µg per mg of dried material. In other words, the mescaline concentration can vary substantially (Helmlin and Brenneisen 1992, 94). Human pharmacological experiments have clearly shown that the effects produced by cactus material from younger specimens are considerably more intense than those produced by older, woody individuals (Manuel Torres, pers. comm.).

In addition to **mescaline**, *Trichocereus pachanoi* contains tyramine and **β -phenethylamines** (Mata and McLaughlin 1976*). Also present are trichocerine (Polia and Bianchi 1991, 66), hordenine, 3,4-dimethoxy- β -phenethylamine, and anhalonidine (Brown and Malone 1978, 14*).

Even snails that live on the cactus are said to contain mescaline (Furst 1996*).

“According to the *curandero* teachings, there are different types of the San Pedro cactus that can be distinguished on the basis of the number of their longitudinal ribs. Four-ribbed cacti, like four-leaved clovers, are considered to be very rare and very lucky. They are attributed with special healing properties because they correspond to the ‘four winds’ and the ‘four roads,’ supernatural powers associated with the cardinal directions that are invoked during the healing rituals. The San Pedro species that are found in the foothills of the Andes are considered especially effective, regardless of the number of ribs, because the soil there has more minerals.”

DOUGLAS SHARON

MAGIER DER VIER WINDE [WIZARD OF THE FOUR WINDS]

(1980, 66)

The feline oracle god of Chavín de Huántar (Peru) holding the psychedelic San Pedro cactus in his right hand, a clear indication that the cactus was already in use for divinations during the pre-Hispanic period.

Ritual snail collectors are shown with columnar cacti, most likely *Trichocereus pachanoi* or another *Trichocereus* species. The sacred snails actually do often sit between the ribs of *Trichocereus pachanoi*. (Painting on a Moche vessel, Chimú, approximately 500 C.E.)

Effects

The effects of *Trichocereus pachanoi* are typically characterized as psychedelic or entheogenic. These effects make it appear to be the ideal shamanic drug for out-of-body journeys, et cetera (Giese 1989b, 83; Turner 1994, 32 f., 36*).

I have carried out experiments with varying dosages of the powder. With 1 g, I did not experience any effects. Two to 4 g produced a mild stimulation that persisted for approximately six to eight hours. This amount functions as a true tonic and restorative. I have also experimented with this dosage in the high mountains, where I noticed a distinct improvement in performance. If a person eats something during the time in which the effects are felt, the effects will increase as digestion begins.

With amounts of 5 to 6 g, empathogenic sensations appear alongside of the tonic qualities. Ten grams of the powder are unequivocally psychedelic, although few hallucinations occur. The psychedelic effects manifest more in the emotional domain. Very profound psychedelic effects can be achieved by taking some 50 µg of LSD with 10 g of San Pedro powder (cf. ergot alkaloids).

Recently, the use of cactus powder (sometimes in combination with *Peganum harmala* seeds) as a smoking substance has been on the rise. Whether psychoactive effects can be produced in this manner is questionable. I have not noticed any effects from such use.

Commercial Forms and Regulations

The cactus can be obtained through the international cactus trade (the seeds are also available from time to time). At present, there are no import restrictions.

“It is certainly not pleasant to eat San Pedro. Most hard-core consumers can stand the taste. But it is difficult to consume the amount of cactus that is needed for an intensive trip. The taste of the various *Trichocereus* species varies from extremely bitter to neutral, but those species that have a less intense taste tend to have a slimy consistency. With these, this consistency is the greatest barrier to being able to consume large quantities. I chew the cactus to a paste and swallow it with liquid. It is also helpful to eat whole-grain bread to bind the liquid in the stomach. The dark green flesh directly under the skin contains the most active ingredients and should be eaten first. The V-shaped strips should be pressed flat so that the flesh can be scratched from the skin. The flesh of the protruding ribs can be eaten like an ear of corn. The middle part is woody and inedible. The effects begin some 45 minutes after ingestion, and since it takes a while to eat the cactus, one can feel the effects while still eating.”

D. M. TURNER

DER PSYCHEDELISCHE REISEFÜHRER [THE PSYCHEDELIC TRAVEL GUIDE] (1997, 39*)

Trichocereus peruvianus Britton et Rose

Peruvian Columnar Cactus

Family

Cactaceae (Cactus Family); Cereus Subdivision

Forms and Subspecies

One geographically isolated variety has been referred to as *Trichocereus peruvianus* var. *truxilloensis*.

Synonyms

Echinopsis peruvianus (cf. *Echinopsis* spp.)

Folk Names

Cuchuma, peruanischer kaktus, Peruvian columnar cactus, San Pedro

History

This species was first described botanically in 1937 by Britton and Rose in their large monograph on cacti (2:136). Apart from this, nothing is known about the plant's history.

Distribution

This *Trichocereus* species is found almost exclusively in Peru at altitudes of around 2,000 meters.

Cultivation

Trichocereus peruvianus grows as fast or even faster than *Trichocereus pachanoi*, but only when it is watered daily. During arid periods, it requires considerably less water.

Appearance

Trichocereus peruvianus is distinguished from *Trichocereus pachanoi* primarily by its considerably longer, harder, and more pointed spines. It is very similar to *Trichocereus bridgesii* (cf. *Trichocereus* spp.) but does not grow as large, attaining a height of only 2 to 4 meters.

Psychoactive Material

—Fresh cactus flesh

—Dried rind powder

Preparation and Dosage

See *Trichocereus pachanoi*. Because of the long spines, care should be taken when preparing this cactus (wear gloves!). A piece of cactus approximately 10 cm long is sufficient for one person.

Ritual Use

As with *Trichocereus pachanoi*. *T. peruvianus* is sometimes regarded as the “male” counterpart of *T. pachanoi*.

Artifacts

It is possible that some pre-Columbian representations of cacti on Peruvian ceramics may be depictions of *T. peruvianus*.

Medicinal Use

As yet unknown

It is possible that *Trichocereus peruvianus* was known in Europe as early as the eighteenth century, for it may be identical with “*Cereus peruvianus*.” (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The Peruvian columnar cactus *Trichocereus peruvianus* has deep ribs. It frequently has four ribs, regarded as symbolic of the four cardinal points. The cactus is rich in mescaline.

The rare variety *Trichocereus peruvianus* var. *truxilloensis* occurs in northwestern Peru, the area in which *trujillo* coca (*Erythroxylum novogranatense* var. *truxillense*) is grown.

Constituents

Trichocereus peruvianus contains approximately three times as much **mescaline** as other *Trichocereus* species (Turner 1994, 31*). Its concentration of mescaline is said to be the same as or even higher than that of peyote (cf. *Lophophora williamsii*) (Pardanani et al. 1977, 585). On occasion, it may contain up to ten times as much mescaline as *Trichocereus pachanoi* (Rob Montgomery, pers. comm.).

Effects

See *Trichocereus pachanoi*.

Commercial Forms and Regulations

The cactus is available through the international cactus trade and is not subject to any regulations.

Literature

See also the entries for *Trichocereus pachanoi*, *Trichocereus* spp., and **mescaline**.

Pardanani, J. H., J. L. McLaughlin, R. W. Kondrat, and R. G. Cooks. 1977. Cactus alkaloids. XXXVI. Mescaline and related compounds from *Trichocereus peruvianus*. *Lloydia* 40 (6): 585–90.

Trichocereus spp.

Columnar Cacti

Family

Cactaceae (Cactus Family); Cereus Subdivision

Synonyms

Echinopsis spp.

Helianthocereus pasacana (Rümpl.) Backeb.

Folk Names

Achuma, cardón, cardón grande, columnar cactus, pasakana,^{[310](#)} säulenkaktus, San Pedro

Psychoactive Species in the Genus

Trichocereus

Trichocereus bridgesii (Salm-Dyck) Britt. et Rose

Trichocereus cuscoensis Britt. et Rose

Trichocereus fulvinanus Ritt.

Trichocereus macrogonus (Salm-Dyck) Ricc.

Trichocereus pachanoi Britt. et Rose

Trichocereus peruvianus Britt. et Rose

Trichocereus taquimbalensis Card.

Trichocereus terscheckii (Parmentier) Britt. et Rose

Trichocereus validus (Monv.) Backeb.

Trichocereus werdermannianus Backeb.

Mescaline has been detected in all of these species (Agurell 1969; Mata and McLaughlin 1976). Several of these species are known as San Pedro or are seen as substitutes for it (see ***Trichocereus pachanoi***).

While the following species have been chemically investigated, no mescaline has (yet) been detected in them:

Trichocereus spachianus (Lem.) Ricc.^{[311](#)}

Trichocereus candidans Britt. et Rose

Distribution

These species occur in Ecuador, Peru, Bolivia, northern Chile, and Argentina.

Cultivation

Trichocereus bridgesii can be grown from seed and requires conditions similar to those required by ***T. pachanoi***. The other *Trichocereus* species can be grown from seed and also propagated from layers or cuttings.

Appearance

All species of *Trichocereus* develop long, ribbed columns with varying numbers of spines. Hybrids of different *Trichocereus* species now exist.

Ritual Use

In Bolivia, where *Trichocereus bridgesii* is commonly referred to as *achuma*, the cactus is said to be used both traditionally by the Indians and “for its stimulating effects upon the psyche” by young people in La Paz (Giese 1989b, 225*). Davis reported that this species has potent psychedelic effects (Giese 1983, 375*).

The *pasakana* cactus (*Trichocereus pasacana* [Webb.] Britt. et Rose) appears to have a long history of cultural use in South America. *Trichocereus pasacana* fruits have been found in a cave near Jujuy (Argentina) in layers that have been dated to 7670 to 6980 B.C.E. They were also found in all subsequent layers, i.e., continuously. They first begin to appear together with coca leaves (*Erythroxylum coca*) in layers from the fifteenth century (Inca period). It is unclear whether the cactus was used for psychoactive or simply culinary purposes in early times. The fruits (sans seeds) and flowers are still used today in the area of Jujuy to produce *llypta*, the alkaline coca additive (Fernández Distel 1984).

A flowering *Trichocereus huanucensis* from Peru

The Bolivian *Trichocereus bridgesii* is consumed as a psychedelic recreational drug in La Paz.

The border of Puna, the high plain between northern Chile and northwestern Argentina, is the area of natural occurrence of the *pasakana* cactus (*Trichocereus pasacana*), one of the oldest psychoactives in the plant world. Its fruits and flowers are burned to make ashes, which are added to coca quids for chewing.

A *Trichocereus* species with fruit.

In the Chaco region of northwestern Argentina, a tall, red-blooming *Trichocereus* species is called San Pedro. It is said to produce psychoactive effects. (Photographed in its natural habitat)

There are now numerous crosses and hybrids among *Trichocereus* species that can no longer be unequivocally assigned to a specific species. Whether these contain mescaline is unknown.

Trichocereus atacamensis, indigenous to northern Chile (Atacama Desert), has stimulating powers and may possibly contain mescaline and similar constituents. This *Trichocereus* species is easily recognized by its extremely long spines (up to 20 cm in length). (Photographed in its natural habitat)

Northwestern Argentina is home to the red-blooming *Trichocereus tarijensis* [syn. *Trichocereus poco*] (Fernández Distel 1984) and the mescaline-containing *Trichocereus terscheckii* (Mata and McLaughlin 1982, 114*). There they are known as San Pedro or *cardón santo*, “sacred cactus.” The Mataco have used the cactus flesh of these and perhaps other species to make *llypta* for coca chewing. Such coca quids are said not only to taste better but also to be much more potent.

Trichocereus atacamensis appears to have been used in the Atacama Desert in prehistoric times in connection with **snuffs**.

Constituents

Mescaline and occasionally other **β-phenethylamines** are present in *Trichocereus* species (Aguirell 1969b). *Trichocereus terscheckii* contains 0.25 to 1.2% alkaloids (primarily trichocerine and mescaline; cf. Reti and Castrillo 1951 and Herrero-Ducloux 1932).

Trichocereus pasacana has been found to contain the alkaloid hordenine, which may have sympathomimetic effects (Aguirell 1969a; Fernandez Distel 1984). The alkaloid candicine has also been detected (Meyer and McLaughlin 1980).

Effects

The cactus flesh of *Trichocereus atacamensis* (Phil.) Britt. et Rose [syn. *Helianthocereus atacamensis* (Phil.) Bckbg., *Cereus atacamensis* Phil.] (cf. Aldunate et al. 1981, 211*) has a very bitter taste (quite similar to that of *Trichocereus pachanoi*) and has distinctly stimulating properties.

Trichocereus terscheckii is said to produce the same effects as ***Trichocereus pachanoi***.

Commercial Forms and Regulations

It is occasionally possible to purchase seeds of various *Trichocereus* species. The cacti are not subject to any special regulations.

History

The ritual and medicinal use of the psychoactive seeds of the ololiuqui vine dates back far into the pre-Hispanic period. There has been evidence of the use of the “little gods” (= seeds) among the Aztecs and other Mesoamerican peoples since early colonial times. Sahagun documented the divinatory and medicinal uses. Hernandez was the first to discuss the plant and its properties. Ximenez described the plant and its use in *Cuatrolibros de la naturaleza* (1790). The most comprehensive report comes from Ruiz de Alarcón.

In the early twentieth century, it was thought that the use of ololiuqui had died out. The botanical source was also long uncertain. For example, ololiuqui had been interpreted as *Datura innoxia* or *Lophophora williamsii* (Safford 1915; Reko 1934). It was once even thought that ololiuqui must have been a poppy species (*Papaver* spp., *Argemone mexicana*) with narcotic properties (Cerna 1932, 305*).

The botanical identity of ololiuqui was first clarified in the 1940s by Richard Evans Schultes (Davis 1996, 94 ff.*; Schultes 1941). In the early 1960s Albert Hofmann isolated the active constituents, which he recognized to be **ergot alkaloids** that were closely related to the constituents of *Claviceps purpurea* and LSD (Hofmann 1961). From a chemotaxonomic perspective, this discovery was an absolute sensation. At the time, no one had thought it possible that a primitive fungus was able to biosynthesize the same substances as a highly developed flowering plant. For this reason, Albert Hofmann was greeted with severe skepticism and disbelief when his report was first published and when he made his first presentations on the subject.

Distribution

The plant is very likely from tropical Mexico but is now very common in Cuba as well as on other islands of the West Indies and on the North American Gulf Coast. It also occurs in Central America; its southernmost occurrence is in the Amazon basin of southern Colombia (Richardson 1992, 69*). The plant was introduced into the Philippines at an early date and has now become wild there (Brenneisen 1994, 1014).

Cultivation

Propagation occurs via the seeds, which are preferably pregerminated or raised in growing pots until they are seedlings. Cultivation is not a particularly successful venture, as typically only a few seeds germinate. The plant requires a tropical climate and relatively large amounts of water and does not tolerate any frost (cf. also *Ipomoea violacea*).

Appearance

The large, woody, perennial creeper (up to 8 m long) has cordate leaves (5 to 9 cm long, 2.5 to 6 cm wide) and flowering branches that grow from the leaf axils. The branches bear the funnel-shaped flowers in clusters or umbels. The sepals are only about 1 cm wide, while the white petals can attain a length of 5 cm. The fruits contain only one light brown or ocher seed. In Mexico, the plant flowers

between December and March. The flowers are the source of a great amount of (psychoactive) **honey**. Most of the honey produced in Cuba is from *Turbina corymbosa*.

The genus *Turbina* is composed of twelve to fifteen species, some of which are similar in appearance, but only a few of which are known (Brenneisen 1994, 1013). They occur in tropical Africa and on New Caledonia (Schultes 1941, 20). The seeds of other *Turbina* species may also one day be found to contain psychoactive **ergot alkaloids**, as does *Argyreia nervosa*. Ololiuqui is the only New World species in the genus.

This is most likely the earliest non-Indian illustration of the ololiuqui vine (*Turbina corymbosa*). (From Francisco Hernandez, *Rerum medicarum Novae Hispania thesaurus*, Rome, 1651)

Psychoactive Material

- Fresh or dried seeds (*Turbina corymbosa* seeds, pascua, piule,³¹³ badoh, ololiuqui)
- Leaves
- Roots

Preparation and Dosage

The fresh or dried seeds normally are added to such alcoholic drinks as mescal (cf. *Agave* spp.), *aguardiente* (sugarcane liquor; cf. **alcohol**), *tepache* (maize beer, **chicha**), and **balche'** (Schultes 1941, 37). The fresh seeds, when crushed, are added to pulque (cf. *Agave* spp.) and allowed to steep. This drink, known as *piule*, can be drunk to attain hypnotic states.

Fifteen or more seeds can be ground and allowed to soak in one-half cup of water (Gottlieb 1973, 39*). The Zapotec say that a shamanic dosage consists of thirteen pairs of seeds (Fields 1968, 206); traditional dosages also are said to consist of fourteen or twenty-two seeds (Wasson 1971, 343). Because such traditional dosages did not elicit any effects among Western test subjects, experiments were conducted using larger quantities:

Ingesting 60 to 100 seeds led to apathy, indifference, and increased sensitivity to optical stimuli. After some 4 hours, there followed a longer-lasting phase of relaxation and well-being. In contrast, in eight male subjects, dosages of up to 125 seeds did not elicit any effects except vomiting. (Brennesien 1994, 1015)

Dosages as high as three hundred to five hundred seeds have also been tested, usually with unsatisfactory results and such severe side effects as vomiting, diarrhea, et cetera (Brenneisen 1994, 1016).

Literature from the colonial period mentions an ointment known as “sacred flesh” that was prepared from the ashes of burned insects, tobacco (*Nicotiana tabacum*, *Nicotiana rustica*), and ololiuqui seeds (José de Acosta, *Historia natural y moral de las Indias* . . . , Seville 1590).

The root is purportedly used for divinatory purposes, but the manner of preparation is unknown (Fields 1968, 206).

Ritual Use

The plant and its psychoactive effects are discussed in some detail in the colonial literature:

Its leaves are slender, ropelike, small. Its name is ololiuhqui. It inebriates one; it makes one crazy, stirs one up, makes one mad, makes one possessed. He who eats of it, he who drinks it, sees many things that will make him afraid to a high degree. He is truly terrified of the great snake that he sees for this reason.

He who hates people causes one to swallow it in drink and in food so as to make one mad. But it smells sour; it burns a little in the throat. It is applied on the surface alone to treat gout. (Sahagun, Florentine Codex 11.7*)

The Spanish physician Francisco Hernandez wrote about ololiuqui in his *Rerum medicarum Novae Hispaniae thesaurus*:

There is a plant in Mexico that is called snake-plant, a vine with arrow-shaped leaves, which is thus also called arrow plant. The seed is used in medicine. Ground and drunk with milk and Spanish pepper, it takes away pains, heals all manner of ailments, inflammations, and ulcers. When the priests of the Indians wish to commune with the spirits of the dead, they eat these seeds to induce a delirium and then see thousands of satanic figures and phantasms around them. (In Rätsch 1991a, 193*)

The Spanish missionary Hernando Ruiz de Alarcón has provided us with the most detailed reports of the Indian uses of magical plants (cf. *Lophophora williamsii*, *Nicotiana rustica*). His writings were published in 1629 under the title *Treatise on the Heathen Superstitions That Today Live Among the Indians Native to This New Spain*. (This work became a kind of “witches’ hammer,” providing the juristic basis for persecuting witches in the New World.) He has the following to say about the use of ololiuqui, which is equated with the use of peyote:

A comparison of the psychoactive seeds of the two vines traditionally used in Mexico: on the left are the light-colored seeds of

Turbina corymbosa (= *badoh blanco*) and on the right the dark seeds of *Ipomoea violacea* (= *badoh negro*).

The so-called *ololiuhqui* is a seed like lentils or lentil vetch which, when drunk, deprives one of judgment. And the faith that these unhappy natives have in this seed is amazing, since, by drinking it, they consult it like an oracle for everything whatever that they want to know, even those things which are beyond human knowledge, such as knowing the cause of illnesses, because almost everyone among them who is consumptive, tubercular, with diarrhea, or with whatever other sickness of the persistent kind right away attributes it to sorcery. And in order to resolve this doubt and others like it, such as those about stolen things and of aggressors, they consult this seed by means of one of their deceitful doctors, some of whom have it as their job to drink this seed for such consultations, and this kind of doctor is called *Pàyni*, because of the job, for which he is paid very well, and they bribe him with meals and drinks in their fashion. If this doctor either does not have this function or wishes to excuse himself from that torment, he advises the patient himself to drink that seed, or another person for whose services they also pay as they do the doctor, but the doctor indicates to him the day and the hour in which he is to drink it, and he tells him for what purpose he will drink it.

Finally, whether it is the doctor or another person in his place, in order to drink the seed, or peyote, which is another small root and for which they have the same faith as for that other seed, he closes himself up alone in a room, which usually is his oratory, where no one is to enter throughout all the time that the consultation lasts, which is for as long as the consultant is out of his mind, for then they believe the *ololiuhqui* or peyote is revealing to them that which they want to know. As soon as the intoxication or deprivation of judgment passes from this person, he tells two thousand hoaxes, among which the Devil usually includes some truths, so that he has them deceived or duped absolutely. . . .

Also they make use of this drink to find things that have been stolen, lost, or misplaced and in order to know who took or stole them. . . .

When the wife leaves the husband or the husband the wife, they also take advantage of *ololiuhqui*, and in this case the imagination and fantasy work also, and even better than in the case of sicknesses, because in this second case conjectures follow that are the cause of more vehement suspicion, and thus it works with greater strength at the time of the intoxication, since it is easily seen that one person will be persuaded that another carried off his wife or stole his property. . . .

Finally these prophets make use of *ololiuhqui* or of peyote to solve these riddles, in the way already described. Then they say that a venerable old man appears to them who says that he is the *ololiuhqui* or the peyote and that he has come at their call in order to help them in whatever way might be necessary. Then, being asked about the theft or about the absent wife, he answers where and how they will find it or her. . . .

Here it should be carefully noted how much these miserable people hide this superstition of the *ololiuhqui* from us, and the reason is that, as they confess, the very one they consult orders them not to reveal it to us. . . . And thus their excuse is *ipampa àmo nechtlahueliz*, which is as if to say “in order that the *ololiuhqui* will not declare himself to be my enemy.” (Ruiz de Alarcón, treatise I, chapter 6; 1984, 59–60, 65, 67)

This use of *ololiuhqui* seeds has continued in the same manner with only slight variations into the present day among the Zapotec, Mixtec, Mazatec, and Mixe. Among the Mixe, the plant and its parts (seeds, et cetera) are regarded as apotropaic. Witches can be kept away from the house if the appropriate parts of the plant are used. The seeds are used in the same manner as mushrooms (cf.

Psilocybe mexicana). Twenty-six seeds is given as a dosage (Lipp 1991, 190*). The Zapotec consider the plant sacred, “like a little god”; they ingest thirteen individual seeds or thirteen pairs of seeds (= twenty-six) for divinatory, clairvoyant, and medicinal purposes (Fields 1968). The seeds are powdered (if possible by a virgin), soaked in water, and then ingested. In some areas, they are purportedly also made into a **snuff** (Furst 1976b, 155*). As the seeds are being collected, the patient should direct the following prayer to the plant (Fields 1968, 206): “I come here to purchase something from you. With your permission, you will heal my illness.”

Several hours after the patient has ingested the seeds, things of importance are revealed to him in a dreamlike, hypnotic state. Two children (*niige*) or the *badoh* plant itself appear to the afflicted person and tell him the reasons for his illness. The patient usually stammers, and the *curandera* will interpret his sounds and words. After the session, she speaks with the patient about the messages from the plant (Fields 1968, 207).

In the area of the Maya (Yucatán), the medicinal and ritual use of the ololiuqui vine was documented during the colonial period. It was consistently listed under the name *xtabentum*, “jewel cord,” in the Mayan lexica and was described in the *Libro de Judío*:

The plant, *tabentun*, is a vine that gets white flowers. It is common in the gardens. Its quality is “moderate” [humoral doctrine] and it has many effects; the most well known is for those who cannot urinate. It can open the channels in which there is a stone. The bees take honey from its flowers. (Rätsch 1986a, 232*)

A depiction of the World Tree on a stele from the Classic Mayan period, showing how the tree grows out of the “earth monster” and is entwined by a vine that may be interpreted as *Turbina corymbosa*.

Honey plays an important role in the cult of the Maya during the production of the mildly alcoholic ritual drink known as *balche'*, the use of which extends far back into the Classic Mayan period and is still found in the Yucatán today. *Xtabentum* honey is popular for making **balche'** because it improves its effects. The seeds also are ingested with *balche'*. One Mayan shaman (*h-mèn*) had the following to say about *xtabentum*:

Especially when it is freshly harvested, ground, and taken as a drink; and when one drinks enough of it, one sees thousands of spirits, has contact with the devil and with hell. . . . When someone loses something valuable, we give him xtabentum to drink. Before he falls asleep, we repeatedly say into his ear: “Where is the lost object.” And we describe it. He becomes clairvoyant in the ensuing xtabentum sleep and sees where the object is. And if it was stolen, he will recognize the thief. Because the sleep is not deep, we can speak with him by calling to him repeatedly, as with people under hypnosis. He will give clear answers, although slowly and haltingly. In the inebriation of xtabentum, one also becomes weak and regrets his sins. He admits to everything if he is asked. (Leuenberger 1979, 83 f.*)

Artifacts

Pre-Columbian art contains many illustrations of plants and floral elements that can be interpreted as vines (e.g., as ***Ipomoea violacea***). Some of the images contained in the wall paintings at Tepantitla (Teotihuacán) are particularly fascinating. Numerous vinelike plants bear white flowers whose petals contain disembodied eyes. Peter T. Furst views these as representations of the *Turbina* vine. They are in a direct iconographic association with a deity that was once interpreted as the (Aztec) rain god Tláloc (cf. ***Argemone mexicana***) but probably represents a mother goddess (Furst 1974).

The Mayan codices also show vines that may represent ololiuqui (Rätsch 1986a, 232*). The *Codex Magliabecchi* contains a depiction of the plant as a climber on a field that is borne by rattlesnakes (cf. Guerra 1990, 177*).

The plant is depicted on a Cuban stamp that was issued at Christmas 1960–61 (Schultes and Hofmann 1992, 158*).

Medicinal Use

The Yucatec Maya use the plant medicinally as a diuretic and to treat wounds and bruises (Pulido S. and Serralta P. 1993, 20*). In Tecún Umán (Guatemala), the leaves are used to treat tumors (Fields 1968, 206). The plant finds use in Cuban folk medicine as an aid to parturition (Seoane Gallo 1984, 853*).

Constituents

The fresh seeds (only in the embryo) contain 0.012 to 0.07% indole or **ergot alkaloids** (ergoline alkaloids). The primary alkaloid is ergine (= 5R,8R-(+)-lysergic acid amide, LA-111 = ergo-basin), which comprises 50% of the total amount. The most important secondary alkaloid is erginine (= isoergine, 5R,8S-(+)-isolysergic acid amide); also present are small amounts of chanoclavine, elymoclavine, and lysergol. Terpene glycosides (e.g., epicorymbosin) and galactomannanes have also been detected (Brenneisen 1994, 1014; Cook and Kealand 1962).

The leaves and stalks, but not the roots, also contain psychoactive **indole alkaloids**. The concentration in the dried leaves ranges from 0.016 to 0.027% and in the dried stems from 0.01 to 0.012% (primarily ergine and erginine = isoergine) (Brenneisen 1994, 1014).

Effects

Ololiuqui seeds do not produce psychedelic effects like those of ***Psilocybe spp.***, LSD, or ***N,N-DMT***. Instead, they produce a hypnotic state similar to that induced by ***Ipomoea violacea***. The Indians report powerful visions, even with very low doses. It is possible that the ololiuqui experience is particularly amenable to cultural conditioning. Or perhaps the seeds invoke visionary effects only when they are

ingested by a qualified shaman.

While the main active constituent ergine has been demonstrated to produce psychoactive effects, these are not comparable to those produced by LSD. Rather, ergine induces a kind of trance or twilight sleep with dream images (Brenneisen 1994, 1015 f.).

“With the studies of ololiuqui, my work in the area of hallucinogenic drugs nicely came full circle. It now formed a circle, one could say a magical circle; the starting point was the studies on the production of lysergic acid amides of the type of the naturally occurring ergot alkaloid ergobasin. These led to the synthesis of lysergic acid diethylamide, of LSD. The work with the hallucinogenic substance LSD then led to studies of the hallucinogenic magic mushroom teonanacatl, from which the active principles psilocybin and psilocin were isolated. The concern with the Mexican magic drug teonanacatl led to work on a second Mexican magic drug, ololiuqui. In ololiuqui, lysergic acid amides, including ergobasin, were once again found to be the hallucinogenic substances, and this closed the magical circle.”

ALBERT HOFMANN

LSD—MEIN SORGENKIND [LSD— MY PROBLEM CHILD]

(1979, 149 f.*)

Lysergic acid amide (LSA, ergine)

This pre-Columbian representation of a plant on a wall painting in Tepantitla, Teotihuacán, can be interpreted as *Turbina corymbosa*.

Commercial Forms and Regulations

Although the plant is not subject to any legal restrictions, it is almost impossible to obtain. Plant material cannot be procured even in Mexico. Seeds are sometimes available from ethno-botanical suppliers (in very limited quantities). Unfortunately, many seeds that are sold as ololiuqui actually come from ***Ipomoea* spp.** (usually devoid of active constituents) or some other Convolvulaceae.

The liquor known as xtabentum is available for purchase in Mérida or Valladolid (Yucatán). But it is doubtful whether this is actually made with **honey** from *Turbina corymbosa*.

Turnera diffusa Willd. ex Schultes

Damiana

The yellow-blooming damiana (*Turnera ulmifolia*) occurs throughout the American tropics and has spread to Asia as well as various islands in the Indian Ocean. (Photographed on Oahu, Hawaii)

Family

Turneraceae (Turnera Family)

Forms and Subspecies

The damiana that is found in Baja California has been described as a variety: *Turnera diffusa* Willd. var. *aphrodisiaca* (Ward) Urban

Synonyms

Turnera aphrodisiaca L.F. Ward

Turnera aphrodisiaca Willd.

Turnera humifusa Endl.

Turnera pringlei Rose

Folk Names

Ajkits, damiana, damiana amarilla, damiana americana, damiana de California, garañona, hierba de la mora, hierba de la pastora (Spanish, “plant of the shepardess”),³¹⁴ hierba del pastor (Spanish, “plant of the shepherd”), hierba del venado (Spanish, “plant of the deer”), itamo real, jícamo real, Mexican damiana, mezquitillo, miixkok, misibkok (Mayan, “asthma sweeper”), misibkook, mis kok (Mayan, “asthma broom”), old woman’s broom, oreganillo (“little oregano”), oreja de venado (Spanish, “ear of the deer”), paraleña, pastorcita (Spanish, “little shepherdess”), pastorica, rosemary, salverreal, San Nicolás, shepherd’s herb, stag’s herb, xmisibkok, xmisibkook

Species Also Referred to and Sold as Damiana

(Martínez 1994, 120*)

<i>Turnera pumilla</i> L.	bruja (Spanish, “witch”)
<i>Turnera ulmifolia</i> L.	clave de oro (Spanish, “gold clove”)
<i>Chrysactinia mexicana</i> A. Gray	false damiana
<i>Bigelowia veneta</i> A. Gray [syn. <i>Haplopappus</i> <i>discoideus</i>]	false damiana
<i>Haplopappus laricifolius</i>	false damiana

History

It is very likely that damiana was in use as a medicine and love drink in northern Mexico and the area of the Maya during prehistoric times. The missionary Jesús María de Salvatierra first mentioned its aphrodisiac use among the Indians of northern Mexico in his *Chronica* of 1699. The name *damiana* is derived from that of either Saint Damian, the patron saint of pharmacists, or Peter Damiani, who railed against the immorality of the clergy in the eleventh century.

The first botanical description of the plant was written by Austrian botanist Josef August Schultes (1773–1831) in 1820. In the nineteenth century, the plant was included in the U.S. (1874) and Mexican pharmacopoeias as a tonic and aphrodisiac (Martínez 1994, 121*). It was introduced into Europe in 1880 (Hirschfeld and Linsert 1930, 174*). Since the late 1960s, the plant has been regarded as a “legal high” and as a substitute for marijuana as well as tobacco (***Cannabis indica*, *Nicotiana tabacum***).

Prior to Prohibition in the United States, Dr. John S. Pemberton (1831–1888), the inventor of Coca-Cola, developed a tonic beverage inspired by Vin Mariani. Known as French Wine Coca, it contained extracts of coca, cola, Mediterranean sweet wine, and damiana (cf. ***Erythroxylum novogranatense***).

Distribution

Damiana occurs from Southern California (Baja) to Argentina. The main region of the plant is in northern Mexico and Baja California.

Cultivation

The plant can be grown from seed (very difficult) as well as cuttings. It requires a warm or hot climate but does not have any great requirements in terms of soil type (Grubber 1991, 26 f.*). Damiana also grows well in desert zones (Miller 1985, 21*).

Appearance

The plant usually attains a height of about 30 cm but in rare cases can grow as tall as 2 m. The leaves, which are alternate, lanceolate, serrated, and covered with a few hairs, can grow up to 2 cm in length. The yellow flowers, which are only 12 mm in length and grow from the leaf axils, bloom from July

to September. The round, three-chambered capsule fruit is just 2 to 4 mm in size and contains only one or two pear-shaped seeds.

The damiana plant may be named after Saint Damian, the patron saint of pharmacists. (Colorized woodcut showing the brothers Cosmas and Damian; title page by Hans Wechtlin to *Feldbuch der Wundartzney*, by Hans von Gersdorf, Strassburg, 1517)

Dried damiana herbage (*Turnera diffusa*).

Damiana can be easily confused with other species in the genus *Turnera* as well as with *Chrysactinia mexicana*. It can be distinguished from the rich green *Turnera ulmifolia* on the basis of the greenish blue color of its leaves and its distinctly smaller flowers.

Psychoactive Material

—Herbage sans roots (herba damianae, damiana herbage)

Preparation and Dosage

The dried herbage can be prepared as a tea or an alcohol extract, smoked, or burned as incense. For aphrodisiac purposes, one can either smoke a joint made from the leaves or drink a tea prepared from the herbage (Gottlieb 1974, 27 f.*).

Damiana herbage is an ingredient in some psychoactive **smoking blends** (Miller 1985, 23*). It is especially popular as a substitute for tobacco (*Nicotiana tabacum*) for smoking together with hashish (see *Cannabis indica*, *Cannabis sativa*).

Damiana tea can be prepared as an infusion, a decoction, or a cold-water extract. An infusion of damiana herbage, to which orange blossoms can be added if desired, should be allowed to steep for three to five minutes. Boil the herbage for up to an hour to produce a decoction that is more potently effective. Cold-water extracts should be allowed to sit for twenty-four hours. The dosage for teas is 4 g per cup or mug (Lowry 1984, 267). The dosages can be increased as desired, as side effects are unknown.

For aphrodisiac purposes, damiana is often combined with equal parts of saw palmetto fruits (cf. **palm wine**, **wine**) and occasionally also with cola nuts (***Cola** spp.*). A preparation of former times known as *píldoras de damiana* consisted of 5.5 g of phosphorus, 9 g of ***Strychnos nux-vomica***, and 10 g of damiana (Martínez 1994, 122*). Damiana also can be combined with pure **strychnine** (Lowry 1984).

The herbage is well suited for making liqueurs. In Mexico, it is used to manufacture a liqueur that is alleged to have aphrodisiac effects.

Damiana Liqueur

1 bottle (0.7 l) **alcohol** (white rum [sugarcane spirits] or tequila [cf. ***Agave** spp.*])
approximately 10–20 g damiana herbage (*Turnera diffusa*)
approximately 20–25 g saw palmetto fruits (fructus sabalae serrulata tot.) (cf. **palm wine**)
2 vanilla pods (= 7–9 g) (*Vanilla planifolia*) 4 cinnamon sticks (approximately 15 g) (*Cinnamomum verum*)
approximately 2 g mace (***Myristica fragrans***)
approximately 0.5 g galangal root (*Alpinia galanga* [L.] Willd. [syn. *Maranta galangal* L.]) or *Alpinia officinarum* Hance) (cf. ***Kaempheria galanga***)

Slice the vanilla pods lengthwise or in half. Add all of the ingredients to the spirits and allow the mixture to sit in a warm location for at least two weeks. Then either filter out the ingredients or leave them in the bottle. Drink one small glassful daily or one hour before an erotic encounter.

A Mexican Recipe for an Aphrodisiac Damiana Tea

30% damiana (*Chrysactinia mexicana* Gray)
10% gobernadora (*Larrea tridentata* [DC.] Cav.; also *Larrea divaricata* [?])
50% damiana californica (*Turnera diffusa* Willd.)
10% garañona (*Castilleja canescens* Benth. or *Castilleja arvenis* Schl. et Cham.)

Combine all the ingredients. Add 2 teaspoons of the mixture to 1 liter of water; drink 1 cup after every meal.

“Damiana has mild diuretic and aphrodisiac effects, especially among women. Most specialists consider the libido-promoting effects to be induced psychogenically as a result of the mental state of expectation of the believed effectiveness.”

BRUNO WOLTERS

AGAVE BIS ZAUBERNUS [AGAVE TO MAGIC NUT]
(1996, 59*)

Ritual Use

No traditional use of damiana based upon its psychoactivity is known from Mexico.

In the voodoo cult practiced in the southern United States, damiana is consecrated to the love goddess Erzulie and is used in love magic (Müller-Ebeling and Rätsch 1986, 122 f.*; Riva 1974).

The use of damiana herbage as an **incense** is most likely a modern invention. Because it is also regarded as an aphrodisiac when burned, damiana herbage is often added to so-called Pan, Venus, or love incenses. When used as a fumigant, damiana produces a pleasantly herbal, sweet scent that is

characteristic and easily recognizable when encountered again. It combines very well with copal (resin of *Protium copal* or *Bursera* spp.; cf. ***Bursera bipinnata***).

“The effects of damiana apply especially to the genital area. According to information provided by American physicians, its effects are exciting to the highest degree and are in this regard comparable to the effects of coca.”

MAGNUS HIRSCHFELD AND RICHARD LINSERT *LIEBESMITTEL* [LOVE AGENTS] (1930, 174*)

The Maká Indians once had a magic custom that used the roots of *Turnera ulmifolia* to improve the sound of the flutes they used in rituals (Arenas 1987, 287*).

Artifacts

In Mexico, a commercial damiana liqueur is bottled in containers in the shape of a female torso, an advertisement for the aphrodisiac effects of the drink (Rätsch 1990, 160*).

Medicinal Use

In Indian medicine, damiana is used primarily in the treatment of asthma. This use is reflected in the Mayan name *mis kok*, “asthma broom,” for the plant “sweeps away” the illness. When used for this purpose, the herbage can be drunk as a tea, burned as a fumigant, or smoked. In Mexico, damiana’s good reputation as an aphrodisiac has led to the nickname “shirt remover” (Argueta V. et al. 1994, 566*). In Mexican folk medicine, damiana tea is drunk twice a day for fifteen days as a diuretic and to regulate the menstrual cycle (Jiu 1966, 256*). The Indians of northern Mexico use the plant primarily to treat muscle weakness and nervousness and, of course, as an aphrodisiac (Martínez 1994, 121*). Damiana is also used in northern Mexico to treat stomach problems, rheumatism, headaches, and scorpion stings (Wolters 1996, 57*). A variety of different preparations are drunk to treat smoker’s cough (cf. ***Nicotiana tabacum***) (Argueta V. et al 1994, 566*).

In the Bahamas, the steam produced when damiana herbage is boiled in water is inhaled to treat headaches (Brown and Malone 1978, 12*). Bed wetters drink a damiana tea in the morning for three or four consecutive days “to strengthen their backs” (Eldridge 1975, 320*).

In phytotherapy, damiana has been found to be especially effective in treating menstrual pains and cramps, as it not only has antispasmodic properties but also improves the mood. When used for this purpose, cassia cinnamon (*Cinnamomum aromaticum* Nees [syn. *Cinnamomum cassia* Bl.]) can be added to the tea (Lowry 1984).

A tincture (mother tincture) of the dried leaves, known as Damiana, is used in homeopathy as an aphrodisiac and for other purposes (Schneider 1974, 3:362*):

Should be of use for sexual neurasthenia. Sexual weakness as a result of nervous prostration. Incontinence in older persons. Chronic prostatorrhea. Kidney and bladder catarrh; frigidity in women. Helps to produce a normal menstrual flow in young girls.—Dosage. —Tincture and liquid extract, amounts of 10–40 drops. (Boericke 1992, 292*)

Damiana also is found in many homeopathic compounds used to treat such ailments as sexual weakness. For example, Damiana Pentarkan consists of damiana, ginseng (***Panax ginseng***), muira puama (***Liriosma ovata***), phosphoric acid, and ambergris.

Constituents

Damiana leaves are 0.2 to 0.9% **essential oil**, 6% hard brown resin, approximately 8% soft resin, 3.5% tannin, and 6% starch (Brown and Malone 1978, 12*). According to the Mexican pharmacopoeia, the herbage contains 8.06% chlorophyll, white resin, and essential oil; 6.39% hard

brown resin; 3.46% tannin; and 7.08% yellow dye (Martínez 1994, 120*). According to a different analysis, the herbage contains 0.51% essential oil of a greenish color, two resins, 0.7% arbutin, the bitter substance damianin, tannin, sugar, and albuminoids (Steinmetz 1960). The essential oil consists of some twenty substances, of which 1,8-cineol, α -pinene, β -pinene, and *para*-cymene have been identified (Auterhoff and Hauffel 1968; Argueta V. et al. 1994, 566*). About half of the essential oil consists of sesquiterpenes (guajan derivatives and similar substances) and the other half of monoterpenes (pinene, thymol); cineol and *para*-cineol were detected in only a few of the samples (Wolters 1996, 59*). Although it has often been claimed that **caffeine** is present in the leaves, this is questionable (Lara Ochoa and Marquez Alonso 1996, 47*; Lowry 1984, 268). In contrast, the stems have been determined to contain caffeine (Argueta V. et al. 1994, 566*). The flavone 5-hydroxy-7,3',4'-trimethoxyflavone has been isolated from the herbage (Domínguez and Hinojosa 1976), as has tetraphylline B (Spencer and Seigler 1981). **Ephedrine** is not present.

The leaves of the related *Turnera ulmifolia* contain procyanidin, and the seeds and leaves higher concentrations of **caffeine** (Wolters 1996, 59*).

Effects

Smoking the herbage produces a pleasant state of euphoria and mild, marijuana-like effects (Miller 1993, 8*). The “high” lasts for some sixty minutes (Lowry 1984, 268). Drinking the tea or other preparations produces effects that are only subtly perceptible and in no way spectacular. Damiana has effects upon the lower abdomen, which can result in an increase in the flow of blood into the region. Women have repeatedly reported that damiana has a very relaxing effect on menstrual cramps or pains.

The herbage is generally considered to have tonic, diuretic, stimulant, and aphrodisiac effects.³¹⁵ Damiana received the best marks in a test of different plants and natural drugs said to have aphrodisiac properties (Radakovich 1992, 32). An ethanol extract of the plant had antibiotic effects upon *Staphylococcus aureus* and *Bacillus subtili* (Argueta V. et al. 1994, 566*). Jiu (1966, 257*) was able to measure an effect upon the central nervous system.

The love plant damiana inspired the German electronic musician Rüdiger Gleisberg to create this album. (BSC Music/Rough Trade 1997)

Commercial Forms and Regulations

Damiana is available without restriction from pharmacies and herb shops (damiana folium conc., herbae damianae). In the United States, tinctures and extracts of damiana can be purchased in health

food stores and supermarkets. Damiana mother tincture is available in Europe. Damiana extracts and drops are sold in sex shops.

A “damiana essence” is occasionally offered for sale. However, this is actually davana oil, which is obtained from different stock plants (e.g., *Artemisia pallens*; cf. ***Artemisia spp.***). Raw plant material from *Turnera ulmifolia*, *Haplopappus* spp., and *Chrysactinia mexicana* is also sold under the name *damiana*.

History

The renowned paleoanthropologist Björn Kurtén has reconstructed the prehistory of humans in northern Europe in novel form. He places the invention of an inebriating drink made from plants from the Heath Family there in the early Stone Age. During the Middle Ages, a wine made from bog bilberries was produced in Scandinavia. In Siberia, shamans used the berries together with fly agaric mushrooms (*Amanita muscaria*), a custom that may also have been known in Europe. In Tyrolia (Austria), it is still said that children will lose their minds if they eat bog bilberries (Engel 1982, 109*).

Distribution

The bog bilberry is a circumpolar plant that is at home in North America and in Siberia. It is also frequently encountered in dwarf shrub heaths and arolla pine forests in the Alps, e.g., on Bettmeralp and in other locations in Valais (Switzerland) (Hecker 1995, 288*).

Cultivation

Propagation is performed from seeds, which can be raised in seedbeds that should be kept moist. The seedlings can then be transplanted as desired.

Appearance

This undershrub can grow as tall as 1 meter. It has alternate, summer-green, deciduous leaves. The pinkish white flowers hang in clusters. The round, blue, pruinose fruits resemble blueberries; they produce a colorless juice and have a sour/sweet taste. The plant flowers in June and July, and the fruits mature in the fall (August to September).

Other *Rauschbeeren* (“Inebriating Berries”)

The German name *rauschbeere*, “inebriating berry,” is also given to several other plants, especially the evergreen dwarf shrub *Empetrum nigrum* L. (Empetraceae/Crow Berry Family), known as the black crow berry. This inebriating berry occurs in two subspecies: ssp. *hermaphroditum* (Lange) Böcher [syn. *Empetrum hermaphroditum* (Lange) Hagerup] and ssp. *nigrum* (Zander 1994, 558*). This Scandinavian plant has a long history of use as an inebriant:

In Norway, the juice of the drunken berry or inebriating berry (*Empetrum nigrum* L.) was used to make wine. King Sverre (12th century) attempted to use such native wines to drive out the foreign wine that German merchants were importing in. In 1203, Bishop Jon taught the Icelanders how to make a wine like the one that King Sverre had taught him about. It was apparently this wine or another that was prepared from berries that was involved when the Norwegian and Icelandic clergy asked Pope Gregory IX for permission to use domestic wine during mass because true wine was not available in the country. Although the Pope did not give his permission, tradition says that such inebriating berry wine was used in Iceland for Holy Communion. (Hartwich 1911, 761*)

Even today, the plant has a reputation of being a hallucinogen: “The inebriating berry of the North Sea coast, which is consumed raw and cooked, causes inebriated states and hallucinations but is not a [narcotic]” (Körner 1994, 1572*).

The entire plant contains quercetin, ursolic acid, rutin, isoquercitrin, ellagic acid, andromedotoxin, and alkaloids. **Honey** from this plant can be toxic (Roth et al. 1994, 319*).

The cowberry (*Vaccinium vitis-idaea* L.) is also known colloquially as “inebriating berry,” perhaps because its berries are also used to produce inebriating beverages (e.g., Kroatzbeeren liquor).

Vaccinium floribundum H.B.K. var. *ramosissimum* (D. Don) Sleumer, a Bolivian species closely related to *Vaccinium uliginosum*, is known locally as *macha-macha* (cf. **macha**). The same name is given to the related ***Pernettya* spp.** (von Reis Altschul 1975, 215*), which also produce inebriating fruits (cf. **chicha**).

The bog bilberry (*Vaccinium uliginosum*), an alpine native, can have inebriating effects. (Wild plant, photographed near the Aletsch glacier, Bettmeralp, Switzerland)

The German name for the bog bilberry, *rauschbeere* (“inebriating berry”), is appropriate, for the fruits can produce an inebriated state if enough are consumed. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The plant can be easily confused with the true blueberry (*Vaccinium myrtillus* L.) and other members of the Heath Family (e.g., *Vaccinium vitis-idaea* L., *Vaccinium oxycoccus* L.), especially before the fruits ripen.

Psychoactive Material

—Fruits (uliginosi fructus, fructus uliginosi, rauschbeeren, rauschbeerfrüchte, bog bilberries)

—Leaves (uliginosi folium, folia uliginosi, rauschbeerenblätter, bog bilberry leaves)

Preparation and Dosage

The fresh berries or the juice pressed from them is ingested. One handful of berries is said to be sufficient to induce inebriating effects. Bog bilberry has retained its reputation as an inebriant in part because a type of **wine** is made from the plant:

In Norway, the juice of the fruits of *Vaccinium uliginosum* L., the bog bilberry, with some sugar, which is also a popular additive in the production of berry wine, is allowed to ferment into a wine. (Hartwich 1911, 761*)

In Siberia, the juice pressed from fresh bog bilberries is mixed with dried fly agaric mushrooms (*Amanita muscaria*) and drunk (Lewin 1980 [orig. pub. 1929], 168*; Schultes 1969, 246*). Water and yeast were sometimes added to the mixture to produce a kind of **beer**. It is possible that the berries were also used as an additional inebriating additive to Germanic **mead** and beer.

The berries can be preserved by drying. They should be collected when ripe and dried in the sun or in a warm location.

The dried leaves can be smoked (cf. **smoking blends**, **kinnikinnick**) or brewed into a tea known as *batum* (Lewin 1980 [orig. pub. 1929], 352*).

Ritual Use

In Old Germanic times, the **wine** produced from bog bilberries apparently was consumed as part of certain drinking rituals, for it was used as a wine in early Christian masses. Since the Catholic Church integrated traditional pagan customs into the local liturgies to ensure its position of power, it seems reasonable to assume that bog bilberry wine was once an offering drink to the Germanic gods, e.g., to Odin/Wotan, who the Eddas tell us was the “wine drinker” of the gods (cf. **mead**).

For information about the shamanic use of bog bilberries in Siberia, see *Amanita muscaria*.

Artifacts

It is possible that some skaldic songs and head rhymes were inspired by bog bilberry wine (cf. **mead**).

Medicinal Use

Bog bilberry leaves were used in folk medicine in the same manner as bilberry or bearberry leaves (*Arctostaphylos uva-ursi*; cf. **kinnikinnick**). A tea (cold-water extract) of bog bilberry leaves and/or fruits is drunk for diarrhea and bladder ailments (Pahlow 1993, 245 f.*).

Constituents

The entire plant contains flavanols, flavonoid compounds, tanning agents, vitamins (especially C),

minerals, a glycoside, and arbutin derivatives (Pahlow 1993, 254*).

The inebriating constituents of the berries are apparently a metabolic product or a constituent of a parasitic fungus (*Sclerotinia megalospora* Wot.) that often infects the fruits (Frohne and Pfänder 1983, 111*). To date, however, no constituent has been isolated or identified (Roth et al. 1994, 718*). Because the inebriation is likely a metabolic product of a fungus, the active constituent may be some type of **ergot alkaloid**.

The leaves contain hyperoside, ursolic acid, αmyrine, friedelin, oleanolic acid, (+)-catechin, and organic acids (Roth et al. 1994, 718*). The quercetin derivative found in the leaves, quercetin-3-glucuronide (Gerhardt et al. 1989), may be a narcotic compound (cf. *Psidium guajava*).

Effects

Consuming the fruits is reported to induce an inebriation characterized by excitation, pupillary dilation, feelings of dizziness, and vomiting and numbness (Frohne and Pfänder 1983, 111*; Roth et al 1994, 719*; Zipf 1944). Sometimes the only effect reported is “nausea” (Root 1996, 32 f.*).

Commercial Forms and Regulations

None

Veratrum album Linnaeus

White Hellebore

Family

Liliaceae (Lily Family; previously Melanthiaceae)

Forms and Subspecies

The American hellebore is sometimes regarded as a distinct species but more recently has been considered a subspecies of white hellebore (Roth et al. 1994, 725*):

Veratrum album L. ssp. *viride* Ait.

Veratrum album L. var. *viride* Baker

Synonyms

Veratrum viride Baker

Folk Names

Brechwurz, condision, elabro bianco (Italian), elleborus albus, European white hellebore, false hellebore, fieberstellwurz, gärwere, gentiana maior, germander, germar, germara, germâra, germaren, germarrun vel hemerun, germer, germerra, germerwurz, gonos aetou (Greek, “eagle’s chest” or “summer bird child”), heimwurz, helleboros leukos, helleborus albus, hemer, hemera, hemerum, kondochi, kundush (Persian), lagnion (Gaulish, “physician plant”), langwort, läusekraut, lüppwurz, marsithila (“seat of a sea demon”), melampodium, nieskraut, nieswurz, politizon, rumex albus, scamphonie, schampanierwurtzel, sichterwurtz alba, sitterwurz, sittirwurz, süttirwurz, somphia (Egyptian), veladro, vératre blanc (French), veratro bianco (Italian), weiß nießwurtz, weiße nieswurz, weißer germer, white-flowered veratrum, white hellebore, winterwurz, wis niswurz, wiswurz, witte nieswortel (Dutch)

History

According to Theophrastus, the two types of *helleboros*, black hellebore (*Helleborus niger* L.) and white hellebore (*Veratrum album*), were the most important of all medicinal plants in prehistoric Greece. They were the central medicines of the *rhizotomes*, diggers who nourished the magical plants with shamanic rituals. Hellebore was a sacred plant of the gods. The name *helleboros* may be derived from *hella-bora*, “food of Helle.” Helle was a Pelasgian goddess for whom the Hellespont was named (Graves 1948, 440*). The most important mode of application of the root was nasally, as **snuff**. The artificially induced sneezing (the German name *nieswurz* means “sneezing root”) was believed to cause the demons of sickness to leave the body. “The white sneezing plant, which very quickly produces sneezing, is best; but it is much more terrible than the black [*Helleborus niger* L.]” (Pliny 25.23, 56).

The plant’s use as a sneezing powder has continued into the present day, although it has become increasingly profane. White hellebore is now mixed into Schneeberger Schnupftabak (Snow Mountain Snuff), which is used as an agent of pleasure (Höfler 2990, 85*; Schneider 1974, 3:386*). The root has been used as a sneezing powder in pranks, e.g., on New Year’s Eve (cf. *Calliandra*

anomala). White hellebore has some significance as a psychoactive substance in occultism (Werner 1991, 469*).

“We ate poisonous fungi and *Veratrum album* as well; the herbage of the white hellebore.

All of them the faces of night!

I wanted to call it out loud and could not.

I wanted to go to the side and could not.

.....

Albine Veretrine turned around to me once more

And made an obscene gesture.

I wanted to turn my eyes to the side or

Close my eyelids

And could not . . .”

GUSTAV MEYRINK

“BAL MACABRE”

IN *DES DEUTSCHEN SPIEBERS WUNDERHORN 1* [THE GERMAN PHILISTINE’S MAGIC HORN] (1984, 63*)

The typical wild form of white hellebore (*Veratrum album*) with white flowers. (Wild plant, photographed on Weissenstein, Jura, Switzerland)

A green-flowering form of the alpine *Veratrum album*. (Wild plant, photographed in Valais, Switzerland)

The rootstock of white hellebore (*Veratrum album*) is rich in highly active substances.

Infructescence of the American hellebore (*Veratrum album* ssp. *viride* = *Veratrum viride*).

Distribution

The plant occurs throughout Eurasia, especially in the Alps, the Pyrenees, central Asia, Scandinavia, Finland, Siberia, North America, and Alaska. The plant is frequently encountered among tall herbaceous vegetation, in mountain meadows, and in clearings. In Switzerland, white hellebore is part of the typical flora of the Jura.

Cultivation

Propagation can be performed with the seeds or with scions or root segments. The plant loves calciferous soils and also does well in humus- and nutrient-rich soil.

Appearance

This herbaceous perennial can attain a height of up to 1.5 meters. It has a straight, thick, round, fleshy stalk to which the broad, ovate, continuous, alternate leaves (25 to 30 cm long) are directly attached. The plant has a cylindrical rootstock from which numerous fleshy albeit thin roots as long as 20 cm develop. The green or white flowers are only 1 cm in size and are found in thick terminal panicles. The flowering period usually lasts from June to August. The fruits are small, brown, roundish capsules that are filled with seeds.

White hellebore can be easily confused with the closely related North American species or subspecies *Veratrum viride* Ait. The plant also can be taken for the toxic yellow gentian (*Gentiana lutea* L.), although it can be distinguished by the arrangement of the leaves: white hellebore has three leaves at each stem attachment, while the gentian has decussate leaves that are streaked with numerous leaf nerves and whose footstalks become shorter toward the top (Pahlow 1993, 122*).

White hellebore is also easily confused with the West Indian sabadilla (*Schoenocaulon officinale* [Cham. Et Schlecht.] A. Gray [syn. *Veratrum sabadilla*]) (cf. Pereira 1849, 111*; Wolters 1996, 230*).

Psychoactive Material

- Rootstock with roots; rhizome (rhizoma vera-tri alba, radix veratri albi, veratri albi rhizome, germerwurzel, weiße nieswurzel, radix ellobori albi, radix campanica, white hellebore root)
- Leaves (folia veratri albi, germerblätter, nieswurzblätter, white hellebore leaves)

Preparation and Dosage

The roots of wild plants are collected in September or October, dried well, and powdered. Together with *Nicotiana tabacum*, the root powder is one of the ingredients in Schneeberger Schnupftabak, a modern European **snuff**.³¹⁶

The dried leaves can be smoked alone or used as an ingredient in **kinnikinnick** or other **smoking blends**. For psychoactive purposes, white hellebore roots also appear to work well in combination with *Amanita muscaria* (Meyrink 1984*)

The root has been (accidentally) used to distill a “gentian liquor” (cf. **alcohol**) (Hruby et al. 1981), the effects of which can be devastating (Roth et al. 1994, 723*).

It has been suggested that white hellebore may have been an ingredient in **witches’ ointments**. In early modern times, it was used as an inebriating additive to **beer**, and possibly to **mead** and **wine** as well.

Casual use of *Veratrum album* is very dangerous! One to 2 g of the dried root can be sufficient to cause death through respiratory and circulatory paralysis (Frohne and Pfänder 1983, 153*; Roth et al. 1994, 723*). No information is available about smoking dosages.

Ritual Use

The Greeks and Romans used white hellebore, which was dug up in a ritual similar to that used for *Mandragora officinarum*, as a ritual cleansing agent that was not only snuffed but also strewn about in houses and hearths (Höfler 1990, 82*).

The prophets and magicians of late antiquity called the plant the “seed of Hercules” (Dioscorides 4.148), thereby associating it with the semi-divine sperm. Unfortunately, only vague information about its magical uses has come down to us. Apparently, the “prophets and magicians” referred to in the sources were Celtic Druids. In late antiquity, Herakles/Hercules enjoyed great popularity in Gaul, becoming an object of Celtic mythology and consecration rituals (Botheroyd 1992, 157). This may have been the reason why hellebore branches were hung on houses as an apotropaic protection. It is certain that the Gauls used the root as an arrow poison (Pliny 25.25, 61).

Botanical illustration of the white hellebore (*Veratrum album*). (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

It is possible that the Celts used white hellebore for psychoactive purposes. The Celtic mother goddess Cerridwen, who was related to Demeter, or Ceres, was said to know the secret of the “drink of inspiration and all wisdom.” Anyone who partook of it attained enlightenment and was able to experience the past, present, and future as one (cf. **mead**). The mythically and ritually significant “cauldron of Cerridwen”³¹⁷ contained “probably a mash of barley, acorns, honey, bull’s blood, and such sacred herbs as ivy [*Hedera helix*], white hellebore and laurel [*Laurus nobilis*]” (Graves 1948, 439 f.*).

Honey mead was brewed in a cauldron for the “festival of the other world,” which was strikingly shamanic (Botheroyd 1992, 182). It appears as though the intention of this ritual was to journey into the other world through the aid of the drink, for it is “the fount of all wisdom; here is where the heroes learned their magical arts, the poets obtained inspiration, and the Druids their magic with which they cast spells in the real world. Here too was where the wondrous treasure was guarded that the brave wished to raise: here dwelled absolute reality” (Botheroyd 1992, 18).

The Germanic name for the plant, *germâr*, is “probably the name of a old Germanic hero known for his use of the spear” (Höfler 1990, 84*). The Germanic tribes regarded the root as a *marrensitz*, i.e., as a place where elves would dwell (Höfler 1990, 85*). The ancient Germans may have used the plant to travel into other worlds where they could contact the elves, both the light elves in the heavens and the dark elves in the earth. It is possible that white hellebore was inhaled or smoked in the form of **incense** during the Germanic period, a use that continued into the late nineteenth century (Werner 1991, 468 f.*): “In Tyrolia, dried leaves of white hellebore are smoked from time to time” (Höfler

1990, 84*).

The Flathead Indians knew the North American hellebore (*Veratrum viride*) by the name *steso'o*, “sneeze,” and used the powdered root as a **snuff** that would induce sneezing and thereby clear the respiratory tract (Hart 1979, 273*). The dried roots were smoked together with tobacco (*Nicotiana* spp.) or bearberry leaves (see **kinnikinnick**). The Blackfeet call the closely related *Veratrum eschscholtzii* A. Gray *etarva-asi*, “that which makes you sneeze,” and snuff the dried and powdered root as a headache remedy (Johnston 1970, 309*). In the Pacific Northwest, the Quinault call the North American hellebore *tcî'ai'nix*, while the Cowlitz Indians call it *mimu'n*,³¹⁸ and the plant appears to have had a certain significance in shamanism. It is said that a small piece of the root was chewed, and the resulting saliva was spat onto the water “to make sea monsters disappear” (Gunther 1988, 24*)!

Artifacts

Although *helleboros* was of great importance in ancient Greece, it does not appear in Greek art. Similarly, no snuff paraphernalia has been discovered or even described.

White hellebore inspired the author Gustav Meyrink (1868–1932) to several pieces of literature (Meyrink 1984*). In the French comic series *The Smurfs*, by Peyo, Papa Smurf is constantly preparing magical drinks from white hellebore. The drawings in which the effects of these alchemical brews are shown are both turbulent and amusing (cf. ***Cannabis indica***).

Medicinal Use

In ancient times, white hellebore was used medicinally to treat a number of afflictions, especially those of a psychological nature:

The body must be prepared beforehand for seven days by spicy food and abstention from wine, on the fourth and third day through vomiting, on the day preceding through fasting. White hellebore is also given in something sweet but is best in lentils or in a mush. . . . The emptying begins after about four hours; the entire treatment is over in seven hours. In this manner, white hellebore heals epilepsy, . . . dizziness, melancholy, insanity, possession, white elephantiasis, leprosy, tetanus, tremors, foot gout, dropsy, incipient tympanic water, stomach weakness, charley horse, hip pains, four-day fever, if this will not disappear in any other way, persistent coughing, flatulence, and recurrent stomachaches. (Pliny 25.24, 59 f.)

Hildegard of Bingen made similar use of white hellebore: “The white *sichterwurtz* dispels, when mixed with wild thyme [*Thymus pulegioides* L.] and fennel [***Foeniculum vulgare***] and fat . . . , even madness in a man” (*Physica* 1.130). The ancient Germans also used the root to induce abortions (Höfler 1990, 84*).

In Persia (Iran), the fresh root is used to produce a paste that is applied externally to relieve headaches and neuralgia (Hooper 1937, 183*). In Russian folk medicine, the root was administered to children in **honey** as an anthelmintic (Rowell 1978, 265*). White hellebore was used both internally and externally in the folk medicine of the Alpine countries, and for both humans and animals. Ointments, poultices, and washings with extracts of white hellebore were used externally to treat scabies, lice, psoriasis, and other skin diseases. The root powder was used internally for melancholy (= depression), asthma, dropsy, paralysis, rheumatism, and fever (Pahlow 1993, 242*).

White hellebore (*Veratrum album*) is also known as the “white sneezing plant,” even though it is not related to the true sneezing plant (*Helleborus*). In earlier times, two forms were distinguished and were referred to as the “male” and the “female.” (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“Sneezing plant put in the nose cleanses the brain and makes one sneeze.”

LEONARD FUCHS *KREÜTTERBUCH* [HERBAL] (1543, CH. 103)

“The white sneezing plant is important in magic as a narcotic agent much used for fumigations and witches’ ointments.”

HELMUT WERNER

LEXIKON DER ESOTERIK [DICTIONARY OF THE ESOTERIC] (1991, 469*)

In homeopathic medicine, a tincture obtained from the dried rootstock (Veratrum—White Hellebore) is used in D3 and above in accordance with the medical description for such afflictions as mood disorders, depression, and the consequences of fright, anger, and migraines (Pahlow 1993, 242*; Schneider 1974, 3:386*).

Constituents

The entire plant contains steroid and steroidlike alkaloids with a C₂₇ steroid framework (protoverine, jervine, protoveratrine, germerine, pseudo-jervine, veratrosine, *O*-acetyljervine, jervinone, 1-hydroxy-5,6-dihydrojervine) (Attar-ur-Rahman et al. 1993; Morton 1977, 63*). The root has an alkaloid content of 1.2 to 1.6% and the leaf bases 0.9 to 1.5%. Three ester alkaloids are considered to be the main active constituents: protoveratrine A, protoveratrine B, and germerine. The alkaloid content of the plant can vary considerably depending upon location and altitude. A basic rule is that the higher the altitude in which the plant occurs, the lower its alkaloid concentration (Roth et al. 1994, 723*).

In addition to the alkaloids, the plant contains the glycoside veratramine, chelidonic acid, veratrum acid, and fat (Morton 1977, 63*). White hellebore is very toxic. As little as 1 to 2 g of dried root (corresponding to approximately 20 mg of the ester alkaloids) can be lethal.

Effects

Because *Veratrum album* suppresses the sympathetic centers and induces a serious drop in blood pressure, use of the plant can easily result in coma (Attar-ur-Rahman et al. 1993; Frohne and Pfänder 1983, 152*). Typical symptoms include burning and tingling in the throat, followed by sensations of

numbness and formication (similar to the symptoms produced by *Aconitum*; cf. *Aconitum napellus*). Patients remain conscious until they collapse and death occurs, although hallucinations also occur (Hruby et al. 1981). The toxicological literature contains a description of one case in which a thirteen-year-old boy smoked the dried leaves as “tobacco”; the only symptom reported was diarrhea, which persisted for a week (Roth et al. 1994, 723*).

Commercial Forms and Regulations

White hellebore can be obtained only in homeopathic dilutions from pharmacies. Pharmacologically active preparations are not available. The laws regulating games and practical joke articles prohibit preparations of sneezing powder that contain *Veratrum album* (Roth et al. 1994, 723*).

Literature

A very closely related species (or subspecies, variety?) of the white hellebore (*Veratrum sabadilla*) grows in Mexico and in the Antilles. Research is needed to determine whether this plant has psychoactive effects and has ever been used for psychoactive purposes. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

Virola spp.

Epena, Parika Species

Family

Myristicaceae (Nutmeg Family); there are six sections

Species Used Psychoactively (and Synonyms)

The genus *Virola* encompasses some forty species, all of which are native to tropical (South) America (Plotkin and Schultes 1990, 357). Others recognize forty-five to sixty species (Holmstedt et al. 1982, 217).

Virola species that are made into psychoactive snuffs (Schultes 1979):

Virola calophylla Warb. [syn. *Myristica calophylla* Spruce, *Virola incolor* Warb., *Otoba incolor* Karsten ex Warb.]

Virola calophylloidea Markgraf [syn. *Virola lepidota* A.C. Smith]

Virola cuspidata (Benth.) Warb.

Virola elongata (Spruce ex Benth.) Warb. [syn. *Virola cuspidata* (Spruce) Warb., *Virola rufula* Warb.]

Virola loretensis A.C. Smith

Virola pavonis (DC.) A.C. Smith

Virola rufula (Mart. ex A. DC.) Warb. (questionable)

Virola surinamensis (Rol.) Warb.

Virola theiodora (Spruce ex Benth.) Warb. (some authors regard *V. calophylla* and *V. elongata* as synonyms for *V. theiodora* [Brenneisen and Hasler 1994, 1157])

Virola venosa (Benth.) Warb.

Virola species that are taken orally as hallucinogens:

Virola duckei A.C. Smith (huapa blanca)

Virola elongata (Spruce ex Benth.) Warb.

Virola loretensis A.C. Smith

Virola pavonis (DC.) A.C. Smith

Virola peruviana (A. DC.) Warb.

Virola surinamensis (Rol.) Warb.

A tree from the neotropical genus *Virola*.

History

The use of various *Virola* species as ritual **snuffs** was first discovered in the 1950s by the American ethnobotanist Richard Evans Schultes, who was astonished that this fact had not been noted before (Schultes 1954). The only previous information came from the Brazilian botanist Adolpho Ducke, who wrote that the Indians on the Rio Negro produced a snuff called *paricá* from the leaves of *Virola theiodora* and *Virola cuspidata* (Holmstedt et al. 1982, 216). Astonishingly, Richard Spruce had collected botanical material from a number of *Virola* species between 1851 and 1854 but did not notice the psychoactive use of the bark (Schultes 1983c*).

Distribution

Members of the genus are found primarily in Amazonia and adjacent tropical areas (Brazil, Colombia, Peru, Venezuela). Some species also occur in the tropical zones of Central America (Brenneisen and Hasler 1994, 1154; Schultes 1955, 79f.*). One species (*Virola guatemalensis* [Hemsl.] Ward) is found in southern Mexico and Guatemala; in Chiapas, this plant is known as *cacao volador*, “cacao flying device”³²¹ (Martínez 1987, 1238*).

Cultivation

Virola trees do not appear to be cultivated in Amazonia; no information about possible cultivated forms is available. To date, it does not appear that anyone has had success in cultivating the plants (Rob Montgomery, pers. comm.).

The seeds of *Virola surinamensis*, known as *ucuba*.

The seeds of *Virola oleifera*.

***Virola* Species of Ethnobotanical Significance**

(from Duke and Vasquez 1994, 174 ff.*; Beloz 1992; Schultes et al. 1977; modified and supplemented)

Botanical Name	Indian Name(s) (other than <i>cumala</i>)	Use
Species known as <i>cumala blanca</i>:		
<i>Virola calophylla</i> Warb.	epená	snuff (Bora, Huitoto)
<i>Virola divergens</i> Ducke		
<i>Virola elongata</i> (Benth.) Warb.	anya huapa, ko-de-ko	decoction of the branch tips for arthritic swelling (Barasana); snuff; oral hallucinogen (Bora)
<i>Virola flexuosa</i> A.C. Smith	caupuri de altura, huapa, pucuna huapa	protection insect
<i>Virola loretensis</i> A.C. Smith		hallucinogen (Huitoto)
<i>Virola peruviana</i> (DC.) A.C. Smith	sacha annona, sacha avio, ichilla muyu sebu	bark as hallucinogen
<i>Virola sebifera</i> Aubl. [syn. <i>Myristica sebifera</i> (Aubl.) S.W.]		folk medicine
<i>Virola surinamensis</i> (Rol.) Warb.	nyakwana, ucuba, diaru	snuff (Bora, Huitoto); latex for treating cheek ulcers (Warao)
	caupuri	ayahausca additive (in Iquitos)
	cumala colorada	oral hallucinogen (Bora)
Species known as <i>cumala negra</i>:		
<i>Virola decorticans</i> Ducke		leaf juice for cutting teeth (Jíbaro)
<i>Virola multinerva</i> Ducke	ila yura	timber
Species known as <i>aguano cumala</i>:		
<i>Virola albidiflora</i> Ducke		resin for treating wounds (Kumeo, Tukano)
<i>Virola pavonis</i> (DC.) A.C. Smith	caupuri del bajo, cedro ajua, puliu huapa, pucuna huapa huachig caspi	snuff (Bora, Huitoto) oral hallucinogen (Bora)

Appearance

Virola species are large trees that can grow as tall as 30 meters. The leaves are undivided and pinnate and have continuous margins; there are no stipules. The tiny dioecious flowers grow in fascicles. The fruits are ellipsoid. The leaves can attain a length of more than 30 cm.

The different species are difficult to distinguish from one another.

Psychoactive Material

—Resin (= latex, exudates) and the inner bark (cambium)

Preparation and Dosage

The resin or latex (usually called *oom* or *yá-keoom*) of the *Virola* species can be obtained in a number of ways. An incision can be made in the bark, part of the bark can be removed, or the inner bark (cambium) can be warmed, which will cause the resin to exude. Because the pure resin is sticky, it usually is mixed with plant ashes, e.g., from the bark of a wild cacao tree (*Theobroma subincanum* Mart.; cf. ***Theobroma* spp.**), or with shell lime (from burned freshwater mussels) before being ground (Schultes 1954, 247 ff.). The **snuff** apparently will not have any effects unless the (alkaline) plant ashes are added.

The Indians say that the bark must be harvested in the early morning, before the sunlight has hit the trunk, lest the power of the powder dissipate. The rays of the sun are said to have a considerable

impact upon the effects (Schultes 1954, 248).

For shamanic purposes, the dosage is given as a slightly heaping teaspoon of the powdered resin mixed with the plant ashes. This amount is usually snuffed three times in a row in short intervals (fifteen to twenty minutes) (Schultes 1954, 250).

Some Amazonian tribes make their snuff powder from the dried juice of the bark of different *Virola* species and the ashes of *Theobroma subincanum* Martius or dried leaves of *Justicia pectoralis* Jacquin (Schultes and Holmstedt 1968).

The Desana of the Colombian Vaupés use the inner bark of the species *Virola calophylla*, *V. calophylloidea*, and *V. theiodora* for their snuffs. Depending on the ritual occasion and the desired effects, powdered tobacco leaves (*Nicotiana tabacum*), powdered coca leaves (*Erythroxylum coca* var. *ipadu*), the ashes of *Cecropia* leaves, powdered pieces of bark from *Banisteriopsis* spp., or the lime scratched off stalactites may be added to the finely powdered bark (Reichel-Dolmatoff 1979, 32 f.).

Other recipes are used for oral ingestion. The Colombian Huitoto boil the juice until it has thickened into a syrup. The thickened juice is then rolled into bean-size balls and coated with the ashes of *Gustavia poeppigiana* Berg ex Martius. Three to six of these little balls are swallowed or dissolved in water and drunk (Schultes 1969). Because of the increasing pressures of acculturation, such oral use appears to be disappearing (Schultes et al. 1977, 259).

The Peruvian Bora and Huitoto also knew of oral use. They repeatedly boiled the inner bark (cambium) of a variety of species (especially *Virola elongata*) to yield a paste called *ko'do* that was then swallowed without any further preparation. In other areas, the paste was mixed with the ashes of a species from the genus *Carludovica* (Cyclanthaceae; cf. Bristol 1961) and the leaves of a palm of the genus *Scheelea* (Schultes et al. 1977, 262 f.). The ashes (called “salt”) from the bark of the large tree *Eschweilera itayensis* Kunth (Lecythidiaceae) as well as the ashes from the buds and leaves of *Spathiphyllum cannaefolium* (Dryand.) Schott (Araceae) were added for the same purpose (Schultes 1979, 228).

Some species of *Virola* are used as **ayahuasca** additives. Some shamans in Iquitos add *Virola surinamensis* to the ayahuasca drink so that the ayahuasca will “teach medicine.”

Ritual Use

The Bora and Huitoto of the Orinoco region use *Virola calophylla* as a snuff and also orally as a hallucinogen. They also make snuff from the cambium of *Virola elongata* and *Virola surinamensis* and use the species *Virola pavonis* as a hallucinogen. Usually only shamans use this snuff (which appears to have quite potent effects); they use it to diagnose illnesses.

The use of *Virola* snuffs (*vihó*) is very common among the Desana. Here again, it is normally used only by shamans when they wish to diagnose illnesses. However, all boys who are being initiated into manhood must learn how to prepare the powder during the initiation celebrations, during which they must also use it for the first time (Reichel-Dolmatoff 1979). Many men take it along with **ayahuasca**.

The Quechua of Ecuador use the dried bark secretion of *Virola duckei* A.C. Smith as an oral hallucinogen (Bennett and Alarcón 1994). Unfortunately, no details about the precise nature of their ritual uses have become known.

The Yanomomö (= Waika) use *Virola theiodora* not only as a shamanic hallucinogen but also as an arrow poison (Soares Maia and Rodrigues 1974). They also use *Virola elongata* to manufacture arrow poisons (Macrae and Towers 1984).

The tribes that use *Virola* species to produce psychoactive compounds include the Puinave from the Río Inírida, Kuripako from Río Guainía, Kubeo, Tukano, Desana, Papurí, Barasana, Makuna from Río Piraparaná, Taiwano from Río Kananarí, Brazilian and Venezuelan Yanomamö/Waika,

Mundurukú,³²² Huitoto (= Witoto), Bora, and various small tribes of the Rio Issana (Içana), and presumably other tribes or ethnic groups.

Artifacts

Apart from certain snuff tubes and other paraphernalia, to date no artifacts are known (cf. **snuffs**).

Medicinal Use

Venezuelan shamans smoke the dried inner bark of *Virola sebifera* at dances to treat fever diseases (Altschul 1973, 76*; Plotkin and Schultes 1990, 357). The bark, which is known by the names *wircawei-yek* and *erika-bai-yek*, is boiled to dispel evil spirits (Altschul 1973, 76*). One as yet unidentified *Virola* species is said to be used as a contraceptive (Plotkin and Schultes 1990, 357).

A number of *Virola* species are regarded as brain stimulants and are said to improve both memory and intelligence (Plotkin and Schultes 1990, 357).

Many *Virola* species (e.g., *V. elongata*, *V. melinonii* [Benoist] A.C. Smith, *V. sebifera*, *V. surinamensis*) are used in folk medicine to treat skin diseases (Brenneisen and Hasler 1994, 1158; Plotkin and Schultes 1990, 358 ff.).

The mother tincture of *Virola sebifera* (medicinal content 1/10) is known in homeopathy as *Myristica sebifera* hom. *HAB34* (also *HPUS88*) and is used for such conditions as suppuration (Brenneisen and Hasler 1994, 1157). The agent is regarded as a “medicine with great antiseptic power” (Boericke 1992, 532*). It also is used in homeopathic compound medicines, e.g., Sulfur Pentarkan, which consists of sulfur, *Atropa belladonna*, mercury, “*Myristica sebifera*,” and silicic acid.

Two devices (made of bones and shells) from northwestern Brazil for ingesting *Virola* (parika) snuff powder. (From Koch-Grünberg *Zwei Jahre bei den Indianern Nordwest-Brasiliens*, 1921*)

Constituents

It was once thought that the active constituent of the parica drugs was myristicin (cf. *Myristica fragrans*) (Schultes 1954, 247). However, this conjecture has not been substantiated.

Many *Virola* species contain tryptamines (*N,N*-DMT, 5-MeO-DMT, and others) and β -carbolines. Some, e.g., *Virola cuspidata*, even contain harmane derivatives (6-methoxyharmanolane, 6-methoxyharmane, 6-methoxytetrahydroharmane) as well as diarylpropanes of the virolane and virolin types (Brenneisen and Hasler 1994, 1154). Those *Virola* species that have been the most intensively investigated contain tryptamines, most commonly DMT (Holmstedt et al. 1982).

Virola calophylla contains *N,N*-DMT, MMT, 5-MeO-DMT, 5-MeO-MMT, and β -carbolines (Duke and Vasquez 1994, 174). Astonishingly, no psychoactive indoles or tryptamines have been found in the latex of those species or individuals that produce a great deal of red resin (Schultes et al. 1977, 260). MMT, DMT, and 5-MeO-DMT have been detected in the bark (Farnsworth 1968, 1088*).

The resin of *Virola theiodora* contains 8% 5-MeO-DMT (Soares Maia and Rodrigues 1974).

The bark of *Virola elongata* contains resin as well as sesartemin and yangambin, substances that are said to inhibit aggressiveness.

Although no actual active constituent has yet been found in *Virola surinamensis* (the latex contains diarylpropanoids, neolignans, and long-chain esters: Barata et al. 1978; Gottlieb et al. 1973), its pharmacological activity has been experimentally demonstrated (Beloz 1992). Long-chain esters are found in many *Virola* species (Kawanishi and Hashimoto 1987).

The seeds contain an abundance of oil that is sold under the name *virola fat*, *ucuúba*, or *ucuúba butter* and is reminiscent of cocoa butter (it is even made into candles; Plotkin and Schultes 1990, 357).

Effects

The effects of *Virola* snuffs are described as very intense and not necessarily pleasant. Schultes reported almost only unpleasant side effects as a result of his own experiment (severe headache, ocular pressure, disturbances of coordination, et cetera). Shamans typically enter into a sleeplike trance state accompanied by dreams and hallucinations. It has even been reported that a shaman died while under the influence of *Virola* powder (Schultes 1954, 251).

The Colombian Desana characterize the effects of the snuff as follows: “This *Virola* bark, this lucid dot, it penetrates into us and makes us dizzy/ sedated” (Reichel-Dolmatoff 1979, 36).

The resins of various *Virola* species, especially *Virola elongata*, have antifungal properties (Duke and Vasquez 1994*).

It is uncertain whether oral ingestion can in fact produce hallucinogenic effects:

The efficaciousness of the oral application forms (pills, pastes, etc.) is controversial primarily with regard to the role of monoamine oxidase and therewith the metabolic deactivation of the β -carboline derivatives that inhibit the tryptamine derivatives, as these alkaloids as a rule are biogenically present in only small amounts. It is however conceivable that these alkaloids largely arise only during the preparation of the bark exudates as artifacts of tryptamine alkaloids. It has been conjectured that other constituents of *Virola*, e.g., flavonoids, neolignans, and diarylpropane, may as antioxidants nonspecifically inhibit the oxidative first-pass breakdown of the tryptamine alkaloids through MAO, mixed functioning oxygenases, and are thereby able to increase the oral efficaciousness. (Brenneisen and Hasler 1994, 1158)

Commercial Forms and Regulations

None, apart from the mother tincture known as *Myristica sebifera* (cf. Brenneisen and Hasler, 1994: 1157)

Vitis vinifera Linnaeus

Grape

“In the Dionysian inebriation, in the tempestuous dash of all the scales of the soul in narcotic stimulation or the unleashing of the urges of spring, nature expresses itself in her highest power; she brings individual beings back to one another and allows them to experience themselves as one.”

FRIEDRICH NIETZSCHE *DIE DIONYSISCHE WELTANSCHAUUNG* [THE DIONYSIAN WORLDVIEW] (1870)

Family

Vitaceae (Grape Family; previously also Ampelideae)

Forms and Subspecies

A number of subspecies and varieties of grape have been described:

Vitis vinifera L. ssp. *caucasia* Vavilov

Vitis vinifera L. ssp. *sativa* DC. (cultivated form for producing fruit)

Vitis vinifera L. ssp. *sylvestris* (C.C. Gmel.) Berger (wild form)

Vitis vinifera L. ssp. *vinifera* (cultivated subspecies)

Vitis vinifera L. var. *apyrena* L.

There also are numerous cultivars (grape varietals) that are important primarily in viniculture because of their different tastes (Pabst 1887, 2:211*).

Synonyms

Vitis sylvestris C.C. Gmel.

Folk Names

Angur (Hindi), drakh, draksha (Sanskrit), duracina, grape, grapevine, grape vine, gvid (Celtic, “bush”), ‘inab (Iraq), khamr (Arabic),³²³ palmes, parra, reba, rebe, rebo, rebstock, vigne, vine, vitis sativa (Latin), weinranke, weinrebe, weinstock, wynreben, zame weinreben

Folk Names for Wine

Aqua vitae, oinos, sharab, vin, vinho, vino, vinum, wein, woinos

History

The grape plant originated in Asia and probably was used to prepare inebriating drinks from a very early date. Current research suggests that humans have been making beverages by fermenting grapes for at least some nine thousand years (McGovern 2003). In the summer of 1990, clay drinking vessels were found in Godin Tepe (Iran), chemical analyses of which have clearly shown that they were used for drinking wine. These sensational finds were dated from 3500 to 2900 B.C.E. (McGovern et al. 1995). Soon thereafter, the first well-documented viticulture (vineyards, wine cellars) flourished in Mesopotamia. It quickly spread from Asia Minor to Egypt, Crete, and Greece (Lesko 1978). In ancient times, the Romans spread viticulture into all the areas of their empire that had suitable climate and

soil conditions.

In Egypt, the cultivation of wine did not become established until the New Kingdom, when grapes were pressed and poured into different containers with enthusiasm. Numerous wine flagons have been discovered that include details about the vintage, quality, and location and the name of the head vintner (Lesko 1978). In the Nile valley, wine was a drink of the upper classes; it was enjoyed at private feasts as well as at religious offering festivals (libations).

The spread of viticulture that occurred in the following years was very closely related to the Christianization that was decreed “from above” (Marzahn 1994, 90, 96*). Whereas the Dionysian religion had been a cult of ecstasy, Christianity degenerated into a religion of alcoholics (Daniélou 1992*).

Today, viticulture is practiced throughout the world and has become an industry of great economic significance. The plant itself is not psychoactive, but its most important products, **wine** and distilled **alcohol** (brandy, cognac, et cetera), are.

Distribution

Current evidence indicates that the grape and viticulture originated not in Greece but in Asia Minor. It may have begun in the region between the Caucasus and the Hindukush mountains, where wild grapes can still be found today (Pabst 1887, 2:212*). Today, cultivation has taken the grape into every part of the world (including North and South America, Australia, and South Africa).

A grapevine (*Vitis vinifera*) growing on Crete.

A wild grapevine (*Vitis* sp.) in the Mexican rain forest. (Photographed in Naha', Chiapas, Mexico)

“The wine has been transformed into nectar, thereby breaking the curse that has been attached to it since ancient times. It is now a magical drink that helps in crossing the threshold; it is the blood of the sun and of the moon.”

MIGUEL SERRANO *EL/ELLA—DAS BUCH DER MAGISCHEN LIEBE* [HE/SHE—THE BOOK OF MAGICAL LOVE]
(1982, 32)

Cultivation

Grapes are propagated primarily from cuttings. These are allowed sit in water until they develop roots and then planted. Grapes will grow well only in temperate climates where the average annual temperature does not exceed 17°C (63°F).

The “proper” method for growing grapes was a subject for many authors in ancient times (Hagenow 1982, 171 ff.).

Appearance

This twining climber can grow to a length of over 10 meters. It has a woody, often twisted stem and a woody, branched root that grows deep into the ground. The bush develops numerous climbing branches that divide like forks. The long-stemmed, heart-shaped leaves are retuse, with three to five lobes, and usually have a serrated or jagged margin. The flower panicles develop on the lower vines and have yellow-green, tiny, usually monoclinous flowers. These develop into the characteristic green, reddish, red, or blue clusters of fruits (grapes).

Vitis vinifera can be easily confused with wild *Vitis* species.

Psychoactive Material

—Fruits (grapes)

—Wine

Preparation and Dosage

The juice that is pressed from the grapes is fermented to produce **wine**. Over the course of history, numerous methods have been developed for making wine. Wine is a psychoactive compound in and of itself. But in ancient times, many psychoactive plants were also added to wine (see the table on the following page) to produce specific types of effects (Ruck 1995*). Such additives were known as “flowers of the wine” (Ruck 1982). There were essentially two methods: In the first, the additives were placed directly into the fermenting mixture, while in the second the finished wine served as a solvent for macerating specific substances. One famous concoction was mandrake wine, which was prepared by adding fresh or dried mandrake roots (*Mandragora officinarum*) to the grape must. Other recipes added root pieces to the finished wine. Because wine to which “flowers” had been added had much more potent effects, it was served with great care.

The ancient Greeks were very aware of the significance of dosing wine. The comedy *Dionysos or Semele*, by the poet Eubulos (fourth century B.C.E.), provides an indication:

For reasonable people I prepare only three mixing jars [with wine and water]: one for health (*hygíeia*), which they drink first; the second for love and pleasure, and the third for sleep. When that has been emptied, the people who are called wise will go home. The fourth mixing jar no longer belongs to me, but to immoderation. The fifth is full of howls; the sixth causes gushing and bawling; the seventh brings black eyes; the eighth calls to the servant of the court; the ninth is full of anger and disgust. The tenth leads to madness (*manía*) and stumbling. If you fill it into a small container, then this will easily knock the legs out from under he who empties it and throw him to the ground.

In general, the Greeks regarded their different wines as too inebriating to be consumed undiluted. Prior to consumption, wine was normally mixed with water in a 1:2 or 1:3 proportion. In addition, wine was rarely drunk unadulterated. Numerous aromatic, medicinal, and inebriating additives (*aromatites*) are known from ancient times (Weeber 1993, 35). Although the recipes for most preparations were kept secret, some have come down to us. These indicate that oleander (*Nerium*

oleander L.; cf. **honey**), hemp (“wine of Democritus”; cf. *Cannabis sativa*), opium (cf. *Papaver somniferum*), and various nightshades, especially mandrake (“the grape of the field”; *Mandragora officinarum*) and henbane (*Hyoscyamus niger*), were all added to wine. In ancient Italy, *crapula*, “inebriating resin,” was an important additive (Weeber 1993, 41).

During the Middle Ages, plants were added to wine to produce specific psychoactive effects:

A person in whom melancholy is growing, who has a dark mood and is always sad. And he should drink often the wine with the boiled arum root [*Aaron aculatum* = *Arum maculatum* L.], and it will lessen the melancholy in him, that is, it will disappear, as will the fever. (Hildegard von Bingen, *Physica* 1.49)

Spiced wine continued to enjoy great popularity during the fifteenth and sixteenth centuries. Clareth, also known as Luter drink, was renowned in the city of Bremen and the rest of northern Germany. This was a heavily spiced wine to which honey, sugar, saffron (*Crocus sativa*), cloves, and nutmeg (*Myristica fragrans*) had been added. It was served in the Bremen *ratskeller* (the inn in the city hall) and in the pharmacy of the city hall (Marzahn 1994, 96*).

The grapevine originated in Asia, where it was derived from a wild form. The earliest Chinese literature describes wild grapevines (*Vitis* spp.) under the name *chien-sui-tzû*. (Illustration from *Nan-fang-ts'ao-mu chuang*)

Triumphal procession of the wine god Dionysos, who was originally of Asian origin. (Floor mosaic, Roman period, Cyprus)

“I saw Bacchus on distant crags
teaching songs—posterity, believe it—
and Nymphs learning and the keen
ears of the goat-footed Satyrs.

Euhoe, my mind quivers with strange fear,
and, breast full of Bacchus, rejoices in commotion,
euhoe, spare me, Father Freedom,
spare, fearsome with grievous stem-wand!

It is divine right for me to sing
the stubborn bacchants, the fountain of wine and rivers
of rich milk, the hollow
trunks honey-flow.”

Psychoactive Additives to Wine

(from Krug 1993; Macmillan 1991, 427*; Pabst 1887, 216*; Root 1996*; Ruck 1992; Weeber 1993; supplemented)

Name/Preparation	Stock Plant	Application/Era/Place
arum	<i>Arum maculatum</i> L. (cf. <i>Arisaema dracontium</i>)	Middle Ages
cacao powder	<i>Theobroma cacao</i>	succolade (seventeenth-century Europe)
camphor	<i>Cinnamomum camphora</i>	vinum camphoratum (nineteenth century)
cloves	<i>Syzygium aromaticum</i> (cf. essential oils)	Clareth/Luter drink
coca leaves	<i>Erythroxylum coca</i>	Vin Mariani (nineteenth century)
cola nuts	<i>Cola acuminata</i> (cf. <i>Cola</i> spp.)	<i>kola-wine</i> (Africa)
coriander	<i>Coriandrum sativum</i> (cf. essential oils)	ancient Egypt
<i>crapula</i> (“inebriating resin”)	?	Italy
cubeb	<i>Piper cubeba</i> (cf. <i>Piper</i> spp.)	antiquity, seventeenth-century East India
deadly nightshade	<i>Atropa belladonna</i>	Middle Ages
ergot	<i>Claviceps purpurea</i>	vinum ergotae (nineteenth century)
harmala seeds	<i>Peganum harmala</i>	harmel wine (Morocco)
hemp flowers (female)	<i>Cannabis indica</i> <i>Cannabis sativa</i>	modern era (India) late antiquity
henbane	<i>Hyoscyamus albus</i> <i>Hyoscyamus muticus</i> <i>Hyoscyamus niger</i>	antiquity Egypt Middle Ages
horn poppy decoction	<i>Glaucium flavum</i> Crantz (cf. <i>Papaver</i> spp.)	late antiquity
ivy leaves	<i>Hedera helix</i>	antiquity/Dionysos cult
mandrake	<i>Mandragora officinarum</i> <i>Mandragora</i> spp.	antiquity (Greece, Rome, Egypt) antiquity
monkshood root	<i>Aconitum napellus</i>	folk medicine
mushrooms	<i>Amanita muscaria</i> <i>Psilocybe</i> spp.	antiquity
nightshade	<i>Solanum dulcamara</i> (cf. <i>Solanum</i> spp.)	antiquity
nutmeg, mace	<i>Myristica fragrans</i>	Clareth/Luter drink
olibanum	<i>Boswellia sacra</i>	antiquity (Orient)
opium	<i>Papaver somniferum</i>	antiquity/late antiquity (India); vinum opii (nineteenth century)
poison nut root	<i>Strychnos nux-vomica</i>	antiquity
saffron	<i>Crocus sativus</i>	Clareth/Luter drink
white hellebore	<i>Veratrum album</i>	uncertain
wormwood	<i>Artemisia absinthium</i>	wormwood wine (antiquity to the modern era), vinum de absinthio (nineteenth century)
yellow water lily root	<i>Nuphar lutea</i>	antiquity

Grapes not only are the source of the juice that can be fermented to make wine but also are a very healthful source of nourishment. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Ritual Use

Grape wine was at the center of the cult and mysteries of Dionysos (= Bacchus). Dionysos was both a god of fertility who was venerated as the lord of plants in rural festivals and a shamanic god of psychopharmaka who was celebrated in ecstatic cults and who revealed himself in secret mysteries (Merkelbach 1988).

“The Vine-Dionysus once had no father, either. His nativity appears to have been that of an earlier Dionysus, the Toadstool-god; for the Greeks believed that mushrooms and toadstools were engendered by lightning—not sprung from seed like all other plants. When the tyrants of Athens, Corinth and Sicyon legalized Dionysus-worship in their cities, they limited the orgies, it seems, by substituting wine for toadstools; thus the myth of the Toadstool-Dionysus became attached to the Vine-Dionysus.”

ROBERT GRAVES

THE WHITE GODDESS (1948, 159*)

From *Der Formenschatz* [Treasury of Forms], 1885, no. 105.

Dionysos was the prototypical shaman of the ancient world (Emboden 1977). The mythology that surrounded him was involved with issues of life and death, healing, and ecstasy and frenzy. He was born two or even three times and was once dismembered and killed by the Titans. But since he is a god and by definition immortal, he was born again *knowing*. The experience of being dismembered gave him the knowledge of the infinity of life. The dismembered god demonstrates that no matter what happens, there is actually nothing to fear. Salvation awaits at the end of all horror. Dionysos acts

like a shaman in other ways as well. He has animal spirits that aid him or animal identities (panther, lynx, lion, tiger, dolphin, snake, bull, goat), has ecstatic music (drums, tambourine, cymbals, flutes) at his command that bring him to rapture, and often garbs himself—like the Siberian shamans—in women’s clothing and indulges in transsexual excesses. He is the wearer of a mask and a singer, and his goat song (*tragedy*) is renowned. He is the founder of the theater and of the bacchanal mysteries. He is also knowledgeable about plants and is a healer.

Orgiastic wine festivals were held in many places in Dionysos’s honor, and these often escalated into wild Bacchanalias. The temple of Dionysos in Pompeii had a wine garden in which the symposiums of the inebriated god took place. Great quantities of wine flowed there; wine, the gift of Dionysos, was reverently known as “the blood of the earth” as well as the “blood of Dionysos” or was simply named after the god himself, *Dionysos*. It was hoped that he would make it possible for humans to partake of immortality. Thus did the blind prophet Tiresias speak:

Young man, there are two things that come first for mankind: the goddess Demeter—she is the earth, but call her what you like—she nourishes mortals with food; the son of Semele came later, and he is Demeter’s counterpart, since he discovered and gave to mortals a drink, the juice of the grape. It puts an end to the pain of suffering humans, when they are filled with the stream of the vine, and it gives sleep to forget the troubles of the day; there is no other cure for pain. Itself a god, to the gods it is poured as a libation, so that through Dionysus people may have good fortune. (Euripides, *The Bacchae*, 274 ff.; Eds. D. Franklin, J. Harrison, J. Affleck 2000, 15)

According to mythology, Dionysos carried the first vines to each of the places in the world where grapes still grow and planted them himself (Daniélou 1992a*). In the Greco-Roman world, a goat kid was sacrificed when grapevines were planted so that the grapes would burst from the vines and Dionysos could receive the blood of his favorite animal.

Wine was one of the agents used to induce the Dionysian ecstasy³²⁴ (Detienne 1992; Emboden 1977; Evans 1988). Drinking festivals were held both in Greece and later in the Roman Empire (Murray 1990). Such a drinking festival was known as a *symposion* or *symposium*, “drinking together.” The Latin name for the leader of the symposium was *magister*, “master.” He was responsible for the dosages, for the ratio of wine to water, and for any psychoactive additives that may have been used. As Xenophon stated: “So is it best to come home from drinking: I am no longer sober, but also not too inebriated.” A symposium was first and foremost a communal drinking fest, often of an intellectual nature. This was the place where the philosophy of the ancients (e.g., of Plato and Socrates) was born.

In India and the Himalayan region, wine is sacred to Shiva (cf. *Aconitum ferox*, *Cannabis indica*, *Papaver somniferum*, **alcohol**). Shiva and Dionysos were already being equated in ancient times (Daniélou 1992a*). Wine also plays a significant role in the tantric cult (Serrano 1982). Since one of the aims of the cult was to ritually break social taboos, wine drinking was an important means for doing so, as Hindus are normally forbidden to consume alcohol.

In the Catholic Church, the consumption of wine has remained central to the rite of communion into the present time:

Although wine was already indispensable in the Church because of communion, it also played a role there for other reasons. For the German Pagan honored his gods and folk heroes by raising a glass to them, while the newly converted German Christian drank to commemorate those saints who had gained his admiration because their spiritual or bodily strength had been tested, and the Church in its tolerance incorporated these so-called *minnetrinken* into their rituals after having

tried in vain for centuries to suppress them; the bishops were almost incapable of limiting the number of saints in whose honor, or *minne*, they would drink. (Schultze 1867, 104)

Many contemporary wine aficionados have developed a cult around wine that is known as “wine culture.” But this activity is not so much concerned with the psychoactive or inebriating effects of wine as it is with a gourmet lifestyle, a mania for collecting, and a desire to acquire possessions.

Artifacts

There are numerous ancient representations of the grapevine, the harvest of its grapes, and the consumption of wine as well as its effects. A marble sculpture from the first century C.E. shows a drunken Hercules, naked and holding his penis between his fingers as if urinating (Herculaneum, House of the Deer). The Dionysian mysteries, which were celebrated with wine, are depicted on the murals of Pompeii (Grimal and Kossakowski 1993). Dionysos and his followers, festivals, and symposia have been artistic themes since antiquity (Hamdorf 1986). Some representations appear to make reference to *Amanita muscaria*.

“The vine bears three grapes,
The first brings the loss of the senses,
The second inebriation,
The third crime.”

EPICLETUS C.E. 55–C.E. 135

Dionysos/Bacchus and his wine, festivals, and mysteries were described in numerous ancient writings (Brommer 1959; Merkelbach 1988; Preiser 1981a, 1981b; Weeber 1993).

The number of vessels for drinking wine (kraters, chalices, cups) that have been found is almost beyond count. Some ancient wine chalices have been interpreted as cryptic symbols for *Amanita muscaria* or other psychoactive fungi.

No other ancient deity survived as long as Dionysos/Bacchus. The mysterious god of inebriation continues to inflame people’s feelings. He appears on wine and beer labels and in theaters—in *The Bacchae* of Euripides (ca. 480–406 B.C.E.), *The Bassarids* of Hans Werner Henze (born 1926),³²⁵ and *Ariadne auf Naxos* by Richard Strauss (1864–1949). Richard Wagner (1813–1883) opulently immortalized Dionysos’s wild and erotic festivals (Bacchanalias) in his opera *Tannhäuser*.

The “classic” horror novel *The Elixir of the Devil*, written in 1815 by E. T. A. Hoffmann (1776–1822), revolves around a “wine of Saint Anthony” (cf. *Claviceps purpurea*). The wine, which is preserved as a reliquary in a cloister, is described as a potent psychoactive agent. Anyone who partakes of it is cast into a schizophrenic world of hallucinations that he interprets as “the temptations of the devil.” One monk dares to partake of the drink:

Among these [reliquaries] was a sealed flask, which contained within a seductive elixir that Saint Anthony was said to have taken from the devil. . . . I was overcome by an indescribable longing to find out what was in fact contained within the flask. I was able to take it aside, I opened it and found a wonderfully scented, sweet tasting, potent drink that I drank to the last drop.—How all of my senses then changed, how I experienced a burning thirst for the world, how the vices, in their seductive forms, appeared to be the highest pinnacle of life. (Hoffmann 1982, 123*)

In 1974, the American science-fiction author Robert Silverberg published “The Feast of St. Dionysus,” a story that received the Jupiter Award. In this story, an astronaut who is traveling to Mars ends up in a utopian cult of Dionysos beyond space and time and is initiated into the mysteries of the

god with a special wine:

The rhythms are sharp and fierce. This is the music of the Bacchantes, this is an Orphic song, at first strange and terrifying, and then strangely soft and consoling. . . . Take, eat. This is my body. This is my blood. More wine. Figures move around him, other communicants step forward. He loses all sense of time and space. He separates from the physical dimension and glides over a swelling ocean, a large warm sea, a gently rolling sea that bears him lightly and merrily. He senses light, warmth, size, weightlessness, but he does not feel anything tangible. The wine. The host. Perhaps a drug in the wine? He slips out of the world and into the universe. This is my body. This is my blood. This is the experience of wholeness and unity. I take the cup of the god, and his wine dissolves me. . . . I call the name of the god, and his thunder sedates me. *Dionysos Dionysos!* (Silverberg 1984, 69)

Medicinal Use

Wine had approximately the same significance in Hippocratic medicine as **beer** did in the Babylonian and Egyptian healing arts. White, dark, red, sweet, tart, sweet-smelling, and heavy wines were all used as dietary vehicles for administering medicines. Numerous medicinal wines were made from wine and the appropriate herbs. Dioscorides names many of these.

The healing properties of wine grapes were mentioned in the founding works of Indian Ayurvedic medicine by Susrata and Charaka (Hopper 1937, 186*).

In 1753, a book titled *Der curieus- und offenherzige Wein-Artzt* [The Curious and Open-Hearted Wine Physician] appeared. Written by an anonymous “lover of the economic sciences,” it revived the ancient tradition of healing wines and played an enormous role in popularizing the use of medicinal wines.

Today, wine—in moderate dosages—is still recommended as a healing agent and tonic, particularly for the elderly (Köhnlechner 1978).

Constituents

Wine grapes contain large amounts of grape sugar (= glucose), fructose, saccharose, citric acid, malic acid, tartaric acid, tannic acid, gallic acid, salicylic acid, succinic acid, oxalic acid, potassium salts, and traces of starch (Downton and Hawker 1973). An antifungal substance, α -viniferin, has also been described as a constituent in grapes (Pryce and Langcake 1977).

The alcohol content of wine can vary from 6 to 18%. White wines typically have between 10 and 12%, and red wines between 11 and 15%. It has been rumored that red wine also contains anandamide, a substance analogous to THC (cf. *Theobroma cacao*, **THC**).

The shamanic god Dionysos offers a cup of his sacred wine. (Copperplate engraving, eighteenth century)

Effects

During the eighteenth and nineteenth centuries, there were reports of a variety of peculiar psychoactive effects resulting from the consumption of wine; unfortunately, we have no information about these wines or the pharmacological manipulations that might have led to such effects. All that is known is that these were “old wines” that were prescribed by a physician and said to be healthful:

But these wines also had other wondrous effects: “*I had only but tasted from these barrels*” wrote the theologian Johann Gottfried Hoche in the year 1800, “*and yet the stones on the street appeared to have grown when I came out.*” Wilhelm Hauff had his wonderful *Phantasien im Bremer Ratskeller* [Reveries in the Bremer Council Cellar]³²⁶ after tasting what may have been a [Bremen] rosé from 1615 or 1624, and Heinrich Heine saw drunken angels sitting on the rooftops and the spirit of the world with a red nose after a visit to a *ratskeller*. (Marzahn 1994, 109*)

Is it possible that chemical transformations in wines that have been stored for centuries might produce visionary substances? Unfortunately, it will be a difficult task to perform chemical and pharmacological studies of such old wines, which collectors safeguard as though they were precious jewels.

The effects of wine are very dependent upon dosage (cf. **alcohol**, **beer**). In moderate doses, wine uplifts the spirits, lowers inhibitions, and stimulates. If a person drinks wine and also water throughout the evening (in a ratio of 1:3, 1:2, or 1:1), the pleasantly stimulating and uplifting effects can be enjoyed the whole night. But if too great a quantity is consumed, the experience can end in a “blackout” or loss of consciousness. Individual reactions to wine can vary considerably and are much more difficult to control than, for example, dosages of ***Cannabis indica***. Many people believe that the effects of sparkling wines (champagne, *sekt*) are different from those of wine. The former are more stimulating, have greater aphrodisiac effects, and also stimulate the circulation of the blood (of course, only when consumed in moderation).

In former times, the effects of wine (“drunkenness”) were frequently compared to those of opium (cf. ***Papaver somniferum***).

Commercial Forms and Regulations

Grapes and all types of wine are subject to the laws regulating food. Wine is legal in most countries

of the world. In some Islamic countries, the use of wine is generally forbidden or frowned upon.

“Wine, in which the fire of the sun joins with the liquid element, is seen everywhere as the counterpart to bread, the fruit of the earth. But wine has effects upon man that are more subtle than those of bread, for it becomes blood, life itself. Even more, because of its divine origin, it is a drink of immortality, embodying the presence of the supernatural light, the divine love in humans. It opens the spiritual inebriation, which produces ‘a complete forgetting of all that exists in the world,’ leaving room only for the burning desire to find once more the devoutly loved and unite with him.”

Withania somnifera (Linnaeus) Dunal

Ashwagandha

Family

Solanaceae (Nightshade Family); Subfamily Solanoideae, Solaneae Tribe

Forms and Subspecies

Eight to ten species are currently recognized in the genus *Withania*, most of which occur in North Africa and the neighboring regions of Eurasia (D'Arcy 1991, 79*; Hepper 1991; Symon 1991, 146*).

Two morphologically and geographically distinct varieties or forms of *Withania somnifera* are distinguished in India. One form with a knotty rootstock occurs in the Indus valley. The other form, which has a fleshy root that can take on an anthropomorphic appearance, is found in Punjab and Rajasthan (Kumaraswamy 1985, 113).

Because of the various mixtures of **withanolides**, the species is sometimes subdivided into chemotypes (Eastwood et al. 1980).

Synonyms

Physalis somnifera L.

Solanum somniferum nom. nud.

Folk Names

Agol (Ethiopian), ambubi, amkuram kizhangu (Dravidian languages, “beautiful horse root”), amukkara, asgandh (Hindi), ashvaganda, ashwagandha, aswagandha, beautiful horse root, būdîdân, hajarat el dib (Arabic, “wolf tree”), harhumbashir (Assyrian, “red coral”), henbane,³²⁷ jangida, kakink (Pakistan), kuthmithi, marjân (modern Arabic, “coral”), rasbhari, salztiegel, schlafbeere, schlaffbeeren, schlafmachende schlute, sekran (Syrian, “inebriant”), slaepcruydt, solanum somniferum, timbutti eqli (Assyrian, “ring of the field” or “cantharides”), ‘ubâd (Arabic/Yemen), winterkirsche

History

If the interpretation of the Assyrian name as ashwagandha is correct, the plant was in use for medicinal and narcotic purposes in Mesopotamia (Thompson 1949, 216*). It was well known in ancient Egypt (Germer 1985, 167*), and it was characterized and classified as a *sakrân*, “inebriant,” in Old Arabic. The plant is regarded as a hypnotic and sedative throughout its entire range of distribution (Hooper 1937, 186*). It is possible that the plant was seen as a form of “sleeping strychnos” during late antiquity, e.g., by Pliny (21.180) (cf. ***Datura stramonium***, ***Solanum* spp.**, ***Strychnos nux-vomica***). It may have been identical to the mysterious **haliacacabon**.

It has been claimed that the wondrous root *jangida*, whose praises were sung in the Vedic scriptures—especially the Atharva Veda—and which was regarded as a panacea, amulet, magical agent, and aphrodisiac, is identical to *Withania somnifera* (Kumaraswamy 1985).

The plant has been known in Europe since at least the sixteenth century, for it is described and pictured in most of the herbals written by the fathers of botany.

The fruits of *Withania somnifera*.

The flowering herbage of ashwagandha (*Withania somnifera*).

Distribution

Ashwagandha is originally from North Africa and is very common throughout Iraq (Al-Hindawi et al. 1992). It also occurs in Pakistan and northern India. In China, the plant is a popular ornamental (Lu 1986, 81*).

Cultivation

Propagation is performed via the seeds, which are best pregerminated before planting. Water well at first, then water in moderation. Because the plant does not tolerate any frost, in cold climates it should be kept inside in a pot during the winter. As a houseplant, ashwagandha can blossom several times a year.

Appearance

This perennial, branchy, herbaceous plant can grow to more than 1 meter in height (or in rare cases up to 2.5 meters), but usually it remains a small bush. The small, oval leaves are alternate. The tiny flowers have greenish calyxes and white pistils. They are attached to the upper branches close to the main stem. The red berry fruits (hence the ancient Assyrian name *harhumbashir*, “red coral”; Thompson 1949, 215*) are surrounded by an inflated calyx (similar to ***Physalis spp.***) so that they resemble small lanterns. The small, orange-yellow seeds are round, flat, and 1 to 2 mm in length. The

thin, smooth roots can grow 30 to 40 cm long and 1 to 2 cm thick.

Ashwagandha can be confused with other members of the genus, in particular the Mediterranean *Withania frutescens* (L.) Pauq. and the Canary Island *Withania aristata* (Ait.) Pauq. It also can be confused with smaller members of the genus *Physalis* spp. (cf. **halicacabon**).

Psychoactive Material

—Root

—Aboveground herbage

Preparation and Dosage

The root is dried and left whole or finely ground. The powder can be poured into gelatin capsules for ingestion. A tonic and sedative tea can be prepared by boiling the root cortex for a few minutes. The root powder can be boiled in milk together with **honey** and pippali (*Piper longum*; cf. **Piper** spp.).

In Ayurvedic medicine, a single dosage consists of 250 mg to 1 g of the powdered root (Lad and Frawley 1987, 227*). Pronounced antistress effects occur at dosages of 100 mg of root powder per kg of body weight (Grandhi et al. 1994, 134*).

Tonic effects can be attained by chewing a piece of root the length of half a finger every day. The root has a not-unpleasant taste somewhat reminiscent of that of licorice.

Ritual Use

Ancient Arabs used the root as a tonic, aphrodisiac, and inebriant. Unfortunately, no information about their ritual use has come down to us.

Sushruta, the Indian physician and cofounder of Ayurveda, praised the root as a *rasayana* (an alchemical elixir) and as a *vajikarana* (aphrodisiac) with few equals. For this reason, ashwagandha (sometimes in combination with **Cannabis indica**) was used in sexual magic and tantric rituals as an aid in supporting the required duration of erections. The *vaidyas* (folk healers) still prepare a love drink from the root that is said to attract the opposite sex and make one ready for love (Kumaraswamy 1985, 114, 116, 119).

In Pakistan, the leaves of *panirbad*, the closely related *Withania coagulans* (Stocks) Dun. [syn. *Puneeria coagulans* Stocks], are used (presumably smoked) as an inebriant (Goodman and Ghafoor 1992, 43*). In India, the fruits are used to coagulate milk when rennet cannot be used in rituals and ceremonies for religious reasons (Macmillan 1991, 422*).

Artifacts

The remains of several Egyptian flower garlands have been found in El Faiyûm that date to late antiquity and incorporate ashwagandha fruits (Germer 1985, 167*).

The root was used as a substitute for mandrake (see **Mandragora officarum**).

Medicinal Use

The Assyrians used the root as a fumigant, directing the smoke onto painful teeth (cf. **incense**). This use is similar to the ways in which they used henbane (**Hyoscyamus niger**) (Thompson 1949, 216*). In Yemen, the root is still used for treating toothaches (Fleurentin and Pelt 1982, 102 f.*).

In the folk medicine of the inhabitants of the Golan Heights and the Negev Desert, the leaves, and less frequently the fruits, are applied externally as a paste and massaged into the skin to treat open wounds, swelling, rheumatism, and external inflammation (Dafni and Yaniv 1994, 16*).

In Africa, the root is given to children as a tranquilizer (Schuldes 1995, 77*). In Ethiopia, crushed leaves are smeared onto arthritic joints (Wilson and Mariam 1979, 33*).

In Baluchistan (Pakistan), the root cortex is powdered, mixed with water, and kneaded to a paste that is applied to treat wounds (Goodman and Gharfoor 1992, 42*). In India, the herbage is smoked to soothe coughing and asthma (cf. **smoking blends**) (Macmillan 1991, 425*).

An early illustration of the “sleep-inducing nightshade” (*Withania somnifera*). (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

“*Ashwagandha* is a good food for weak pregnant women; it helps to stabilize the fetus. It also regenerates the hormonal system, promotes healing of tissues, and can be used externally on wounds, sores, etc.”

DAVID FRAWLEY AND VASANT LAD *THE YOGA OF HERBS*
(2001, 161)

Ashwagandha has a significance in Ayurvedic medicine that is similar to that of ginseng (***Panax ginseng***) in Chinese herbalism. Ashwagandha is regarded as a “rejuvenative herb”; “*sattvic* in quality, it is one of the best herbs for the mind upon which it is nurturing and clarifying. It is calming and promotes deep, dreamless sleep” (Frawley and Lad 2001, 161).

Constituents

The plant contains steroid lactones, somniferin, withaferin A, and various steroids (Al-Hindawi et al. 1989, 167). The root contains approximately 2.8% steroid lactones, so-called **withanolides**, and also starch (Grandhi et al. 1994:134). The new **withanolides** withasomnilide, withasomniferanolide, somniferanolide, somniferawithanolide, and somniwithanolide were discovered in the stem bark of a sample from India (Ali et al. 1997).

Effects

The effects of the root are described as tranquilizing, sedative, and generally tonic. An aqueous extract of the root has antistress effects similar to those of ginseng (***Panax ginseng***) (Grandhi et al. 1994, 134). The antiserotinerbic activity results in a stimulation of the appetite. An alcohol extract of the aboveground herbage has quite potent anti-inflammatory properties, primarily as a result of the steroids that are present, especially withaferin A (Al-Hindawi et al. 1989, 167; 1992). No toxic side effects have been reported to date, even when the plant was used during pregnancy (Grandhi et al.

1994, 132). The information concerning inebriating effects is sporadic and unreliable.

Commercial Forms and Regulations

The plant is not subject to any legal restrictions and is freely available. Although the root is difficult to obtain in Europe, it can be obtained in any herb shop in India.

Young plants can be purchased from sources offering ethnobotanical plants and from specialized nurseries.

Little-Studied Psychoactive Plants

Minor Monographs

There are a great number of plants about which almost no ethnobotanical or phytochemical research has been carried out but that are said to have or have been demonstrated to have psychoactive effects. Moreover, some of these plants' botanical identifications are questionable. In the case of some of the plants discussed in these minor monographs, information about their psychoactivity (e.g., in the case of ***Cymbopogon densiflorus***) is contained only in notes found together with old herbarium specimens (Altschul 1975*; von Reis and Lipp 1982*). In other cases, very well-known plants that see occasional use for psychoactive purposes, such as ginger (***Zingiber officinale***), have had little real research into their psychoactive use, preparation, and application. For some plants we have no examples of preparations made with the psychoactive substances they yield (e.g., ***Gomortega keule***). In other cases, plants whose psychoactive effects have been pharmacologically demonstrated have no known or reported traditional use (e.g., ***Mikania cordata***). Many of the plants included in these minor monographs are used primarily as additives to other plant mixtures or products (e.g., ***Alchornea spp.***). These plants do not exhibit psychoactive properties when used alone but have synergistic effects when combined with other substances.

This section will certainly provide many suggestions and impulses for future ethnopharmacological and phytochemical studies.

To the extent that it is possible, the minor monographs also include references to specialized literature. For many of the plants, however, the slim or sparse research situation means that there are no writings dedicated specifically to them.

The Genera Discussed in This Section

Ailanthus, Alchornea, Amaranthus, Anarmita, Archontophoenix, Armatocereus, Aspidosperma, Astragalus, Atherosperma
Benthamia, Bernoullia, Boophane, Brosimum, Bursera
Caesalpinia, Capsicum, Cardamine, Carissa, Castanopsis, Cecropia, Clematis, Comandra, Conium, Cordia, Cordyline, Coriaria, Crotalaria, Cymbopetalum, Cymbopogon, Cyperus, Cypripedium
Delphinium, Dictyoloma, Dictyonema, Dimorphandra, Dioscorea
Elaeophorbia
Ferraria
Gaultheria, Gelsemium, Gloeospermum, Gomortega, Goodenia
Hedera, Helichrysum, Helicostylis, Hieracium, Hipomosa, Homalomena, Huperzia
Iresine, Iryanthera
Jasminum, Jatropha, Juanulloa
Kaempferia
Lagochilus, Lancea, Leonotis, [lichen non ident.], Limonium, Lobelia, Lotus, Lucuma, Lupinus, Lycopodium
Macropiper, Magnolia, Malva, Manihot, Maquira, Matayba, Mentha, Metteniusa, Mikania, Mirabilis, Monadenium, Monodora, Mostuea
Neoraimondia, Nephelium

Ocimum, Osteophloeum, Oxytropis
Pancratium, Pandanus, Pedilanthus, Peperomia, Pernettya, Persea, Petunia, Peucedanum,
Philodendron, Physalis, Pithecellobium, Polypodium, Pontederia, Pseuderanthemum
Quararibea
Ranunculus, Rauvolfia, Rhododendron
Sanango, Santalum, Scirpus, Sclerocarya, Scoparia, Securidaca, Senecio, Sida, Sloanea, Spiraea,
Stephanomeria, Stipa
Teliostachys, Terminalia, Tetrapteris, Thamnosma, Thevetia, Tillandsia, Tribulus, Trichocline,
Trichodesma
Umbellularia, Ungnadia, Urmenetea, Utricularia
Valeriana, Vanda, Voacanga
Zea

“From the 1930s to today, interdisciplinary activity in psychopharmacology, botany, and anthropology began uninterruptedly to increase. . .

In spite of the pharmaceutical, phytochemical, and ethnobotanical advances that have been made in the past 125 years, there still remains a tremendous amount of work to be done on these ‘plants of the gods.’”

RICHARD EVANS SCHULTES AND ALBERT HOFMANN

PLANTS OF THE GODS

(1992, 185*)

The attractive devil’s tobacco (*Lobelia tupa*) is from southern Chile and develops magnificent flowers. Studies about and tests of the plant are lacking.

Ailanthus altissima (Mill.) Swingle

[syn. *Ailanthus glandulosa* Desf., *Ailanthus peregrina* (Buc'hoz) Barkl.]
(Simaroubaceae)—tree-of-heaven

Originally from China, the tree of the gods has now been introduced into Europe and North America (Zander 1994, 98*). An herbarium specimen collected in Pennsylvania in 1937 bears the note, “Seedling ‘of a possibly narcotic plant’ ” (von Reis and Lipp 1982, 146*). No research has been conducted to ascertain whether the tree actually does have psychoactive effects. The main agent (5%) is quassiine (= ailanthine), with the molecular formula $C_{36}H_{50}O_{10}$ (Reichert et al. 1949, 3:169*).

***Alchornea* spp.**

(Euphorbiaceae; Acalyphoideae)

This tropical genus is composed of some seventy species, most of which are found in the Americas, although a few are native to Africa (Schneider 1992, 166). The South American *Alchornea castaneifolia* (Willd.) Juss. is used in Peru as an **ayahuasca** additive. The bark of this species, known as *pájaro arbol* (Spanish, “bird tree”), exhibits antifungal properties (Ott 1993, 403*). The Tikana Indians use the bark medicinally to treat diarrhea (Schultes and Raffauf 1986, 265*). It is not known whether the plant itself is psychoactive.

In Africa, the bushy species *Alchornea floribunda* Muell. Arg. is known as *niando* or *malande*. Found in the tropical regions between Sierra Leone and Zaire, it was formerly used ritually in the *bieri* ancestor cult (Smet 1996*). The fresh or dried root (which is also known as *niando*) is sometimes added to iboga preparations (see ***Tabernanthe iboga***). The plant is also used as a stimulant and inebriant in many parts of Africa (Raymond-Hamet 1952). It is regarded as a marijuana substitute (see ***Cannabis indica***) and smoked as an aphrodisiac as well (De Wildeman 1920; Schneider 1992, 171). “The natives of the Congo add ground roots of *A. floribunda* to palm wine for several days to prepare a stimulating drink, *niando*. The drink serves both as an aphrodisiac and to maintain vigor for wars and tribal festivals” (Scholz and Eigner 1983, 78*). The effects have been described as follows: “As a narcotic hallucinogen, the root drug added to palm wine initially induces a phase of stimulation, then a profound fatigue with isolated fatal results” (Schneider 1992, 71).

In contrast to an earlier report (Paris and Goutarel 1958), the plant does not contain **yohimbine**, although it does contain the alkaloids alchorneine, isoalchorneine, alchorneinone, and pyrimidine along with imidazole derivatives (Khuong-Huu et al. 1972; Ott 1993, 403*). The quantity of alkaloids can vary considerably. It is usually the highest in the roots, where it can range from 0.6 to 1.2%. As a free base or in the form of a simple derivative, alchornine has antidepressive, spasmolytic, and anticholinergic properties (Schneider 1992, 170 f.).

The closely related African species *Alchornea cordifolia* (Schum. et Thonn.) Muell. Arg. is easily confused with *A. floribunda*. It has a number of ethnomedical uses. Its large leaves are used to package cola nuts (***Cola* spp.**) for transport (Schneider 1992, 170). In West Africa, the dried leaves are used to brew a tonic (Assi and Guinko 1991, 26*).

Raymond-Hamet. 1952. L’ *Alchornea floribunda* Müller ou Niando. *Revue Internationale de Botanique Appliquée et d’Agriculture Tropicale* 32:427–42.

***Amaranthus* spp.**

(Amaranthaceae)—amaranths

In South America, a number of *Amaranthus* species are roasted into ashes and used as *llypta* for chewing coca (see *Erythroxylum coca*). In Mexico, a **chicha** brewed from the seeds of *Amaranthus caudatus* L. is offered to Mother Earth and ritually consumed before the planting of a new field (Early 1992, 29). In Ecuador, the flowers of *Amaranthus hybridus* L. are decocted into a red liquid that is mixed with rum to produce a drink known as *draque*, which is used to purify the blood and regulate menstruation (Early 1992, 30). A species of *Amaranthus* was used by the Cherokee of North America for ethnogynecological and ceremonial purposes (Ott 1993, 403*).

The African niando bush (*Alchornea floribunda*) is one of the sacred plants of the Bwiti cult. (Photograph: Giorgio Samorini)

The prickly amaranth (*Amaranthus spinosus*) is from India.

Fruits of the Southeast Asian cocculus bush (*Cocculus* sp.) have toxic and psychoactive properties.

The Lodha, a tribal people from West Bengal, are said to smoke the dried, pulverized roots of *Amaranthus spinosus* L. (prickly amaranth, *cauleyi*, *kateli*, *tanduliyah*) as a hallucinogen. A paste of the plant is said to produce “temporary insanity.” In Ayurvedic medicine, the plant is considered a tonic and is used to treat hallucinations (Warrier et al. 1993, 1:107*) In Swaziland (Africa), the entire plant (*Amaranthus spinosus*) is burned to ashes and used as a **snuff**, either alone or mixed with tobacco (*Nicotiana tabacum*) (Ayensu 1978, 32*).

There is no information available about psychoactive substances in this genus (cf. also *Iresine* spp.).

Anarmita cocculus Wight et Arnott

[syn. *Anarmita paniculata* Colebrooke, *A. baueriana* Endl., *A. jucunda* Miers, *A. populifolia* (DC.) Miers, *A. toxifera* Miers, *Cissampelos cocculus* (L.) Miers, *Cocculus lacunosus* (Lam.) DC., *C. populifolius* DC., *C. suberosus* DC., *Menispermum cocculus* L., *M. heteroclitum* Roxb., *M. lacunosum* Lam.]

(Menispermaceae)—cocculus bush

This shrubby climber, a member of the Moonseed Family, is indigenous to eastern India. The round fruits, which are red when fresh and can be as large as 1 cm, are known as cocculus seeds (fructus cocculi), fish seeds, or crazy seeds (cf. **witches’ ointments**) (Schneider 1974, 1:90*). The fruits contain 1.5 to 5% picrotoxin, consisting of picrotoxine and pikrotoxin, as well as bases of the berberine and aporphinal alkaloid types. Picrotoxin has stimulating effects on the central nervous system but can lead to coma and delirium. It is considered one of the most effective antidotes for barbiturate poisoning (Roth et al. 1994, 122*). Cocculus seeds were used in early modern times as an inebriating additive to **beer** (Tabernaemontanus 1731*).

Cocculus seeds are now illegal in Germany under the Cosmetic Law of June 19, 1985. Their only

use today is in homeopathy. The closely related species *Cocculus leaeba* DC. and *Cocculus pendulus* are reputed to be psychoactive (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 368*).

Literature

Hänsel, Rudolf, and Renate Seitz. 1992. *Anarmita*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:267–72. Berlin: Springer.

Archontophoenix cunninghamiana (H. Wendl.) H. Wendl. et Drude

[syn. *Ptychosperma cunninghamiana* H. Wendl., *Seafortia elegans* Hook. non R. Br.]

(Palmae)—king palm

This frond palm, which can grow as tall as 25 meters, belongs to the Subfamily Arecoideae. Originally from Australia (Queensland, New South Wales), it bears round, red berries approximately 2 cm in size. The seeds inside are covered by wide fibers. The Papuas (Papua New Guinea) are said to chew the ripe seeds, which have an inebriating effect, as an **alcohol** substitute (Bärtels 1993, 43*). It is possible that the king palm was used to make **palm wine**.

The exotic cocculus seeds (*Anarmita cocculus*) were used as an inebriating beer additive during the seventeenth and eighteenth centuries. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

Botanical illustration of a Southeast Asian cocculus bush. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

***Armatocereus laetus* (H.B.K.) Backeb.**

(Cactaceae)

This cactus, known in Peru as *pishicol*, is reputed to be psychoactive and is one of the plants of the San Pedro cult (see *Trichocereus pachanoi*). No chemical studies have been conducted (Ott 1993, 396*).

***Aspidosperma quebracho-blanco* Schlecht.**

[syn. *A. chakensis* Speg., *A. crotalorum* Speg., *A. quebracho* Griseb., *Macaglia quebracho* O. Ktze., *Macaglia quebracho-blanco* (Schlecht.) Lyons]

(Apocynaceae)—white quebracho

The white quebracho tree is found throughout Argentina (Chaco), Peru, and Bolivia. It grows up to 20 meters in height and has mythological, ritual, and ethnomedicinal significance. Among many South American Indian cultures, it is an important shaman's tree that shamans occasionally climb to communicate with animal spirits (cf. *Jatropha grossidentata*). The tree, known as *no'dik*, yields a bark that the Pilagá Indians (Chaco) decoct to treat stomach upsets, cough, headaches, and syphilis. It also finds use as an analgesic and an abortifacient (Filipov 1994, 185*). The Ayoreo Indians, who live in Paraguayan Chaco, consider the tree, which they call *ebedu*, to be a panacea and they use it to treat all manner of ailments (Schmeda-Hirschmann 1993, 107, 108*).

The common name quebracho, "ax breaker," is used for a number of species of hardwood trees: horco quebracho (*Schinopsis haenkeana* Engler), quebracho colorado chaqueño (*Schinopsis balansae* Engler), quebracho colorado santiagueño (*Schinopsis quebracho-colorado* [Schlecht.] Barkley et Meyer), quebrachillo (*Diatenopteryx sorbifolia* Radlk.), and quebracho blanco chico (*Aspidosperma triternatum* Rojas Acosta [syn. *Aspidosperma quebracho-blanco* Schlecht. ssp. *brevifolium* Hassl]) (cf. Santos Biloni 1990, 35, 107, 109, 199, 239*). In Peru, Quechua speakers refer to *Aspidosperma quebracho-blanco* as willca (kachakacha in Aymara); the name willca is usually used as a name for *Anadenanthera colubrina* (Santos Biloni 1990, 118*).

Quebracho bark has often been attributed with aphrodisiac powers with psychoactive effects (Schuldes 1995, 20*). The bark of *Aspidosperma quebracho-blanco*, which finds phytotherapeutic use

for asthma, contains some thirty **indole alkaloids**, including six principal alkaloids (totaling at least 1%): quebrachine (= **yohimbine**), aspidospermine, quebrachamine, hypoquebrachine, and aspidosamine (Santos Biloni 1990, 119*). The fruits contain the **indole alkaloid** aspidospermatine; the leaves also contain indoles. Pharmacological studies are lacking (Hoffmann-Bohm 1992, 401 f.).

Literature

Hoffmann-Bohm, Kerstin 1992. *Aspidosperma*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:400–405. Berlin: Springer.

Botanical illustration of the white quebracho tree (*Aspidosperma quebracho-blanco*), a member of the Dogbane Family. (From Köhler's *Medizinal-Pflanzen*, 1889)

Astragalus spp.

(Leguminosae: Fabaceae)—locoweeds

Of the more than five hundred species of this genus in North America, a few are referred to by the Spanish-English name *locoweed*, “crazy weed” (cf. ***Oxytropis* spp.**), and have toxic or psycho-tropic properties (Turner and Szczawinski 1992, 122*). Many *Astragalus* species of the North American prairies have cytotoxic properties, i.e., they kill cells and can thus be used in the treatment of cancer (McCracken et al. 1970). The common name of this plant refers to observations that grazing sheep, cattle, and horses “flip out” or “go crazy” after eating *Astragalus* or *Oxytropis*. In South Dakota, I once heard that the Dakota Indians used to and possibly still do eat (or perhaps smoke) locoweeds to produce visions. To date, no constituents with psychoactive or psychotropic effects have been found. The nitrogenous substance miserotoxin (or a derivative) may be responsible for these effects (Williams et al. 1975). Miserotoxin (= 3-nitro-1-propyl- β -D-gentiobioside) occurs especially in *Astragalus miser* Dougl. var. *serotinus* (Gray) Barneby and in at least ten additional species (Majak and Benn 1988). *Astragalus* species also possess unusually high concentrations of selenium (Emboden 1976, 160*; Turner and Szczawinski 1992, 123*).

The Navajo utilize a hallucinogenic loco-weed, perhaps blue loco (known in Navajo as *dibéhaich’iidii*, “gray sheep scratcher”), together with ***Datura innoxia*** in magical rituals. They regard blue loco as a “life medicine” (Mayes and Lacy 1989, 59*).

Astragalus species are found throughout the world. In North America, some of them are known as locoweed. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Quebracho bark (*Aspidosperma quebracho-blanco*), which contains yohimbine, in its crude form.

The following species are said to be psycho-active: *Astragalus amphioxys* A. Gray, *A. besseyi* Rdb., *A. cagopus*, and *A. mollissimus* Torr. (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*). The Mexican species *Astragalus amphioxys* [1095] Gray is also attributed with such properties (Reko 1938, 187*).

The Old World species *Astragalus micro-cephalus* Willd. and *Astragalus gummifer* Labill. provide a gum (tragacanth) that is used in the production of **incense** (Scholz 1992).

The Tasmanian tree *Atherosperma moschatum*, known as “southern sassafras,” has a strong safrole scent.

(Photographed in the cold rainforest of Tasmania)

The rainforest tree *Bernoullia flammea*, shown here in front of a pyramid in Tikal (Guatemala), is also known as *amapola* (“opium”).

***Atherosperma moschatum* Labill.**

(Monimiaceae)—southern sassafras, black sassafras

This tree, which can grow as tall as 45 meters, is found in the cool and temperate rain forests of Tasmania (Collier 1992, 24; Kirkpatrick and Backhouse 1989, 59). It is usually referred to as sassafras³²⁸ or, less frequently, as southern sassafras and should not be confused with the true *Sassafras albidum* of America.

Early European settlers prepared a tonic tea from the fresh or dried bark, which contains safrole and smells strongly of sassafras (Cribb and Cribb 1984, 172*). The settlers on the Australian mainland made a similar tea from the bark of what they called “real sassafras,” the closely related tree *Doryphora sassafras* Endl. (Collier 1992, 24; Cribb and Cribb 1984, 174*). The black wattle tree (*Acacia decurrens*; cf. *Acacia* spp.) was used in the same manner. Apparently the settlers learned to use these tea plants through trial and error and not from the Aborigines (Low 1992a, 34*).

Tea made from the bark of the trunk (eight strips, 5 to 7 cm in length, steeped in 1/4 liter of water for five to eight minutes) has a strong safrole taste and leaves a slightly numb but invigorating

sensation in the mouth and throat. The effects are clearly stimulating; higher dosages produce the typical safrole effects. Of particular interest is the report that early settlers used the leaves and bark in place of hops (*Humulus lupulus*) to brew **beer** (Pettit 1989, 62). It is conceivable that the beer yeast metabolizes the safrole into an amphetamine derivative during the fermentation process. Home brewers in Tasmania allegedly still make a psychoactive sassafras beer.

In addition to the safrole-containing oil (cf. **essential oil**), the bark of *Atherosperma moschatum* contains several alkaloids: berbamine (main alkaloid), isotetradrine, isocorydine, atherospermidine, atherosperminine, spermathridine, atheroline, moschatoline, and methoxyatherosperminine (Lassak and McCarthy 1987, 80*).

Pettit, Rose. 1989. Tasmanien: Reisen auf der urwüchsigen australischen Insel. Alpers: SYRO.

Benthamia alyxifolia (Benth.) Tieghem

(Loranthaceae)—mistletoe

This Australian plant, which is similar to the true mistletoe (*Viscum album* L.; Loranthaceae), is a parasite on several plants, including *Duboisia myoporoides* (see **Duboisia spp.**). The leaves contain **scopolamine** and are smoked in Australia as an inebriant (Bock 1994, 85*). It is possible that the scopolamine is extracted from the host tree *Duboisia myoporoides* as a result of the mistletoe’s parasitic activity and is then incorporated into the plant’s own tissue.

Bernoullia flammea Oliver in Hook.

(Bombacaceae)—amapola blanca

This tree grows to a towering height of 40 meters in the tropical lowlands of Guatemala (El Petén), where it is known as *amapola blanca*, “white opium [tree]” (cf. **amapola**). It has a whitish bark and fire-red flowers, and its fruits are filled with winged seeds that are reminiscent of those of both *Banisteriopsis caapi* and the maple tree (*Acer* spp.; Aceraceae) (Lanza Rosado 1996, 22 ff.). The seeds are smoked by the Guatemalan people living in the area around the spectacular Mayan ruins of Tikal and are said to have a strong, opium-like effect (Rob Montgomery, pers. comm.; Brett Blosser, pers. comm.). The tree is known in Itza Maya as *chunte*’ and in Yucatec Maya as *wakut*.

Literature

Lanza Rosado, Felipe. 1996. *Manual de los árboles de Tikal*. Alicante and Barcelona: Agencia Española de Cooperación International.

Boophane disticha (L. f.) Herbert

[syn. Amaryllis disticha L., Haemanthus toxicarius Thumb., Boophane toxicaria (L. f.) Herb., Brunsvigia toxica Ker., Bufane toxicaria Herb., Buphane toxicaria Thunberg, Haemanthus lemairei (L. f.) Herbert; also Buphane, Boöphone, Boophone] (Amaryllidaceae)—fan lily, cowbane

The bulb of this African species of amaryllis is used in folk medicine and to manufacture arrow poisons. The Bushmen use it as a hunting poison (Neuwinger 1994, 4 f.*). It is also used in (ritual) suicides (Lewin 1912). Another use occurred in the secret initiation ceremonies of the South African Basuto. The young boys ate the crushed bulb together with other ingredients so that they could contact their ancestors. The first signs of inebriation were interpreted to mean that the spirit of adulthood had entered into them. A dried powder of the bulb also serves as a ritual and psychoactive **incense**:

The Sotho, among whom the plant enjoys a particularly high status (e.g., they call October, the month in which the plant flowers, *mphalane es leshoma* = *Boophane* stalk), utilize the “alcoholizing” properties of *Boophane disticha* during the preliminaries of initiation. A powder made from the bulb is mixed with other plants and heated, and the smoke is inhaled. It makes the initiates drunk as if from alcohol. When signs of intoxication appear, this taken as a sign that the spirit of manliness has entered into the youths. (Neuwinger 1994, 7*)

In West Africa, *Securidaca longepedunculata*, which contains **ergot alkaloids**, is used together with *Boophane* for psychoactive purposes (Neuwinger and Mels 1997).

Fresh *Boophane* bulbs contain 0.31% alkaloids (buphanidine, undulatine, buphanisine, buphanamine, nerbowdine, lycorine), which exhibit the same bioactivity as the **tropane alkaloids** in *Datura* (Hauth and Stauffacher 1961; Rauwald and Kober 1992, 527; Tupin 1912; Roth et al. 1994, 179*). Some of the alkaloids also have **morphinelike** structures and effects (Neuwinger 1994, 6 f.*). Overdoses can be fatal. Both the ethnographic and the ethnopharmacological literature contain numerous indigenous reports of distinct hallucinogenic effects. In Zimbabwe, the bulb is used to help the ancestor spirits appear (de Smet 1996, 142 f.*). The bulb also has folk medical uses; it is taken internally to treat hysteria and insomnia (Rauwald and Kober 1992, 528).

Brosimum acutifolium ssp. obovatum (Ducke) C.C. Berg

(Moraceae)

The Amazonian Palikur and Wayãpi Indians use parts (which?) of this tree, known as *tamamuri* or *congona*, as hallucinogens, especially in initiation rites (Duke and Vasquez 1994, 32*). It is doubtful whether this vague information is correct. Coumarins (pyranocoumarins, furocoumarins) have been found in this species and in other Amazonian members of the genus (Gottlieb et al. 1972). Whether these have psychoactive effects, however, is unknown.

Literature

- Gottlieb, O. R., M. Leão da Silva, and J. G. Soares Mia. 1972. Distribution of coumarins in Amazonian *Brosimum* species. *Phytochemistry* 11:3479–80.

Bursera bipinnata Engl.

[syn. *Elaphrium bipinnatum* (DC.) Schlecht.] (Burseraceae)—sacred copal

Today, this balsam bush is known in Mexico as *copal amargo*, *copal cimarrón*, *copal chino*, *copal de santo*, *copal de la virgin*, *copalio*, *palo copal*, and *pom*, and it is used as a ritual **incense**. Emmar (1937*) suggested that the tree was known as *teuvetli* in pre-Spanish times and that it was used in the

preparations for Aztec human sacrifice (cf. *Datura innoxia*). It is said that a decoction made from the resinous bark was administered to the victims prior to the ceremony. The extract was probably mixed with pulque (cf. *Agave spp.*), for the prisoners were required to drink four bowls of pulque prior to the ceremony (Davies 1983, 244). This beverage produced a subdued or sedated state of consciousness but did not impair muscle coordination or the ability to move. Both were needed, for the victims had to ascend the steep steps of the temple pyramids before their hearts were cut out of their chests while they were still alive (Tyler 1966, 291*). Unfortunately, it is uncertain whether the Aztec tree *teuvelti* is botanically identical to *Bursera bipinnata* (Emboden 1979, 4*).

In South Africa, the fan lily (*Boophane disticha*), also known as cowbane, is called *malgif*, “crazy poison.” (From Neuwinger)

The strange and magical African root *Boophane disticha*. (From Lewin, “Untersuchungen über *Buphane disticha* [*Haemanthus toxicarius*],” 1912)

In Mexico, many species of the genus *Bursera* produce aromatic resins used as incense.

The yün-shih fruit (*Caesalpinia decapetala*).

Literature

Davies, Nigel. 1983. *Opfertod und Menschenopfer*. Frankfurt/M.: Ullstein.

Caesalpinia decapetala (Roth) Alston

[syn. *Caesalpinia sepiaria* Roxb.³²⁹]

(Leguminosae)—yün-shih, caesalpinia

This yellow-flowering climber is found in the Himalayas and in central Asia and China (Polunin and Stainton 1985, 89*). Known as *yün-shih*, the plant is used in traditional Chinese medicine to treat worm infestations, malaria, and inflammations. It is claimed that it was once used in China as a hallucinogen (Li 1978, 20*). According to ancient Chinese sources, the flowers “contain occult powers.” The *Pên Ts’ao Ching*, the famous herbal of Li Shih-chên, states:

[The flowers] make it possible for one to see spirits but make one idiotic if consumed in excess. When consumed over a long period of time, they produce levitation of the body and promote communication with the spirits.

In the herbal *Tao Hung-ching*, one can read:

[The flowers] dispel the evil spirits. When added to water or burned [i.e., as an **incense**], spirits can be called. . . . The seeds are like those of *lang-tang* [see *Hyoscyamus niger*]; when they are burned, spirits can be called.

The Chinese botanist Hui-Lin Li has suggested that these statements are indicative of a psychoactive use as well as of psychoactive effects of the flowers and seeds (Li 1978, 20*). Whether these text passages actually do refer to psychoactivity has not yet been established. After all, there are hundreds of plants that are used in magical rituals and spirit conjurations, even though they do not exhibit the slightest psychoactive effects (cf. Gessmann n.d.*; Mercatante 1980*; Schöpf 1986*). Still, an alkaloid of unknown chemical makeup has been discovered in *Caesalpinia decapetala* (Schultes

and Hofmann 1992, 37*). Its method of action is unknown.

An Indian relative, *Caesalpinia bonduc* (L.) Roxb. [syn. *Caesalpinia cristata* L.], was once proposed as a candidate for **soma**. The beautiful paradise flower (*Caesalpinia pulcherrima* (L.) Sw. [syn. *Poinciana pulcherrima* L.]) is a symbol of the divine phallus in the cosmic vulva and is thus sacred to the Hindu god Shiva; *C. decapetala* is often mistaken for the yellow-blooming variety of the cultivated *C. pulcherrima*. The related American species *Caesalpinia echinata* Lam. is used in South America as an **ayahuasca** additive.

Capsicum spp.

(Solanaceae)—chili pepper

In the tropical regions of the Americas, there are many species (approximately forty) and cultivated varieties of chilies or chili peppers, most of which are used as spices (Andrews 1992). Chilies also have ethnomedical and ritual significance (Long-Solís 1986). The pods are used as medicines to treat a variety of diseases and have bactericidal properties (Cichewicz and Thorpe 1996). In higher dosages (30 to 125 mg), chilies are considered to be aphrodisiac (Gottlieb 1974, 19*). It is possible that they are psychoactive under certain circumstances. Indeed, chilies are used as

The climbing *yün-shih* shrub (*Caesalpinia decapetala*) is reputed to have psychoactive effects. (Illustration from the *Chêng-lei pên-ts'ao*, 1249)

One of the many forms of chili pepper (*Capsicum* sp.), a plant of the Americas, that the Indians have cultivated.

***Carissa edulis* (Forsk.) Vahl**

(Apocynaceae)—dagams

The root of this member of the Dogbane Family is very popular in Kenyan folk medicine. A decoction of the root is drunk to treat headaches and as an aphrodisiac and stimulant. In Ghana, the root is used to treat diminishing virility. In South Africa, a stimulating and aphrodisiac tea is made from the stem. The plant contains **indole alkaloids** and may have psychoactive effects (Omino and Kokwaro 1993, 171, 176*).

Castanopsis acuminatissima

(Fagaceae)—kawang

People from the Banz region of Papua New Guinea steam and eat the seeds of this tree. When consumed in sufficient quantity, they are said to have sedative or psychoactive effects similar to those of certain mushrooms (***Russula*, *Boletus***) (Schleiffer 1979, 91*).

additives to many different psychoactive products, including **ayahuasca**, **balche'**, **beer**, cacao (see ***Theobroma cacao***), **incense**, kava-kava (see ***Piper methysticum***), and **snuff** (cf. ***Nicotiana tabacum***) (Weil 1976). The Kakusi Indians of Guyana use *Capsicum* species as a stimulant (Schultes 1967, 41*). The Waorani Indians of Ecuador cultivate *Capsicum chinensis* Jacq. and use the fruits as a stomachic. When the men are too strongly inebriated from ayahuasca, their women give them chilies to help them become sober (Schultes and Raffauf 1991, 35*).

In the “drug scene,” the dried remnants of rotten green paprika pods (*Capsicum frutescens* var. *grossum*) are sometimes used as a marijuana substitute (see ***Cannabis indica***).

All species of this genus contain the hot compound capsaicin (chemically related to vanillin) (Weil 1976). Some species also contain flavonoids. *Capsicum annum* L. contains steroidal alkaloids and glycosides (Schultes and Raffauf 1991, 35*).

Weil, Andrew. 1976. Hot! Hot!—I: Eating chilies. *Journal of Psychedelic Drugs* 8 (1): 83–86.

***Cardamine* sp.**

[syn. *Dentaria* sp.] (Cruciferae)—pepper root, tooth root

There are reports that this little-known plant (possibly *C. concatenata*) was used as a hallucinogen by the Iroquois (Moerman 1986, 100, 604*). Unfortunately, chemical and ethnobotanical information is lacking (Ott 1993, 405*). The “cuckoo flower” (*Cardamine pratensis* L.) was once used to treat epilepsy (Millspaugh 1974, 88*).

***Cecropia* spp.**

(Moraceae)—ant tree

In Mexico (Veracruz), *Cecropia mexicana* Hemsl. [syn. *Cecropia obtusifolia* Bert., *Cecropia schiedeana* Klotzsch]) is known as *guaruma*. The large, dried leaves are smoked as a marijuana substitute (see ***Cannabis indica***); the effects are said to be similar to those produced by cannabis (Ott 1993, 405*). In Palenque, severe delirium effects have been observed in *Cecropia* smokers (Chan K'in Tercero, pers. comm.). In Mexican folk medicine, the fresh leaves are used to prepare a bath for relieving pain (Argueta et al. 1994, 706*). The plant contains sterols and tannins (pirogalole). The leaves contain various sugars (rhamnose, glucose, xylose), stigmasterol and three isomers, and 4-ethyl-5-(*n*-3-valeroil)-6-hexahydrocumarin (cf. **coumarins**) and 1-(2-methyl-1-nonen-8-il)-aziridin (Argueta et al. 1994, 706*). Tests on rats have demonstrated antihypertensive effects (Vidrio et al. 1982).

The leaves of a very similar species, *Cecropia peltata* L. [syn. *Cecropia asperrima* Pitt.], known locally as *guarumbo* or *tzon ndue*, contain leucocyanidin; the bark contains sterin and ursolic acid; and the latex has been found to contain the alkaloid cowleyine (Wong 1976, 115*). In Yucatán, a tea made from the leaves is consumed for diabetes (Argueta et al. 1994, 708*).

In South America, the leaves of various species are burned to ash and used as *llipta* for coca chewing (***Erythroxylum coca***).

Literature

Vidrio, H., et al. 1982. Hypotensive activity of *Cecropia obtusifolia*. *Journal of Pharmaceutical Science* 71 (4): 475–76.

***Clematis virginiana* L.**

(Ranunculaceae)—Virginia clematis

The stems of this plant were reputedly used by the Iroquois of North America as a bath or wash to produce “strange dreams.” Unfortunately, no additional ethnographic or chemical information is available (Ott 1993, 406*). Other *Clematis* species are toxic and irritate the nervous system (Roth et al. 1994, 241*). In Bavaria, the sprouts of *Clematis vitalba* L. were once smoked as a tobacco substitute (cf. ***Nicotiana tabacum***).

Comandra pallida

(Santalaceae)

The North American Kayenta Navajo allegedly used this plant as a narcotic. No other information is available (Ott 1993, 406*).

***Conium maculatum* L.**

(Apiaceae)—poison hemlock

Since ancient times, hemlock has “enjoyed” an infamous reputation as a poisonous plant, known as a

killing poison (“Socrates’ cup”) and sedative, but it is also known as an aphrodisiac. According to Germanic legend, hemlock was avoided by both man and beast. It was said that only the toad, which would “suck its poison,” liked to live in its vicinity (Perger 1864, 184*). Hemlock thus stands in close association with the toad goddess, an earth deity venerated especially by Baltic tribes (the ancient Prussians) (Gimbutas 1983; cf. **bufotenine**).³³⁰

Saxo Grammaticus has described how Haddingus, who was raised by the giants but later became a favorite of Odin, was once visited at the hearth in the evening by an apparition of a woman who wore hemlock in her garb. This woman, interpreted as a shamanic helping spirit, placed her cloak around Haddingus and led him across a bridge, into the underworld, and to the realm of the dead (Lichtenberger 1986, 31 f.). In Scandinavia and England, hemlock was a magical plant closely associated with Wotan/Odin. This can be seen in the Norwegian name for the plant, *woden-dunk*, and the Anglo-Saxon *wôde-hwistle*, “rage reed/ Wotan’s whistle.” The English word *hemlock*, literally “hemp leek,” still recalls the rune magic *lina laukaR*. In Old High German, the plant was known as *wuotscerling* or *wode-scerne*, “rage hemlock” (Höfler 1990, 95*). Hemlock was one of the primary ingredients in the **witches’ ointments**. Andrés Laguna, a sixteenth-century physician from Lorraine, once found a vessel full of “witches’ ointment.” He analyzed its contents and found henbane (*Hyoscyamus niger*), mandrake root (*Mandragora officinarum*), and hemlock. He rubbed the ointment onto a woman, who then fell into trance.

In Bohemia, hemlock is reputed to have once been used as an additive to **beer**. Unfortunately, we know nothing about the effects of such a brew (Hansen 1981*). Perhaps all of the people who tried it died from overdoses . . .

The entire plant contains approximately 2% alkaloids. The fruits exhibit especially high concentrations, as much as 3.5%. The principal alkaloid is coniine (approximately 90% of the total alkaloid content); γ -coniceine, conhydrine, pseudoconhydrine, and methylconiine are also present (Teuscher 1992). Toxic effects include rapid paralysis, sensations of cold, lack of sensation, and, finally, death through respiratory paralysis (Roth et al. 1994, 259*).

Literature

***Cordia boissieri* DC.**

(Boraginaceae)—nacahuita

It is said that the fruits of this Mexican plant have inebriating effects (von Reis Altschul 1975, 237*).

***Cordyline fruticosa* (L.) A. Chev.**

[syn. *Cordyline terminalis* (L.) Kunth] (Agavaceae, previously Liliaceae)—*ti*

This Polynesian plant, which is now found throughout the world as an ornamental and potted plant, is called *kî*, *tî*, or *ti* in Hawaii (Krauss 1993, 186*). There, the plant acquired a great significance in magical and religious rituals:

Tî received heavy ceremonial use as well and frequently was planted around *heiau* [temples]. Priests wore leaves about their necks as an indication of high rank or divine power, and it was among the plants customary on the altar of the *hâlau hula*, representing Laka, the goddess of hula [a sacred dance]. It was also valued as a charm against evil spirits. (Abbott 1992, 115)

An inebriating beverage was brewed from this Hawaiian magical plant:

On Hawaii and Samoa, the roots or rhizomes are used to prepare an inebriating beverage. Since the rhizomes contain sugar [saccha-rose], the drink may contain alcohol. The leaves of the plant are made into belts for dancing and loincloths. The root is also used to treat diarrhea and dysentery. *Cordyline ti* Schott [apparently a synonym] is also used on some South Seas islands to produce an inebriating drink. (Hartwich 1911, 811*)

It is unknown whether **alcohol** was the only active component of this drink, which was presumably similar to beer (cf. **beer**), or whether it also contained other psychoactive substances.

Literature

Abbott, Isabella Aiona. 1992. *Lâ'au Hawaii: Traditional Hawaiian uses of plants*. Honolulu: Bishop Museum Press.

***Coriaria thymifolia* H.B.K. ex Willd.**

(Coriariaceae)—tannic sumac

This shrub is found in the high mountains from Colombia to Chile, where it is known as *shanshi*. In Ecuador, its fruits are reportedly eaten to produce an inebriated state. The eater is said to experience “sensations of soaring through the air” (Alvear 1971, 22*; Schultes and Hofmann 1992, 40*). The effects are said to be similar to those produced by ***Petunia violacea***. *Coriaria thymifolia* grows in Mexico as well; it has been suggested that it was the Aztec inebriant known as *tlacopétatl* (Díaz 1979, 93*). In the Las Huarungas region, a lake plateau in the northern Peruvian Andes, the local healers (*curanderos*) refer to *Coriaria thymifolia* as *contra-alergica*, “against allergies.” They use the herbage to prepare a bath additive (*baño*) that they use to wash patients suffering from allergic reactions. I was unable to learn of any psychoactive use there. Astonishing numbers of *Coriaria thymifolia* can be found in the area around Macchu Picchu.

The fruits contain catechol derivatives and probably several sesquiterpenes (Schultes and Farnsworth 1982, 178*). Other sources state that a toxic substance named coriamyrtine has been isolated from the plant. The effects are described as initially stimulating but then becoming less pleasant. Death from nervous exhaustion can result (Blohm 1962, 62*). Coriamyrtine is a sesquiterpene; other sesquiterpenes coriatine, tutine, and pseudotutine have also been reported (Emboden 1979, 175*).

The closely related species *Coriaria ruscifolia* L., which is known in Chile as *deu*, *dewü*, *huique*, *huiqui*, and *matarratones* (literally “killer of rats”), is reputed to be a hallucinogen. It is definitely poisonous. The fruits are made into rat poison in Chile (Mösbach 1992, 89*) and are said to be lethal for small children (Donoso Zegers and Ramírez García 1994, 46*). The Mapuche use a tea made from the leaves as an emetic (Houghton and Manby 1985, 94*).

The *ti* plant (*Cordyline fruticosa*), which the Hawaiians venerate as sacred, was formerly used as a magical plant and inebriant. (Photographed on Oahu, Hawaii)

A tannin sumac (*Coriaria* sp.) used in South America for psychoactive purposes.

Coriaria thymifolia. (Photographed near Machu Picchu, Peru)

***Crotalaria sagittalis* L.**

(Fabaceae, Leguminosae)—rattle box

The Delaware-Okla Indians of North America regarded the root of this papilionaceous plant as “a very strong narcotic” (Moerman 1986, 140*). Other species of the genus contain potent liver toxins (Ott 1993, 406*). Also present are flavonoids (Fleurentin and Pelt 1982, 96 f.*), amino acids, and alkaloids, including neurotoxins (Pilbeam et al. 1979, 1983, 1983; Wong 1976, 126*). The dried seedpods of various *Crotalaria* species can be used as rattles, hence the English name “rattle box.” In Argentina, the pods of *Crotalaria incana* L. are used to magically heal deafness (Schmeda-Hirschmann et al. 1987).

One related species, *Crotalaria juncea* L., is known as Bengali hemp, East Indian hemp, and Bombay hemp. These names suggest that the species may be psychoactive.

Literature

Schmeda-Hirschmann, Guillermo, Lucia Franco, and Estebán Ferro. 1987. A magic use of *Crotalaria incana* pods. *Journal of Ethnopharmacology* 21:187–88.

Many species of cypress grass (*Cyperus* spp.) are used in South America for ethnopharmacological purposes, including as ayahuasca additives. (Wild plant, photographed in northwestern Argentina)

A grass from the genus *Cyperus* that is known in Amazonia as *piripiri* but has not yet been botanically identified is infested by a fungus that likely produces ergot alkaloids.

***Cymbopetalum penduliflorum* (Dunal) Baill.**

(Annonaceae)

This plant was known among the Aztecs as *xochinacatzli*, “ear flower”; the aromatic flower was called *teonacatzli*,³³¹ “sacred ear,” and it was said that “it inebriates like mushrooms” (Sahagún). The dried flowers were smoked together with tobacco (*Nicotiana tabacum*) (Díaz 1979, 94*). Today, the flowers are used in Mexico as a spice for cacao drinks (see *Theobroma cacao*) and are known as *hueynacatzli* (Ott 1993, 406*). It has been suggested that this plant is the still unidentified Aztec inebriant **poyomatli** (Díaz 1979, 94*).

***Cymbopogon densiflorus* (Stendl.) Stapf**

(Gramineae)

This perennial plant is found in the Congo, Gabon, and Malawi (cf. **madzoka medicine**). Medicine men in Tanganyika used to smoke an extract of the leaves of this citronella, which have a lemon scent, either alone or mixed with tobacco (*Nicotiana tabacum*), in order to induce divinatory dreams so that they could predict the future (von Reis and Lipp 1982, 10*). The leaves were used by magicians in central Africa (Krause 1909, 4). The genus *Cymbopogon* is rich in essential oils (Schultes and Hofmann 1992, 41*). The **essential oil** of *C. densiflorus* has been chemically investigated, and it does not contain any psychoactive compounds (Da Cunha 1972; Koketsu et al. 1976).

Literature

- Da Cunha, A. P. M. A. 1972. Estudio químico e cromatográfico de óleo essencial de *Cymbopogon densiflorus* (Stendl.) Stapf, de Angola. *Anais da Academia Brasileira de Ciências* 44 suppl.: 285–88.

- Krause, M. 1909. Die Gifte der Zauberer im Herzen Afrikas. *Zeitschrift für experimentelle Pathologie und Therapie* 6:1–4.

***Cyperus* spp.**

(Gramineae-Poaceae)—sedges, piri-piri

The Amazonian Sharanahua Indians use a *Cyperus* species that has been infested with the fungus *Balansia cyperi* Edgerton as an **ayahuasca** additive. This fungus is related to ergot (*Claviceps purpurea*) and contains as yet unidentified **ergot alkaloids**. Many species of *Cyperus* that are used ethnogynecologically appear to be infested with this or another fungus of the genus *Balansia* (Ott 1993, 396*).

The Ecuadoran Shuar, Achuar, and Aguaruna use various *Cyperus* species that they call *piri-piri* (including *C. articulatus* L., *C. odoratus* L., and *C. prolixus* Humb. et Kunth) not just as ayahuasca additives but also as psychoactive substances in their own right. Some Shuar shamans (*uwishin*) drink a tea made from the root that serves them in place of ayahuasca when they are making diagnoses. The tea enables them to enter into trance and communicate with the dead (Bennett 1992, 490, 492*). The neighboring Secoya utilize *piripiri* to dispel evil spirits and to induce labor (Cipoletti 1988). The Jívaro add *Cyperus* extracts to their drinking tobacco (see *Nicotiana tabacum*). The women of the Achuar Jívaro use the rhizome of the species *Cyperus prolixus* H.B.K., infested with *Balansia cyperi* Edgerton, to induce labor (Lewis and Elvin-Lewis 1990). The species *Cyperus articulatus* and *Cyperus prolixus*, when infested with *Balansia cyperi*, contain as yet unidentified **ergot alkaloids** (Plowman et al. 1990).

In Venezuela, *Cyperus articulatus* L.—like other psychoactive plants (e.g., *Brugmansia* spp., *Iochroma fuchsioides*)—is known as *borrachera*, “inebriating agent,” because of its psychoactive effects. In El Salvador, the plant finds folk medicinal use as an analgesic for treating tooth-aches (von Reis and Lipp 1982, 15*).

Literature

Cypripedium calceolus (Willd.) Correll var. *pubescens*

[syn. *Cypripedium calceolus* L., *Cypripedium luteum* Ait. var. *pubescens* Willd., *Cypripedium parviflorum* Willdenow, *Cypripedium pubescens* Willd.]

(Orchidaceae)—yellow lady’s slipper

The North American Menominee Indians added this orchid to their sacred bundles to promote supernatural dreams (Moerman 1986, 604*). This possibly psychoactive plant was utilized by the neighboring Cherokee as a sedative and analgesic. The American colonists used the root as a substitute for the sedative valerian (*Valeriana officinalis*) to treat nervousness, hysteria, and insomnia (Emboden 1976, 166*; Millspaugh 1974, 683 f.*; Veit 1992, 1123). The aboveground parts of this orchid, which is now protected by law, probably contain cypripedine and similar chinones. To date, no investigations of the root have been carried out (Veit 1992, 1123).

Veit, Markus. 1992. *Cypripedium*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:1122–24. Berlin: Springer.

Delphinium consolida L.

[syn. *Consolida regalis* S.F. Gray, *Delphinium nudicaule*]

(Ranunculaceae)—larkspur

The Mendocino Indians of California regarded this plant, a species introduced from Europe that is closely related to the common larkspur (*Delphinium elatum* L.), as a narcotic. It is questionable whether the plant does in fact have psychoactive properties. Only toxic glycosides and aconitine-like alkaloids (delphinium alkaloids) have been found in the genus (Ott 1993, 407*; Roth et al 1994, 296*). Other *Delphinium* species were used as ceremonial medicine (Moerman 1986, 150*). In the Himalayas, leaves of *Delphinium brunonianum* are mixed with *Nicotiana rustica* and smoked (Atkinson 1989, 756*).

The Cappella Indians of California used the root of *Delphinium consolida* L. as a sleeping aid for children (Emboden 1976, 160*). It contains aconitine-like diterpene alkaloids, delphinine, delphinedin, and ajacine (Emboden 1979, 176*; Wren 1988, 167*). The diterpenoid alkaloid tricornine occurs in a very rare Californian species, *Delphinium tricornne* Michx. (Pelletier and Bhattacharya 1977).

Literature

Pelletier, S. William, and J. Bhattacharya. 1977. Tricornine, a new diterpenoid alkaloid from *Delphinium tricornne*. *Phytochemistry* 16:1464.

Dictyoloma incanescens DC.

(Rutaceae)—tinquí

The bark of this tree contains *N,N*-dimethyl-5-methoxytryptamine (= **5-MeO-DMT**) (Pachter et al. 1959*). It may be suitable as an ingredient in **ayahuasca analogs**. 5-MeO-DMT was first discovered in this plant.

Dictyonema sp. nov.

(Basidiolichenes, Dictyonemataceae)—lichen

The Waorani, who live in the Ecuadoran region of Amazonia, appear to have a psychoactive use for this lichen. It is said that the Waorani shamans formerly called the lichen *nenendape* and used it as a ritual entheogen (Davis and Yost 1983). Mixed with several unidentified mosses (Bryophyta) known as *quiguiwai*, the lichen was made into a tea that a shaman would drink when he wanted to cast a spell over or magically kill a person (Davis and Yost 1983, 163, 170, 209*). To date, only one other lichen has been reported to have psychoactive effects (cf. **Lichen non ident.**).

Sedges (*Cyperus* spp.) are occasionally infested by fungi that can introduce psychoactive metabolites into the plant material. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

Many species of larkspur (*Delphinium* spp.) are cultivated as ornamentals.

The seeds of the South American tree *Dictyoloma incanescens*, in which 5-MeO-DMT was first demonstrated to occur naturally.

Literature

Davis, E. W., and J. A. Yost. 1983. Novel hallucinogens from Ecuador. *Botanical Museum Leaflets* 29 (3): 291–95.

Dimorphandra parviflora

(Leguminosae)

The seeds of this Brazilian tree are used to prepare *paricá snuffs* (cf. ***Virola* spp.**). The seeds likely contain alkaloids and may have psychoactive effects (Ott 1993, 407 f.*). It is possible that the botanical name is incorrect or out of date.

Dioscorea composita Hemsl.

(Dioscoreaceae)—barbasco, camotillo

This tuberous plant is alleged to have psychoactive effects:

The camotillo induces not an inebriation but rather a latent semiconscious state that does not manifest itself until long after consumption. Affected persons become indifferent to their surroundings and external impressions. Thinking becomes restricted and is typically concerned with an event that lies far back in their life that they, in the manner of a mono-maniac, continually attempt to reconstruct in their daydreams. (V. Reko 1938, 191*)

It is said that Empress Charlotte of Mexico was robbed of her wits by this agent (cf. ***Datura innoxia***).

In Malaysia, the root tuber of a wild yam species (*Dioscorea triphylla* Lam. [syn. *Dioscorea daemona* Roxb., *Dioscorea hirsuta* Blume]), known locally as *gadong*, is attributed with narcotic powers. A hallucinogenic paste is mixed from the green shoots, opium (cf. ***Papaver somniferum***), seeds of ***Datura metel***, and the green inner bark of *Glycosmis citrifolia* (Rutaceae) (Gimlette 1981, 220, 222*).

Dioscorea tubers are occasionally used in **beer** brewing.

Elaeophorbia drupifera (Thonn.) Stapf

(Euphorbiaceae)—ayañ beyem

This little-known African spurge may have psychoactive effects (Schultes and Hofmann 1980, 367*). In West Africa, the herbage is used to treat animal bites and as a purgative (Ayensu 1978, 123*). The latex of the fresh plant is occasionally dripped into the eyes of initiates of the Bwiti cult in order to induce more powerful visions (see ***Tabernanthe iboga***).

Ferraria glutinosa (Bak.) Rendle

(Iridaceae)—gaïse noru noru

The San, or !Kung Bushmen, of the western Kalahari Desert conduct collective healing dances in which they strive to attain an ecstatic trance state. The dancers achieve the healing trance (*kia*) by dancing for hours, sometimes in combination with the consumption of *dagga* (***Cannabis sativa***) or the plant they call *gaïse noru noru* (also called **!kaishe**) (Dobkin de Rios 1986). A drink concocted from the root was apparently used more often in earlier times. One Bushman provided the following

description of its effects:

Everybody at the dance, every man at the dance, drank it. . . . Anybody who danced would take it. The thing is that those who hadn't reached *kia* yet would drink more than those who had already reached *kia*. We elders who had experienced *kia* long ago would just drink a little of the preparation. . . . You start to feel something moving around in your stomach, in your chest, and in your back, a pulsating feeling in your back like a jabbing. . . . You feel your front spine starting to pulsate with your heartbeat and starting to tremble. . . . The reason I say this *gaise noru noru* is powerful is because you just didn't take it. You had to be washed, and you had to be fed certain foods. Certain *[sic]* foods were prohibited to you, and meat that was hunted, the blood of it, was rubbed on you. Then you were washed again with something else. All that is associated with this *gaise noru noru*. And that's why I say it was powerful. (In Katz 1982, 284, 286, 293)

It is possible that the plant used to be smoked or dropped in a tortoise shell onto hot coals and the smoke inhaled (Winkelman and Dobkin de Rios 1989, 56). The root contains substances that have been little studied but may possibly have hallucinogenic or psychoactive effects. Other species of the genus *Ferraria* and related plants have potent toxic properties (Winkelman and Dobkin de Rios 1989, 54).

The botanical identification of *gaise noru noru* as *Ferraria glutinosa* has been occasionally called into question but does appear to be correct (Dobkin de Rios 1984, 205, 208; 1986). The ethnomusicologist Richard Katz has reported another plant, called *gwa*, that was used in a drumming dance to induce *kia*. Unfortunately, this plant has not been botanically identified (Dobkin de Rios 1984, 205 f.). The Bushmen may also have used other plants to induce *kia*: *Albizia anthelmintica* A. Brongn. (Leguminosae), *Cassia* spp. (Leguminosae), *Cissampelos mucronata* A. Rich (Menispermaceae; contains psychoactive compounds), *Loranthus oleaefolius* Cham. et Schlectend. (Loranthaceae; said to contain **scopolamine**), and *Plumbago zeylanica* L. (Plumbaginaceae). The ethnographic literature, however, contains references only to folk medicinal uses (Winkelman and de Rios 1989, 54 f.). It is hoped that additional research into these questions will be carried out.

This rock art by an ancestor of the Bushmen in Nicosasanatal (South Africa) depicts the collective dance of ecstasy in which *Ferraria glutinosa* and other psychoactive plants were used. (From Müller-Ebeling 1991)

Botanical illustration of *Gelsemium sempervirens*. (From Köhler's *Medizinal-Pflanzen*, 1887)

Only the signs pointing toward a Mapuche settlement (southern Chile) recall the endangered *keule* or *queule* tree (*Gomortega keule*), the mysterious plant from which the locale took its name.

***Gaultheria* sp.**

(Ericaceae)—borrachera

An herbarium specimen of an unknown *Gaultheria* species collected by J. A. Steyermark in Venezuela in 1971 bears a note stating that this member of the Heath Family, closely related to ***Pernettya* spp.**, is known as *borrachera*, “drunken maker” (von Reis and Lipp 1982, 227*). In Chile, a number of different *Gaultheria* species are used to manufacture **chicha**. In North America, *Gaultheria procumbens* L. (mountain tea, Canadian tea, Labrador tea) is used as a tea substitute (Lewin 1980 [orig. pub. 1929], 352*). The leaves contain **essential oils** and gaultherine (Roth et al. 1994, 367*).

***Gelsemium sempervirens* (L.) Jaume St.-Hil.**

[syn. *Gelsemium nitidum* Michx.]

(Loganiaceae)—Carolina jessamine

This aromatic wild jasmine is from North America, where Indians have long used it as a medicinal plant (Rätsch 1991a, 146*). The Aztec-speaking peoples of Mexico call this yellow-flowered climber *xomil-xihuite*, “paralyzing poison.” The neighboring Otomí Indians know it as *beho-sito*, “glass coffin.” The root was allegedly used as a poison in trials by ordeal. The effects are said to be quite drastic: “The person who has been poisoned enters a paralyzed state while remaining fully conscious, with open eyes; they cannot move, and yet they perceive with terrible clarity all of the things that are occurring around them” (V. Reko 1938, 168*). This pattern of effects is strongly reminiscent of that of the Haitian **zombie poison**. It is said that Mexicans used to add the root to schnapps (**alcohol**) to lend it a special effect (Reko 1938, 167*).

Profound psychic alterations with strong hallucinations occur even when *Gelsemium* is used for medicinal purposes (Lewin 1980 [orig. pub. 1929], 192*). It is for this reason that *Gelsemium* has repeatedly been characterized as a psycho-active plant or even a hallucinogen (Emboden 1976, 165*; Schultes and Hofmann 1980, 367*). The entire plant, but especially the root, contains **indole alkaloids**: gelsemicine, gelsemine, gelse-dine, and sempervirine, some of the effects of which resemble those of **strychnine**. Gelsemine paralyzes the central nervous system (Blaw et al. 1979; Roth et al. 1994, 368 f.).

Literature

Blaw, M. E., M. A. Adkisson, D. Levin, J. C. Garriott, and R. S. A. Tindall. 1979. Poisoning with Carolina jessamine (*Gelsemium sempervirens*). *Journal of Pediatrics* 94:998–1001.

***Gloeospermum sphaerocarpum* Tr. et Pl.**

(Violaceae)

The Amazonian Waunana Indians drink a cold-water extract of the leaves of this plant, which they call *tamarillo*, as a “ceremonial hallucinogen” (Duke and Vasquez 1994, 81*). Additional ethnopharmacological research is required.

***Gomortega keule* (Moldenke) I.M. Johnst.**

[syn. *Gomortega nitida* Ruíz et Pavón] (Gomortegaceae)—keule

This tall tree, the only species in the Family Gomortegaceae (related to the Family Lauraceae), is

endemic to southern Chile. The Mapuche Indians call it *keule*, *queule*, *queuli* (pronounced kay-ulay), *linge*, or *hualhual* (literally “vicinity”) and may once have used it as a psychoactive substance. The round fruits have inebriating effects, especially when fresh, and may even be hallucinogenic, possibly as a result of the essential oils they contain (Schultes and Farnsworth 1982, 180*). The opposite lanceolate leaves are said to contain an **essential oil** (Schultes and Hofmann 1980, 334*). A number of derivatives of methoxylated **coumarins** have been detected (D. McKenna 1995, 101*). Chemical studies of the fruits have not yet been conducted (Ott 1993, 408*).

Unfortunately, this fruit tree is very rare. It is found only in a single one-hundred-square-mile expanse (Schultes and Hofmann 1980, 334*) in the coastal area between Maule and Arauco, somewhat south of Concepción (Mösbach 1992, 79*). The tree appears to be on the brink of extinction.

The plant was first described by the Spanish botanist Don Hipólito Ruíz, who encountered it on a 1777–1788 expedition to Peru and Chile. He reported that the leaves have a sour-astringent taste and, when chewed, stick to the teeth as a result of their resin content. Rubbed between the fingers, they exude a scent reminiscent of that of rosemary and turpentine. “The beautiful fruits are as large as small chicken eggs, are shiny, have a yellow color, and invite one to eat them. But you will get a headache if you eat too many of them” (Schultes 1980, 97*).

The yellow fruits contain an extremely hard stone. They ripen toward the end of April and are used to make marmalade (Donoso Zegers 1995, 94*). They are regarded as culinary delicacies. A fishing village of the Mapuche (“earthlings”), on the coast some 50 km north of Valdivia, is named Queule after this mysterious tree. None of its residents seems to have any knowledge of the tree or of its purported psychoactive use. The fruits may formerly have been used in the preparation of **chicha**; for this reason, they are still reputed to be psychoactive.

***Goodenia* spp.**

(Goodeniaceae)—goodenia

In the ethnobotany of the Aborigines, plants of the genus *Goodenia* enjoy a certain reputation as healing and food plants as well as **pituri** or pituri substitutes (O’Connell et al. 1983, 109). The Goodeniaceae are well represented in Australia. In addition to the genus that gave the family its name, *Scaevola taccada* (pipe tree) is especially important. This bushy shrub is a typical coastal plant that grows in sandy soil. The Aborigines use the juice of the fruits as an eye remedy and as an antidote for animal stings and bites. The ends of the branches are hollow; they are used as pipes for smoking pituri (Wightman and Mills 1991, 46 f.).

In the language of the Alyawara, *Goodenia lunata* J.M. Black is called *ngkulpa ankirriyngka*. The Alyawara mix the dried leaves with plant ashes (primarily from *Ventilago viminalis* Hook.; Rhamnaceae) and chew the result. They place it in the same folk taxonomic category as wild tobacco (***Nicotiana* spp.**) (O’Connell et al. 1983, 109*). Macerations of the fresh leaves are used in a manner similar to those made from wild tobacco, namely for poisoning the watering holes of the emu (98*). When smoked or chewed, the leaves of *Goodenia lunata* appear to have mild psychoactive effects.

Literature

Wightman, Glenn, and Milton Andrews. 1991. *Bush Tucker Identikit: Common native food plants of Australia’s top end*. Darwin: Conservation Commission of the Northern Territory.

***Hedera helix* L.**

[syn. *Hedera caucasigena* Pojark, *Hedera chrysocarpa* Walsh, *Hedera helix* var. *chrysocarpa* Ten., *Hedera taurica* Carr., *Hedera helix* var. *taurica* Tobler]

(Araliaceae)—ivy

Ivy is an ancient sacred plant that was associated with the cult of Dionysos, the god of wine, inebriation, and ecstasy. Dioscorides described three types of ivy,³³² one of which bore the same name as the god, *Dionysos*. Plutarch, the philosopher, oracular priest, and disciple of Dionysos, wrote in his *Roman Questions* (112) that ivy contains “powerful spirits” that produce outbursts of madness and cramps. Ivy could induce an “inebriation without wine,” or a type of possession in those who had a natural tendency to enter ecstatic states. When ivy leaves are added to wine (see *Vitis vinifera*), the resulting mixture is able to produce a delirium, “a confusion that can otherwise be produced only by henbane” (see *Hyoscyamus niger*). The Roman naturalist Pliny the Elder also wrote of the psychoactive effects:

The little-studied Australian *Goodenia lunata* is used as a **pituri** substitute. (Wild plant, photographed in Tasmania)

Many authors of antiquity characterized ivy (*Hedera helix*) as a psychoactive plant. (Wild plant, photographed in northern Germany)

[Ivy] confuses the mind, cleanses, when drunk in excess, the head; taken internally, it damages the nerves, but is healthy for these same nerves when applied externally. . . . As a drink, [all species of ivy] are diuretic, soothe headaches, especially in the brain. . . . The berries, which are the color of saffron, provide certain protection against inebriation when they are taken beforehand as a drink. (Pliny 24.75/78)

Ivy has been linked to the Dionysian ecstasy of the maenads (= female bacchantes, bassarides; cf. *Vitis vinifera*) primarily through the work of Robert Graves and his book *The White Goddess*. It has been rumored that Graves wrote this book while under the influence of **psilocybin**. Otherwise, the ancient sources would be difficult to interpret in this manner:

October was the season of the Bacchanal revels of Thrace and Thessaly in which the intoxicated Bassarids rushed wildly about on the mountains, waving the fir-branches of Queen of Artemis (or Ariadne) spirally wreathed with ivy—the yellow-berried sort—in honour of Dionysus . . . , and with a roebuck tattooed on their right arms above the elbow. They tore fawns, children and even men to pieces in their ecstasy. The ivy was sacred to Osiris as well as to Dionysus. Vine and ivy come next to each other at the turn of the year, and are jointly dedicated to resurrection. . . . It

is likely that the Bassarids' tipple was “spruce-ale,” brewed from the sap of silver-fir [*Abies cephalonica* Loud.] and laced with ivy; they may also have chewed ivy-leaves for their toxic effect. Yet the main Maenad intoxicant will have been *amanita muscaria*. (Graves 1966, 183*)

The botanical identity of the inebriating ivy is a total mystery: “However, the Dionysian ivy was not the one native among us but the northern Indian with the yellow berries, of which it is said that it grows only on the mountain of Meros, near Indian Nysa” (Duerr 1978, 213*). This may refer to Himalayan ivy (*Hedera nepalensis* K. Koch [syn. *Hedera himalaica* Tobl.]), which bears orange-yellow fruits.

Some subjects who have smoked the dried leaves have reported them to be inebriating.

Ivy leaves contain glycosides, inositol, chlorogenic acid, hedera tannic acid, malic acid, formic acid, and triterpene hedera saponines (α -hedrine), as well as the trace elements arsenic, zinc, copper, manganese, iodine, lithium, and aluminum. The alkaloid emetine has been found in Egyptian specimens (Horz and Reichling 1993, 399). In the toxicological literature, it is noted that “a 3-year-old child ate a large amount and had hallucinations” (Roth et al. 1994, 391*). To date, however, no truly inebriating substances have been found in ivy. Francesco Festi has worked extensively on the botany and phytochemistry of ivy and has not found the slightest evidence of the presence of psychoactive compounds (F. Festi, pers. comm.).

It may be that the ancient word for ivy was a catchall phrase for climbing plants. There are vines (*Convolvulus tricolor*) in the Mediterranean region whose seeds contain lysergic acid derivatives. Or “ivy” may have been a designation for another plant that is no longer known or able to be identified but which had potent inebriating effects and contained psychoactive compounds.³³³ Imagine that a medical historian of the future finds an article written in the present that notes, “Grass has potent effects when smoked.” He might think that people were smoking grass from their lawns as an inebriant. If he were to smoke it himself, he would find that it produces no such effects. How would he know that “grass” is a common and generally understood name for hemp (*Cannabis sativa* or *Cannabis indica*) and for its female flowers?

Literature

Horz, Karl-Heinrich, and Jürgen Reichling. 1993. *Hedera*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:398–407. Berlin: Springer.

Helichrysum foetidum (L.) Moench

(Compositae: Asteraceae)—stinking strawflower

It is said that the magician-physicians of the African Zulu made a powder of this strawflower that they inhaled or smoked in order to induce a divinatory trance. This vague information comes only from a note belonging to an herbarium specimen of this plant and has no other ethnographic support (von Reis and Lipp 1982, 303*). *Helichrysum stenopterum* is said to have been used in the same manner (de Smet 1996, 142*; von Reis and Lipp 1982, 303*). Various derivatives of phloroglucinol have been detected in this plant (Jakupovic et al. 1986). Other members of the genus have yielded **coumarins** and **diterpenes** (D. McKenna 1995, 101*; Schultes and Hofmann 1992, 44*). *Helichrysum serpyllifolium*, which has been characterized as “Hottentot tea,” is drunk as an infusion (Lewin 1980 [orig. pub. 1929], 352*).

One of the difficult-to-identify species of strawflower (*Helichrysum* sp.).

Literature

Jakupovic, J., J. Kuhnke, A. Schuster, M. A. Metwally, and F. Bohlmann. 1986. Phloroglucinol derivatives and other constituents from South African *Helichrysum* species. *Phytochemistry* 25:1133–42.

Helicostylis tomentosa (Poepp et Endl.) Rusby

(Moraceae)—takini

In Amazonia, the inner bark of this tree, known locally as *misho chaqui*, is said to be used as a hallucinogen. Animal tests have shown that rats exhibit the same symptoms after ingesting this plant as they do when inebriated with ***Cannabis*** (Buckley et al. 1973; Duke and Vasquez 1994, 86*).

The magicians of the Caribs and Africans living in the wilds of Guyana used various species of the genus *Helicostylis* (*H. pedunculata* Benoist) to induce visions (Schultes and Farnsworth 1982, 184*). The reddish sap of this sacred tree is made into a raw drug known as *takini* (D. McKenna 1995, 101*; Schultes and Hofmann 1992, 45*).

Literature

Buckley, J. P., R. J. Theobald Jr., I. Cavero, et al. 1973. Preliminary pharmacological evaluation of extracts of takini: *Helicostylis tomentosa* and *Helicostylis pedunculata*. *Lloydia* 36:341–45.

Hieracium pilosella L.

(Cichoriaceae; Compositae/Asteraceae)—hawkweed, hairy hawkweed, long-haired hawkweed

This plant was originally native to Eurosiberia but is now common in Switzerland and has spread even to North America (Lauber and Wagner 196, 1204*).

In Denmark, the yellow-blossomed herbage, known as *håret høgeurt*, is smoked in joints. One gram is said to produce good psychoactive or euphoriant effects (Larris 1980). The plant is known as hawkweed in the United States and was used by the Iroquois for ethnomedicinal purposes (Ott 1993, 409*). The leaf rosette (without the roots) of the blooming plant, which is common to meadows and moorlands, is collected and dried in the shade. It is sold in pharmacies and herb shops under the names *herba auriculae muris* and *hieracii pilosellae herba*. It contains tannins, flavonoids, and umbelliferone. It is used in folk medicine to treat and strengthen the eyes (as a tea or eyewash). The German name for the plant, *habichtskraut* (“goshawk’s weed”), is derived from the belief that goshawks receive their excellent vision from this plant (Pahlow 1993, 146*). This belief may be rooted in Old Germanic shamanism. In Germany, the plant formerly was reputed to offer magical protection against witches and magic (Perger 1864, 133*). Also known as little mouse ears or nail weed, the plant is said to be harmful to sheep (Chamisso 1987, 228*).

Today, hawkweed is usually sold in German pharmacies under the name *pilosellae herba*. When I smoked about 1 g, I felt slightly euphoric and cannabis-like, but relatively weak, effects.

Literature

Larris, S. 1980. *Forbyde Hallucinogener? Forbyd Naturen at Gro!* 4th ed. Nimtoffe: Forlaget Indkøbstryk.

Hipomosa carnea

(Convolvulaceae)—Matacabra

This plant, which is supposedly also known as *flore* or *chalviande*, is said to be used as a hallucinogen in the coastal region of Ecuador (Alvear 1971, 23*). Whether the botanical identification given by Alvear is correct is more than doubtful. It may be that the plant being referred to is actually *Ipomoea carnea*, which is also called *matacabra* (“goat killer”) (see *Ipomoea* spp.).

Homalomena sp.

(Araceae)—ereriba

This tropical araliaceous plant is said to have been used as a hallucinogen in Papua New Guinea. The leaves of this plant (possibly *Homalomena belgraveana* Sprague) were ingested together with the bark of *Galbulimima belgraveana* (F. Muell.) Sprague³³⁴ [syn. *Himantandra belgraveana* F. Muell.] and the root of *Zingiber zerumbet* (L.) Sm. [syn. *Alpinia speciosa*] (see *Zingiber officinale*). This allegedly produced strong visions followed by intense dreams (Barrau 1958). Since this plant is known locally as *maraba*, the same name given to *Kaempferia galanga* and *Galbulimima*, the botanical identity of this purported hallucinogen is still in question. Chemical studies are lacking (Schultes and Hofmann 1995, 45*).

In former times, hawkweed (*Hieracium pilosella*) was hung in many German houses as a protection against witchcraft (woodcut from Tabernaemontanus 1731)

Dried hawkweed (*Hieracium pilosella*) herbage is used as a mild acting marijuana substitute.

Many species of the genus *Homalomena*, which is found throughout Southeast Asia, have not yet been botanically described, even though they are likely used for ethnomedicinal purposes (a *Homalomena* sp. from Malaysia).

The species *Homalomena cordata* Schott and *H. versteegii* Engler are used in New Guinea for rain and love magic, respectively (Ott 1993, 409*). Chemical studies of these species are also lacking (D. McKenna 1995, 101*). The ginger-scented rhizome of the East Indian species *Homalomena aromatica* was once used as an aphrodisiac (Hirschfeld and Linsert 1930, 180*). In Papua New Guinea, an ointment is made from the stem of a *Homalomena* species known as *iva iva* together with coconut oil (cf. *Cocos nucifera*) (von Reis and Lipp 1982, 10*).

Literature

Barrau, Jacques. 1958. Nouvelles observations au sujet des plantes hallucinogènes d'usage autochtone en Nouvelle-Guinée. *Journal d'Agriculture Tropicale et de Botanique Appliquée* 5:377–78.

Huperzia selago (L.) Bernh. ex Schrank et Mart.

[syn. *Lycopodium selago* L., *Urostachys selago* (L.) Herter]

(Lycopodiaceae)—devil's claw

This club moss (cf. *Lycopodium clavatum*, *Lycopodium* spp.), which is found in circumpolar and Antarctic regions and is also known as fir club moss, heckenysop, devil's clover, and selago, is an ancient Celtic-Germanic magical plant that was highly esteemed among the Druids:

It was gathered with great care, no iron instrument was allowed to touch it, even bare hands were unworthy of this honor. A special covering, or “sagus,” was used with the right hand. This covering had to be consecrated and secretly received from a holy personage with the left hand. It could be collected only by a white-clad druid with bare feet that had been washed in clear water. Before he collected this plant, he had to make an offering of bread and wine; after this, the plant was carried away from the place in which it grew in a new, clean cloth. In the “Kadir Taliesin,” selago is referred to as “the gift of god,” and in modern Welsh as the “gras duw,” or the “grace of god.” This plant was viewed primarily as an amulet that protected its possessor against all harm. (Schöpf 1986, 58*)

The herbage contains 0.1 to 0.9% total alkaloids, which have been characterized as “selagine” and

comprise lycopodines, arifoline, pseudoselagine (= isolycodoline), selagine, and lycodoline. The entire plant can induce vomiting, dizziness, wooziness, and unconsciousness in humans (Roth et al. 1994, 407*).

***Iresine* spp.**

(Amaranthaceae)

Various species of this genus are used in South America as **ayahuasca** additives. Some species, under the name *cimora* or *timora*, are added to San Pedro drinks (see *Trichocereus pachanoi*). *Iresine* species also are said to be the main ingredient or at least one of the main ingredients in the mysterious South American magical drink **cimora** (Ott 1993, 409*). Unfortunately, chemical studies are lacking.

Betacyanin has been detected in the herbage of the Caribbean *Iresine herbstii* Hook. f. (Wong 1976, 119*).

***Iryanthera juruensis* Warb.**

(Myristicaceae)—forest cacao

This small tree, also known as *cedro ajua*, *huapa*, *pucuna huapa* (“blowpipe huapa”), or *sacha cacao* (“forest cacao”), provides a resin that is used in the manufacture of **snuff**. It may be psychoactive. Active substances have not yet been detected (Ott 1993, 409*).

The Amazonian Indians (Venezuela, Colombia, Peru, Brazil) produce a **snuff** from *Iryanthera macrophylla* (Benth.) Warb. that may be psycho-active. One analysis found **5-MeO-DMT** in this plant material (Schultes 1985, 131); later studies have been unable to confirm this (Ott 1993, 409*).

The Bora and Witoto formerly used *Iryanthera ulei* Warb. as an oral hallucinogen. 5-MeO-DMT has also been found in the bark of this plant. *Iryanthera longiflora* Ducke is said to be a hallucinogen as well (Davis and Yost 1983, 186*).

Literature

Schultes, Richard Evans. 1985. De Plantis Toxicariis e Mundo Novo Tropicale Commentationes XXXV: Miscellaneous notes on biodynamic plants of the northwest Amazon. *Journal of Ethnopharmacology* 14:125–58.

Devil’s claw (*Huperzia selago*) has certain psychoactive effects and is an ancient Celtic-Germanic ritual plant. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Some species of the genus *Iresine*, from the Family Amaranthaceae, are used in the manufacture of South American shamans' drinks (ayahuasca, cimora).

***Jasminum* spp.**

(Oleaceae)—jasmine

The flowers of several jasmine species are the source of the aromatic jasmine oil (oleum jasmini), which contains eugenol and plays an important role in the perfume industry (cf. **essential oils**). Moreover, two African species have been reported to have psychoactive effects. In Abyssinia, the leaves of *Jasminum floribundum* R. Br. (known as *hab el tsalim*) are used as an “inebriating agent”; the leaves of *Jasminum abyssinicum* R. Br. are used in Eritrea for the same purpose (Hartwich 1911, 811*). The constituents are unknown. ***Gelsemium sempervirens*** is also known as yellow jasmine.

***Jatropha grossidentata* Pax et Hoffm.**

(Euphorbiaceae)—purgative nut

In the shamanism of the Ayoré Indians of Paraguay, the dried root of the plant, known as *caniroja*, is smoked in order to communicate with animal spirits and to initiate novices into shamanism. The shamans (*naijna*) occasionally climb into a quebracho tree (***Aspidosperma quebracho-blanca***) and sit in its crown, where they smoke the roots. In this way, they are able to speak directly to the animals (Schmeda-Hirschmann 1993, 108, 109*). During a self-experiment under the supervision of one of the last Ayoreo shamans, no psychotropic effects of any kind could be observed. However, rhamnofolane and **diterpenes** have been found in the roots (Jakupovic et al. 1988; Schmeda-Hirschmann et al. 1992), which require further investigation (the active principle in ***Salvia divinorum*** is also a diterpene). In South America, other *Jatropha* species are regarded as aphrodisiacs (Schultes 1980, 104*). In northern Peru, *Jatropha macrantha* Arg. is known locally as *huanarpo macho* and is one of the most famous aphrodisiacs for men. Further study is needed to ascertain whether this species has psychoactive effects.

Literature

Jakupovic, J., M. Grenz, and G. Schmeda-Hirschmann. 1988. Rhamnofolane derivatives from *Jatropha grossidentata*. *Phytochemistry* 27:2997–98.

Schmeda-Hirschmann, G., F. Tschritzis, and J. Jakupovic. 1992. Further diterpenes and a lignan from *Jatropha grossidentata*. *Phytochemistry* 31:1731–35.

***Juanulloa ochracea* Cuatrecasas**

(Solanaceae)—ayahuasca

This nightshade is known in Colombia as *ayahuasca* and may possibly be utilized as an **ayahuasca** additive (Ott 1993, 410*; Schultes and Raffauf 1991, 39*). It may also have been used alone for psychoactive purposes. In the region of Limón (Costa Rica), the leaves and stems are used to treat wounds (Schultes 1978a, 192*). The alkaloid parquine (cf. ***Cestrum parqui***) has been detected in the genus, which is composed of some twelve species (Schultes 1979b, 151*; Schultes and Raffauf 1991, 39*).

***Kaempferia galanga* L.**

(newly written as *Kempferia galanga*) (Zingiberaceae)—galanga

A member of the ginger family, galanga is also known as the galgant-spice lily, resurrection lily, and *hinguru-piyali*. It is found in the tropical regions of Africa and in Southeast Asia. The very aromatic rootstock (rhizome), which often looks like a hand and is usually referred to as *maraba*, is used throughout the range of the plant as a spice and as a remedy for treating digestive ailments. *Kaempferia* has a strong, refreshing taste. In Malaysia, the root formerly was added to an arrow poison made with *Antiaris toxicaria* (Schultes and Hofmann 1995, 47*). *Kaempferia galanga* is one of the ingredients in the Indonesian spice mixture known as *jamu* (Rehm 1985) and is the main ingredient in those mixtures that are produced for tonic and aphrodisiac purposes (Macmillan 1991, 424*). In Japan, the root is sometimes used in the manufacture of **incense**. In Thailand, the root and young leaves are added to curries. The crushed root, mixed with whiskey (cf. **alcohol**), is applied as a paste to the forehead and scalp as a folk medicine for treating headaches (Jacquat 1990, 117).

The inhabitants of the area around Mount Hagen (Papua New Guinea) supposedly use or once used the rhizome as a hallucinogen, similar to ***Homalomena* spp.** (Barrau 1962). “The root is used as a spice and inebriant throughout all of Southeast Asia. . . . The rhizome induces hallucinations (without any side-effects)” (Bremness 1994, 180*). A European report states that ingestion of the powdered root produces “a surprising clarity of thought and alterations in vision” (Schuldes 1995, 46*). The rootstock is rich in **essential oils**, the composition of which is unknown. It may contain psychoactive substances (Schultes and Hofmann 1992, 47*). Reports following ingestion of the powder often indicate mild or even no effects (Schuldes 1995, 95*). This may be due to the fact that the experimenters did not use genuine *Kaempferia* roots, for *galanga* is a name that has produced much confusion. Another member of the ginger family, galgant (*Alpinia officinarum* Hance [syn. *Languas officinarum*]), is known by the name *galanga* or *little galanga*. It too is used as a spice (Norman 1991, 64*). In Germany, *Alpinia galanga* (L.) Willd. [syn. *Galanga major* Rumpf., *Maranta galanga* L., *Languas galanga* Sw.] is known by the name *large galanga root*, and *Alpinia officinarum* by the name *little galanga root* (Jacquat 1990, 118; Norman 1991, 45*; Seidemann 1993, 180*).

The packaging of a traditional Indonesian *jamu* mixture, whose main component (20%) is *Kaempferia galanga* and which also includes gingerroot (*Zingiber officinale*), licorice root (*Glycyrrhiza glabra*), and *sindora* fruits. This *jamu* is recommended as a potent aphrodisiac and tonic for both men and women. The finely crushed herbal ingredients are mixed with some lukewarm water, freshly pressed curcuma juice, and a raw egg (if desired) and drunk in the morning, preferably before breakfast. The drink, of course, should be consumed daily!

The most renowned aphrodisiac in Peru is *huanarpo macho* (*Jatropha macrantha*), which is reputed to have psychoactive effects. The raw plant material, seen here, is macerated with high-proof alcohol.

Galanga (*Kaempferia galanga*), found throughout Southeast Asia, produces a very aromatic rhizome.

Literature

Barrau, Jacques. 1962. Observations et travaux récents sur les végétaux hallucinogènes de la Nouvelle-Guinée. *Journal d'Agriculture Tropicale et de Botanique Appliquée* 9:245–49.

Jacquat, Christiane. 1990. *Plants from the markets of Thailand*. Bangkok: Editions Duang Kamol.

***Lancea tibetica* Hook. f. et Thoms.**

(Scrophulariaceae)—depgul

In Ladakh, India, the root of this plant (known locally as *depgul*) is roasted, crushed, and either smoked together with tobacco (*Nicotiana tabacum*) or drunk in milk. The product is called *berzeatsink* and is said to have potent stimulant and activating effects (Navchoo and Buth 1990, 320*).

The true galanga root (from the stock plant *Kaempferia galanga*) is only rarely found in trade. It is usually confused with the rootstock of galgant (*Alpinia galanga* [syn. *Languas galanga*], *Alpinia officinarum* [syn. *Languas officinarum*]). In this illustration from an early modern herbal, the rhizome of “large galgan” is probably identical to *Kaempferia galanga*. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Seeds and herbage of *Lagochilus inebrians*.

The South African wild dagga (*Leonotis leonurus*) in bloom.

***Lagochilus inebrians* Bunge**

(Labiatae)—intoxicating mint

This bushy mint is native to the central Asian steppes of Turkistan and Uzbekistan. It is gathered in autumn and hung on the rafters to dry over the winter. The leaves are used to make a tea that is sweetened with honey and induces a mild state of euphoria, although it also can be used as a sedative (D. McKenna 1995, 103*). In Russian folk medicine and phytotherapy, the plant is also used to treat allergies and skin diseases and to promote blood coagulation (Schultes and Hofmann 1992, 47*).

The dried material (leaves) contains up to 17% lagochiline, a diterpene alkaloid (the average is around 3%; Schultes 1970, 41*; Tyler 1966, 287*). Numerous studies are available in the Russian literature. The plant is, or at least was, listed as a natural tranquilizer in the Russian pharmacopoeia (D. McKenna 1995, 103*; Scholz and Eigner 1983, 78*).

***Leonotis leonurus* (L.) R. Br.**

(Labiatae)—lion's tail, lion's ear

This South African bush bears orange blossoms and is purported to have hallucinogenic effects (Schultes and Hofmann 1980, 367*). In Africa, it is known by the names *dacha*, *daggha*, and *wild dagga*, “wild hemp” (cf. ***Cannabis indica***). The Hottentots (Khoikhoi; Heusaquas) and Bushmen smoke the buds and leaves as inebriants (Schleiffer 1979, 93 ff.*; Schuldes 1995, 48*). This bush may be one of the inebriating plants subsumed under the name *kanna* (cf. ***kanna***, ***Mesembryanthemum* spp.**, ***Sceletium tortuosum***). The resinous leaves and the resin rubbed off or extracted from them are smoked either alone or mixed with tobacco (***Nicotiana tabacum***) (Grubber 1991, 44*). In northern California, many people now smoke the leaves and orange flowers. Chemical studies are lacking (Ott 1993, 411*). The rather bitter-tasting smoke of flowers grown in California has a mild psychoactive effect reminiscent of that of both ***Cannabis*** and ***Datura***. In eastern South Africa, the closely related species *Leonotis ovata* is reportedly used for the same purpose (Schleiffer 1979, 93*).

Another closely related species, *Leonotis nepetaefolia* (L.) R. Br., is used in Caribbean folk medicine. The leaves and flowers of this species have yielded bound oils, bitter principles, **diterpenes**, **coumarins**, and resins (Argueta V. et al. 1994, 229*; Puroshothaman et al. 1974a, 1974b; Wong 1976, 136*). In Mexico, this plant is known as *flor de mundo*, “world flower,” or *mota*. The name *mota* is normally used to refer to marijuana (cf. ***Cannabis indica***); this may indicate that the plant is used as a marijuana substitute. The extract of this plant has antispasmodic effects and appears to inhibit acetylcholine and histamine (Argueta V. et al. 1994, 229*).

Literature

———. 1974b. Nepetaefolinol and two related diterpenoids from *Leonotis nepetaefolia*. *Journal of the Chemical Society, Perkin Transactions 1* (1): 2661.

Lichen non ident.

(family non ident.)—jievut hiawsik

The Pima and O’odham (= Papago) Indians both use the name *jievut hiawsik*, “earth flower,” to refer to lichens that live on rocks. One species, which unfortunately has not been identified botanically, exudes a strong scent, has an ashen gray color, and lives on rocks and old, dry wood. The lichen once had a religious significance. It was mixed with tobacco (*Nicotiana tabacum*) and smoked during the summer dances (cf. **kinnikinnick**). It is said to have an effect similar to that of marijuana (*Cannabis indica*) and to “make young men crazy.” The Pima believe that a man can conquer any woman after he has smoked the lichen (Curtin 1984, 77). Until now, lichens have been almost completely unknown as psychoactive substances in ethno-pharmacology (cf. *Dictyonema*). Recently, beard lichens have found use as **incense**.

Literature

Curtin, L. S. M. 1984. *By the prophet of the earth: Ethnobotany of the Pima*. Tucson: University of Arizona Press.

Indian tobacco (*Lobelia inflata*), with flowers and fruits.

***Limmonium macrorhabdos* O. Kuntze**

(Plumbaginaceae)—staspak

In Ladakh, the sun-dried leaves of this plant, known as *staspak*, are drunk in the form of a cold-water extract (the powder is left in the water for about one week). The drink, called *staspakchek*, is said to produce strong inebriating effects and even to be dangerous (Navchoo and Buth 1990, 320*).

***Lobelia inflata* L.**

(Campanulaceae)—Indian tobacco, pukeweed This delicate lobelia is native to North America, where it is known by the names *pukeweed* and *Indian tobacco*. The plant was used ceremonially by the North American Crow Indians and played a role in the love

magic of the Pawnee and Mesquakie (Ott 1993, 411*). *Lobelia* is one of the ingredients in **kinnikinnick** and other **smoking blends**. The Indians also smoked the plant medicinally for asthma, bronchitis, irritations of the throat, and coughs. The herbage is finding increasing use as a tobacco substitute (see *Nicotiana tabacum*), especially among people who are trying to quit tobacco. Smoked by itself, lobelia is clearly psychoactive. It has both sedative and stimulating effects, which can surprise those who have no prior knowledge of the plant.

The herbage contains more than twenty piperidine alkaloids. The main alkaloid, α -lobeline, is a **nicotine** antagonist (Szôke et al. 1993) and is used as a nicotine substitute for medical withdrawal (Krochmal et al. 1972, 216). The α -lobeline content is almost twice as high in cultivated plants as in wild specimens (approximately 1.05 to 2.25% of dry weight; Krochmal et al. 1972, 216).

In Mexico, a closely related species, *Lobelia cliffordiana* L., is numbered among the *hierbas locas*, the “herbs that make one crazy” (Martínez 1987, 427*; Reko 1938, 185*). It too may be suitable as an inebriating ingredient in **smoking blends**. An Asian species, *Lobelia nicotianaefolia*, is known as *rasni* or “wild tobacco.” The long, tobacco-like leaves of this plant, which can grow up to 3 meters in height, are said to be poisonous but can be smoked (Macmillan 1991, 430*). The name *Lobelia longiflora* L. is an outdated synonym for *Hippobroma longiflora* (L.) G. Don, which is one of the ingredients in the South American **cimora** drink (Zander 1994, 312*).

Literature

Szôke, É., A. Krajewska, and A. Nesmélyi. 1993. NMR characterization of alkaloids from *Lobelia inflata*. *Planta Medica* 59 suppl.: A704.

Lobelia tupa L.

(Campanulaceae)—tupa, devil’s tobacco

This large lobelia, the flowers of which are fiery red, is found in the wild in South America in the Andes and their foothills. It is cultivated throughout the world as an ornamental. The most common name for this conspicuous plant is *tupa*, which can be translated as “spot,” “point,” “sunspot” or even “mark of disgrace.” Many inhabitants of the Andes consider this campanulaceous plant to be toxic and avoid it. Since it is often called *tabaco del diablo* (“devil’s tobacco”), it was once thought that it might have psychoactive or even hallucinogenic effects (Schultes and Hofmann 1992, 47*). However, there is no ethnographic evidence indicating that devil’s tobacco is or ever was used ritually for psychoactive purposes.

In Chile, *Lobelia tupa* and several other species are referred to as *trupa*, *tupa*, or *tabaco del diablo* (*Lobelia excelsa* Bonpl., *Lobelia polyphylla* H. et A.; cf. Mösbach 1992, 105*). The Mapuche use the name *tupa* to refer to a related species, *Lobelia salicifolia* Sweet, which they use as a medicinal plant to treat flu (they make a tea from the leaves). The latex is said to induce severe inflammation of the eye and of the digestive tract, together with vomiting and diarrhea (Houghton and Manby 1985, 100*).

Lobelia tupa has been shown to contain piperidine alkaloids; these do not, however, have any unequivocal psychoactive effects. As with ***Lobelia inflata***, the principal alkaloid in the leaves is α -lobeline (Kaczmarek and Steinegger 1958). Lobelamidine and norlobelamidine are also present (Kaczmarek and Steinegger 1958; Schultes and Farnsworth 1982, 177*). Smoking the dried leaves strongly stimulates the production of saliva and an immediate stimulation occurs that is similar to that produced by *Lobelia inflata* and ***Nicotiana tabacum***. The white smoke is relatively easy to inhale and produces almost no irritation (cf. **smoking blends**).

Literature

Kaczmarek, F., and E. Steinegger. 1958. Untersuchungen der Alkaloide von *Lobelia tupa* L. *Pharm. Helvetica Acta* 33:257–62.

***Lotus wrightii* (A. Gray) Greene**

(Leguminosae)—deervetch, Wright’s horn clover

The Navajo Indians regard this plant as a “life medicine” and use it ritually in hunting (Vestal 1958, 32*). The Apache used the roots as an inebriating additive for their homemade beer (see **beer**). It is possible that the root cortex contains alkaloids, e.g., tryptamines, which are also found in many other plants of the same family.

***Lucuma salicifolia* H.B.K.**

(Sapotaceae)—zapote borracho

The Aztecs of Mexico called the fruits of this Sapodilla Family species, the flesh of which is bright yellow, *cozticzápotl* (“dizzy-making fruit”), *cochiz tzapotl*, *zapote somnífero*, or *zapote blanco*. It is said that excessive consumption of the fruits can result in a peculiar state of inebriation not unlike that produced by alcohol. This is why the fruit is now known primarily as *zapote borracho*, “drunken zapote” (Martínez 1987, 1154*). Mexican farmers are said to use it to produce a state of inebriation. “In Oaxaca and Puebla, zapote fruits are purchased by barkeepers (as well as by housewives) and added to brandy (as we do with other fruits and rum). They impart a beautiful, cognac-like color to cheap alcohol and are said to make this ‘stronger,’ i.e., the inebriating effects that the drinker desires are manifested more rapidly than after the consumption of normal brandy” (V. Reko 1938, 151 f.*).

Both *zapote blanco*, “white zapote,” and *zapote dormilte*, “sleep-inducing zapote” (*Casimiroa edulis* Llave et Lex. [syn. *Casimiroa sapota* Orst., *Fagara bombacifolium* Krug et Urbán, *Zanthoxylum bombacifolium* A. Rich, *Zanthoxylum aracifolium* Turcz.]; Rutaceae), have also been identified as *cozticzápotl* (Argueta V. et al. 1994, 1413*). They also are reputed to have sedative and hypnotic effects. The seeds, burned to ashes, were ingested by the Aztecs as a sleeping agent (Navarro 1992, 94*). Even today, a tea made from the leaves is used in Mexican folk medicine for sleep disorders and to regulate and stimulate dreaming (Argueta

V. et al. 1994, 1413*). The seeds of *Casimiroa edulis* have been found to contain the alkaloids *N*-benzoyltyramine, methylhistamine, casimiroin, fagarine, and casimiroidin as well as **coumarins** (**scopoletin**) (Aebi 1956; Argueta V. et al. 1994, 1414*; Emboden 1979, 6, 173*). The leaves contain methylhistamine and dimethylhistamine as well as rutin (Argueta V. et al. 1994, 1414*). The Aztec name *cozticzápotl* has also been interpreted as referring to ***Calea zacatechichi*** (Lara Ochoa and Marquez Alonso 1996, 123*).

Literature

Aebi, A. 1956. The isolation of casimiroidin from the seeds of *Casimiroa edulis*. *Helvetica Chimica Acta* 39:1495.

***Lupinus* spp.**

(Fabaceae)—lupines, wolf’s beans

Several species of lupine (*Lupinus albus* L., *L. angustifolius* L., *L. luteus* L.) are found in the Mediterranean region. In ancient times, they were used for medicinal (described in Dioscorides 2.132), ritual, and apparently psychoactive purposes. The pilgrims who came to the Greek death oracle of Acheron (near Ephyra, Thesprotia, northern Greece)—the entrance to Hades—were required to eat large quantities of lupine seeds so that they could contact the souls of the dead

(Dakaris 1989). “A strict diet was used to psycho-logically prepare them for communicating with the underworld in the narrow passages of the labyrinthine shrine. . . . The consumption of the alkaloid-containing lupine seeds induced in the pilgrims the state of inebriation that the priests desired and diminished their faculties of perception, preconditions that were necessary for the initiated to be able to feign a genuine communication with the shadow figures of the deceased” (Baumann 1982, 146*). Since the oracular priests jealously guarded their secrets, we unfortunately know nothing precise about the ways in which the lupines were actually used (Vandenberg 1979*). It is likely that, in addition, sulfur was burned as a fumigant (Dakiris 1989, 160).

“Zapote. Tree belonging to the Sapatoceae. The Cora in the Mexican Sierra Madre occidental hang its branches on their huts to protect the newborn from evil demons.”

SIEGFRIED SELIGMAN

DIE MAGISCHEN HEIL- UND SCHUTZMITTEL AUS DER BELEBTEN NATUR [THE MAGICAL HEALING AND PROTECTIVE AGENTS FROM ANIMATED NATURE]

(1996, 290*)

According to other sources, the pilgrims ate not lupine seeds when they visited the oracle but “pig beans,” which were probably *Hyoscyamus*. These induced “states of dizziness, unreal sensory perceptions, and passivity” (Dakaris 1989, 162 f.). Lucian described a séance in which the sea onion was used as a magical plant (cf. **moly**).

Lupine seeds contain a number of toxic substances: lupanine, 13-hydroxylupanine, angustifoline, 13-tigloyloxylupanine, albine, multiflorine, α -isolupanine, 4-hydroxylupanine, ammodendrine, anagryne, and sparteine (Roth et al. 1994, 473*). Lupanine is chemically related to **cytisine**. A new alkaloid, (–)-(trans-4’- β -D-glycopyranosyloxy-3’-methoxycinnamyl)-lupinine, has been detected in the yellow lupine (*Lupinus luteus*) (Murakoshi et al. 1979). However, nothing is known about the pharmacology of this substance.

Lupine seeds were once brewed as a coffee substitute (*Coffea arabica*). In Mexico, the lupine species *Lupinus elegans* H.B.K. is known as *hierba loca*, “crazy herb” (Martínez 1987, 427*). It may have inebriating effects (cf. *Astragalus* spp.).

Literature

Dakaris, Sotiris. 1989. Das Totenorakel am Acheron. In *Tempel und Stätten der Götter Griechenlands*, ed. Evi Melas, 157–64. Cologne: DuMont.

Murakoshi, Isamu, Kazuo Toriizuka, Joju Haginiwa, Shigeru Ohmiya, and Hirotaka Otomasu. 1979. (–)-(Trans-4’- β -D-glycopyranosyloxy-3’-methoxycinnamyl)-lupinine, a new lupin alkaloid in *Lupinus* seedlings. *Phytochemistry* 18:699–700.

In ancient times, yellow lupine, also known as wolf's bean (*Lupinus luteus*), apparently was associated with magical practices and lycanthropy (transformation of a human into a wolf).

Some species of the genus *Lupinus* appear to contain psychoactive substances.

Lupinine

***Lycopodium clavatum* L.**

(Lycopodiaceae)—club moss

Lycopodium clavatum L. and other club mosses indigenous to Europe (***Lycopodium* spp.**; cf. also ***Huperzia selago***) are known by a variety of common names, including Druid's foot herb, Druid's foot, Druid's plant, Druid's flour, Druid's foot flour, witches' plant, witches' flour, witches' flour plant, witches' dust, snake moss, devil's claw, devil's claw flour, devil's rubbish, and disquiet. The spores are known as witches' flour, Druid's flour, lightning powder, dusting powder, and moss powder. These names suggest an ancient use in pagan rituals and strong associations with witchcraft. One German name, *bärlapp*, means "uterine ointment" (Beckmann and Beckmann 1990, 196*).

Lycopodium clavatum and similar species (*L. cernuum* L., *L. hamiltonii* Spreng., *L. serratum* Thunb., *L. subulifolium* Wall. ex Hook. et Grev.) are found also in Nepal. There, the club moss is sacred to the Hindu god Vishnu and is used in garlands and other objects at his festivals.

Club moss (*Lycopodium clavatum* L.) contains a toxic or psychoactively effective alkaloid complex that is generally referred to as "clavatine" which even includes **nicotine** (Roth et al. 1994, 477*).

***Lycopodium* spp.**

(Lycopodiaceae)—condor plants, condoros

In northern Peruvian *curanderismo*, a variety of club mosses are used by folk healers as medicinal

plants, amulets, and additives to the San Pedro drink (cf. *Trichocereus pachanoi*). In the northwestern lowlands, club mosses are normally subsumed under the name *cóndor*, *condor*, or *condor plant*. In the highlands of Huancabamba and Las Huarinas, they are known as *huaminga*. Only one as yet unidentified species is included among the magical plants of the category *hornamo* (cf. *Senecio* spp.). Club mosses are also used as bath additives and for magical defense during healing rituals (Giese 1989, 227f.*).

Lycopodium magellanicum condoro

Lycopodium reflexum condoro

Lycopodium saururus hierba del cóndor cóndor misha

Lycopodium spurium trencilla del lago

Lycopodium tetragonum condorillo de quatro filos

Lycopodium vestitum trencilla blanca

When *condorillo* or *cóndor misha* is added to the San Pedro drink, the plant spirit appears to the *curandero* as a condor. At the behest of the healer, the condor can go on astral journeys and fulfill small tasks. As a result, he can remedy harmful magic and bring the lost soul back to a patient suffering from *susto*, “fright” (Giese 1989, 249*). There may even be some club moss species with psychoactive effects:

It is possible that *Lycopodium* sp. also augments the hallucinogenic effects of the San Pedro drink. Manuel, a plant dealer from Trujillo, said that the plant that he called “trenza shimbe” and appears to be the same as “cóndor misha” serves to improve the “visionary sight.” (Giese 1989, 228*)

One plant dealer at a “witches’ market” in Chiclayo in July 1997 told me that *condoro*, which I was

able to identify as *Lycopodium magellanicum*, has hallucinogenic effects, especially when combined with *Trichocereus pachanoi*.

More than one hundred alkaloids have been found in the genus *Lycopodium* (Gerard and MacLean 1986). To date, it is uncertain whether there are any psychoactive alkaloids among these. Six alkaloids have been detected in the Chilean species *Lycopodium magellanicum* (Loyola et al. 1979).

It is possible that a psychoactive use of club mosses is known in Chile or was practiced in former times. *Lycopodium paniculatum* A.N. Desv. is called *llanca-lahuén*, “precious medicine,” in Mapuche and is known in the local Spanish as *licopodio*, *pimpinela*, and *palmita* (Mösbach 1992, 55*). The Mapuche use another species, *Lycopodium gayanum* Remy et Fée, which they call *ngalngal*, as a sedative medicine. In the local Spanish, it is known as *harina de los brujos*, “flour of the witches” (Mösbach 1992, 55*).

Literature

Gerard, Robert V., and David B. MacLean. 1986. GC/MS examination of four *Lycopodium* species for alkaloid content. *Phytochemistry* 25 (5): 1143–50.

Loyola, Luis A., Glauco Morales, and Mariano Castillo. 1979. Alkaloids of *Lycopodium magellanicum*. *Phytochemistry* 18:1721–23.

Macropiper excelsum (Forster) Miq.

(Piperaceae)—Maori kava

Since *Piper methysticum* does not grow in New Zealand, the Maoris looked for a substitute when they settled the islands. They found it in the form of an indigenous pepper species, which they used like *Piper methysticum* to produce a kavalike drink. The plant contains an **essential oil** with the active substances myristicin and elemicine (Bock 1994, 98*).

Magnolia virginiana L.

[syn. *Magnolia glauca* L.] (Magnoliaceae)—Virginia magnolia, swamp sassafras

The Rappahannock Indians snuffed the leaves and bark of this North American tree as a mild inebriant (cf. **snuff**). Chemical studies and additional ethnographic data are lacking (Ott 1993, 412*). Virginia magnolia, which has a safrole scent, is also known in the United States as swamp sassafras (Grieve 1982, 716*). It contains an **essential oil** that clearly includes a high quantity of safrole (cf. *Sassafras albidum*).

Because of its aromatic leaves, the North American *Magnolia virginiana* is also known as sweet bay.

Another magnolia species has been associated with the Aztec inebriant **poyomatli**. Magnolias have been shown to contain alkaloids, e.g., magnoflorine (Roth et al. 1994, 479*).

Malva rotundifolia

(Malvaceae)—panirac

An herbarium specimen collected by E. Bacon in Afghanistan in 1939 bears the remark “the seeds make one drunk” (von Reis and Lipp 1982, 178*).

Matayba guianensis

(Sapindaceae)—papa-para

A note attached to an herbarium specimen collected by J. A. Steyermark in Venezuela in 1945 reads, “Fruit poisonous or makes one ‘*loco*’ [= crazy] when eaten” (von Reis and Lipp 1982, 169*).

Manihot anomala* Pohl ssp. *anomala

(Euphorbiaceae)

The dried root of this manioc species, which is known as *sienejna*, is used by the Ayoreo Indians of Paraguay to initiate a shaman (*naijna*) so that he can communicate with the spirits (Schmeda-Hirschmann 1993, 108*). But not all of the Ayoreo believe that this plant works. It is said that the shaman feels as though he is drunk when he smokes *sienejna*. In this state, the spirits of the animals (especially those of iguanas, poisonous snakes, and birds) meet him in the shape of small people so that they may let him know of their whereabouts (Schmeda-Hirschmann 1993, 109*). Smoking experiments, however, have not revealed any type of hallucinogenic or other psychotropic effect (Schmeda-Hirschmann 1993, 111*). Chemical studies and other experiments are still needed.

***Maquira sclerophylla* Ducke**

[syn. *Olmedioperebea sclerophylla*] (Moraceae)—rapé dos indios

In the central Amazonian region (Xingu) of Brazil, the bark and perhaps the seeds of this tree, which can grow as tall as 30 meters and is known locally as *rapé dos indios*, are made into a **snuff** that is purported to have hallucinogenic effects and is consumed at religious festivals (Schultes and Raffauf 1990, 318*). This practice has apparently died out (D. McKenna 1995, 101*). The powder is said to stimulate the central nervous system and cause euphoria and visual hallucinations. Unfortunately, pharmacological studies of these effects using human subjects have not yet been conducted (Carlini and Gagliarid 1970; D. McKenna 1995, 101*). One experiment with rats and guinea pigs revealed—as is typical—little but amphetamine-like reactions (Carvalho and Lapa 1990). Earlier studies demonstrated the presence of **coumarins**. Later investigations revealed the presence of cardiac glycosides as well (Ott 1993, 412*).

Literature

Carlini, E. A., and R. J. Gagliarid. 1970. Comparação das ações farmacológicas de estratos brutos de *Olmedioperebea calophyllum* e *Cannabis sativa*. *Anais do Academia Brasileira dos Ciencies* 42:400–412.

Carvalho, João Ernesto de, and Antonio José Lapa. 1990. Pharmacology of an Indian-snuff obtained from Amazonian *Maquira sclerophylla*. *Journal of Ethnopharmacology* 30:43–54.

***Mentha pulegium* L.**

(Labiatae)—pennyroyal

This mint species, once known as *blechon* or *glechon*, was apparently an ingredient of **kykeon**, the potion drunk by initiates to the Eleusinian mysteries (Ruck 1995, 142*). Aristophanes, in *Pax*, mentions a drink containing pennyroyal that was named *kykeon* and which Hermes, the messenger of the gods, recommended as a protection against disease. Pennyroyal was also used to produce love drinks and was considered an obscene metaphor for a woman’s pubic hair and a symbol of illicit

sexuality. The herbalist Bodin (1591) identified it with Homer's **nepenthes**. Pennyroyal was one of the most renowned abortifacients of antiquity and was used medicinally to treat cramps in the lower abdomen (Rätsch 1995a, 237 f.*). In ancient times, it was also burned as an **incense**. In South America, the dried plant is still used as a ritual incense and is offered to the earth goddess Pachamama (Ott 1993, 412*).

Pennyroyal (*Mentha pulegium*) plays a significant role in ethnogynecology and as a ritual incense.

A medicinal use of pennyroyal can still be found in the folk medicine of Cyprus, where fresh leaves are eaten in salad to treat male impotency. They are also consumed as a tea for stimulant and tonic purposes.

Pennyroyal has medicinal and ritual significance for the pagan Berber peoples of the Atlas Mountains (Morocco) that may have its roots in ancient ideas. A tea made from the herbage is drunk to treat abdominal pains, colic, rheumatism, and flatulence and as a tonic and digestive. During the summer solstice, the plant is burned as a ritual incense to protect humans and animals against misfortune. The feast consumed on the night of the summer solstice consists of snails that have been cooked in salt, pepper (*Piper nigrum*; cf. **Piper spp.**), pennyroyal, and thyme (*Thymus* spp.). Eating this preparation ensures good health throughout the coming year. The medicinal properties of the plant are said to be best when the plant is collected shortly before the solstice. It is used externally to treat wounds and is taken internally to treat coughs and colds (Venzlaff 1977*).

Hildegard von Bingen had the following to say about the psychoactive effects of pennyroyal: “He who has pains in the brain so that he is ill should add pennyroyal to wine and boil it, and he should lay it on his head while still warm, and he should tie a cloth over this, so that the brain is warm and suppresses the madness in him” (*Physica* 1.126).

Pennyroyal contains 1 to 2% **essential oil**, 80 to 94% of which is pulegone, a substance that can induce abortions in animals and humans (Boyd 1992). Piperitone and (-)-limonene also occur (Roth et al. 1994, 493*). Use of the plant as an abortifacient can be dangerous (Gunby 1979, Vallance 1955), and deaths have been reported (cf. *Focus* [1994] 32:95). Higher dosages of *oleum pulegii* can produce delirium and an anesthesia-like paralysis. Apart from the essential oil, no psychoactive compounds have been isolated (Ott 1993, 412*).

***Metteniusa edulis* Karst.**

[syn. *Pentandria monogynia* L., *Gamopetalae nuculiferae* Endl.]

(Metteniusaceae)—macagua, urupagua, canyí

The three species of the genus *Metteniusa* in Colombia thrive primarily in cloud forests. These trees bear large fruits (Gentry 1993, 474 f.*). The genus constitutes its own family but is also assigned to the families Alangiaceae and Icacinaceae (Brako and Zarucchi 1993, 573*). Karsten has even seen a certain resemblance to the Convolvulaceae:

The fruit and seed formation of this tree—whose bitter-tasting seeds are a not unimportant source of nourishment for the tribe of Arguaco Indians who inhabit the peaks of the mountains of St. Marta—isolate it from its natural relatives, the Cordiceae and the Asperifoliae. (Karsten 1858, 1:80)

In the Sierra Madre de Santa Marta, the tree is known as *canyí*. It is said to have ritual significance for the Kogi of Colombia.³³⁵ The priests (*mamas*) attribute strong psychoactive effects to the tree's chestnutlike fruits (Reichel-Dolmatoff 1977, 285*). Whether this plant truly is psychoactive is questionable, for it is eaten as a food in Venezuela, albeit after having been cooked (Lozano-C. and Lozano 1988, 26).

Another species, *Metteniusa tessmanniana* (Sleumer) Sleumer [syn. *Aveledoa tessmanniana* Sleumer], is found in Peru (Brako and Zarucchi 1993, 573*).

Literature

Karsten, Hermann. 1858–61. *Florae Columbiae*, I. Berlin.

Lozano-C., Gustavo, and Nulia B. de Lozano. 1988. *Metteniusaceae*. Vol. 11 of *Flora de Colombia*. Bogotá: Universidad de Colombia.

Fruits and seeds of the tree *Metteniusa edulis*, which the Kogi use to obtain a psychoactive product. (From Karsten, *Florae Columbiae*, 1858–61)

Mikania cordata (Burm) B.L. Robinson

(Compositae)

This shrub is common throughout the hot zones of India. The leaves are used in traditional medicine to treat itchiness and as a wound plaster. Neuropharmacological studies in animals (mice) have demonstrated that the root extract induces profound behavioral changes, particularly the disappearance of aggressive behavior. The root extract appears to have strong narcotic effects upon the central nervous system as well as analgesic properties (Bhattacharya et al. 1988).

In the medicine of the Andean Callawaya, a closely related species (*Mikania scandens* Willd., known as *guaco*) is used together with other plants (see *Erythroxylum coca*, *Cytisus spp.*) to treat rheumatism (Bastien 1987, 131*).

Literature

Bhattacharya, Siddhartha, Siddhartha Pal, and A. K. Nag Chaudhuri. 1988. Neuropharmacological studies on *Mikania cordata* root extract. *Planta Medica* 54:483–87.

Mirabilis multiflora (Torr.) Gray

(Nictaginaceae or Nyctaginaceae)—four-o'clock

The so-called Hopi hallucinogen belongs to the four-o'clocks, those amazing flowers whose blossoms always close at the same time each late afternoon. Known as *so:'ksi* or *so'kya*, the plant produces red flowers and a long, deeply penetrating root. Hopi medicine men chewed the root or drank the juice pressed from it in order to obtain diagnostic visions (Whiting 1939, 75). Twenty-eight to 57 g of the root is said to result in a "half-hour of gaiety." The Zuni Indians bake a bread using flour made from the root and, interestingly, use the bread as an appetite suppressant (Moerman 1986, 293*). The active principles are unknown (Ott 1993, 413*). The botanical name *Mirabilis nyctaginea* is also sometimes applied to this questionable hallucinogen (Moerman 1982, 81 f.*).

On the basis of this information from the older ethnographic literature and the superficial similarities between this genus and the nightshades, many closet shamans believe that another four-o'clock, *Mirabilis jalapa* L., is also psychoactive. The seeds of this plant, which is now cultivated throughout the world as an ornamental, are used ethnomedicinally as an antibacterial and anti-inflammatory agent (Kusamba et al. 1991). It is unknown whether the tuberous root has psychoactive effects. The Pima Indians of northern Mexico use the leaves to brew a tonic for the elderly (Pennington 1973, 221*).

Literature

Kusamba, Chifundera, Kizungu Byamana, and Wa Mpoyi Mbuyi. 1991. Antibacterial activity of *Mirabilis jalapa* seed powder. *Journal of Ethnopharmacology* 35:197–99.

Whiting, Alfred F. 1939. *Ethnobotany of the Hopi*. Museum of Northern Arizona Bulletin no. 15. Flagstaff.: Northern Arizona Society of Science and Art.

Monadenium lugardae N.E. Br.

(Euphorbiaceae)—tshulu, mhlebe

This South African spurge is used for folk medicinal purposes in Eastern Transvaal (Mpumalanga) and is reputedly psychoactive (Schultes and Hofmann 1980, 367*). Ingestion of a large piece of the root tuber (how much?) is said to cause hallucinations and delirium. The local diviners sometimes swallow pieces of the root in order to obtain prophetic visions. The plant contains bioactive alkaloids (Gundiza 1991; de Smet 1996, 143 f.*) and may contain methylamines (Emboden 1979, 184*).

Literature

Gundiza, M. 1991. Effect of methanol extract from *Monadenium lugardae* on contractile activity of guinea-pig ileum. *Central African Journal of Medicine* 37:141–44.

Monodora myristica Gaertner

(Curcubitaceae)—Jamaican nutmeg, calabash nutmeg tree

In West Africa, this treelike curcubit is known as *pebe*. Its seeds are reputedly used to establish contact with the water spirits (*mamiwata*). Apparently they are ingested and also smeared on the arms. The seeds are used by the Pygmies as a stimulant and to treat headaches. With a scent reminiscent of that of nutmeg, they are also used as a substitute for the true nutmeg (*Myristica fragrans*), which may also represent a *pebe* for contacting the water spirits (Wagner 1991; cf. also Ott 1993, 413 f.*). The seeds contain an **essential oil** in which myristicin or safrole may be present; this would make them a useful psychoactive substance. African slaves introduced the plant into the Caribbean, where the seeds are

used as a spice (Bärtels 1993, 69*).

This four-o'clock (*Mirabilis* sp.) bears a strong resemblance to the nightshades and may be regarded as psychoactive for this reason. (Wild plant, photographed in southern Mexico)

The treelike curcubitaceous *Monodora myristica*, which has a scent like that of nutmeg.

Another curcubit species (*Echinocystis lobata* Torr. et Gray) is rumored to be psychoactive or even hallucinogenic (Schultes and Farnsworth 1982, 188*; Schultes and Hofmann 1980, 367*).

Literature

Wagner, Johanna. 1991. Das “dawa” der *mamiwata* (Ein möglicherweise pharmakologischer Aspekt des westafrikanischen Glaubens an Wassergeister.) *Integration* 1:61–63.

Mostuea spp.

(Loganiaceae)

In Gabon, the species *Mostuea gabonica* Baillon and *Mostuea stimulans* Chevalier, known locally as *sata mbwanda* or *sété mbwundè*, are regarded as potent aphrodisiacs. Their effects are said to be identical to those of ***Tabernanthe iboga***. The roots of the plants, which have a taste like that of cola nuts (***Cola* spp.**), produce euphoria and inebriation. The root was chewed extensively throughout the night and was swallowed by itself or mixed with iboga to produce sexual excitation (Chevalier 1946, 1947). Alkaloids are present in the genus *Mostuea*. The root cortex of *Mostuea stimulans* contains 0.33% alkaloids of an unknown structure. They have a pharmacological activity like sempervirine and gelsemine (cf. ***Gelsemium sempervirens***) and effects similar to those of **strychnine** (de Smet 1996, 144*).

Literature

Chevalier, A. 1946. La *Sata mbwanda* racine stimulante et aphrodisiaque employée par les Noirs du Gabon et son identification botanique. *Comptes Rendus de l'Academie des Sciences* 223:767–69.

———. 1947. Les *Mostuea* africains et leurs propriétés stimulantes. *Revue de Botanique Appliquée* 27:104–9.

***Neoraimondia arequipensis* (Meyen) Backeb.**

[syn. *Neoraimondia macrostibas* (Schum.) Britt. et Rose] (Cactaceae)

This South American cactus from northern Peru has the reputation of being psychoactive or hallucinogenic (Schultes and Farnsworth 1982, 187*). It is one of the ingredients of the psycho-active **cimora** drink. It apparently contains β -**phenethylamines**.

***Nepeta cataria* L.**

(Labiatae)—catnip

Cats seem to be magically attracted to this plant (and to its varietals), which is frequently grown as an ornamental, and they appear to feel a strong psychoactive effect—hence its name (Siegel 1991a*). The dried leaves can be smoked alone or in **smoking blends**. The extract can be sprayed onto other smoking herbs. A tea made from equal parts of catnip and damiana (***Turnera diffusa***) (add 2 tablespoons of each to 1/4 liter of water and allow to steep for five minutes) is said to have mild euphoriant effects (Schuldes 1995, 54*).

Catnip contains an aromatic **essential oil** composed of nepetalactones, dihydronepetalactone, and isodihyronepetalactone. It also contains the psychoactive alkaloid actinidine. There are many reports of the psychoactive efficacy of smoking catnip leaves, including some from sources that may be taken seriously (Ott 1993, 414 f.*; Schultes 1970, 42*).

Amazingly, the active substances in catnip (nepetalactones) are also found in the animal kingdom. They have been demonstrated to be present in the toxin of *Myrmacomecocystus*, a genus of ant from California. As part of their initiations, some California Indians swallowed these ants alive (wrapped in eagle down) to induce altered states of consciousness. The ants apparently bit into the stomach lining, thereby introducing the active principles into the blood. The ritual use of psychoactive ants was very similar to the use of ***Datura wrightii*** (Blackburn 1976*).

Literature

Jackson, B., and A. Reed. 1969. Catnip and the alteration of consciousness. *Journal of the American Medical Association* 207:1349–50.

Catnip (*Nepeta cataria*).

***Nephelium topengii* (Merr.) H.S. Lo**

(Sapindaceae)

This Southeast Asian tree may be identical to a plant that ancient Chinese sources refer to as *lung-li*, which was said to have hallucinogenic effects (Li 1978, 24 f.*). *Nephelium*, however, contains only toxic cyanogenic glycosides (Schultes and Hofmann 1995, 51*; Schultes and Farnsworth 1982, 187*). This botanical identity is questionable (Li 1978, 24*).

***Ocimum micranthum* Willd.**

[syn. *Ocimum guatemalense* Gandoger] (Lamiaceae, Labiatae)—small-flowered basil, American basil

In Amazonia, where this plant is known as *alba-haca*, *iroro*, *pichana albaca*, or *pichana blanca*, it is said that this basil species is hallucinogenic (Duke and Vasquez 1994*). The leaves are used as an **ayahuasca** additive. The herbage has ethno-medicinal use as an analgesic in Mexico and Guatemala (Alcorn 1984, 715*; Ott 1993, 416*). The plant is known as *xkakaltun* in the Yucatán, where it is regarded as a **honey** plant (Barrera M. et al. 1976, 263*) and is used in an abortifacient medicine (Rätsch and Probst 1983). The Siona Indians call the aromatic plant *gõnõ ma'nya*, “chicha perfume,” and it is similarly known as *kõnõ na'nya* among the Secoya (Vickers and Plowman 1984, 16*). It apparently was once used as a **chicha** additive. In Brazil, where the plant is known as *mangericão*, it is used in the Candomblé cult as an ingredient in the initiatory drink (see **madzoka medicine**). It has folk medicinal significance in the Caribbean. The plant contains an **essential oil** (Wong 1976, 137*) whose constituents include camphene, cineol, linalool, myrcene, *cis-trans*-ocimene, α -pinene, β -pinene, α -terpineol, aromandrene, β -caryophyllene, β -elemene, Δ -elemene, γ -elemene, α -humulene, neriol, and eugenol (Argueta V. et al. 1994, 89*; Maia et al. 1988).

Sacred basil (*Ocimum sanctum* L. [syn. *Ocimum tenuiflorum* L.]), a relative that is better known by the names *tulasi*, *tulsi*, and *madura-tala* (Knecht 1985), is not itself psychoactive,³³⁶ although it is chewed as a substitute for **betel quids** (Macmillan 1991, 424*).

Literature

Ocimum micranthum, a basil species found throughout tropical America, where it is used for ethnopharmacological purposes.

***Osteophloeum platyspermum* (DC.) Warburg**

(Myristicaceae)—huapa

It has recently been discovered that the Ecuadoran Quecha use a tree that they call *anya huapa*, *huachig caspi*, *huapa*, *llauta caspi*, or *machin cara yura* (“monkey bark tree”) as a hallucinogen. It is possible that this tree was already in use for this purpose in pre-Columbian times, for the informants explained that their ancestors used this plant to communicate with phantoms and spirits. The red sap from the trunk, which is ingested orally, must be boiled before use and is sometimes mixed with *quando* (***Brugmansia* spp.**) and *tzicta* (*Tabernaemontana sananho* Ruíz et Pav.; see ***Tabernaemontana* spp.**). The Quechua drip some of the red sap into the nostrils of their dogs so that they are better able to hunt. A chemical quick test (Dragendorff test) has confirmed the presence of alkaloids (Bennett and Alarcón 1994). The Makú Indians drink the sap of the tree, which they call *tugnebãnpe*, to treat colds (Prance 1972a, 20*). In the region around Manaus, the leaves are smoked as a treatment for asthma (Schultes 1978b, 230*; 1983b, 347*).

Literature

Bennett, B. C., and Rocío Alarcón. 1994. *Osteophloeum platyspermum* and *Virola duckei* (Myristicaceae): Newly reported as hallucinogens from Amazonian Ecuador. *Economic Botany* 48 (2): 152–58.

***Oxytropis* spp.**

(Leguminosae: Fabaceae)—locoweeds

Several species from the genus *Oxytropis* are known in North America by the Spanish-English name *locoweed*, “crazy weed” (cf. ***Astragalus* spp.**), and have toxic or psychotropic properties (Turner and Szczawinski 1992, 122*). The Indians used some species for medicinal purposes (Johnston 1970, 314*). Several species were used as a ritual or medicinal wash during sweathouse ceremonies (Moerman 1986, 320 f.*). In Mexico, the species *Oxytropis lamberti* Pursh. is called *hierba loca*, “crazy herb” (Martínez 1987, 427*; Reko 1938, 185*).

***Pancratium trianthum* Herbert**

(Amaryllidaceae)—pancrat lily, kwashi

This African sea lily, known as *kwashi*, is said to be a popular hallucinogen among the Bushmen of Botswana. Cut into slices, the bulb is rubbed into incisions made on the scalp (de Smet 1996, 142*).

The Mediterranean pancrat lily (*Pancratium maritimum*) is similar to the related African species and bears enchanting flowers.

One of the many species of screw pine (*Pandanus* sp.) found throughout Southeast Asia.

Among the some fifteen species in the genus, this species is considered the most poisonous; it contains a variety of cardiac toxins (Schultes and Hofmann 1992, 52*). A Russian study isolated trisperidine, tacettin, hippeastrine, pancratine, galanthamine, lycorine, hordenine, and two unidentified bases from the bulb (Munvime and Muravjoza 1983). The main alkaloid in the bulb of the Mediterranean *Pancratium maritimum* L. is lycorine (Sener et al. 1993). Lycorine, which is present in many amaryllis species, causes paralysis of the central nervous system (Roth et al. 1994, 854*).

Literature

Munvime, F. D., and D. A. Muravjova. 1983. Alkaloids of *Pancratium trianthum* Herb. *Farmatsiya* 32:22–24.

Sener, B., S. Koenuekol, C. Krukl, and U. K. Pandit. 1993. Alkaloids of lycorine and lycorenine class from *Pancratium maritimum* L. *Archiv für Pharmazie* 326:61–62.

***Pandanus* sp.**

(Pandanaceae)—screw tree

In Papua New Guinea, the fruit of an as yet unidentified *Pandanus* species is said to be used or to have been used as a hallucinogen. Unfortunately, we have no dependable ethnographic or ethnobotanical information about this. The fruits of several *Pandanus* species have been found to contain *N,N*-DMT (Schultes and Hofmann 1992, 52*). The species *Pandanus antaresensis* St. John is used in Papua New

Guinea as an analgesic (Ott 1993, 401*). The Australian Aborigines make a **wine** from the fruits of *Pandanus spiralis* R. Br. (Bock 1994, 147*).

In Nepal, the screw pine (*Pandanus nepalensis* St. John [syn. *Pandanus furcatus* auct. non. Roxb.]) is considered sacred to Ganesha, the Hindu elephant-headed god. The leaves of the kevada or aromatic screw pine *Pandanus odoratissimus* L. [syn. *P. tectorius* auct. non. Soland. ex Parkinson], which is called *ketaka* in Sanskrit, are offered to his father Shiva (Majupuria and Joshi 1988, 170 f.*). In Ayurvedic medicine, the leaves are used as a tonic aphrodisiac, while in Thailand they are often used as a cooking spice (Norman 1991, 66*). In Hawaii, root tips that grow above the ground are used together with sugarcane juice to make a tonic (Krauss 1981, 6*). The flowers contain a stimulating **essential oil** composed of benzyl benzoate, benzyl acetate, benzyl alcohol, geranol, linalool, guiacol, phenethyl alcohol, and aldehydes (Majupuria and Joshi 1988, 171*). In India, the ripe spadix of *Pandanus tectorius* Parkins. ex Du Roi [syn. *Pandanus odoratissimus* L. f.] is the source of the so-called kewda perfume, one of whose uses is to aromatize smoking tobacco (*Nicotiana rustica*, *Nicotiana tabacum*) (Bärtels 1993, 122*).

In the Seychelles, a number of species known as *vacoa* are regarded as aphrodisiacs (Müller-Ebeling and Rätsch 1989, 72*).

***Pedilanthus* spp.**

(Euphorbiaceae)—shoe flower

In Peru, *Pedilanthus retusus* Benth. is known locally as *misha*. This name is typically used as a folk taxonomic catchall for the various angel's trumpets (*Brugmansia* spp.) but is also occasionally given to other psychoactive plants (cf. *Lycopodium* spp., *cimora*). At the Institute for Traditional Medicine in Lima, it is claimed that *Pedilanthus retusus* is a potent hallucinogen, for it is said to contain a substance similar to **mescaline**.

***Peperomia* spp.**

(Piperaceae)—tsemsem, dwarf pepper

The Shuar of the Ecuadoran rain forest use this epiphytic, tropical pepper plant as a “mild hallucinogen.” Parents given newborns who are just a few days old leaves that they have chewed. Older children are given the plant so that they may find their dream souls (*arutam*) (cf. *Brugmansia suaveolens*, *Nicotiana tabacum*) (Bennett 1992, 492 f.*). The leaves apparently are also used as an **ayahuasca** additive.

A South American peperomia (*Peperomia* sp.), also known as dwarf pepper.

The master plant *piri-piri* (*Peperomia galioides*), which is used in the San Pedro cult.

Peat myrtle (*Pernettya mucronata*).

Found from Costa Rica to southern Chile, *Pernettya prostrata* is reputed to be a psychoactive plant.

In South America, many species of the genus *Pernettya* were or still are used to prepare inebriating drinks. (Wild plant, photographed in Valdivia, southern Chile)

Several *Peperomia* species contain alkaloids (Schultes and Raffauf 1990*). *Peperomia galioides* H.B.K., which is known in Peru as *piri-piri*,³³⁷ is added to the San Pedro drink (cf. *Trichocereus pachanoi*) to lend the psychoactive effects “more clarity, brightness, and distinctness” (Giese 1989, 252*).

In Trinidad, the dried leaves of *Peperomia emarginella* (Sw.) C. DC. are smoked for asthma. The **essential oil** has antispasmodic effects (Wong 1976, 114*).

***Pernettya* spp.**

(Ericaceae)—peat myrtle

Several species of this South American member of the Heath Family are reputed to be psychoactive. The fruits of *macha-macha* (see **macha**), an Andean species (*Pernettya prostrata* [Cav.] Sleumer var. *pentlandii* [DC.] Sleumer) from Cochabamba (Bolivia), are said to cause dizziness when eaten in excess: “The fruit has a soporific property. A tame monkey who ate the berries of plants I had set aside to preserve became totally drunken” (Steinbach in Schultes 1967, 279; von Reis Altschul 1975, 215*) Some species and varieties are considered toxic (*Pernettya prostrata* var. *purpurea* [D. Don] Sleumer, *Pernettya mucronata* [L. f.] Gaudich. ex Spreng.). *Pernettya prostrata* (Cav.) DC. may be known as **macha** or *macha-macha*, “drunk,” in Quechua. This information, however, is questionable (Franquemont et al. 1990, 66*).

In Chile, *Pernettya furens* (Hook. ex DC.) Klotzch is known as *huedhued* or *hierba loca*, “crazy herb,” and is said to cause mental confusion and possession (Schultes and Hofmann 1992, 53*). The fruits of *Pernettya parvifolia* Benth., known as *taglli*, are reputed to have toxic and hallucinogenic properties (Alvear 1971, 23*; Schultes and Farnsworth 1982, 179*). Andromedotoxins (= grayanotoxins) have been detected (Ott 1993, 417*). *Pernettya mucronata*, which is sometimes grown in Europe as an ornamental, also contains acetylandromedole (= andromedotoxin) (Roth et al. 1994, 549*). Sesquiterpenes have been demonstrated in *Pernettya furens* (Hosozawa et al. 1985).

Whether the fruits have psychoactive effects and were or are used culturally for psychoactive purposes is questionable. It is likely that the ripe fruits were used solely as a material for brewing **chicha**. Other species are used in Chile to prepare chicha (Mösbach 1992, 100*). In northern Peru, folk healers (*curanderos*) use a *Pernettya* species known as *toro-maique* as an inebriating additive to the San Pedro drink (cf. *Trichocereus pachanoi*). The addition of this plant is said to give the drink “more power”; the spirit of the plant appears to the healer in the form of a bull (Giese 1989, 228*). In Venezuela, various species of the genus (perhaps including *P. prostrata*) are called *borrachera*, *borrachero*, *borrachera*, *borrachero*, or *chivacú* (Blohm 1962, 74*; von Reis and Lipp 1982, 228*). In South America, all plants with psychoactive or inebriating effects are typically subsumed under the name *borrachero*. For this reason, it is entirely possible that the Venezuelan peat myrtle exhibits some type of psychoactivity.

Probably the earliest depiction of an American peat myrtle (*Pernettya ciliata* Schlect. et Cham.). (From Hernández, 1942/46 [Orig. pub. 1615]*)

Literature

Hosozawa, S., I. Miura, M. Kido, O. Munoz, and M. Castillo. 1985. Sesquiterpenes from *Pernettya furens*. *Phytochemistry* 24 (10): 2317–23.

Schultes, Richard Evans. 1967. De Plantis Toxicariis e Mundo Novo Tropiale Commentationes I. *Botanical Museum Leaflets* 21 (9): 265–84.

Persea indica (L.) Spreng.

(Lauraceae)—viñatigo

This tree, a relative of the avocado (*Persea americana* Mill.), belongs to the indigenous flora of the Canary Islands, where it is known as *viñatigo*. It is said that a person should not take a siesta or sleep under the tree because doing so will provoke a state of inebriation. Goats eat the foliage and branches with gusto, because it makes them “drunken.” A psychoactive use has not yet been determined (vries 1993).

Literature

vries, herman de. 1993. Über die Wirkungen von *Persea indica* (L.) Spreng. *Integration* 4:57.

Petunia violacea Lindl.

(Solanaceae)—petunia, shanín

It is said that the Indians of the Ecuadoran highlands smoke this plant, known as *shanín*, the effects of which resemble those of *Coriaria thymifolia*. The plant is said to give its user “the feeling of rising into the air or floating weightlessly away” (Alvear 1971, 23*; Schultes and Hofmann 1992, 53*). Chemical studies to date have not detected the presence of any alkaloids (Butler et al. 1981; Ott 1993, 417*). It is possible, however, that new **diterpenes** may be present, as they have been found in a relative, *Petunia patagonica* (Speg.) Millan (Guerreiro et al. 1984). Ketones have also been found in the genus (Elliger et al. 1990).

Literature

Butler, Edward Grant, Trevor Robinson, and Richard Evans Schultes. 1981. *Petunia violacea*: Hallucinogen or not? *Journal of Ethnopharmacology* 4 (1): 111–14.

Elliger, Carl A., Anthony C. Waiss Jr., Marby Benson, and Rosalind Y. Wong. 1990. Ergostanoids from *Petunia parodii*. *Phytochemistry* 29 (9): 2853–63.

Guerreiro, Eduardo, J. de Fernandez, and O. S. Giordano. 1984. Beyerene derivatives and other constituents from *Petunia patagonica*. *Phytochemistry* 23 (12): 2871–73.

***Peucedanum japonicum* Thunb.**

(Umbelliferae)—fang-k'uei

This Japanese species of master plant is also found in China. Known as *fang-k'uei*, the species is mentioned in the herbal *Tao Hung-ching*: “feverish persons should not take it, for it stupefies and enables spirits to appear.” This passage has been interpreted as indicating a possible psychoactivity (Li 1978, 21*).

The roots (radix peucedani, qian hu, zenko) of several closely related species are used in traditional Chinese medicine to treat disorders of the lung and spleen (Paulus and Ding 1987, 376). The root of *Peucedanum decursivum* (Miq.) Maxim. is regarded as a nerve tonic and aphrodisiac (Stark 1984, 95*). The roots of the species known as *zenko* (*Peucedanum praeruptorum* Dunn) are used in Japanese kampo medicine to treat fever, shivering, and headaches (Tsumura 1991, 175*).

Alkaloid-like substances do occur in the genus *Peucedanum*. **Coumarins** have been detected in *Peucedanum japonicum* (Schultes and Hofmann 1992, 54*). Additional chemical studies are needed (Ott 1993, 417*).

Asian species of *Peucedanum* have been used as aphrodisiacs and tonics in Chinese medicine since ancient times. (Illustration from the *Ch'unghsiu cheng-ho pen-ts'ao*)

***Philodendron scandens* K. Koch et Sello**

(Araceae)—heartleaf philodendron

A note attached to an herbarium specimen collected in Peru in 1969 reads, “Narcotic, used to induce sleep” (von Reis and Lipp 1982, 20*). The principal agent of the allergologically efficacious plant is thought to be 5-heptadecatrien-8(Z),11(Z), 14(Z)-benzylresorcinol (Roth et al. 1994, 559*). A related *Montrichardia* species is used as an **ayahuasca** additive.

***Physalis* spp.**

(Solanaceae)—*Physalis* species

The genus *Physalis* is composed of some 120 species and is thus the largest genus of its family (Lu 1986, 80*). Several species are regarded as toxic, some are raised as ornamentals popular for their unusual flowers (Chinese lanterns), and others have ethnomedical significance. *Physalis pubescens* L. and *Physalis peruviana* L. (Cape gooseberry) are the two species most commonly grown for their fruit. Very mild toxic effects have been observed following consumption of a large number of berries of *Physalis peruviana* (Roth et al. 1994, 560*). The calyx, which surrounds the seeds like a lantern, can be smoked. It has definite psychoactive effects that tend to be narcotic in nature.

The violet-flowered petunia (*Petunia violacea*) is a common ornamental.

Physalis angulata L., a species from the northwestern Amazon, is said to be mildly narcotic. Its juice finds use in Brazilian folk medicine as a treatment for earaches (Schultes and Raffauf 1991, 43*). *Physalis minima*, a species from the Caroline Islands known as *poowa*, bears fruits that are said to have an inebriating effect when consumed in excess (von Reis Altschul 1975, 269*).

The roots of some species of the genus have yielded **tropane alkaloids** as well as alkaloids of the hygrine type (von Reis Altschul 1975, 269*). The Jew's cherry or lampion flower, *Physalis alkekengi* L. (cf. **halicacabon**), contains the mildly toxic bitter principles physaline A, B, and C (Roth et al. 1994, 560*).

This may be one of the earliest illustrations of an American species of *Physalis*. (From Hernández, 1942/46 [Orig. pub. 1615]*)

The papery bladder that surrounds the *Physalis* fruit is reminiscent of a Chinese lantern. When smoked, it produces mild narcotic effects.

The South American leguminous tree *Pithecellobium discolor*.

A polypody (*Polypodium* sp.) growing on the trunk of a tree.

***Pithecellobium* spp.**

[sometimes written as *Pithecolobium*] (Leguminosae)—jurema branca

The genus *Pithecellobium* encompasses some two hundred species. It is closely related to and is easily

confused with the genus *Mimosa*. In the Brazilian Amazon, the name *jurema* is usually given to ***Mimosa tenuiflora*** [syn. *Mimosa hostilis*], which is used to prepare an **ayahuasca**-like drink. However, several species of the genus *Pithecellobium*, e.g., *P. diversifolium* (known as *jurema branca*, “white jurema”), also appear to be used for that purpose (Rätsch 1988, 83*).

In Brazil, the use of a *vinho do jurema* made from *Pithecellobium* has become established among the followers of various cults of West African origin. Apparently the use is connected with the Camdomblé god Ossain, who is regarded as a great magician, protector, and discoverer of healing herbs. Psychoactive and other constituents of the genus are largely unknown. Alkaloids and flavonoids have been detected (Schultes and Raffauf 1990, 251*).

The species *Pithecellobium laetum* Benth., which is known as *remo caspi*, *pashaquillo*, or *shimbillo*, contains alkaloids and is used as an **ayahuasca** additive. In Mexico, the species *Pithecellobium arboreum* (L.) Urb. and *P. donnellsmithii* Britt. et Rose are known as *frijolillo* (Martínez 1987, 1189 f.*). This name is also used for ***Sophora secundiflora***.

***Polypodium* sp.**

(Polypodiaceae)—polypody, tree fern

The Spanish botanist Hipólito Ruíz (1754–1816), who traveled through South America in the eighteenth century, provided the first descriptions of many plants and returned with extensive collections of botanical materials. In his *Relación*, he reported a number of experiences and provided ethnobotanical notes from Peru and Chile (Schultes 1980, 89*). Ruíz described a polypody known as *cucacuca*, *incapcocam*, or *coca del Inca* under the binomial *Polypodium incapcocam* (nomen nudum), whose botanical identity even Richard E. Schultes was unable to determine. Ruíz noted that the Indians had informed him that the Incas used the leaves of this plant instead of coca (see ***Erythroxylum coca***). Moreover, the powdered plant was said to be used (how?) in place of tobacco (***Nicotiana** spp.*) in order to “clear the head” (Schultes 1980, 89*).

Whether *Polypodium* does indeed have psychoactive effects remains to be seen, although it is possible. Interestingly, the root of one species of the genus *Polypodium* whose identity has not been specified is ingested orally together with the seeds of ***Anadenanthera colubrina***. It may contain MAO-inhibiting **β-carbolines** (or other substances with the same effects). The root of the common polypody (*Polypodium vulgare* L.), also known as sweet angel, contains small amounts of an essential oil, tannin, bitter principles, and sweet-tasting saponins (Pahlow 1993, 119*).

It is quite possible that there are other psychoactive ferns; even German folklore contains tales of *filices*, “ferns” (e.g., the worm fern, *Aspidium filix-mas*)—also called *irrwurz* (“confused root”)—that have magical powers, make the devil appear, and can make one invisible (Marzell 1964, 33 ff.*; Schöpf 1986, 84 f.*). There are also ferns that were added to **beer**. In Mexico, a fern known as *itamo real*³³⁸ (*Pellaea cordata* J. Sm.) is said to have inebriating effects (Díaz 1979, 93*).

***Pontederia cordata* L.**

(Pontederiaceae)

In the Colombian region of the Amazon, this plant is known as *amarrón borrachero* (“hazelwort inebriator”). It is used as an **ayahuasca** additive but may also possibly be used alone for psychoactive purposes (Schultes 1972, 141*). The plant is used ethnomedicinally to treat facial paralysis (Schultes 1981, 5*). There is also a North American variety: *Pontederia cordata* L. var. *lancifolia*.

***Pseuderanthemum* sp.**

(Acanthaceae)—dormidero

A note on an herbarium specimen collected by Killip and Smith in Peru in 1929 describes this as a “narcotic plant” (von Reis and Lipp 1982, 281*). The Spanish name *dormidero* means “sleep inducer.”

***Quararibea* spp.**

(Bombacaceae)

The genus *Quararibea* consists of some twenty-nine species (Schultes 1957, 249). In Mexico, the aromatic leaves (“cacao flowers”) of the small tree *Quararibea funebris* (La Llave) Vischer [syn. *Lexarza funebris* La Llave, *Myrodia funebris* Benth.] are used as a spice for cacao drinks (see ***Theobroma cacao***) (Rosengarten 1977; Schultes 1957). They have been described as a possible hallucinogen and also have been identified as the mysterious Aztec inebriant **poymatli**. According to Jonathan Ott, who has experimented with these flowers as well as cacao preparations containing them, *Quararibea* flowers are not psychoactive (Ott 1993, 418*). However, several interesting substances are present (γ-butyrolactones, alkaloids) that may indeed have psychotropic effects (Raffauf and Zennie 1983).

The Peruvian inebriant **espingo**, which has not been clearly identified, has also been interpreted as the fruit of a *Quararibea* species. In Amazonia, *Quararibea* species are used as **ayahuasca** additives, and they are also added to Peruvian San Pedro preparations (see ***Trichocereus pachanoi***). The Kofán Indians use *Quararibea putumayensis* Cuatr. in the manufacture of arrow poisons (Ott 1993, 418*).

Schultes, Richard Evans. 1957. The genus *Quararibea* in Mexico and the use of its flowers as a spice for chocolate. *Botanical Museum Leaflets* 17 (9): 247–64.

***Ranunculus* sp.**

(Ranunculaceae)—buttercup

In ancient China, a species of the genus *Ranunculus* (perhaps *Ranunculus acris* L. var. *japonicum* Maxim.) was known by the names *shui lang* and *maoken*. Unintentional consumption was said to result in a kind of delirium (Li 1978, 24*). The genus contains glycosides (protoanemonin) (Frohne and Pfänder 1983, 173*; Schultes and Hofmann 1995, 54*). Whether there really is a psychoactive species is questionable.

The fern is one of the Germanic magical plants. Whether it is in fact psychoactive is unknown, but possible. (Woodcut from Tabernaemontana, *Neu Vollkommen Kräuter-Buch*, 1731)

The cacao flower tree *Quararibea funebris*, a native of Oaxaca (Mexico).

The buttercup (*Ranunculus acris*), a Ranunculaceae, is associated with an ancient Chinese magical drug.

***Rauvolfia serpentina* (L.) Bentham ex Kurz**

[formerly spelled *Rauwolfia*] (Apocynaceae)—snakeroot

Rauvolfia, or snakeroot, is occasionally regarded as a psychoactive plant. This is due primarily to theoretical considerations concerning the yohimbane-type alkaloids, here represented by corynanthine, isorauhimbine, and **yohimbine** (Kähler 1970). The principal active agent, however, is the alkaloid reserpine; its primary effect is hypotensive, although it also has sedative properties. *Rauvolfia* thus induces sleep (Hänsel and Henkler 1994, 369). Reserpine appears to work in a manner similar to the neuroleptics and played a significant role in the study of the function of the monoamine transmitter in the nervous system (D. McKenna 1995, 103*). It is conceivable that certain as yet unknown methods of preparation could yield psychoactive effects. In addition, the some sixty species in the genus may very well include some that contain much higher concentrations of yohimbine and induce very different effects. Apart from *Rauvolfia serpentina*, the pharmacologically most important species are the African *Rauvolfia vomitoria* Afzel and the American *Rauvolfia tetraphylla* L. [syn. *Rauvolfia canescens* L., *R. hirsuta* Jacq., *R. heterophylla* Roem. and Schult.], which is also sometimes referred to as *borrachero* (“inebriator”; cf. ***Brugmansia***) (Morton 1977, 243–57*). Most of the species are tropical and are found in both the Old and the New Worlds. Many species have ethnomedicinal significance. β -yohimbine has been detected in *Rauvolfia vomitoria* (Hofmann 1955; Stoll et al. 1955). In India, *Rauvolfia serpentina* has a long history as an antidote for snakebite (Jain 1991, 153*). Circumcised boys in Kenya use *Rauvolfia caffra* Sond. [syn. *R. natalensis* Sond.], known locally as *mwerere*, *rerendet*, *omomure*, or *mutu*, as a tea for inducing sleep. The stalks are used as a fermentation agent for making **beer** (Omino and Kokwaro 1993, 173*).

This illustration may be the earliest European representation of the Indian snakeroot (*Rauvolfia serpentina*). (Woodcut from Garcia da Orta, *Colloquies on the Simples and Drugs of India*, 1987 [orig. pub. 1563])

The leaves of the Caucasus rhododendron (*Rhododendron caucasicum*) have a resinous aroma and were once inhaled as an inebriating incense.

The aromatic high mountain rhododendron (*Rhododendron lepidotum*) is an important source of incense in the Himalayas. (Wild plant, photographed in Langtang, Nepal)

The yellow-blossomed *Rhododendron cinnabarinum* is found in the Himalayas. Burned as an incense, this plant has potent effects upon yaks.

The flowers of the Pontic alpine rose (*Rhododendron ponticum*) contain a nectar that bees transform into a psychoactive honey. (Photographed near the Aletsch glacier, Switzerland)

***Rhododendron caucasicum* Pallas and *Rhododendron* spp.**

(Ericaceae)—Caucasus alpine rose, rhododendrons The Osset live in the mountains of the northern Caucasus and are thought to be later descendants of the ancient Scythians. The Oriental scholar Julius Klaproth visited the Osset during the nineteenth century and returned with a description of a divination ritual in which the Caucasus rhododendron (whether the botanical identification is correct remains open) was used as a psychoactive incense (Klaproth 1823, 2:223 f.):

He described their ardent devotion to the prophet Elias, who was regarded as their greatest protector. In caves consecrated to him, they [the Osset] offered goats and consumed their flesh; after which they spread the skins out under a large tree and honored these in a special fashion on the prophet's feast day so that he would keep away the hail and grant them a bountiful harvest. The Osset would often go to these caves to inebriate themselves on the smoke of *Rhododendron caucasicum*, which would cause them to sleep deeply. The dreams that appeared to them under these circumstances were interpreted as prophecies. (Ginzburg 1990, 165)

The Caucasus rhododendron (section *Pontica*) is a broad bush that grows to only about 1 meter in height. The flowers are creamy or pale yellow, sometimes with pink spots. The plant typically blooms from April to May and is found primarily at an altitude between 1,800 and 2,700 meters. It is found across northeastern Turkey and the Caucasus Mountains (Cox 1985, 175). Its evergreen leaves are weakly aromatic. *Rhododendron caucasicum* is only rarely encountered in rhododendron gardens, for it is much more difficult to cultivate than are other species.

In Nepal, the closely related *Rhododendron lepidotum* Wall. ex Donn (in two forms: var. *album* Davidian and var. *minutiforme* Davidian; cf. Cox 1985, 113f.) is still used today as a ritual and shamanic incense, the effects of which are very subtle (see **incense**). In Tibet and China, other rhododendron species are also used as incense. The yellow-flowered *Rhododendron cinnabarinum* Hook f. is found in the high mountains of Sikkim. Its smoke is said to have a profound effect on yaks, producing a strong inebriation and altering their behavior. It is possible that it also has psychoactive effects upon humans.

In Nepal, the leaves of a *Rhododendron* species are mixed with tobacco (***Nicotiana tabacum***) for smoking. A **snuff** is made from the bark of a *Rhododendron* species and tobacco leaves (Hartwich 1911, 108*).

Other rhododendron species, e.g., the rusty-leaved alpine rose (*Rhododendron ferrugineum* L.) and the Pontic rhododendron (*Rhododendron ponticum* L.), yield a psychoactive/toxic **honey**. The Tartars made a tea from the leaves (ten or more) of the gold-yellow alpine rose (*Rhododendron chrysanthum* Pall. [syn. *Rhododendron officinale* Salisb., *Rhododendron aureum* Georg]) that is said to have produced a state of inebriation (Roth et al 1994, 612*). There is also a cultivar, *Rhododendron x sochadzeae*, resulting from a cross between *R. ponticum* and *R. caucasicum* (Cox 1985, 175 f.). This rare ornamental variety may have potent psychoactive effects.

The aromatic species of rhododendron contain relatively high concentrations of **essential oil**. Mongolian species contain primarily limonene, aromadendrene, caryophyllene, Δ -cadinene, β selinene, and gurjunene (Satar 1985).

It would be an interesting task to investigate a possible cultural link between rhododendron forests and psilocybin mushrooms. Rhododendron groves are a preferred habitat of some psychoactive mushrooms, e.g., ***Psilocybe cyanescens***.

***Sanango racemosum* (Ruíz et Pav.) Barringer**

[syn. *Gomara racemosa* Ruíz et Pav., *Gomaranthus racemosus* (R. et P.) Rauschert, *Sanango durum* Bunting et Duke]

(Loganiaceae)—sanango

This rare and mysterious bush is related to ***Desfontainia spinosa***. It is found in the rain forests of Amazonia at altitudes up to 100 meters (Brako and Zarucchi 1993, 619*) and is endemic to Peru (Gentry 1993, 564*). The leaf is used as an inebriant. Reports circulate of its wondrous effects. However, there have been few ethnopharmacological investigations into this promising plant.

The leaves of the mysterious Amazonian magical plant *Sanango racemosum*.

***Santalum murrayanum* (Mitch.) Gardner**

(Santalaceae)—bitter quandong

This Australian tree is a relative of sandalwood (*Santalum album* L.; cf. **incense**). The Aborigines of

Lake Boga use the bark as a narcotic. From it, they produce an inebriating drink known as *cootha* (Bock 1994, 108*). The bark of the trunk contains 0.21% alkaloids, which have strong toxic effects above a certain dosage (2g/kg) (Collins et al. 1990, 65, 128*).

The leaves and wood of *gumamu*, the closely related species *Santalum lanceolatum* R. Br., were used by the Bardi during healing rituals as a medicinal **incense** (Lands 1987, 17). It is said that this treatment was “too strong” for children; this incense may be psychoactive. Alkaloids have been found in the leaves, trunk wood, and bark (Collins et al. 1990, 65*).

Literature

Lands, Merrilee, ed. 1987. *Mayi: Some bush fruits of Dampierland*. Broome, Australia: Magabala Books.

Scirpus spp.

(Cyperaceae)—bakana, simse

In Northern Mexico, the Tarahumara use a species from the genus *Scirpus* as a hallucinogen. They call the plant *bakánoa*, *bakánawa*, *bakánowa*, or *bakana*. The ethnobotanist Robert Bye has stated that this grass is the most important hallucinogen of the central and western Tarahumara (= Rarámuri), being even more important than peyote (*Lophophora williamsii*) (Bye 1979b, 35*). Little is known about the ritual use:

Bakánowa is another medicinal plant used in rituals. A ceremony known as simse is associated with and named after the plant simse, bot. *Scirpus* sp. It is regarded as a source of vigor and is ritually venerated, especially by older women and men, who nourish it with offerings. Bakánowa is a kind of counterpart to híkuri [= peyote]. The plant is sought for in the western Sierra Tarahumara. The ceremonial circle with the offering altar also faces to the west, while the ritual semantics depict the híkuri to the east. The bakánowa root is clearly a potent drug that is not ingested in most cases but [is] merely ritually venerated. Here, some healers use a notched piece of wood, as in the híkuri rites. (Deimel 1996, 12)

Nourishing the plant with offerings is considered important for health. One Tarahumaran healer said, “If god onorúame, the goddess maria mechaka, or the dead or the sacred plants híkuri and bakánowa go hungry, humans will become ill” (Deimel 1996, 12).

The root is used in folk medicine as an anal-gesic and to treat the insane. The plant is regarded as a protective amulet and as a remedy for all mental illnesses. This is why it is periodically brought offerings. Anyone who treats the plant poorly will be punished with disease. Eating the root tuber is said to induce a deep sleep accompanied by visions and allows one to travel to other dimensions. Unfortunately, the species the Tara-humara use has not yet been identified.

Alkaloids have been found in one species of the genus *Scirpus* (Bye 1979b, 36*). These may be **ergot alkaloids** (cf. *Cyperus* spp.) that are deposited as metabolites of a parasitic fungus.

In South America, *Scirpus* species have been used since pre-Columbian times to produce mats and other woven goods, including some intended for ritual use (Towle 1952, 232 f.).

Literature

Deimel, Claus. 1996. *Híkuri ba—Peyoteriten der Tarahumara*. Ansichten der Ethnologie 1. Hannover: Niedersächsisches Landessmuseum.

Towle, Margaret Ashley. 1952. Plant remains from a Peruvian mummy bundle. *Botanical Museum Leaflets* 15 (9): 223–46.

Sclerocarya caffra Sond.

(Anacardiaceae)—marula

This tree, a relative of the cashew (*Anacardium occidentale* L.), can grow as tall as 18 meters. It supposedly is or was consumed in South Africa for its inebriating properties (Lewin 1980 [orig. pub. 1929], 297*). It is possible that *marula* was the **kanna** plant or one of the plants known as kanna (Schultes and Farnsworth 1982, 174*). The closely related species *Sclerocarya schweinfurthiana* Schinz. has also been characterized as psychoactive (Lewin 1980, 297*; Schultes and Farnsworth 1982, 187*). Constituents are unknown (Emboden 1979, 191*).

***Scoparia dulcis* L.**

(Scrophulariaceae)—vacourinha, sweet broom

In Amazonia, this plant is referred to as *bati matoshi* or *piqui pichana*, and its dried leaves are smoked as a marijuana substitute (see ***Cannabis indica***) (Duke and Vasquez 1994, 154*). In Brazil, the herbage finds folk medicinal use as an astringent and antispasmodic (Grieve 1982, 427*). The plant is known in central Africa as *osimmiseng*, and its leaves are used in a magical medicine for spells with “worms” (Akendengué 1992, 170*). Members of the Bastar tribe (India) make the leaves into pills that are swallowed to treat “weakness of the semen” (Jain 1965, 244*). The plant contains labdane (**diterpenes**).

***Securidaca longepedunculata* Fresenius**

(Polygalaceae)

A native of western and tropical southern Africa, this tree is used in many cultures as a poison in trials by ordeal and in ordeals for uncovering witchcraft (Neuwinger 1994, 682 ff.*). In West Africa, it is used together with ***Boophane disticha*** for psychoactive purposes. This species is also venerated as a fetish tree in West Africa and is used to provide magical protection from the “evil eye” and the illnesses of the deceased. The plant is one of the most renowned and legendary medicinal plants and abortifacients in Africa. The Nigerian Hausa call it *uwar magunguna*, “mother of medicine.”

Among the Kusase, who live in the extreme northeast of Ghana, the plant is used as a psycho-active substance when a new *baga* (“diviner”) is being initiated. A **snuff** is made of *pelig* roots (*Securidaca longepedunculata*), *datin-vulin* roots (*Ipomoea mauritiana* Jacq. [syn. *Ipomoea digitata* auct. non. L., *Ipomoea paniculata* (L.) R. Br.]; cf. ***Ipomoea* spp.**) or *bailla/punung-buur* roots (*Tinospora bakis*), the root cortex of the *zurmuri* pepper (*Piper guineense* Schumach. et Thonn., also known as ashanti pepper; cf. ***Piper* spp.**), red *nansus* pepper (*Schinus molle* L.; cf. ***chicha***), and the dried head of a bat. The snuff is blown into the initiate’s nose, whereupon he falls into a trancelike state. The Ngindo of Tanzania use a flour made from the root as a snuff for headaches (Neuwinger 1994, 685*).

In Ethiopia, smoke from the root is inhaled as a medicinal **incense** to treat flatulence. In Gambia, “crazy” people burn the root cortex and inhale the smoke (Neuwinger 1994, 684*).

The root contains methylsalicylate, the bark contains the alkaloid securine, and the leaves have yielded tannins, saponins, terpenes, et cetera (Lenz 1913). Securine has stimulating effects upon the central nervous system and can produce effects like those of **strychnine** (Neuwinger 1994, 686). The root contains various **indole alkaloids**, particularly the psychoactive elymoclavine, from the family of the **ergot alkaloids** (Costa et al. 1992).

Literature

Costa, C., A. Bertazzo, G. Allegri, O. Curcuruto, and P. Traloli. 1992. Indole alkaloids from the roots of an African plant, *Securidaca longepedunculata*. *Journal of Heterocycl. Chem.* 29:1641–47.

Lenz, W. 1913. Untersuchungen der Wurzelrinde von *Securidaca longepedunculata*. *Arbeiten aus dem Pharm. Inst. d. Univ. Berlin* 10:177–80.

***Senecio* spp.**

(Compositae)

Many species of this genus, which encompasses some 1,300 species and is found throughout the world, are said to be psychoactive (Schultes and Farnsworth 1982, 188*; Schultes and Hofmann 1992, 56*) or are at least associated with psycho-active plants or preparations (see ***Lophophora williamsii***, ***Trichocereus pachanoi***). The Mexican species *Senecio cardiophyllus* Hemsl. is even referred to as *peyote* (Martínez 1994, 384*). Many *Senecio* species are used in South America as ritual **incense** (Aldunate et al. 1981*). In the Andes regions, they are known as *cundur-cundur* and appear to be mythologically associated with the condor, an animal sacred to the Indians. A *Senecio* species known as *chula-chula* is chewed together with coca (see ***Erythroxylum coca***). Many *Senecio* species contain alkaloids of the pyrrolizidine type (Röder and Wiedenfeld 1977; Schultes and Hofmann 1992, 56*). Cyanoglycosides have also been found (Schultes 1981, 43*). The alkaloid jacobine, together with other pyrrolizidines, passes into the **honey** that is produced from these plants (Frohne and Pfänder 1983, 66*).

In Nepal, various yellow-blooming crucifers are used as ritual offerings. A psychoactive use is unknown.

Literature

Röder, Erhard, and Helmut Wiedenfeld. 1977. Isolierung und Strukturaufklärung des Alkaloids Fuchsisenesionin aus *Senecio fuchsii*. *Phytochemistry* 16:1462–63.

A number of *Senecio* species are used in Mexico and South America to prepare psychoactive drinks and as ritual incense. (A *Senecio* species from Argentina)

***Sida acuta* Burm. f.**

(Malvaceae)

This prostrate or sometimes bushy plant with yellow flowers is found in the tropical zones of Central and South America. The Cuna Indians (Darien, Panama) esteem the plant, which they call *kwala*, as a “mystical medicine” (Duke 1975, 292*). A tea made from the leaves is consumed in Bangladesh to help induce sleep (Ott 1993, 419*).

Among the Maya, this species is known as *chichibeh* (“the little one on the path”). On the Mexican Gulf Coast, its leaves, like those of the closely related *Sida rhombifolia* L., are smoked as a marijuana substitute (see ***Cannabis indica***). The two species are known locally as *el macho*, “the male” (*S. rhombifolia*), and *la hembra*, “the female” (*S. acuta*) (Schultes and Hofmann 1980, 347*). Both of these *Sida* species apparently contain **ephedrine** (Schultes and Hofmann 1992, 56*). When drying, the herbage of *Sida acuta* exudes a distinct aroma of **coumarin**. The leaves are said to contain saponins. Several studies of Caribbean and Philippine specimens of *Sida acuta* have demonstrated the presence of asparagine and **ephedrine** in the roots (Wong 1976, 132*). The alkaloids choline, pseudoephedrine, β -**phenethylamine**, vasicine, vascicine, vasinole, and vasicinone have been found in all parts of *Sida rhombifolia*. The stem contains the **indole alkaloids** hipaphorine, hipaphorine methylester, and cryptolenine. The leaves contain traces of an **essential oil**. The seeds contain sesquiterpenes (gospol, et cetera) (Argueta et al. 1994, 615*).

Sloanea laurifolia

(Elaeocarpaceae)—taque

An herbarium specimen collected by J. A. Steyermark in Venezuela in 1945 bears the note “Fresh fruit are said to produce a kind of *loco* [= crazy] feeling. . . . [T]he ground fruit is boiled” (von Reis and Lipp 1982, 175*). The fruit is also known as *arepa de maiz*, “maize breads” (cf. ***Zea mays***).

***Spiraea caespitosa* Nutt. ex Torr. et A. Gray**

[syn. *Petrophyton caespitosum* (Nutt. ex Torr. Et Gray) Rydb., *Spirea caespitosum*] (Rosaceae)—meadowsweet

The North American Navajo-Kayenta Indians are said to have used this bushlike plant as a narcotic (Moerman 1986, 466*). However, it contains only salicylic acid and should therefore be effective solely as an analgesic (Ott 1993, 420*; Grieve 1982, 525*).

***Stephanomeria pauciflora* (Torr.)**

A. Nels.

(Asteraceae)—blue gum

The root of this plant is said to have been used by the Navajo-Kayenta Indians as a narcotic (Moerman 1986, 469*). It is questionable whether this information is correct, for the root is also used as a kind of chewing gum (Vestal 1952, 53*). The chemistry of the plant is unknown (Ott 1993, 420*). It is, however, regarded as a “life medicine.” Perhaps it is a psychoactive chewing gum.

***Stipa* spp.**

(Gramineae)—sleepy grass

Various species of the genus *Stipa* are found from Texas to Guatemala. In the White Mountains of the region of the Rio Grande, *Stipa vaseyi* Scribn. [syn. *Stipa robusta* (Vasey) Scribn.] is known by the name *popoton sacaton*, which is probably of Aztec origin (Emboden 1979, 191*). This grass is said to have inebriating effects and in Guatemala supposedly is used as a sleeping agent. A related species, *Stipa viridula*, is purported to have a narcotic effect (Emboden 1976, 161*). It has recently been

claimed that another species native to the American Southwest, *Stipa robusta*, exhibits strong psychoactive effects. This sleepy grass lives in a symbiotic relationship with a fungus (*Acremonium*) that is thought to produce the **ergot alkaloid** D-lysergic acid amide (cf. *Turbina corymbosa*) in the seeds. It has been claimed that a dosage of nine seeds will produce LSD-like effects (DeKorne 1995, 127*). Ethnographic evidence for any psycho-active use is lacking.

Sida acuta herbage is thought to contain ephedrine. (Wild plant photographed in Belize)

The herbage of *Sida rhombifolia* is smoked as a marijuana substitute. (Wild plant photographed in northwestern Argentina)

Meadowsweet (*Spirea* spp.) contains analgesic salicylic acid derivatives.

Several American species from the genus *Stipa* are known by the name *sleeping grass* and consumed as sedative teas. (*Stipa ichu* from Chiapas, Mexico)

***Teliostachys lanceolata* Nees var. *crispa* Nees ex Martius**

(Acanthaceae)

This Acanthaceae, known as *toé negro* (cf. ***Brugmansia suaveolens***), is used by the Colombian Kokama Indians both as an **ayahuasca** additive and as a psychoactive substance in its own right. For this purpose, ten leaves are boiled for seven hours over a low flame. The effects are said to be strong. A person loses his or her vision for three days, but during this time he or she can communicate with the spirit of the plant (Schultes 1972, 139*). Chemical studies of the plant have demonstrated that the leaves are devoid of alkaloids (Ott 1993, 402*). The plant is added to ayahuasca only when it is intended for use in “witchcraft” (Duke and Vasquez 1994, 167*).

***Terminalia bellirica* (Gaertner) Roxburgh**

(Combretaceae)—bahera, bellerian myrobalan

The Lodha of West Bengal eat the dried seeds of this plant in order to induce hallucinations. In Southeast Asia, the seeds are known for their narcotic properties. They are used in traditional Chinese medicine as an anthelmintic agent, in Kerala to treat asthma, and in Nepal as a laxative (Ott 1993, 420*). In India, the tree (known as *vibhitika*) is associated with the goddess Kali and is used in black magic to kill enemies (Gupta 1991, 94*).

Bellerian myrobalan is closely related to black myrobalan (*Terminalia chebula* [Gaertn.] Retz.), which is venerated as a sacred tree in Nepal and India. It is said that the god Indra, inebriated on **soma**, was imbibing the drink of immortality (*amrita*, ambrosia) and let fall a drop from heaven to earth; from this drop the myrobalan tree arose. In Tantra, eating myrobalan is said to summon the goddess Shri, the erotic consort of Vishnu (Majupuria and Joshi 1988, 109*).

Myrobalan (Sanskrit *harîtaki*) is an attribute of the Tibetan Medicine Buddha (Bhaisajya-guru) and symbolizes the “elixir of long life.” The second attribute of the Medicine Buddha is the begging bowl, carved out of lapis lazuli, that is filled with *amrita* (= ambrosia), the “divine nectar of enlightenment”

(cf. **soma**) (Birnbaum 1982, 123 ff.).

Literature

Birnbaum, Raoul. 1982. *Der Heilende Buddha*. Bern: O. W. Barth/Scherz.

Tetrapteris methystica Schultes

[syn. *Tetrapteris styloptera* Jusseiu] (Malpighiaceae)—caapi, pinima

This little-known, yellow-flowered climbing bush was first described in 1954 by Richard E. Schultes. The Makú, who live on the Río Tikié (Amazonia), call it *caapi* (cf. ***Banisteriopsis caapi***) and use it for ritual purposes (Schultes 1954, 204). They manufacture from the bark a psychoactive drink that apparently has effects like those of **ayahuasca** and is used in a similar manner. The bark may contain **β-carbolines** (Schultes and Hofmann 1992, 58*).

The Tanimukas call the closely related yellow-flowered *Tetrapteris styloptera* Jussieu—most likely a synonym—*weé-po-awk*. They use the powdered bark medicinally as a hemostatic (Schultes 1983, 137).

Tetrapteris mucronata Cav., known as *caapipinima*, also appears to be used for psychoactive purposes (Schultes and Hofmann 1992, 66 f.*).

Literature

Schultes, Richard Evans. 1954. *Plantae Austro-*

Americanae IX: *Plantarum Novarum vel Notabilium Notae Diversae*. *Botanical Museum Leaflets* 16 (8): 179–228.

———. 1983. *De Plantis Toxicariis e Mundo Novo Tropicales Commentationes XXXI*: Further ethnopharmacological notes on malpighiaceae plants of the northwestern Amazon. *Botanical Museum Leaflets* 29 (2): 133–37.

The seeds of bellerian myrobalan (*Terminalia bellirica*) purportedly are used as a hallucinogen in West Bengal. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Thamnosma montana Torr. et Frem.

(Rutaceae)—turpentine broom

Shamans of the North American Kawaiisu Indians were said to drink a tea from this plant so that they

could become “crazy like coyotes,” i.e., transform themselves into these animals (Moerman 1986, 481*). The plant contains numerous **coumarins** that may have psychoactive effects. It is also possible that it contains **N,N-DMT** (Ott 1993, 420*).

***Thevetia* spp.**

(Apocynaceae)—rattle tree

The genus *Thevetia* is composed of nine species, known as rattle trees or tropical oleander (Anzeneder et al. 1993, 61*). The peels of the fruits are hard and are used to make rattles and clappers for Indian dances.

The Peruvian rattle tree (*Thevetia peruviana*) is planted in tropical gardens around the world for its beautiful flowers.

A number of tillandsias. (Photographed in northern Peru)

One species whose identity has not been clarified is known in Colombia and the surrounding regions as *cabalonga blanca*. It is considered a weaker relative of the true **cabalonga**. *Cabalonga blanca* is said to have magical powers and psychoactive effects and is used as an **ayahuasca** additive.

In Mexico, *Thevetia thevetioides* (H.B.K.) K. Schum. is known as *yoyotl* and is used in folk medicine as a cardiac stimulant and analgesic (Jiu 1966, 252*). *Thevetia peruviana* (Pers.) Schum. [syn. *T. neriifolia* Juss.], known as yellow oleander, is originally from Peru but is now cultivated as an ornamental in all tropical zones of the world, and it is the species whose chemical makeup is best known. The seeds are rich in cardiac glycosides, e.g., peruvoside (Steinegger and Hänsel 1972, 193*). Eight to ten seeds is reportedly the lethal dose for an adult (Roth et al. 1994, 699*). In the Mexican state of San Luis Potosí, *Thevetia peruviana* is known as *palo de San Antonio*, “tree of St. Anthony” (Aguilar Contreras and Zolla 1982, 196*). The name may very well be derived from a psychoactive effect (see ***Claviceps purpurea***). On the Gulf Coast of Mexico, in the territory of the Huastec, the plant is known as *cabalonga de la huasteca* (Aguilar Contreras and Zolla 1982, 196*).

***Tillandsia* spp.**

(Bromeliaceae)—tillandsias

Tillandsias are epiphytes that grow on typical American flora. In pre-Columbian Peru, they were used as a stuffing in the false heads of mummies (Towle 1961, 31*). Tillandsias appear on Mochican ceramic paintings in connection with winged shamans (Andritzky 1989, 169 f.*). It may be that a psychoactive use was once known but has now been forgotten. The plant depicted in the paintings of the Mochica is sometimes interpreted as *Tillandsia purpurea* Ruiz et Pav. (Ott 1996, 108*). Flavonoids have been found in this species (Arslanian et al. 1986). The Tarahumara Indians refer to *Tillandsia mooreana* Smith as *waráruwi*, “peyote companion” (cf. *Lophophora williamsii*), and presumably used it as a peyote substitute (Ott 1996, 108*). The Tarahumara use a related species, the ball moss (*Tillandsia recurvata* [L.] L.), which they call *muchiki chabóame*, as a cough medicine (Deimel 1989, 61). This plant was previously identified as *Tillandsia inflata* Mez. (Bye 1975).

In Brazilian ethnomedicine, *Tillandsia usneoides* (L.) L. (Spanish moss) is used as an analgesic. It is said that a watery extract of this plant induces “visions” (Ott 1996, 420*).

Literature

Arslanian, R. L., et al. 1986. 3-n-methoxy-5-hydroxyflavonols from *Tillandsia purpurea*. *Journal of Natural Products* 49 (6): 1177–78.

Bye, R. A. 1975. Plantas psicotrópicas de los Tara-humaras. *Cuadernos Científicos CEMEF* 4:49–72.

Deimel, Claus. 1989. Pflanzen zwischen den Kulturen: Tarahumaras und Mestizen der Sierra Madre im Noroeste de México. *Ethnobotanische Vergleiche. Curare* 12 (1): 41–64.

Ethnographic objects first brought the tropical rattle tree (*Thevetia* spp.) to the attention of Europe. The hard fruit husks were used as rattles for Indian rhythm instruments and dance belts and anklets. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Winged shamans with featherlike tillandsias. (Painting on a Moche ceramic vessel, from Kutschner 1954)

Tribulus terrestris L.

(Zygophyllaceae)—small caltrops

In Ayurvedic medicine, *Tribulus terrestris* is utilized as an aphrodisiac and as a geriatric agent. This plant, also known as *zama* or *zimpating*, produces fruits that are used in Ladakh to fortify **beer**. The young branches and ripe fruits also are crushed and consumed in milk. High dosages (how high?) are

said to produce delirium (Navchoo and Buth 1990, 319, 320*). The plant has been shown to contain steroids and sapogenin along with some five alkaloids, including harmane, **harmine**, and harmol (Ott 1993, 426*; Festi and Samorini 1997, 26).

In Baluchistan (Pakistan), 10 to 20 g of the dried fruits (*ghur gan*) are ground, mixed with water, and drunk to increase the sexual abilities of men. The ground fruits (*gurgandako*) of the closely related species *Tribulus longipetalus* Viv. [syn. *Tribulus alatus* Del.] are used as a medicinal **snuff** for treating stuffy noses (Goodman and Ghafoor 1992, 55*).

Literature

Festi, Francesco, and Giorgio Samorini. 1997. *Tribulus terrestris* L. (tribolo/caltrop). *Eleusis* 7:24–32.

Trichocline spp.

(Compositae: Mutisieae)—coro

In the Chaco region of northern Argentina, a number of species of the genus *Trichocline* are utilized as psychoactive substances. Locals call them *coro* or *contrayerba*.³³⁹ Jesuit reports from the eighteenth century describe how the Calchaqui Indians used the ground roots to strengthen their **chicha** (**beer** made from maize or other plants). The Mocovies, Toba, and Mataco³⁴⁰ smoke the powdered root alone or mixed with tobacco (cf. **smoking blends**). The smoke is said to have medicinal effects upon stomachaches. Today, the root is also burned alone or with tobacco as an **incense**. The most commonly used species are *Trichocline reptans* (Webb.) Rob., *Trichocline exscapa* Griseb., and *Trichocline dealbata* (Hook. et Arn.) Griseb. (Zardini 1975, 649 f.; 1977). Unfortunately, no chemical studies of the root have been conducted to date. The roots supposedly are sold at herb stands in Argentinian markets in the Chaco region. In Salta, a seller from Germany offered imported calamus roots (*Acorus calamus*) as *coro*.

Literature

Zardini, Elsa M. 1975. Revision del genero *Trichocline* (Compositae). *Darwiniana* 19:618–733.

———. 1977. The identification of an Argentinian narcotic. *Botanical Museum Leaflets* 25 (3): 105–7.

Trichodesma zeylancium R. Br.

(Boraginaceae)—bush tobacco Also known as cattle bush, this shrubby plant has blue flowers and lanceolate leaves and was once used as an inebriant (Webb 1969). In Australia (Arnhem Land), the dried leaves formerly were used as a substitute for tobacco (*Nicotiana tabacum*) (Low 1990, 190*). The entire plant contains 0.01 to 0.07% alkaloids (Collins et al. 1990, 31*).

Literature

Webb, I. J. 1969. The use of plant medicines and poisons by Australian Aborigines. *Mankind* 7:137–46.

Umbellularia californica (Hook. et Arn.) Nutt.

(Lauraceae)—California bay

This evergreen tree is known variously as California laurel, California bay, California olive, Oregon myrtle, pepperwood, headache tree, and California sassafras (Fuller and McClintock 1986, 184*). Its leaves are rich in an **essential oil** with a high concentration of safrole; the principal constituent, however, is umbellulone (Fuller and McClintock 1986, 184*). The bark of the trunk is said to contain **5-MeO-DMT** (Rob Montgomery, pers. comm.). No traditional psychoactive use of this plant is known (cf. *Sassafras albidum*). The leaves are used in folk medicine for headaches (hence the common

name headache tree), colic, and diarrhea (Grieve 1982, 716*). In California, the leaves are used as a spice in place of those of the true bay tree (*Laurus nobilis*).

The caltrop (*Tribulus* spp.) is related to Syrian rue (*Peganum harmala*) and may be useful as a source of β carboline. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

The psychoactive roots of various *Trichocline* species are known in South America as *contrayerba*. They may have served as the model for this European illustration. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

The very pungent-smelling leaves of the California bay tree (*Umbellularia californica*) contain safrole. The bark of the tree is alleged to contain 5-MeO-DMT. (Wild plant photographed in Occidental, California)

***Ungnadia speciosa* Endl.**

(Sapindaceae)—Mexican horse chestnut

It has been suggested that the seeds (sometimes called Texas buckeyes) of this small tree were once used for psychoactive purposes in northern Mexico and Texas (Schultes and Hofmann 1992, 59*). The black seeds, which are 1.5 cm in length, have been found in archaeological contexts together with peyote (*Lophophora williamsii*) and mescal beans (*Sophora secundiflora*) (Adovasio and Fry 1976*). *Ungnadia* seeds contain cyanogenetic compounds (Seigler et al. 1971).

The Mexican horse chestnut (*Ungnadia speciosa*) may be one of the psychoactive plants longest used by humans.

The small plant *Urmenetea atacamensis*, used as a coca substitute, thrives in the driest desert in the world. (Wild plant, photographed in the Atacama Desert, northern Chile)

Literature

Seigler, D., F. Seaman, and T. J. Mabry. 1971. New cyanogenetic lipids from *Ungnadia speciosa*. *Phytochemistry* 10:485–87.

***Urmenetea atacamensis* Phil.**
[formerly also referred to as *Retanilla ephedra*

(Vent.) Brogn.] (Compositae)—coca del suri
This plant, which can grow up to 10 cm in height, is found only in the Atacama Desert of northern Chile—the driest desert in the world—where the local oasis dwellers know it as *coquilla*, “little coca,” or *coca del suri*, “coca of the *suri* bird.” Until recently, the whitish, downy leaves were chewed either alone or together with *llypta* as a coca substitute (see ***Erythroxylum coca***). The inconspicuous plant is used as a source of nourishment by the ostrichlike cursorial birds known as *suri*. A tea of the leaves is used as a treatment for altitude sickness (*puna*) (Aldunate et al. 1981, 218*).

Chewing the leaves produces a slight sensation of numbness in the mouth. A mild psychoactivity (cocalike stimulation) was also observed. Smoking the dried leaves (a good dosage is 0.3 g) produces clear psychoactive effects that are initially somewhat narcotic and then more stimulating. The effects are similar to those produced from smoking dried coca leaves (see ***Erythroxylum coca***). Chemical studies are lacking.

***Utricularia minor* L.**
(Lentibulariaceae)—little bladderwort

In Ladakh, this insectivorous plant is known as *lingna*. There, the dried and powdered leaves are roasted on a flat stone, after which the powder is mixed with water and put in a bottle, which is then buried for ten to fifteen days. The Ladakhis enjoy this drink (*lingeatzish*) primarily in winter. It is said to have very inebriating effects and can cause death if consumed in excess (Navchoo and Buth 1990, 320*).

Valerian (*Valeriana officinalis*) is renowned for its folk medicinal uses as a sleeping and calming agent.

The aromatic roots of the Himalayan valerian species *Valeriana jatamansi* are used as a ritual incense.

***Valeriana officinalis* L.**
(Valerianaceae)—valerian

Valerian is an Old Germanic ritual and healing plant. It was sacred to the goddess Hertha, who rode upon the red deer. Wieland, the shamanic smith of the Germanic mythological world, used the root to heal diseases. For this reason, valerian was also known as *velandswurt*, “Wieland’s root” (Weustenfeld 1995, 13*). In earlier times, valerian was hung on houses as a protection against witches and witchcraft, evil spirits, and devils. The root was also used as a fumigant to keep away the devil (cf. **incense**). In the early modern period, valerian root was regarded as an aphrodisiac and was used to treat the “sacred disease” (epilepsy) (Knoller 1996, 12 f.). It was also known as theriac root, for it was an important ingredient in the panacea **theriac** (Weustenfeld 1995, 15*).

Valerian (along with the variety *Valeriana officinalis* L. var. *sambucifolia* Mikan.) is also called cat weed and is renowned for the power it has to attract cats (cf. ***Nepeta cataria***). The sedative effects that the root has upon the nervous system are quite well known (Pahlow 1993, 64*). Valerian roots are sometimes characterized as a “legal high” with psychoactive powers (Schultes and Hofmann 1980, 368*). In particular, a tea made of equal parts of valerian root and kava-kava (***Piper methysticum***) is

said to produce “beautiful dreams” (Schuldes 1995, 76*). When mixed with hops (*Humulus lupulus*), valerian yields a potent tea for inducing sleep (cf. also **diazepam**).

In South America, *Valeriana longifolia* H.B.K. is regarded as a panacea and stimulant for elderly people suffering from infirmity. There, various *Valeriana* species are referred to as *contrayerba* (cf. **Trichocline** spp.). *Valeriana adscendens* Turz. is known as *hornamo morado* in Peru, where it is used as an additive to San Pedro drinks (cf. **Trichocereus pachanoi**). The North American Blackfeet Indians smoke the roots of *Valeriana sitchensis* Bong, known as tobacco root, either alone or mixed with tobacco (see **kinnikinnick**) (Johnston 1970, 320*). In India and Nepal, the aromatic root of *Valeriana jatamansi* (DC.) Jones [syn. *Valeriana wallichii* DC.], known as *samyo* or *muskbala*, is used as a fumigant or as an ingredient in **incense** for magical and religious rites (Shah 1982, 298*; Shah and Joshi 1971, 421*). The aromatic root of *jatamansi* or *masi*, the closely related species *Nardostachys jatamansi* (D. Don) DC., is even more highly regarded; it is used both as an incense and to treat epilepsy (Shah 1982, 297*). Whether these two incenses have psycho-active properties, as is sometimes asserted, remains an open question. The sesquiterpene ketone valeranon, which is present in *Valeriana officinalis*, *Valeriana jatamansi*, and *Nardostachys jatamansi*, is presumably responsible for the sedative (tranquilizing) effects (Hörster et al. 1977).

The alkaloid actinidine has been found in the genus (Schultes 1981, 42*). Of interest for further research into a possible psychoactivity beyond the sedative effects is the finding that an aqueous extract influences the central nervous system neurotransmitter GABA (γ-aminobutyric acid; see **Amanita muscaria**, **ibotenic acid**, **muscimole**) (Santos et al. 1994).

Vanda roxburghii R. Por.

(Orchidaceae) [syn. *Vanda tessellata* (Roxb.) G.

Don)—vanda

When bees sip nectar from these beautiful orchids, which are found in Sri Lanka, India, and Burma (Myanmar), they soon fall to the ground in a narcotized stupor (cf. **honey**). In India, a psychoactive use of this plant is said to have been derived from observations of this occurrence: “Ayurvedic shamans used the flower in a decoction to achieve the hypnotic narcosis of their office, permitting them a transcendent state of being” (Emboden 1979, 17*).

No active principles are known (Emboden 1979, 194*).

Voacanga spp.

(Apocynaceae)—voacango bush

The bark and seeds of the African species *Voacanga africana* Stapf³⁴¹ contain up to 10% **indole alkaloids** of the iboga type (cf. **Tabernanthe iboga**, **ibogaine**) and reportedly induce stimulating and hallucinogenic effects (Bisset 1985b; Oliver-Bever 1982, 8). The principal alkaloid is voacamine. African sorcerers are said to use the seeds to produce visions. In West Africa, the bark is utilized as a hunting drug and stimulant (Schuldes 1995, 77*). It also is regarded as a potent aphrodisiac. The bark

of *Voacanga bracteata* Stapf is used in Gabon to get “high” (most likely as a marijuana substitute; cf. *Cannabis indica*). It contains 2.46% alkaloids (voacamine, voacamine-*N*-oxide, 20-epi-voacorine, voacangine) that, although closely related to the compounds found in *Tabernanthe iboga*, apparently produce only mild depressant effects (de Smet 1996, 145*; Puiseux et al. 1965).

Voacanga dregei E. H. Mey. is also said to produce hallucinogenic effects (Schultes and Hofmann 1980, 366*). West African sorcerers ingest the seeds of *Voacanga grandiflora* (Miq.) Rolfe for visionary purposes. Unfortunately, the details of this use are still unknown, as the sorcerers keep their knowledge secret.

Zea mays L.

(Gramineae: Poaceae)—maize

First cultivated in Mexico some four thousand years ago, maize is the single most important source of nourishment for many Central and South American Indians. Grains of maize (ferment) are also used to brew numerous **beers** as well as **chicha** (Wedemeyer 1972).

Corn silk (stigmata maydis) plays a role in Indian medicine. It also has some significance in modern phytotherapy, where it is used as a diuretic (Czygan 1989; Rätsch 1991a, 174–78*). In addition, it is “smoked by the Indians in Peru as an inebriant” (Roth et al 1994, 742*; Czygan 1989, 326). In the “drug scene,” corn silk is smoked for inebriating purposes, both alone and as an ingredient in **smoking blends**. In North America, corn silk is one of the ingredients in the ceremonial “tobacco” **kinnikinnick**. The silk (or, more precisely, styles) contains up to 85% alkaloids of an as yet unknown structure (possibly from the family of the **ergot alkaloids** or tryptamine derivatives) that are able to induce states of excitation and delirium when inhaled (Roth et al. 1994, 742*).

Literature (selection)

Wedemeyer, Inge von. 1972. Mais, Rausch- und Heilmittel im alten Peru. *Ethnomedizin* 2 (1/2): 99–112.

Zingiber officinale Roscoe

(Zingiberaceae)—ginger

Ginger comes from the tropical rain forests of Southeast Asia, but it has been planted throughout tropical Asia for at least three thousand years (Norman 1991, 62*) and is now planted in tropical areas around the world. It has acquired an ethnopharmacological significance among many American Indian peoples. It is frequently used both as a spice and as a medicine, e.g., for upset stomachs (Rätsch 1994b, 58*). In Ecuador, where ginger is known as *ajej*, the Shuar, Achuar, and Aguaruna all use it as a hallucinogen. The shamans ingest ginger to obtain magical power (Bennett 1992, 493*). The Cariña

rub a mixture of gingerroot and tobacco (*Nicotiana tabacum*) onto the eyelids of apprentice shamans so that they may be able to see the spirits of the forest. Ginger is also one of the initiatory plants of the novice shamans on the Indonesian island of Siberut:

Voacanga grandiflora produces fruits that resemble testicles. African sorcerers use the fruit as a visionary inebriant.

Corn silk (*Zea mays*) contains a psychoactive alkaloid.

Used throughout the world as a spice, ginger (*Zingiber officinale*) also has a certain significance as a magical shamanic drug.

Indians use ginger (*Zingiber officinale*), which they cultivate in the American tropics, for both medicinal and psychoactive purposes. (Photographed in Chiapas, Mexico)

Finally, every novice is given “seeing” eyes. He goes with the teacher to a secluded spot in the vicinity and must make a promise never to betray the secret. . . . Old shamans explain that the novice is called upon to massage a small disease stone out of a spear that he has brought with him and which the ancestors have placed inside as a test. After he has attempted this for a while without success, the master shows him how it is done. Afterward, burning ginger juice is dripped from a little bottle into the novice’s eyes and he becomes able “to see.” The master then asks him what he sees. (Schefold 1992, 116)

Ginger extracts have clear effects upon the central nervous system, but whether they are able to induce hallucinations (in what dosages?) is questionable (Bennett 1992, 490*). The use of ginger as an aphrodisiac is widespread. The Secoya number ginger among the *nuni*, the plants of supernatural origin (Vickers and Plowman 1984, 33*).

In Papua New Guinea, the roots of bitter ginger, a wild ginger species (*Zingiber zerumbet* [L.] Sm.), are known as *kaine*. They purportedly were used together with a *Homalomena* species (***Homalomena* sp.**) as a hallucinogen (cf. also ***Kaempferia galanga***). In the South Pacific, a ginger species is used for magical purposes. On the Gazelle Peninsula (formerly New Pomerania), ginger leaves and roots are used in all magical acts.

For these reasons, ethnologists have characterized ginger as the “mandrake root of the indigenous people” (cf. ***Mandragora officinarum***) (Meier 1913).

Poison hemlock *Conium maculatum* L. (From *Giftgewächse* [Poisonous Plants], 1875)

Reputed Psychoactive Plants

“Legal Highs”

Because of the increasingly strict drug laws that began to be implemented in the 1960s, aficionados have looked for new possibilities for obtaining a legal high. In doing so, they have swallowed or smoked a large number of legally obtainable plant products. Some of these legal highs do in fact have psychoactive effects, others work for only some of their users (e.g., *Coleus blumei*), and still others appear to have not much of an effect upon anyone. At the beginning of the 1970s, brochures and booklets introducing these legal plants began to appear (Gottlieb 1973*; Grubber 1991*). Through these as well as the “grapevine,” knowledge (or semi-knowledge) about exotic and legal psychoactive plants was disseminated (Brown and Malone 1978*). At the same time, numerous popular myths and legends about the efficacy of various plants also arose. This section provides a short introduction to those plants that are still regarded as legal highs but whose psychoactive properties are doubtful. It should be noted, however, that psychoactivity in these plants cannot be ruled out. Perhaps future research will uncover some interesting insights concerning, for example, appropriate methods of preparing and processing these plants, possible synergistic relationships with other ingredients, and other useful information.

“ ‘Legal high’ means it does not work!”

Terence McKenna

(lecture, February 1996)

The Genera Discussed in This Section

Actinidia, Anethum, Arisaema

Borago

Catharanthus, Cineraria

Daucus, Digitalis, Dioon

Equisetum, Evodia

Foeniculum

Hydrangea

Laurus, Liriosma

Matricaria (= *Chamomilla*), *Musa*

Panax, Phrygilanthus, Podophyllum, Polygala

Scutellaria, Sebastiana, Swainsonia

Ungernia

Wisteria

Many long-known medicinal plants now have a reputation of being psychoactive and are regarded as legal highs. It is highly questionable whether fennel, horsetail, and the others actually do produce anything apart from a placebo-induced state of inebriation. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731.)

From time to time, the leaves of the carrot (*Daucus carota*) have been smoked as a marijuana substitute. This “legal high” is sometimes attributed with a certain psychoactivity.

***Actinidia polygama* (Sieb. et Zucc.) Planch. ex Maxim.**

(Actinidiaceae)—Chinese cat powder

It is rumored that the dried leaf of this tree, which is closely related to the kiwi bush (*Actinida chinensis* Planch.) (Schneebeli-Graf 1992, 93*), is a potent inebriant or strong tranquilizer for animals; hence its common name *Chinese cat powder*. In Asian zoos, it purportedly is used to sedate large wild cats. The branches and young leaves of this plant are said to produce hallucinogenic effects (Grubber 1991, 60*). The bush is found in Manchuria, Korea, Japan, and western China and on the island of Sakhalin. Both metatabilacetone and actinidine have been found in this plant (Emboden 1979, 168*).

***Anethum graveolens* L.**

(Apiaceae: Umbelliferae)—dill

Known primarily as a spice, dill has also long enjoyed a reputation as an aphrodisiac. It is also said to be an inebriant, for “the garden plant is numbered among the so-called legal highs; when dried and smoked, dill induces a mild euphoria” (Sahihi 1995, 153*). In the American “drug scene,” dill leaves are sometimes smoked mixed with glutamate. Dill contains an **essential oil** (approximately 4%) consisting of carvone, limonene, phellandrene, terpinene, and myristicin. It is likely that dill is considered to be psychoactive because it contains myristicin (cf. *Myristica fragrans*) as well as dillapiol, a nonaminated precursor for the synthesis of DMMDA-2 (cf. *Petroselinum crispum*) (Gottlieb 1973, 12*). However, as Hildegard von Bingen noted, “[N]o matter how [dill] is eaten, it makes people sad” (*Physica* 1.67).

***Arisaema dracontium* (L.) Schott**

(Araceae)—green dragon, dragon root

Also known as memory root, dragon root is reputed to have hallucinogenic effects (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 366*). There are several potentially toxic plants in the Family Araceae (e.g., *Arum*, *Dieffenbachia*, *Dracunculus*) as well as such questionable hallucinogens as sweet flag (*Acorus calamus*) (cf. Plowman 1969). The genus *Arisaema* is known for its allergenic effects when touched or eaten. Fruits and other parts of the plant contain microscopically small needles of crystallized calcium oxalate, contact with which can lead to heavy histamine secretion (Turner and Szczawinski 1992, 116*). The homeopathic agent *Arum dracontium* hom. is obtained from the flowers of this plant. The Ojibwa Indians are said to have used the root to counteract witchcraft (Moerman 1982, 101*). The related species *Arum maculatum* L. was used as a wine additive (cf. *Vitis vinifera*).

Literature

Plowman, Timothy. 1969. Folk uses of New World aroids. *Economic Botany* 23 (2): 97–122.

Many species of jack-in-the-pulpits (*Arisaema*), members of the Family Araceae, are capable of producing dangerous toxic effects. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

A species of Chinese cat powder (*Actinidia* sp.) has a psychoactive effect upon cats.

Dill (*Anethum graveolens*) has a folk reputation as an aphrodisiac. It is used in the “drug scene” as a marijuana substitute.

***Borago officinalis* L.**

(Boraginaceae)—borage

This ancient cultigen and spice plant, which is common in Europe and North America, is purported to have psychoactive or hallucinogenic effects (Farnsworth 1972, 68*; Schultes and Hofmann 1980, 367*). Borage contains the slightly toxic pyrrolizidine alkaloids lycopsamine and intermedin, as well as their acetyl derivatives, amabiline and thesinine (Roth et al. 1994, 169*). In phytotherapy, borage is indicated for several conditions that are at least partially related to consciousness (Haas 1961): “An invigorating tea of leaves and flowers is ideal for stress, depression, or following a treatment with cortisone. Borage mitigates fever, dry coughs, and skin rash. The oil of the seeds is helpful for menstrual problems, nervous intestinal complaints, high blood pressure, and hangovers” (Bremness 1995, 233*). Borage pills are sold to dehydrate and “purify the blood.” Flowers harvested during the time of blossom are ingested as a folk medicinal sedative (Ratka 1992).

Literature

Haas, H. 1961. Pflanzliche Heilmittel gegen Nervenund Geisteskrankheiten. *Arzneimittel-Forschung* 4:49–59.

Ratka, Otto. 1992. *Borago*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:528–32. Berlin: Springer.

Today, borage (*Borago officinalis*) is usually planted as an ornamental.

The white-blossomed variety of the Madagascar periwinkle (*Catharanthus roseus* f. *albus*).

Madagascar periwinkle (*Catharanthus roseus*) was first encountered in the Caribbean. It is said to have psychoactive effects, although we know of no appropriate methods of preparation.

***Catharanthus roseus* (L.) G. Don**

[syn. *Ammocallis rosea* Small, *Lochnera rosea* (L.) Reichb., *Vinca rosea* L.]

(Apocynaceae)—Madagascar periwinkle

The Madagascar periwinkle is apparently from the West Indies (Caribbean) but was first described for Madagascar (Morton 1977, 237*). It has pink flowers but also occurs in a pure white form (*Catharanthus roseus* f. *albus* [Sweet] Woodson). This evergreen is one of the truly well-investigated medicinal plants and is the subject of a rich monographic literature. In Caribbean folk medicine, periwinkle tea is used to treat diabetes. In Florida, the leaves are dried and smoked as a marijuana substitute (see ***Cannabis indica***) (Morton 1977, 241*). It has often been claimed that the dried leaves are also smoked in Europe and are able to produce “euphoria and hallucinations” (Schuldes 1995, 30*). On the islands of Guadeloupe, the plant is known as *herba aux sorciers* (“plant of the

sorcerers”); it may possibly be used in magical voodoo rites (see **zombie poison**).

The plant contains more than seventy alkaloids, most of them **indole alkaloids**, some of which are of the **ibogaine** type (e.g., catharanthine; Scott et al. 1980). The root cortex contains the sedative and antihypertensive alstonine (cf. ***Alstonia scholaris***) (Morton 1977, 238*). Recent investigations have shown that different laboratory methods can influence the biosynthesis of indole alkaloids and may even be able to control it to produce a desired outcome (Schrisema and Verpoorte 1992). In the future, this may make it possible to breed strains that will in fact produce psychoactive indoles of the ibogaine or voacangine types (cf. ***Tabernanthe iboga***, ***Voacanga spp.***).

The use of *Catharanthus* is not without risk. Chronic use has been observed to result in severe damage to the central and peripheral nervous systems (Morton 1977, 241*; Roth et al. 1994, 204*).

The dwarf periwinkle (*Vinca minor* L.), also known as the sorcerer’s violet (Emboden 1974, 66*), is occasionally characterized as having psychoactive properties (Schultes and Hofmann 1980, 366*). It contains a number of indole alkaloids (including vincamine) with antihypertensive effects (Roth et al. 1994, 730*; Wilms 1972). “It was believed to offer protection against witches and storms and was also used at séances. Periwinkle was a component of many love drinks” (Weustenfeld 1995, 45*).

Literature (selection)

Schrisema, J., and R. Verpoorte. 1992. Regulation of indole alkaloid biosynthesis in *Catharanthus roseus* cell suspension cultures, investigated with ¹H-NMR. *Planta Medica* 58 suppl. (1): A608.

Scott, A. Ian, Hajime Mizukami, Toshifumi Hirata, and Siu-Leung Lee. 1980. Formation of catharanthine, akuammicine and vindoline in *Catharanthus roseus* suspension cells. *Phytochemistry* 19:488–89.

Wilms, K. 1972. Chemie und Wirkungsmechanismus von Vinca-Alkaloiden. *Planta Medica* 22:324–33.

Cineraria aspera Thunb.

(Compositae)—mohodu-wa-pela

It is rumored that this South African plant has psychoactive or hallucinogenic effects (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*). Unfortunately, details about its use or effects are lacking (Emboden 1979, 173*).

Daucus carota L. ssp. *sativus* (Hoffm.) Schübl. et G. Martens

(Umbelliferae)—carrot

It is difficult to believe that this popular vegetable could have any psychoactive effects, but the reports to this end are numerous (Schultes and Hofmann 1980, 367*). The aboveground leaves are dried and smoked and are said to produce marijuana-like effects (cf. ***Cannabis indica***). Amazingly, no information is available about the components of the leaves (Roth et al. 1994, 295*). In former times, carrot root was used as a counterfeit mandrake (see ***Mandragora officinarum***). The leaves and corolla of the Eurasian wild carrot (*Daucus carota* L. ssp. *carota*) are said to produce “better” effects. Mattioli wrote that combining the seeds with **theriac** will incite “unchaste desires.”

Digitalis purpurea L.

(Scrophulariaceae)—common foxglove Common throughout the mountains of central Europe (Alps) and found in many gardens as an ornamental, foxglove is one of the most potent poisonous plants known. This notwithstanding, there are rumors that the herbage is used for psychoactive or even hallucinogenic purposes (Schultes and Hofmann 1980, 367*). Foxglove contains several cardiac glycosides that have medicinal value when used in low dosages (Withering 1776/1785); higher

dosages can cause cardiac arrest (Luckner and Diettrich 1992). As little as 0.3 g of dried leaves can be dangerously toxic for adults (Roth et al. 1994, 307*).

Literature

Luckner, Martin, and Beate Diettrich. 1992. *Digitalis*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 4:1168–87. Berlin: Springer.

Withering, William. 1963. *Bericht über den Fingerhut und seine medizinische Anwendung mit praktischen Bemerkungen über Wassersucht und andere Krankheiten*. Mannheim: Boehringer.

Red foxglove (*Digitalis purpurea* L.). (From *Giftgewächse*, 1875)

In some circles, dwarf periwinkle (*Vinca minor*) is esteemed as a magical plant. It is said that the flowers are able to stimulate channeling.

When dried, the flowering top of wild carrot (*Daucus carota* ssp. *carota*) is claimed to be usable as a marijuana substitute.

The pharmacologically highly active foxglove (*Digitalis purpurea*) is sometimes attributed with mind-altering powers.

***Dioon edule* Lindl.**
(Cycadaceae)—Mexican cycad

This edible cycad is from Mexico, where it is known as *chamal*. It is reputed to have psycho-active or even hallucinogenic effects (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*). This assumption is apparently due to the fact that in Mexico the plant is also known as *hierba loca*, “crazy herb” or “crazy-making herb,” and is said to cause animals to act strangely (Reko 1938, 185*). No other details suggesting any actual psychoactivity are known (Aguilar Contreras and Zolla 1982, 91*). The large seeds yield a good starch flour (Bärtels 1993, 59*). In Mexican folk medicine, the seeds are utilized to treat neuralgia (Martínez 1994, 409*). The plant contains the biflavones amentoflavone (main component), bilobetin, sesquioflavone, ginkgetin, sciadopitysin, 7,4’,7”,4”-tetra-*O*-methyamentoflavone, and diooflavone (Dossaji et al. 1973, 372).

Literature

Dossaji, S. F., E. A. Bell, and J. W. Wallace. 1973. Biflavones of *Dioon*. *Phytochemistry* 12:371–73.

***Equisetum arvense* L.**
(Equisetaceae)—field horsetail

The horsetail is a well-known medicinal plant that is used in folk medicine around the world to treat diarrhea. It is uncertain why it is sometimes characterized as psychoactive (Schultes and Hofmann 1980, 367*). It contains primarily silicic acid (up to 10%), flavonoids, saponins, potassium salts, and other compounds (Pahlow 1993, 273*). The closely related species *Equisetum fluvatile* L. and *Equisetum hyemale* L. are regarded as mildly toxic. The marsh horsetail (*Equisetum palustre* L.)

contains the alkaloids palustrine and palustridine, which can cause the “staggers” in animals. All species of *Equisetum* have been found to contain traces of **nicotine** (Roth et al. 1994, 321 f.*). In southern Mexico, *Equisetum myriochaetum* Schlecht. et Cham. is regarded as an aphrodisiac (Rätsch 1994b, 86*; cf. Pérez G. et al. 1985). Alison B. Kennedy has proposed that the **soma** plant was a Himalayan species of *Equisetum*.

Literature

Pérez Gutiérrez, R. M., G. Tesca Laguna, and Aleksander Walkowski. 1985. Diuretic activity of Mexican equisetum. *Journal of Ethnopharmacology* 14:269–72.

***Evodia bonwickii* F. Muell.**

[= *Euodia*]
(Rutaceae)

This plant has a reputation of producing “psycho-tomimetic” effects (Farnsworth 1972, 71*; Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 368*). The shrub is used in Papua New Guinean ethnomedicine for treating psychological complaints (Scott 1963). **Coumarins** have been detected in several species of the genus (*E. alata* F. Muell., *E. beleha* Baill., *E. hupehensis* Dode, *E. viteflora* F. Muell.).

Literature

Scott, K. 1963. Medicinal plants of the Mt. Hagen people in New Guinea. *Economic Botany* 17:16–22.

Foeniculum vulgare

[syn. *Foeniculum officinale*]
(Umbelliferae)—fennel

It has often been claimed that fennel or fennel oil can have psychoactive effects (Albert-Puleo 1980, 339). This psychoactivity has been suggested since at least the time of Hildegard von Bingen, who noted, “No matter how it is eaten, it makes people happy. . . . Even a person who is plagued by melancholy, he should pound fennel to a juice and rub this often on the forehead, temples, chest, and abdomen, and the melancholy in him will yield” (*Physica* 1.66).

Smoked, the herbage of this well-known spice is said to be psychoactive (Schultes and Hofmann 1980, 367*). Fennel contains a sweet-smelling **essential oil** (around 6%) consisting primarily of *trans*-anethol and fenchene (Brand 1993; Pahlow 1993, 132*). Fennel tea finds folk medicinal use as a calmative (which is probably how it acquired its psychoactive reputation). The seeds are said to contain the greatest amount of “psychotropic oil” in the plant (Grubber 1991, 32*). Estragole, found in the essential oil, is regarded as a precursor to 4-methoxy-amphetamine (Gottlieb 1973, 50*). Anethol has a primarily estrogenic effect (Albert-Puleo 1980). Fennel and anise are used in Greece in the production of ouzo (see **alcohol**).

The Mexican cycad *Dioon edule* is edible and is said to have inebriating effects.

The marsh horsetail (*Equisetum arvense*) is a very common wild plant in Europe.

The blossoming herbage of wild fennel (*Foeniculum vulgare* var. *vulgare*) is said to be usable as a marijuana substitute.

The Asian *Hydrangea paniculata* in full bloom.

Hydrangea paniculata Sieb. var. *grandiflora*

(Saxifragaceae)—peegee hydrangea

This garden and ornamental plant, which is from China and Japan (Grubber 1991, 39*), has occasionally been described as a euphoriant, although its use is “strongly unadvised” (Schuldes 1995, 41*). When smoked, the dried leaves and flowers are said to have effects similar to those of marijuana (see *Cannabis indica*). The leaves contain the isocoumarin hydrangenol, which has been linked to contact allergies (Roth et al. 1994, 411*). Other constituents include a substance known as hydrangin, saponins, and hydrocyanic acid compounds (Gottlieb 1973, 20*).

Literature

Takeda, Kosaku, Tomoko Yamashita, Akihisa Takahashi, and Colin F. Timberlake. 1990. Stable blue complexes of anthocyanin-aluminium-3-*p*-coumaroyl- or 3-caffeoyl-quinic acid involved in the blueing of *Hydrangea* flower. *Phytochemistry* 29 (4): 1089–91.

Laurus nobilis L.

(Lauraceae)—true laurel, sweet bay

The evergreen laurel tree was sacred to the ancient Greeks. It was consecrated especially to Apollo, the god of mental ecstasy. According to ancient mythology, the plant was originally an enchanting woman or nymph named Daphne. Hence, *daphne* was another name for this tree in ancient times.³⁴² The aromatic leaves were once used as an additive to **beer** and **wine**.

Laurel leaves were an important **incense** at Delphi. The Pythia, the oracular priestess of Delphi, would chew fresh laurel leaves and inhale laurel smoke before falling into a trance, during which she would open up her body to the god Apollo and allow him to utter prophecies through her mouth (cf. *Hyoscyamus albus*). The ancient singers, poets, and seers who chewed laurel leaves or inhaled the smoke were known as *daphnephages* (Melas 1990, 54 ff.). The priest-physicians of Asclepius (cf. *Papaver somniferum*) would inhale laurel smoke so that they could diagnose the causes of diseases (so-called daphnomancy). Their practice entailed more than simply inhaling the smoke, however, for they also interpreted the crackling of the burning leaves as well as the shape of the rising smoke (Rätsch 1995a, 222 –27*).

In the ancient literature (Dioscorides, Pliny), the true laurel was characterized as a potent psychoactive plant. According to Proclus, laurel smoke was well suited for holding spirits that appeared so that they could be placed into service. To date, all attempts at using laurel for psychoactive purposes have failed. It is likely that other plants were also known as *daphne* in ancient times, and one of these species—whose botanical identity has remained unknown—may have been psychoactive:

The leaves of other trees or bushes that we refer to as laurel are usually bitter and often even toxic. The snowball [*Viburnum* spp.] is known as bastard or stone laurel, while rose laurel refers to the oleander [*Nerium oleander*; cf. **honey**], summer laurel to the sassafras tree [***Sassafras albidum***], poison laurel to the false star anise [*Illicium anisatum* L. (syn. *Illicium religiosum* Sieb. et Zucc.)], wild laurel to the English holly [*Ilex aquifolium* L.; cf. ***Ilex paraguariensis***], camphor laurel to the camphor tree [***Cinnamomum camphora***], mountain laurel to the laurel rose [*Kalmia* spp.; cf. **kinnikinnick**], and cherry laurel to the cherry laurel [*Laurus cerasi*]. The most poisonous are the leaves of the mountain laurel, which the Delaware Indians used to prepare their version of the hemlock drink [cf. ***Conium maculatum*, witches' ointments**] for purposes of committing suicide. (Root 1996, 240*)

Umbellularia californica is known as California laurel; its leaves are used as a substitute for those of the true laurel.

Laurel leaves (from *Laurus nobilis*) contain 2% **essential oil**, consisting of cineol, pinene, phellandrene, sesquiterpenes, eugenol, terpineol, linalool, geraniol, and bitter substances.

Literature

Melas, Evi. 1990. *Delphi: Die Orakelstätte des Apollon*. Cologne: DuMont.

A laurel tree (*Laurus nobilis*) at the temple of Apollo at Delphi.

The powdered wood of *Liriosma ovata* is found in international trade under the name *muira puama*.

True chamomile (*Matricaria recutita*) is an ancient medicinal plant that is sometimes attributed with psychoactive powers.

***Liriosma ovata* Miers**

[syn. *Dulacia inopiflora* (Miers) O. Kuntze, *D. ovata* (Miers) K., *Liriosma inopiflora* Miers, *L. micrantha* Spruce ex Engl.]
(Olacaceae)—potency wood, muira puama

This small tree, which grows to a height of only about 15 meters, comes from tropical South America (the Amazon basin). The wood of the trunk and roots is marketed internationally under the name *lignum muira puama* and is esteemed chiefly as an aphrodisiac (potency wood!) and nerve tonic (600 to 1,200 mg) (Gottlieb 1974, 54*; Stark 1984, 87*). Small pieces of the wood are added to a number of psychoactive **smoking blends**. It is sometimes claimed that the wood produces not just erotic but also psychoactive effects. The constituents are completely unknown (Schweins and Sonnenborn 1993, 706). The dried roots of a related tree, *Ptychopetalum olacoides* Benth., are also sold under the same name (*lignum muira puama* and also *radix muira puama*). These roots contain a mixture of esters composed of the behenic acid ester of lupeol (0.4 to 0.5%), phytosterols, and an **essential oil** consisting of camphene, camphor, β -caryophyllene, α -humulene, and α and β -pinene. This root is said to have aphrodisiac effects. Experimental and pharmacological studies, however, are lacking (Brand 1994, 308 f.).

Literature

Brand, Norbert. 1994. *Ptychopetalum*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 6:307–10. Berlin: Springer.

Schweins, Sabine, and Ulrich Sonnenborn. 1993. *Liriosma*. In *Hagers Handbuch der pharmazeutischen Praxis*, 5th ed., 5:706–7. Berlin: Springer.

***Matricaria recutita* L.**

[syn. *Matricaria chamomilla* L., *Chamomilla recutita* (L.) Rauschert]
(Asteraceae)—true chamomile

Chamomile was one of the most highly esteemed medicinal plants of Asclepius, the late ancient Greek god of healing (cf. ***Laurus nobilis***, ***Papaver somniferum***). It appears that the temple sleepers who came to seek help found that chamomile was frequently recommended during their therapeutic and visionary dreams (Rätsch 1995a, 194*). It is uncertain why chamomile acquired its reputation as a psychoactive plant (Schultes and Hofmann 1980, 367*). The entire plant contains an **essential oil** of complex composition whose main components are α -bisabolol and chamzulene. Also present are flavonoids and **coumarins**, which produce the well-known anti-inflammatory effects of chamomile only in connection with (synergistically with) the **essential oil** (Schilcher 1987). Apart from occasional allergic reactions, the toxicological literature contains no reports of truly interesting effects (Roth et al. 1994, 489*).

Literature

Schilcher, Heinz. 1987. *Die Kamille*. Stuttgart: WVG.

***Musa x sapientum* L.**

(Musaceae)—banana

In the mid-1960s, a rumor surfaced espousing the idea that dried banana peels or scrapings of the inner peel could be smoked and that the effects were identical to those of marijuana (cf. ***Cannabis indica***) (Schultes and Hofmann 1980, 367*). This rumor was based in no small part on the song “Mellow Yellow,” by the folk/rock singer Donovan (DeRogatis 1996, 59; Krikorian 1968, 385). Many young hippies of the time truly believed that it was possible to “take a trip” using these dried or baked peels. *Time* magazine featured a lead article “Tripping on Banana Peels” (April 1967) that popularized the idea even more. In the United States, the government actually initiated studies to determine whether the banana should be scheduled as a dangerous drug (because of the tremendous “danger of misuse”). The rumor has remained alive up to the present day, and from time to time it appears anew. It has even been claimed that banana peels contain a highly efficacious alkaloid called “bananadine” (Krikorian 1968). The only substance in bananas that may possibly be active is serotonin. According to our current pharmacological understanding, however, serotonin is inactive when ingested orally (cf. ***Panaeolus subbalteatus***).

Toward the end of the 1960s, smoking dried banana peels became a popular way to get “high.” (Banana inflorescence with unripe fruit)

Literature

Krikorian, A. D. 1968. The psychedelic properties of banana peel: An appraisal. *Economic Botany* 22:385–89.

***Panax ginseng* C.A. Mey**

[syn. *Panax schinseng* Th. Nees]

(Araliaceae)—ginseng (panacea)

Ginseng is the most renowned medicinal plant in Asia and has become the very symbol of traditional Asian or Chinese medicine and phytotherapy. The plant has also been called the mandrake of the East and the Chinese mandrake (cf. ***Mandragora officinarum***, ***Phytolacca acinosa***) (Kirchdorfer 1981, 30 ff.). These names may be the origin for ginseng’s reputation as a psychoactive plant (Schultes and Hofmann 1980, 367*). Ginseng is one of the most well-known aphrodisiacs and is also regarded as a panacea (Kimmens 1975). The ginsenosides in the root have general tonic and stimulating (“harmonizing”) effects on the body and mind (Fulder 1984, 1985). The Chinese say that ginseng “kindles the inner fire.” Ginseng is used in homeopathy for a variety of ailments, including defects of memory and depression. It is found in numerous traditional and modern nerve tonics (Hu 1976). Ginseng is a harmonizing and somatensive medicine, i.e., it stimulates in a completely nontoxic manner and produces no stress. It increases the flow of oxygen to brain cells and can even alleviate the lack of oxygen in the brain that can be caused by amphetamines and other stimulants (Fulder 1995, 210). It lowers the amount of **alcohol** in the blood by about half, i.e., consuming ginseng can shield a person from becoming inebriated (Lee 1996, 47 ff.).

In the toxicological literature, the side effects of frequent use of ginseng are given as euphoria and sleeplessness (Roth et al. 1994, 532*). The dried leaves find use in **smoking blends**. It is doubtful whether these have psychoactive effects. The same is true for American ginseng, *Panax quinquefolium* L. (Emboden 1986, 165*; Pritts 1995).

Pritts, Kim Derek. 1995. *Ginseng: How to find, grow, and use America’s forest gold*. Mechanicsburg, Pa.: Stackpole Books.

***Phrygilanthus eugenioides* (L.) H.B.K.**

(Loranthaceae)

A relative of mistletoe (*Viscum album* L.), *Phrygilanthus eugenioides* is used in the voodoo cult as a magical plant. It is said to have psychoactive or hallucinogenic powers (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*). Curiously, the ancient texts suggest that mistletoe may also produce psychoactive effects (cf. ***Benthamia alyxifolia***).

***Podophyllum peltatum* L.**

(Podophyllaceae)—mayapple

The mayapple is from North America, where it is also called mandrake, wild mandrake, American mandrake, Indian apple, devil’s apple, et cetera (Morton 1977, 87*). The number of names can lead to

some confusion. *Mandrake* is actually the English name for *Mandragora officinarum*. Settlers applied the name to the mayapple because North American Indians used its root as an amulet and as medicine (Emboden 1974, 149*). Because of this confusion, many people, especially English-speaking Americans, continue to believe that the mayapple is psychoactive. But the root contains no known psychoactive constituents, only toxic glycosides and podophyllin, a resin with cathartic effects (Meijer 1974; Morton 1977, 88*).

The Asian mayapple (*Podophyllum pleianthum* Hance [syn. *Dysosma pleiantha* (Hance) Woodson]), a native of China and Japan, is mixed with hemp (*Cannabis sativa*) and sweet flag (see *Acorus calamus*) to produce a psychoactive substance that “allows one to see spirits” (Li 1978, 23*). In the Kumaon region of India, the seeds of a species known as *bankakri* (*Podophyllum hexandrum* [syn. *P. emodi* Wall. ex Hook. f. et Th.]) are used to ferment an alcoholic beverage (**beer**) (Shah and Joshi 1971:417*).

In homeopathy, the extract Podophyllum is still used in various dilutions. While developing its symptom picture, some strong alterations of consciousness were observed:

The Asiatic ginseng root and especially the wild-grown Korean ginseng root are attributed with aphrodisiac, stimulating, and magical powers as well as with mind-altering effects. (Typical *Panax ginseng* roots from Korea)

The mayapple (*Podophyllum peltatum*), which blooms in the month from which it takes its name, is also known as the American mandrake.

Podophyllum exhibits a bilious temperament. . . . Furthermore, there exists the delusion of a serious heart or liver disease, he [the patient] believes that he is becoming seriously ill and will die. Everything makes him melancholy and sad, and nowhere does he see a ray of light. Sometimes, the delusion arises that through his own fault he has gambled away his own grace or endangered the well-being of his soul by a mortal sin. Still others feel as if the clouds in heaven were too dark or everything were running the wrong way. (Vonarburg 1996, 215)

This example provides a clear illustration of the ways in which the psychological patterns that arise when a medicine is administered can be influenced and shaped by a person’s culture.

Literature

Meijer, Willem. 1974. *Podophyllum peltatum*—may apple: A potential new cash-crop plant of eastern North America. *Economic Botany* 28:68–72.

Polygala tenuifolia Willd.

(Polygalaceae)

This plant is native to China and Inner Mongolia and is the source of *yuan-zhi* (= *yuan-chih*, radix polygalae), which traditional Chinese medicine prescribes to “calm the mind” and “heal emotional disorders.” It is used to treat nervousness, sleeplessness, forgetfulness, mood swings, and depression (Paulus and Ding 1987, 258*). Also known as *chodat* and *hsiao-ts’ao*, the plant was prescribed in Taoist medicine to increase brain activity and enhance memory. This may be the reason why it is occasionally regarded as psychoactive (Schuldes 1995, 63*). It is used in the manufacture of **herbal**

ecstasy. The “active component” is said to be “senegine,” which makes up 7% of the dry weight (Gottlieb 1973, 11*). The chemistry is well understood. The root contains primarily polygalitol, tetramethoxyanthones, and triterpenes (Paulus and Ding 1997, 259*) but not a trace of psychoactive compounds. The very similar *Polygala sibirica* L. is sometimes sold in place of this Chinese root drug.

***Scutellaria lateriflora* L.**

(Labiatae)—mad-dog skullcap

Skullcap is a component of **smoking blends** with alleged psychoactive effects that are offered as a marijuana substitute (see ***Cannabis indica***). The herbage formerly was used as a sedative and nerve tonic and was even prescribed for the treatment of epilepsy, neuralgia, and sleeplessness. The plant contains the flavonoid scutellarin, which has sedative and antispasmodic effects (Foster and Duke 1990, 186*). A species described under the name *Scutellaria arvense* is reputed to have psychoactive or hallucinogenic effects (Schultes and Hofmann 1980, 367*).

***Sebastiania pavonia* Muell. Arg.**

(Euphorbiaceae)

This euphorbia has a questionable reputation as a hallucinogen (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*). This assumption apparently dates back to a report by Victor A. Reko in his book *Magische Gifte* [Magical Poisons] (1938, 176–81*), which claimed that North American Yaqui Indians use the crushed seeds of the plant as a tonic during strenuous exertion.

***Swainsonia galegifolia* R. Br.**

(Leguminosae)

As with so many species from the Legume Family, it has been alleged that this plant may have psychoactive effects (Schultes and Farnsworth 1982, 187*; Schultes and Hofmann 1980, 367*).

Ungernia minor

(Amaryllidaceae)—ungernia

This little-known member of the Amaryllis Family is alleged to have psychoactive or even hallucinogenic effects (Farnsworth 1972, 68*). The biologically active alkaloid ungminorine was discovered in this plant (Abdymalikova et al. 1966). However, not even the botany of this plant is well understood (Schultes and Farnsworth 1982, 187*). It may have been confused with ***Boophane disticha***.

Literature

Abdymalikova, N. V., Y. B. Zakirov, and I. K. Kamilov. 1966. Some pharmacological activities of the new alkaloid ungminorine. *Akad. Nauk. Uz. SSR, Khim. Biol. Otd.* Jg.:36–40.

***Wisteria sinensis* (Sims) Sweet**

[syn. *Wisteria chinensis*]

(Leguminosae: Fabaceae)—Chinese wisteria

This climbing bush is originally from China. It produces clusters of wonderfully aromatic flowers and is now a popular ornamental. The plant has been alleged to be psychoactive, probably because of its close relationship with and similarity to ***Sophora secundiflora*** (Schultes and Hofmann 1980,

367*). The plant contains wistarine, a substance with effects similar to but more mild than those of **cytisine** (Roth et al. 1994, 736*). Wisteria is closely related to the soybean (*Glycine max* Merr.) (Keng 1974, 402*).

Whether there really is a psychoactive species of *Polygala* is doubtful. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Because of its purported inebriating effects, Chinese wisteria (*Wisteria sinensis*) is occasionally used as a tobacco substitute.

Psychoactive Plants That Have Not Yet Been Identified

Both the ancient and the ethnographic literature make mention of a number of psychoactive plants, the botanical identifications of which have not yet been determined.

Early Greek writings contain descriptions of plants with incredible effects and fantastic properties, such as **moly** and **nepenthes**. It is uncertain whether these names refer to real or to imaginary plants. There are many mythical plants, such as the tree of knowledge, the plant of life, the mushroom of immortality (cf. “*Polyporus mysticus*”), and the golden apples of Freia, that do not belong to the plant kingdom as we know it but thrive instead in the mythic beyond.

Some old names for magical plants have been adopted by modern botanical taxonomy and assigned to plants that have nothing in common with the earlier flora. The following genus names were all given by Carl von Linné (Carolus Linnaeus; 1707–1778), the great Swedish naturalist and the founder of binominal nomenclature. In choosing these names, he gave expression to his extraordinary love of classical mythology:

Silphium L. (Compositae)—cup plant, compass plant

Canna L. (Cannaceae)—canna lily

Nepenthes L. (Nepenthaceae)—pitcher plant

Daphne L. (Thymelaeaceae)—spurge laurel (cf. *Laurus nobilis*)

Strychnos L. (Loganiaceae)—nux-vomica (cf. *Strychnos* spp.)

In the ethnographic literature, magical plants are often not identified botanically, as the researchers did not possess sufficient botanical knowledge or they returned without the plant material that would have made an identification possible.

Some of the names for these unidentified plants appear to have been general terms used to refer to a variety of psychoactive plants or substances (e.g., **amapola**, **moly**, **soma**).

“In the meantime, the cunning scoundrel gave me . . . a poisonous drink of I know not what kind, sweet indeed and lovely scented, but also extremely treacherous and confusing to the senses; for immediately after I had partaken of it, everything seemed to spin around me, the entire cave stood upside down, in short, I was no longer my usual self, and I finally sank into a deep sleep.”

LUCIAN

CONVERSATIONS WITH THE SEA GODS (II)

The ancient magical plant ephemeron (“one-day plant”) is often interpreted as the autumn crocus (*Colchicum autumnale*). Up until now, however, it has not been possible to produce the legendary effects of ephemeron using the crocus. The botanical identity of the psychoactive plant of Medea thus remains uncertain.

Achaemenidon

The name of this unidentified plant is derived from that of the ancient **achaimenis**:

A plant that was used in the Orient for love magic, which it is not possible to identify with any of the plants we know of today. It is said to have had the appearance of “electrum” [= amber] and to have grown in Indian Tardistylis. Its root, consumed in the form of a lozenge, supposedly

possessed the ability to evoke “terrible” visions. (Hirschfeld and Linsert 1930, 149*)

Achaimenis

Pliny described a psychoactive plant from *Cheirokmeta*, the lost book of Democritus:

The *achaimenis*, which has the color of amber, grows without a leaf in India in the area of the Taradastyles [an unknown tribe]; when criminals consume this in wine, the torment of the appearances of different gods compels them to admit everything; he also calls [it] *hippophobos* [“horse’s terror”] because the mares in particular watch out for it. (24.161)

This leafless plant may be a psychoactive fungus, such as *Panaeolus subbalteatus*, which grows wherever horses are kept. In the philological literature, the plant is often interpreted as *Euphorbia antiquorum* L.

Aglaophotis

“The Magnificent Shining One”

According to Pliny, Democritus was well versed in magic and knew a great number of magical plants:

And so he told of the plant *aglaophotis*, which is said to have received its name as a result of the wonder humans had for its special color and which thrives in the marble quarries of Arabia on the Persian side, which is why it is also called *marmaritis* [marble plant]; the magicians made use of this when they wanted to summon the gods. (24.164)

This plant has often been interpreted as the peony (*Paeonia* sp.),³⁴³ which is not psychoactive. *Mandragora officinarum* has also been suggested as a possibility.

Amapola

The word *amapola* is used in South America to refer to opium (cf. *Papaver somniferum*). In Mexico and Guatemala, many plants are referred to as *amapola* [N.N.], perhaps because they are able to exert a psychoactive effect or are used in folk medicine as an opium substitute (Martínez 1987, 52 f.* Argueta V. et al. 1994, 119*).

Plants Known as Amapola

The fruits of *Bernoullia flammea*, a tree that grows in the tropical lowlands, recall both the fruits of the genus *Banisteriopsis* and those of the maple (*Acer* spp.). Known in Guatemala as *amapola* (“opium”), the fruits shown here were collected near the ancient ceremonial center of Tikal.

The recipe for a medicine against “evil winds,” consisting of espingo buds, *ashango* seeds, *pucho* seeds, cabalonga, and nutmeg.

In Guatemala, the hollyhock (*Alcea rosea* L.) is known as *amapola*, “opium.” Whether the plant produces narcotic effects has not yet been determined.

The cabalonga fruit, obtained at the “witches’ market” in Chiclayo, Peru.

In Mexico, 4 g of the petals of *amapola* (*Passiflora foetida*?) brewed with 200 ml of water is drunk as a tea to treat lack of dreams, over-excitability, whooping cough, and asthma (de la Rosa 1995, 15). In the tropics, sedative teas made of the flowers or leaves of *Pseudobombax ellipticum* are drunk to treat coughs, asthma, and flu (Argueta V. et al. 1994, 120*). The chemistry is unknown.

Literature

de la Rosa, Francisco. 1995. *Ayúdese con las yerbas y plantas medicinales mexicanas*. Mexico City: Editores Mexicanos Unidos.

Cabalonga Negra

“Black Cabalonga”

In Colombia, the hard fruit of black cabalonga, said to be a large tree, is one of the most sought-after magical agents. It is purported to have potent psychoactive effects. The fruits are rare and are sold under the table at herb markets for exorbitant prices. For this reason, other fruits are often sold in their place:

The true cabalonga can be recognized by placing it under the tongue for a little while. Only a few moments are sufficient to produce sensations of dizziness. . . . The Ashaninka of Atalaya, in whose medicine cabalonga plays a major role, say that it grows in the land of the Amahuaca, in the area around the source of the Rio Inuya. (Faust and Bianchi 1997, 248f.)

In shamanism, black cabalonga is used for healing as well as for harmful magic and also to prepare magical arrows for shamanic battles. *Ayahuasqueros* utilize the hallucinogenic effects of the fruit to learn how to use plants for healing.

At the “witches’ market” (*mercado modelo*) in Chiclayo (northwestern Peru), cabalonga seeds are sold only when asked for and then at relatively steep prices. In the *curanderismo* of the folk healers (*curanderos*), they are an important ingredient in a medicine for treating “evil winds” (*aires*), i.e., illnesses of a psychosomatic or psychological nature. This treatment requires that cabalonga seeds, *ashango* seeds (possibly a Rubiaceae), nutmeg (*Myristica fragrans*), **espingo** buds, and *pucho* seeds (*Nectandra* sp.) be ground; mixed with **chicha**, **wine**, hard liquor (cf. **alcohol**), or water; and ingested.

In northern Peru, the seeds of the Ignatius bean (*Strychnos ignatii*; cf. ***Strychnos* spp.**) are apparently also sold under the name *cabalonga*. These are imported from outside the country and are more prized than those of the Amazonian *cabalonga de la selva* (Giese 1989, 258*).

Black cabalonga has also been interpreted as *Strychnos cabalonga* hort. Lind. and as *Strychnos brachiata* Ruiz et Pav. (cf. ***Strychnos* spp.**).

The name *cabalonga blanca*, “white cabalonga”—considered to be a weaker relative—is used to refer to a *Thevetia* species (***Thevetia* spp.**) that is also used as an **ayahuasca** additive.

In Mexico, several plants are known by the name *cabalonga*, some of which may have psychoactive properties (Martínez 1987, 119*):

In Spanish, the name *cabalonga* is generally used to refer to the Philippine Ignatius bean (*Strychnos ignatii* Bergius; cf. ***Strychnos* spp.**).

Literature

Faust, Franz Xaver, and Antonio Bianchi. 1998. Die mysteriöse Cabalonga. *Yearbook for Ethnomedicine and the Study of Consciousness*, 1996 (5): 247–51. Berlin: VWB.

Channa

See **kanna**.

Plants Known as Cabalonga

cabalonga *Jatropha multifida* L. Euphorbiaceae cabalonga *Strychnos panamensis* Seem. Loganiaceae cabalonga *Thevetia peruviana* (Pers.) Mer. Apocynaceae cabalonga de la huasteca *Thevetia peruviana* (Pers.) Mer. Apocynaceae cabalonga de tabasco *Thevetia peruviana* (Pers.) Mer. et Sandw. Apocynaceae

Charin Peco

This name is used to refer to an unidentified “parasitic plant” that formerly was used in the shamanism of the Peruvian Shipibo Indians as a psychoactive initiatory plant. Its use was apparently identical with the use of another uncertain epiphyte, **shahuan-peco**. However, the effects of charin peco were said to be weaker than those of **shahuan-peco** (see there).

Devil’s Foot Root

In a 1966 article, Varro E. Tyler remarked upon the devil’s foot root or *radix pedis diaboli*, a root that is said to grow on the Ubangi River between the Congo and former French Equatorial Africa. It supposedly has the form of a human foot and is red-brown in color. West African medicine men are said to have used it for trials by ordeal. The root is purported to have psychoactive effects when it is burned as an **incense** and the smoke inhaled. Tyler’s statements were based not upon his own studies but on an article in a book from A. Conan Doyle (*The Complete Sherlock Holmes*) (Tyler 1966, 292*). It is possible that the entire story is nothing more than a late Victorian fiction.

Dionysonymphas

“Bride of Dionysos”

Dionysonymphas is another name for **hestiateris**.

Dodecatheon

“Twelve Gods’ Plant”

Pliny discussed this wondrous and as yet not clearly identified “plant of the gods” directly after **moly**:

After [*moly*], the most highly regarded plant is one that is known as the twelve gods’ plant, recommending it [as a symbol] for the power of all the gods. Drunk in water, it is said to heal all ailments. It has seven leaves that are very similar to those of lettuce [*Lactuca*] and that arise from a yellow root. (*Natural History* 25.28)

The plant may have been a species of *Lactuca* (cf. ***Lactuca virosa***). The Gaul Marcellus (ca. 400 A.D.) wrote in his Latin recipe book *De medicamentis* that dodecatheon was also called *donax* (27.7).

This may be a reference to *Arundo donax*. The twelve gods' plant has also been identified with primrose (*Primula elatior* [L.] Hill or *Primula veris* L.) and butterwort (*Pinguicula vulgaris* L.) (Dierbach 1833, 176*). Other sources suggest that dodecatheon was a medicine compounded from twelve plants that was said to be effective against all diseases (Baumann 1982, 115*). It may have been an alchemical product made of the twelve sacred plants that were consecrated to the twelve Olympian gods. This divine preparation may have borne those who used it up to Olympus (cf. Müller-Ebeling et al. 1998).

Ephemeron

“One-Day Flower”

Since ancient times, the magical plant that Medea used to induce the dragon that guarded the Golden Fleece to fall asleep has been known as *kolchikon*. Linnaeus subsequently chose this name as the genus name for the crocus (*Colchicum autumnale* L.; Baumann 1982, 111*). But ephemeron and the crocus are almost certainly not identical (Engel 1978, 18*). Virgil described how Moeris, a herdsman versed in magic, used this plant to transform himself into a wolf:

This plant here, this poison, gathered beforehand
Moeris himself gave to me; it grows in abundance on the Pontus.
With it—often did I see it—Moeris transformed himself into a wolf
and hid in the forest; in this form, he lured the souls
from the grave; in this form, he could even move the seeds in the ground.

The shifting of forms from human to wolf was well known in ancient times and was usually associated with the consumption of human flesh (Burkert 1997, 98 ff.), and sometimes also with the use of *Aconitum napellus* or *Lupinus spp.* (cf. **witches' ointments**).

The mysterious African devil's foot root is said to resemble a foot—half human, half goat's hoof—and to produce profound psychoactive effects when burned as an incense. The plant may be nothing more than a literary joke. (Illustration from 1910)

Literature

Burkert, Walter. 1997. *Homo Necans: Interpretationen altgriechischer Opferriten und Mythen*. 2nd ed. Berlin: de Gruyter.

Espingo

The literature from the colonial period, and especially Arriaga's report from Peru (1621), makes frequent mention of a fruit named *espingo*, *ishpingo*, *ispinku*, *yspincu*, or *ispincu*. It was said to be rather small and roundish and somewhat similar to an almond. It was used as a medicine and as an inebriating additive to **beer**:

In the plains, from Chancay and downriver, the chicha that the huacas [= temples] offer is known as yale. It is made from zora [= malted maize] mixed with chewed maize and has espingo powder added to it. They prepare the chicha so that it is very potent and syrupy. After they have poured as much of this over the temple as they think proper, the magicians drink the rest. The chicha makes them completely crazy. (Arriaga 1992, 40*)

Espingo had amagical and religious significance similar to that of villca (see *Anadenanthera*

colubrina):

The espingo is a dry, small fruit similar to the round almond, with a penetrating but not very pleasant scent. They bring it from the Chechepoyas [i.e., from the tropical lowlands]. They say that when taken in the form of a powder, espingo is a very effective medicine against stomachaches, bloody diarrhea, and other diseases, and they purchase it for a good price. People are wont to sell espingo for these purposes. Not too many years ago, in Jaén de Bracamoros, the Indios paid their tribute in espingo. The deceased Lord Archbishop forbade the sale of espingo to the Indios under pain of excommunication, for he knew that it was a common offering at the huacas. In the flatlands in particular, there is not a one who has conopas [= images of the gods, sacred objects] who does not also have espingo, no matter how often they have been searched. (Arriaga 1992, 43*)

The Incas offered a **chicha** with an espingo additive at the festivals of Raimi, Citua, and Aymoray (Wassén 1973, 40). One source states that those who consume espingo, e.g., the Incan magicians (*omo*), would “go crazy” because of the fruit (Wassén 1973, 38). In the seventeenth century, the chronicler and missionary Bernabé Cobo claimed that the pleasantly scented fruit of the espingo tree was called *vainilla* (“vanilla”) and was traded over long distances, and that the Indians esteemed it highly for its medicinal properties. Henry Wassén, who has worked on the botanical identification of the stock plant, has assumed that a number of plants with similar properties were subsumed under the name *espingo*. Today, there is still a plant known as *asango-espingo* (perhaps a species from the Rubiaceae or the Lauraceae Family). The following plants have all been suggested as possible candidates for the espingo of the colonial period (cf. Wassén 1979, 59 ff.; 1973, 40):

An espingo necklace from the “witches’ market” in Chiclayo, Peru.

***Quararibea* spp.:** possibly psychoactive (Ott 1993, 418*)

Gnaphalium dysodes Spreng.: unknown³⁴⁴

Trifolium sp. (*trébol*): botanical identity unknown

nambicuara (Bombacaeae): unknown effectiveness

A botanical and anatomical study compared espingo seeds with the seeds of *Quararibea* and concluded that the two may be identical (Bondeson 1973). However, if no additional ethno-historical sources or archaeological or ethnobotanical samples are discovered, the knowledge of the identity of the espingo tree may be lost.

In Ecuador and Peru, the American cinnamon tree (*Ocotea quixos* Lam. [syn. *Nectandra cinnamomoides* Nees]; Lauraceae) is still referred to as *ishpino* or *espingo*. A chemical analysis of a botanically unidentified sample of espingo found substances that have the scent of cinnamon: cinnamaldehyde, *O*-methoxycinnamaldehyde, cinnamic acid, and methylcinnamate. The same substances are found in *Ocotea quixos* (Naranjo et al. 1981). *Ocotea* continues to find favor as a cinnamon-like spice and is used in Ecuadoran folk medicine as an appetite stimulant, disinfectant, and diarrhea remedy. The scented calyxes are used as an aromatic additive to a **chicha** made from maize and sugarcane juice that is known as *alajua*. This mildly alcoholic drink is offered in Ecuador to the ancestors of one’s own family (Naranjo et al. 1981, 234).

Today, the following plants are known in Peru as *ishpingo* or *espingo*:

Ajouea tambillensis Mez (Lauraceae)
Jacaranda copaia (Aublet) D. Don (Bignoniaceae)
Ocotea jelskij Mez (Lauraceae)
Guarea trichilioides L. (Meliaceae): among *ayahuasqueros* (cf. **ayahuasca**)

The wood of this tree is used to make magical wands for the northern Peruvian *mesa* rituals (Giese 1989, 259*; cf. ***Trichocereus pachanoi***).

In northern Peru, espingo buds are still used in folk medicine, sometimes in combination with **cabalonga** and nutmeg (***Myristica fragrans***). The precise identification of these buds is not known.

The South American coca bush *Erythroxylum hondense*.

The coca plant *Erythroxylum cumanense* with its typically small, very round leaves. Many species of *Erythroxylum* contain alkaloids, but most contain only traces of cocaine.

In the Ucayali region of Peru, a leguminous tree, *Amburana cearensis*, is known in the local Spanish as *ishpingo*. Healers and shamans esteem it as a “master plant.” The bark is used to prepare medicinal baths to treat illnesses that are the result of harmful magic (Arévalo V. 1994, 251*).

Gelotophyllis

“The Leaf That Evokes Laughter”

Pliny has provided us with a description of this plant that is based upon the writings of Democritus:

The *gelotophyllis* grows in Bactria [= Afghanistan] and on the Borysthenes [= Dnieper]; when drunk together with myrrh and wine, various figures will float before one’s eyes, and the urge to laugh will cease only if one eats pine nuts with pepper [***Piper spp.***] and drinks honey in palm wine. (24.164)

This “plant that incites laughter” has often been interpreted as ***Cannabis indica***. Indeed, Indian hemp does grow in Afghanistan, and the laughter that the use of hemp can evoke is legendary.

Guanguára

The Kogi Indians of the Sierra Nevada de Santa Marta (Colombia) call their coca *hayo*, a word that comes from the Tairona language. They distinguish three “species” of coca, each of which belongs to

one of the tribes of the region. The Kamkuama tribe, which has now either disappeared or become extinct, cultivated a type of coca that had long leaves. The Kogi plant a variety with small leaves, and the Ika a type with tiny leaves (cf. *Erythroxylum novogranatense*). It is said that the ancestors, i.e., the Tairona, planted or harvested a tree named *guanguára* or *guanguála* in the *páramos* (high marshes) that had cocalike leaves with similar effects (Reichel-Dolmatoff 1985, 1:87*; Uscategui M. 1959, 281 f.*). Unfortunately, the botanical identification of this tree is unknown. It may simply have been another wild species of the genus *Erythroxylum*.

Haoma

The original haoma plant has not yet been identified with certainty. See the section on **haoma** on pages 747 f.

Halicacabon

“Salt Jar”

Also known as *halikákabon* or *halicacabum*, this plant belonged to a group of psychoactive plants known as *trychnos* or *strychnos* (cf. **strychnos manikos**), the botanical identity of which is unknown:

There is yet another kind [of *strychnos*], called “salt jar,” that provokes sleep and can cause death even more quickly than opium; others call it “fool’s herb” [*morion*], still others moly. But it was praised by Diocles and Euenor, and Timaristos even lauded it in a poem, wherein she strangely forgot about its harmlessness, for her, [the plant] is a fast-acting agent for firming up wobbly teeth by rinsing these with halicacabon in wine; at least they added the qualification that this should not be done for very long, lest madness be the result. . . . The root of halicacabon is imbibed as a drink by those who wish to utter prophecies and who want to be seen as truly enthusiastic about God in order to strengthen superstitious conceptions. As an antidote—which I am that much happier to be able to mention—water to which an ample quantity of mead has been added should be drunk warm. And I do not want to neglect to say that halicacabon is so contrary to the nature of the adder that its root, when placed very close to it, will quiet the very deadly power that its stupefaction can bring. This is why grinding it up and adding it to oil it can aid a person that has been bitten. (Pliny 21.180–82)

Halicacabon, a mysterious psychoactive plant of antiquity, was identified in early modern times as the Chinese lantern plant (*Physalis alkekengi* L.). (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

This entheogenic plant has been interpreted as *Atropa belladonna* or *Withania somnifera*. Dioscorides described *morion* as a species of *Mandragora* (cf. ***Mandragora* spp.**).

Leonhard Fuchs depicted two plants under the name *halicacabum* (Fuchs 1545). *Halicacabum vulgare* is the Chinese lantern (*Physalis alkekengi* L.; cf. ***Physalis* spp.**). The other species (*halicacabum peregrinum*, welsch schlutten) is probably *Cardiospermum halicacabum* L. Linnaeus selected the ancient name as a species name for the American balloon vine (*Cardiospermum halicacabum* L.; Sapindaceae), which is not known to have any psychoactive effects.

Hestiateris

“Plant That Gives a Meal”

Pliny's information about this plant is based upon the statements of Democritus, who was well versed in the magical arts:

In Persia, the *hestiateris* has its name from the guest meal, for it produces gaiety there; it is also called *protomedia* ["preferred by the Medians"] because it can be used to ingratiate oneself with their kings; *kasignete* ["the fraternal"] because it grows only with its own kind and not with any other plants; it is also called *dionysonymphas* ["bride of Dionysos"] because it goes wonderfully with wine. (24.165)

This plant has been variously interpreted as *Areca catechu*, pimpinella (*Pimpinella major* [L.] Huds.; Umbelliferae), and *Sanguisorba minor* Scop. [syn. *Poterium sanguisorba* L., *Pimpinella minor* (Scop.) Lam.] (Rosaceae).

Hippophobos

The name means "refused by horses" and is a synonym for **achaimenis**.

Jénen-Joni-Rau

"Water People Medicine"

This as yet unidentified little plant with lanceolate leaves is said to be similar to the **shahuan peco** plant, which is also botanically unknown. The Peruvian Shipibo-Conibo Indians regard it as a "master of the healing arts." A shaman will consume parts of this plant with **ayahuasca** when he wishes to undertake a spirit or astral journey into the water world (Gebhart-Sayer 1987, 337*).

The Andean inebriant *machamacha* may be a pseudoberry. (*Gaultheria acuminata*, from Latin America)

Kanna

Some 250 years ago, the Hottentots (Khoikhoi) chewed kanna, also known as *canna* or *channa*, in order to induce visual hallucinations:

About 200 years ago, Kolbe used the name Kanna (Channa) to refer to a plant whose root he supposedly saw the Hottentots use as an agent of pleasure. They chewed it and retained it in their mouths for a long time. It made them drunken and stimulated. Their "animal spirits became animated," their eyes sparkled, and their faces were marked by laughter and happiness. A thousand charming ideas arose in them, a gentle joy that amused itself over the simplest of jests. When they used too much of the agent, they would ultimately lose consciousness and fall into horrible deliriums. (L. Lewin 1980 [orig. pub. 1929], 296*)

Because the name was used at the end of the nineteenth century to refer to one or more *Mesembryanthemum* species (***Mesembryanthemum* spp.**), it was assumed that the originally described inebriant was in fact *Mesembryanthemum tortuosum* (Hartwich and Zwicky 1914). Today, the valid botanical name for this plant is ***Sceletium tortuosum***. Louis Lewin was of the opinion that the plant may also have been ***Sclerocarya caffra*** or *Sclerocarya schweinfurthiana* (1980, 297*).

In the seventeenth century, white settlers in South Africa applied the name *kanna* to *Aureliana canadensis*, the root of which was used as a substitute for the true mandrake (***Mandragora officinarum***).

The word *kanna* is almost too reminiscent of *cannabis* (cf. ***Cannabis indica***). Perhaps the original *kanna* was actually a mixture of ***Cannabis sativa*** and ***Sceletium tortuosum***.

In its genus name, the canna lily carries on the name *kanna*, spelled as *canna*. Canna seeds are sometimes strung together to make bracelets and necklaces. (*Canna indica*, photographed in Chiapas, Mexico)

Apart from the name, *kanna* has nothing to do with the lilylike plant *Canna indica* L. (Cannaceae), a native of tropical America whose seeds the Indians string into bracelets and necklaces. *Kanna* is sometimes confused with *Salsola dealata* Botsch., known as *ganna*.

Literature

Keu

In 1875, the ethnologist Miklucho-Maclay described an inebriating drink named *keu*, which the Papuas of the Maclay Coast (Papua New Guinea) prepared in a manner similar to the Polynesian kava-kava. Although the men, young men, and boys produced the drink on the occasion of tribal festivals, only the older people were allowed to consume it. It is possible that this bush, the leaves, stalk, and roots of which were used, was ***Piper methysticum***, a different *Piper* species (***Piper spp.***), or an as yet unknown plant. This theory is not unlikely, because we do know that *Piper methysticum* was used on Papua New Guinea (Haddon 1916). But the drink that was prepared from this plant is known as *wati*. More recently, a previously undescribed *Piper* species was discovered on Papua New Guinea. Chemical investigations isolated 2-methoxyangonin, kavalactones, and flavonoids from the material (Hänsel et al. 1966; Sauer and Hänsel 1967).

Macha

In South America, a number of plants of the Family Ericaceae are given the name *macha* or *macha-macha* and are regarded as psychoactive. The ripe fruits are sweet and delicious and invoke inebriating effects when consumed in great quantities. These effects are described as “drunkenness.” The botanist Hippolito Ruíz identified *macha* as *Arbutus parviflora* [nom. nud.!] and characterized the Ericaceae known as *macha-macha* as *Thibaudia* (Schultes 1980, 111*). It is possible that this name refers to various species of the genus *Vaccinium* (cf. ***Vaccinium uliginosum***) or ***Pernettya***. In Peru, the wandering healers of the Callawaya refer to a *Gaultheria* species as *machamacha*; it contains methylsalicylate (Bastien 1987, 128*). There is also said to be *macha-macha* in the Las Huingas region of northern Peru, especially at Laguna Shimbe. Unfortunately, nothing is known about its botanical identity. The Ericaceae *Befaria glauca* var. *coarctata* has fruits that cause dizziness and have a stimulating effect. It is known as *macha-macha* in Bolivia (von Reis Altschul 1975, 214*).

Marari

The renowned ethnologist Alfred Métraux wrote that the shamans of the Mojo Indians (a Brazilian Arawak tribe) consumed a drink called *marari*, which they made from a plant of the same name, when they wished to consult the spirits. The effects of the drink were said to last for some twenty-four hours and were described as excitation, sleeplessness, and pains—nothing particularly pleasant. Marari was said to compare to “our verbena.” It is not clear whether Métraux was comparing this plant to the European verbena (*Verbena officinalis* L.)³⁴⁵ or to another plant from South America that has long been cultivated in the Mediterranean region, lemon verbena (*Lippia citriodora* H.B.K. [syn. *Aloysia triphylla* (L’Herit.) Britt.]). There are a number of plants (*Verbena* spp., *Lippia* spp.) in South America that are very similar to these two verbenas (and which the literature on **essential oils** and **incense** usually confuses). Only careful ethnobotanical research will be able to cast light upon these questions (Schultes 1966, 298*).

The wonderfully scented lemon verbena (*Aloysia triphylla* = *Lippia citriodora*) is also called the lemon bush and is often confused with the true verbena (*Verbena officinalis*).

Literature

Métraux, Alfred. 1943. The social organization and religion of the Mojo and Manasi. *Primitive Man* 16:1–30.

Marmaritis

See **aglaophotis**.

Medeaka

This tropical rain forest plant is found in West Africa, where the Pygmies used it as an alternative agent of pleasure and inebriant to *bangi* (*Cannabis sativa*) and *tava* (*Nicotiana tabacum*):

In an emergency, when there is no tobacco or hemp to be found, the Pygmies turn to the leaves of a forest plant, *medeaka*, which they smoke. The effects are said to be stronger than those of *bangi* [= *Cannabis sativa*]. But it does not seem correct that the leaves of the poisonous *tava* tree are smoked as well. (Schebesta 1941, 179)

The root, which was known as *masili*, was chewed as an aphrodisiac (Schebesta 1941, 236). This plant may be one of the many West African *Mitragyna* species (cf. *Mitragyna speciosa*).

Literature

Schebesta, Paul. 1941. Die Bambuti-Pygmäen von Ituri, vol. 2: Ethnographie der Ituri-Bambuti. Brussels: George van Campenhout.

Moly

Homer provided only a brief description of moly, the divine magical plant of Hermes. Odysseus used moly, which was classified as a *pharmakon*, “remedy/poison,” to protect himself from the sorceress Circe, who had transformed his men into swine (Schmiedeberg 1981). An important piece of information is that Hermes (= Mercury) harvested the plant in Circe’s garden, and thus the messenger of the gods transformed one of Circe’s own magical plants into an almost homeopathic type of antidote:

[Hermes] pulled from the ground a poisonous plant,

Presented it to me and showed me what it was and how it grew.

Black was the root, white as milk were the flowers, the gods

call it moly. It is very difficult for mortal men to find; the gods, of course, can do anything.

(*ODYSSEY* 10.302–6)

Generations of alchemists, Greek scholars, philologists, pharmacologists, and ethnobotanists have attempted to determine the botanical identity of Homer's magical plant (cf. Baumann 1982, 110*; Dierbach 1833, 192*; Rahner 1957*). Even Theophrastus, the father of botany, made an effort to ascertain the botanical identity of the stock plant:

Panakeia, the plant that heals all, thrives in large quantities and prefers rocky ground near Psophis, Moly by Pheneos, and on the mountain of Cyllene. They say that this plant would be like the moly that Homer mentions; that it has a root like an onion and leaves like the squill; and that it is used against magical formulae and magic, but it is not, as Homer stated, difficult to dig up. (Theophrastus, *History of Plants*, 9.15)

Dioscorides (3.21) wrote that the sea holly or sea hulver *Eryngium maritimum* L. (Umbelliferae), prized as an aphrodisiac, was also known as moly (Rätsch 1995a, 228 ff.*).

Moly was already being construed as a psychoactive plant in ancient times. Remarkably, both moly and the magical plant of Circe were interpreted as the mandrake (*Mandragora officinarum*) (Dierbach 1833, 204*; Kreuter 1982, 29*). Dioscorides passed down the name *circeon* for the mandrake (cf. Rahner 1957, 201*) and *mandragora circaea* for the plant that Circe used to transform the men of Odysseus into “swine” (= sexually aroused men):

The Mandragora. Some call it *antimelon* [= “in the apples’ place”], others *dirkaia*, also *kirkaia* [= “plant of Circe”], as the root appears to be effective as a love charm. (Dioscorides 4.76)

According to Apollodorus (second century B.C.), the most important scholar of his time, mandrake (which he called *kirkaia riza*) was used as an amulet against the harmful magic of Pasiphae, daughter of Helios (Circe was also a daughter of Helios), wife of King Minos, and mother of Ariadne and the Minotaur (frag. 2.15).

In late ancient times, it was assumed that the mandrake had been a gift from the Greek/ Egyptian god Hermes Trismegistus—the god of alchemy (Fowden 1993)—and that it was suitable for conjuring up spirits and for use in alchemical practices. Because Hermes/Mercury is depicted in some ancient works of art with an opium capsule in his hand, moly could be interpreted as *Papaver somniferum*.

Bauhinius identified the renowned Hermetic magical plant moly, which Odysseus used to restore the men who had been turned into swine back into men, as rue (*Ruta graveolens* L.; cf. **soma**). Stannard (1962) identified the Hermetic moly with *Peganum harmala* and explicitly referred to a passage in Dioscorides:

The so-called fathers of botany went to great lengths in their efforts to botanically identify moly, the magical plant of Homer. The squill was long considered to be the legendary plant. However, with the discovery of new plants in the New World, many of the species that were returned to Europe were also regarded as candidates. The botanical illustrations, however, suggest a plant that grew from the imagination of the engraver and his client. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Wild rue. Some also call wild peganon the plant that is known as *moly* in Cappadocia and in

Asian Galatia. It is a bush that develops several branches from a single root, it has leaves, much larger and more tender than the other peganon [= rue] and with a penetrating scent, a white flower, small capitula on the tips, larger than with cultivated peganon [= rue], mostly consisting of three parts, in which is found a trigonal, light yellow seed that is useful. In late autumn, the seed becomes ripe and can be used, with honey, wine, chicken gall, saffron [***Crocus sativa***], and fennel juice [***Foeniculum vulgare***], finely ground, to treat dull vision. Some also call this same plant *harmala*, the Syrians *besasa*, the Egyptians *epnubu*, the Africans *churma*, but the Cappadocians *moly*, because it is essentially similar to the *moly*, for it has a black root and white flowers. It grows in hilly and fertile soil. (Dioscorides 3.46)

Moly has long been interpreted to be the squill (*Urginea maritima* [L.] Baker [syn. *Scilla maritima* L.]) (Rahner 1957*):

According to the testimony of Homer, the most renowned of all plants is *moly*, about which he believed that it received its name from the gods; he attributes Hermes with its discovery and use against the strongest enchantment. It is said to grow today in the region of Pheneos and on Cyllene in Arcadia. According to Homer, it is a plant with a round, black root the size of an onion and with one leaf like the squill [*Scilla*], but it is (not) difficult to dig up. The Greek writers have reported its flowers to be yellow, whereas Homer wrote that they are white. I found a physician wise in herbal lore who told me that it also grows in Italy, and after a few days (in autumn) he had one brought to me from Campania that was dug up under difficult circumstances from craggy rocks. It had a 30-foot-long root that was not complete but had been ripped out. (Pliny 25.26–27)

Nevertheless, Lucian describes in a dialogue (Menippus) how the priests or magicians, dressed in the style of the Persians, used the squill as a magical plant for conjuring up the dead for oracular purposes (cf. ***Lupinus spp.***). The squill contains highly effective cardiac glycosides (cf. ***Digitalis purpurea***) (Roth et al. 1994, 714*).

Other plants with bulbs (Liliaceae) have also been interpreted as moly, including *Nectaroscordum siculum* (Ucria) Lindl. [syn. *Allium dios-coridis* Sibthorp, *Allium siculum* Ucria], *Allium magicum* L. (magic leek), *Allium moly* L. (Linnaeus actually named this species after the magical plant), *Allium nigrum* L., and *Allium sativum* L. (Dierbach 1833, 192; Schöpf 1986, 117*). *Allium victorialis* L. is known as false mandrake, for its root was often used in place of that of the true mandrake (cf. ***Mandragora officinarum***).

Wedel, a pharmacologist, wrote in one of his dissertations (*De Mythologia Moly Homeri*, Jena, 1713) that moly was a *Nymphaea* (cf. ***Nymphaea caerulea***). In his work *De Moly Homericum et fibula Circaea* (Lipsiae 1716), D. W. Triller identified moly as black hellebore (*Helleborus niger* L.; cf. ***Veratrum album***, snuff).

It appears that in ancient times, the word *moly* was more or less a catchall term that meant “magical plant” or “entheogen.” It was used to refer to plants that were psychoactive and employed for magical purposes (in a manner quite similar to the use of the words **haoma** and **soma**).

Nepenthes

In the *Odyssey*, Homer sang the praises of the psychoactive effects of a wondrous *pharmakon* called *nepenthes* (literally “consoling plant”):

But Helen, the daughter of Zeus, remembered something:
and immediately put a magical agent into the wine which they drank,
good against sorrow and bilious nature: for all evils
it created forgetfulness. It was in the mixing jug: anyone who then drank of it,
on that day would no tears flow down his cheeks,
even when both his father and mother would die,
yea even when his son, the beloved, or his brother
would be slain with swords by the enemy directly before him,
so that he would see it with his own eyes.
Now the daughter of Zeus could avail herself of agents with such skillful effects.”

(*ODYSSEY* 4.219–28)

The beautiful Helena offering the wondrous nepenthes. (Illustration: John Flaxman)

In late ancient times, the squill (*Urginea maritima* [syn. *Scilla maritima*]) was already being interpreted as the Hermetic magical plant moly. However, any information about the psychoactive effects squill may have has not come down to us. (Wild plant, photographed on Naxos, Greece)

Theophrastus himself attempted to fathom the origins of this *pharmakon*:

The places outside of Hellas that yield special healing herbs are regions in Tyrrhene and Latium (where, it is said, lives Circe), and several regions in Egypt, about which Homer said: Helen brought from there the useful things that Polydamna, the wife of Thon, had given her. There the fruit-bearing earth produces the greatest number of *pharmaka*, many of these are beneficial and others harmful. Among these, so he tells us, was *nepenthes*, the famed *pharmakon* that heals worries and afflictions, for it allows one to forget diseases. These regions have been named by the poets. (*History of Plants*, 9.15)

Because of the effects attributed to it, the Homeric nepenthes has often been interpreted as opium (cf. *Papaver somniferum*) as well as certain other plants:

In contrast, another assumption is more likely, that the agent of Helena was the juice of *Cannabis indica*, hashish. The use of hemp and of pills made from it was . . . known in Egypt at an early date and was very popular, and because of the connections between Greece and Egypt, Homer may . . . have had very good knowledge of this. . . . Moreover, the condition produced by its use, which corresponds to the Oriental names for it, “stimulator of happiness, soul cheerer” [cf. **Oriental joy pills**], accords with that which Homer described, namely a cheerfulness that cannot be dampened by the hardest strokes of fate. (Berendes 1891, 131 f.*)

Since the stock plant was said to be indigenous to Egypt, it has also been identified as Egyptian henbane (*Hyoscyamus muticus*):

The Egyptian priests used this plant in many ways during their religious practices, especially to placate that hostile god whom they called Typhon. The sedative powers of this Egyptian henbane appear to be even more energetic than those of the one we are used to [*Hyoscyamus niger*]; for when someone receives some of the powder of the plant either accidentally or on purpose, there follows a condition of madness that continues for several days, after which clear consciousness returns once more. This plant has been interpreted as the *nepenthes* of Homer, a statement that should not be entirely disregarded, but that in fact has much that speaks for it. (Dierbach 1833, 189*)

Nepenthes has also been identified as *Mentha pulegium*, *Mandragora officinarum*, and even *Catha edulis*.

In modern times, the name *nepenthes* is used to refer to a genus of carnivorous plants (Family Nepenthaceae; pitcher plants) that encompasses a number of species (e.g., *Nepenthes maxima* Reinw., *Nepenthes sanguinea* Lindley). These plants, however, are not psychoactive (Emboden 1974, 135f.*).

Ophiussa

“Snake Plant”

Pliny provided us with a description of this plant, which comes from the island of Elephantine on the Nile, renowned as the place where the mandrake (*Mandragora officinarum*) was found:

The *ophiussa* on Elephantine in the same Ethiopia has a lead-colored and unsightly appearance and is said, when drunk, to produce such dread and such terror of snakes that people would kill themselves out of fear; this is why the desecrators of temples are forced to drink of it. Palm wine is an antidote. (24.163)

This information inspired the film *Young Sherlock Holmes* (from the studio of Steven Spielberg). In this film, an Egyptian sect of murderers kills its victims by shooting an arrow that has been treated with an unidentified hallucinogen into the carotid artery. The victims experience such terrible visions, including snakes, that they commit suicide. Today, many people continue to believe that people will throw themselves out of windows because they have been driven to madness by psychedelics. This motif, which is quite popular in the yellow press, appeared in a novel that Leo Perutz (1882–1957) wrote in 1923, *Der Meister des jüngsten Tages* [The Master of Judgment Day] (cf. *Claviceps purpurea*).

Literature

Perutz, Leo. 1990. *Der Meister des jüngsten Tages*. Reinbek: Rowohlt.

The relatively unknown Mexican *Magnolia dealbata* may have been the source of the Aztec inebriant poyomatli.

Pipiltzintzintli

This Aztec inebriant, also written as *pipizizintli*, *pepetzintle*, *pepetichinque*, and *pipiltzintzin*, is now usually interpreted as *Salvia divinorum*. This interpretation, however, is by no means certain.

Potamaugis

“River Sheen”

Potamaugis is another name for **thalassaigle**.

Poyomatli

This Aztec inebriant is mentioned in the *Florentine Codex*, written in colonial times by Sahagún. It has not yet been clearly identified. One suggestion is *Quararibea funebris* (see ***Quararibea* spp.**, ***Theobroma cacao***). Another possibility is that the name refers to the flowers of ***Cymbopetalum penduliflorum*** (Dunal) Baill. *Magnolia dealbata* Zucc. (see ***Magnolia virginiana***), now known as *eleuch wu*, has also been suggested as a candidate (Diaz 1979, 94*; Ott 1993, 412*). If no additional ethnohistorical sources are discovered, the secret of poyomatli may have been lost with the destruction of the Aztec culture.

Sakaka

The Desana Indians of the Tukano tribe, who live in the Vaupés region of Colombia and Brazil, have different classes of shamans. The sakaka shamans—the word is from the *língua-geral*—specialize in journeying to the underworld, especially the underwater worlds. In order to travel there, a shaman will chew the root of a plant known by the name *sakaka*. This enables him to traverse great distances underwater. Because they are said to be related to malevolent water beings, these shamans are regarded as rather dangerous. To date, the sakaka plant has not been clearly identified; it may be a species from the Family Connaraceae (Buchillet 1992, 212). Whether this genus contains psychoactive species is unknown; several species do have toxic properties (Buchillet 1992, 228). The Indians use some species of the genus *Connarus* as fish poisons (Schultes and Raffauf 1990, 141*).

Literature

Buchillet, Dominique. 1992. Nobody is there to hear: Desana therapeutic incantations. In *Portals of power: Shamanism in South America*, ed. E. J. M. Langdon and Gerhard Baer, 211–30. Albuquerque: University of New Mexico Press.

Semnios

“Sacred Plant”

Also written as *semnos*, *semnios* is another name for **theombrontion**.

Shahuan Peco

“Moult of the Ara Parrots”

The Shipibo-Conibo, who live in the Ucayali region of Peru, use this name to refer to an as yet botanically unidentified “parasitic plant that grows on tall trees” (Illius 1991, 122). It is said to be very rare, is considered to be difficult to find, and cannot be recognized by everyone. This hallucinogenic parasite nests in the forks of branches of various jungle trees in the area around Pucallpa (Peru). It has three-fingered leaves, and the Shipibo-Conibo shamans use only the longest, middle leaflet. The freshly crushed leaflet is either mixed with tobacco (***Nicotiana tabacum***) and smoked or mixed with tobacco juice and drunk. In addition, the diluted juice is rubbed over the entire body (Gebhart-Sayer 1987, 211*).

In former times, anyone who wished to become a *merayabo*, a priest-shaman, was required to use this ominous plant. The novice needed to consume a drink made of the small leaflets and “bathe” in it just once during his training. The visionary effects began some twelve hours later and lasted for a similar period; they were culturally stereotyped:

You hear loud thunder, even when the sun is shining and not a cloud can be seen, you begin to tremble all over your body and you hear voices. The two “lords” of the *shahuan pecó* appear in human form. They threaten the drinker and attempt to talk him out of wanting to make use of the power of the plant. When he has become almost unconscious (*shiná-oma*) as a result of the continued trembling, the two *yoshinbo* [= plant spirits] throw him back and forth many times like a ball. A jaguar appears, bites the adept in the back of the neck, and sucks out all of his blood “so that he becomes light.” Then the jaguar bears him upward for several hours. Suddenly the *meraya-to-be* notices that he can move through the air himself and that he “sees everything.” In the clouds, the *yoshinbo* provide him with information about all manner of diseases. Finally, the jaguar leads him to *anta yoshin*. The *anta yoshin* is a great physician who reveals to the shaman how he can heal himself and protect himself from the attacks of “brujos” (“sorcerers”). (Illius 1991, 122 f.)

Unfortunately, the use of this plant is disappearing among the Shipibo. *Shahuan peco* is an initiatory plant that should be ingested by shamans-in-training after they have been consecrated with **ayahuasca**. It is regarded as the most powerful of the visionary plants (Gebhart Sayer 1987, 340*), and a shaman typically will take it only once during his lifetime. The plant spirit (*shahuan-anta-jonibo*) gives him the ability to undertake spirit or astral journeys into far distant places. One of the few Shipibo shamans actually to have had an experience with this rare plant described its effects:

I shook. Then the two lords of the plant appeared. I also heard the sounds of many other spirits, who threatened me and wanted to deny me the power of the *shahuán-peco*. When I became unconscious, the four lords of the plant threw me around the four corners of the world like a ball. I no longer felt my weight. When I was close to death, the large, shining jaguar *ani ino* came and sucked out my blood and carried me far away. In this way, the shaman learns to fly through the air on his own and to see things from above. In the cloud villages, he meets with the spirits that support him in therapy. During the *shahuán-peco* visions, the shaman sees the people in their true nature, he sees their true intentions, and he sees them naked. (Gebhart-Sayer 1987, 212*)

Another Shipibo shaman clearly recalled his initiation with the plant:

Shahuán peco is stronger than *charin pecó*. Oh, how strong it is! You can hardly stand it—it is much stronger than ayahuasca! Once you have drunk *shahuán peco*, you see all people naked. Then a man comes, a *nai yoshin* (heavenly spirit); he holds an empty book in his hand. He holds it before me. A *pino* (hummingbird) comes and draws *quené* (designs) in the book with its beak. I still possess this book! I open it up and look at the *quené*. The *pino* comes, and I sing with him. I open the book every night—this is why I sing so well! (in Illius 1991, 123)

The statement that *shahuan peco* is considered more highly effective than ayahuasca is worth noting, for the Shipibo are renowned for preparing an especially potent ayahuasca.

Unfortunately, we have no information at all about the botanical classification of this “parasitic plant with small leaves.” It may possibly be a Bromeliaceae. There are reports that one species of *Tillandsia* is used as a psychoactive substitute for peyote (*Lophophora williamsii*).

Literature

Illius, Bruno. 1991. Ani Shinan: Schamanismus bei den Shipibo-Conibo (Ost-Peru). Ethnologische Studien, vol. 12. Münster: Lit Verlag.

Shlain

In Cambodia, *shlain* is a name for both a tree and its product. The very hard wood of the shlain tree is light colored, almost white. It is shaved, mixed with hemp (*Cannabis indica*, *Cannabis sativa*), and smoked. The addition of shlain to the hemp clearly increases the effects of the **THC** and makes it somewhat more psychedelic. The wood has been tested many times with success, but unfortunately its botanical identification is still uncertain. It is, however, possible that it is *Strychnos nux-vomica*. In Cambodia, a traditional cough medicine is made from dried *kancha* (hemp herbage), which is chopped up on a board made from nux-vomica (*Strychnos nux-vomica*) wood. Mixed with small pieces of the wood (which contains **strychnine**), the resulting product is then smoked (Martin 1975, 67).

Silphion

In ancient times, silphion was a renowned medicinal plant, apparently with psychoactive effects. Its botanical identity has been completely lost (Dioscorides 3.84). In modern times, it has been proposed that it might have been food of the gods or devil’s dung (*Ferula asafoetida* L.); it may also have been *Ferula moschata* (Reinisch) Kozo-Polj. [syn. *Ferula sumbul* (Kauffm.) Hook. f., *Euryangium sumbul* Kauffm.], a purportedly hallucinogenic plant (Schultes and Hofmann 1980, 368*; cf. **incense**). It may even have been a species of bracket fungus (*Laricifomes officinalis* [Vill. ex Fr.] Kotl. et Pouz., *Polyporus officinalis* Fr., *Boletus laricis* Jacq.; cf. “**Polyporus mysticus**”):

Bracket fungus. *Agarikon* is regarded as a root, similar to that of *silphion*, however it is not close to the surface like *silphion*, but completely lax. (Dioscorides 3.1)

A remark by Dioscorides concerning silphion’s effects upon glaucoma is reminiscent of the effect of hemp (*Cannabis indica*, *Cannabis sativa*): “It induces sharp-sightedness and dispels the beginnings of glaucoma when it is rubbed in with honey. (3.84)

It has been suggested that the ancient *silphion* plant is now extinct. The genus that bears its name, *Silphium* L. (Compositae), is with certainty not identical to the ancient healing plant, nor is *Thapsia silphium* [syn. *Thapsia garganica* L. var. *silphium*] (Umbelliferae) (cf. Dierbach 1833, 213*).

Soma

The original soma plant has not yet been identified with certainty. Cf. **soma** on pages 792 ff.

Strychnos Manikos

The ancient literature contains descriptions of several species of strychnos, of which the fourth, strychnos manikos (“the strychnos that makes one wild”), must have been a potent psychoactive plant (Theophrastus, Dioscorides, Pliny). Many philologists and botanists have attempted to uncover the botanical identification of strychnos manikos, interpreting it variously as *Atropa belladonna*, *Datura stramonium*, *Solanum* spp., *Strychnos nux-vomica*, *Withania somnifera*, and *Physalis* spp. (Baumann 1982, 111*). It is possible that the name *strychnos* was a catchall term for psychoactive plants.

A piece of wood from the trunk of the Cambodian shlain tree. When ground, it is said to potentiate the effects of hemp.

Suíja

This hallucinogenic plant, found in the Amazonian lowlands of Peru, is a vine “whose leaves are black on top, yellow underneath.” It is said to have effects similar to those of **ayahuasca** but also to produce visions by itself. The shamans of the Shipibo-Conibo Indians regard it as a “master of the healing arts” (Gebhart-Sayer 1987, 340*). The shaman ingests two grated roots with water each night for ten nights. The visionary experience follows the tenth administration. The few known reports of experiences suggest that the effects are very much like the visions produced by ayahuasca (Gebhart-Sayer 1987, 206 ff.*) as well as the effects of **shahuan peco**.

Thalassaigle

“Sheen of the Ocean”

This Indian plant with visionary powers was described by Democritus in a lost work. Pliny paraphrases:

The *thalassaigle* is found on the River Indus and is thus called by another name, *potamaugis* [“river sheen”]; whoever drinks of it becomes insane, whereby strange faces hover in front of him. (24.164)

It is possible that this information refers to **soma**, which was drunk in the Indus Valley.

Theangelis

“Messenger of the Gods”

Pliny wrote the following about this plant, which has been neither identified nor even interpreted:

The *theangelis* comes from the mountains of Lebanon in Syria, from the Dikte Mountains of Crete, and from Babylon and Susa in Persia; when drunk, it imparts magicians with the ability to prophesy. (24.164)

Theombrontion

Pliny, basing his account upon the report of his informant Democritus, notes:

The *theombrontion* grows 30 schoine [app. 166.5 km] away from Choaspes, is the color of the peacock, and has a wonderful scent; the kings of Persia drink it for all physical ailments and to protect themselves from inconstancy of the mind and the sense of justice; because of its powerful effects, it is also called *semnios* [“the exalted” or “the sacred plant”]. (24.162)

This description suggests that this plant had a tonic effect upon the brain. Theombrontion was also an ingredient in a fertility-promoting mixture known as *hermesias* (“drink of Hermes”) that also included pine nuts, **honey**, myrrh (cf. **incense**), saffron (***Crocus sativus***), and **palm wine** (24.166). The name *theombrontion* may have been a corruption of *theos*, “god,” and *bromios*, “food.”

The *theombrontion* plant has sometimes been interpreted as *Aeonium arboreum* (L.) Webb et Berth. [syn. *Sempervivum arboreum* L.] (Crassulaceae).

Tila

Tila is actually the Spanish name for the linden (*Tilia* spp.), which has mild sedative effects (cf. **diazepam**). Since the linden is not indigenous to the Americas, the European name was applied to American plants. Thus, in Cuba, *Justicia pectoralis* is called either *tilo* or *tila*. Numerous plants are known in Latin America as *tila*. In southern Mexico, an as yet unidentified plant is also called *tila*. Its fruits, which resemble the large fruit capsules of *Turbina corymbosa*, are referred to as *flor de tila*, “linden flowers.” A tea made from these flowers is used in folk medicine as a tranquilizer and nerve tonic. This plant may be identical with or related to *Tilia mexicana* Schlechtend. (Tiliaceae) (Argueta et al. 1994, 1337*).

Tobo Tree

There is a sacred mountain in Iran known as Kohi-Gabr, “mountain of the fire worshippers.” In ancient Persia, before the advent of Islam, the fire worshippers were the people who would ritually drink **haoma** (cf. *Peganum harmala*). A ruin at the peak of the mountain is thought to once have been a Zoroastrian fire temple (cf. *Ephedra* spp.):

Concentrated magical essence has remained in this place, and an army of especially gifted genies dwells there. It is said that the “power” causes people who wish to approach the spot to shrink back. . . . Stories relate how those who climbed Kohi returned as madmen or cripples or wasted away. (I. Shah 1994, 153*)

We do not know what really transpired on this mountain. But it was associated both with other places of power and with certain psychoactive substances:

These fruits of an as yet unidentified plant are sold in Mexico under the name *flores de tila*, “linden flowers.” They are said to have narcotic effects.

Not far from this place, there are other mountains that are also linked to magical concepts. Here the fire-worshipping magicians once made offerings of fruit to placate certain spirits and to entice them into captivity so that they would obey their commands. Anyone who wanted to have a wish fulfilled would write it down and place it in a bowl filled with fruit, which the magicians would then take up the mountain. At the peak of one such mountain grew the tobo tree, the tree of eternal bliss. It is said to resemble the tree that stands at the right side of Allah in paradise. Good fairies carry the great sufferings and fears to this place, where they are purified so that the sufferers will be freed from their afflictions. (I. Shah 1994, 153 f.*)

The tobo tree is presumably some type of psychoactive plant that was identified with the tree of knowledge.

“Trees with Special Fruits”

Herodotus (ca. 500–424 B.C.) was a Greek historian and the father of ethnography. In his *Histories*, he provides us with the following story from Assyria:

Of the River Araxes [= Jaxartes/Syr Darja], some say that it is larger than the Istros, others that it is smaller. Numerous islands are said to lie within it, about the size of the island of Lesbos, and these are inhabited by people who dig out all kinds of roots in the summer and nourish themselves from these, but in winter they live from the fruits of trees, which they collect and

store after they have ripened. They also have other trees that bear very special fruits. When many people have come together, they light a fire, sit around it in a circle, and throw these fruits into the fire. When the smell of the burning fruits enters their noses, they become inebriated like the Greeks from their wine. They throw more and more fruits into the fire, so that they become more and more inebriated and finally jump up to dance and to sing. This is what is said about the way they live. (2.202)

The “fruits” being burned here as an **incense** sound suspiciously like female hemp flowers (*Canabis indica*, *Cannabis sativa*) and the ritual like that of the associated Scythian purification ritual. Their true identity, however, cannot be proved.

Woi

The Yecuana Indians of southern Venezuela are said to have used a magical plant called woi, apparently for psychoactive purposes. The botanical identity of this plant is completely unknown (Schultes 1966, 298*).

In ancient times, the dictum that “mushrooms are the food of the gods” was a familiar one (Graves 1957**). Probably the oldest written record of fungi in general was provided by Euripides (480– 406 B.C.). The first written mention of inebriating mushrooms and the rituals associated with them comes from the historical document *Historia General de las Cosas de Nueva España*, which was compiled between 1529 and 1590 by the Franciscan missionary Bernardino de Sahagún. This work contains what is probably the oldest graphic depiction of the ritual consumption of mushrooms (*teonanacatl*). The very earliest representation of mushrooms is a rock painting in the Tassili plain of the southern Sahara (Algeria), which has been dated to the late Neolithic period. The conjectures that Euripides wrote about psychedelic mushrooms and that the rock art in the desert are depictions of early mushroom shamans appear in a new light as a result of the knowledge and discoveries of modern ethnomycology.

The Neoplatonist Porphyrios (third century A.D.) referred to mushrooms as “the children of the gods.” The poets spoke lovingly of the “children of the earth” (Lonicerus 1679, 160*). Many researchers have suggested that the divine “drink of immortality”—whether known as **soma**, **haoma**, *amrita*, ambrosia,³⁴⁶ or *nektar*—was a fun gus or, more precisely, a psychoactive mushroom (Graves 1957**). Even the tree of knowledge has been interpreted as a fly agaric mushroom, and Christianity as originally a secret mushroom cult. Similarly, the Sufis are said to have employed mushrooms, which they called the “bread of crows,” so that they could know God (Shah 1980, 104 ff.*). Terence McKenna (1988*, 1996*) has advanced the hypothesis that psilocybin mushrooms of the species ***Psilocybe cubensis*** were the catalyst in primate evolution that led our apelike ancestors to become human.

We are only beginning to understand the immensely important role psychoactive fungi have played in human cultures. The branch of science that investigates these questions was founded by an American banker, R. Gordon Wasson (1898– 1986), and is known as ethnomycology (Riedlinger 1990**). Those psychedelic or entheogenic mushrooms that contain **psilocybin** and psilocin have had the greatest impact upon the history of culture (Metzner 1970**).

Amazingly, psilocybin mushrooms, first “discovered” in Mexico, are now found on all continents (and are being consumed by increasing numbers of mycophile psychonauts). New species are constantly being described (e.g., *Psilocybe samuensis* Guzmán, Bandala et Allen and ***Psilocybe azurescens*** Stamets et Gartz) and new ranges and occurrences of known species are being discovered.

The Flesh of the Gods

Although ancient Europe almost certainly had its own indigenous mushroom cults (Graves 1957**; Samorini and Camilla 1995**), the first mention of magic mushrooms and their associated rituals is found in (ethnohistorical) sources from the early colonial period of the Americas. Because the Catholic Church and the Mexican and Peruvian Inquisitions forbade the religious use of psycho-active plants and severely punished any transgressions (Andritzky 1987*), the sacred use of mushrooms was forced underground. It was not rediscovered until the 1950s, when the Mazatec shaman María Sabina initiated the Wassons into the nocturnal cult (Wasson 1957**). Today, María Sabina, now deceased, is regarded as a kind of “saint” of the psychedelic movement. The botanical identity of the mushroom that the colonial sources referred to as *teonanacatl* (Nahuatl: “flesh of the gods” or “wondrous mushrooms”) was determined in the late 1930s (Johnson 1940**; Reko 1940**; Schultes 1939,** 1940,** 1978**; Singer 1958**; Wasson 1963**).

Because of their enormous powers, these mushrooms (***Psilocybe mexicana***, ***Psilocybe* spp.**) are often regarded as something sacred or divine or even as deities in their own right. Those who consume the “mushrooms of the gods” in a ritual context undertake a journey into other realities where they might enter the realm of divine beings, retrieve the souls of the sick, and foretell the

future. One Mazatec mushroom shaman had the following to say about such divination:
The words come only when the mushroom is in my body. A wise man does not learn by heart that which he must say in his ceremonies. It is the sacred mushroom that speaks. The wise man simply lends it his voice. (Estrada 1980, 144**)

The *velada*, “night watch,” is a nocturnal meeting in the house of a female or male shaman, during most of which the participants sit in a circle. After **incense** is burned and offerings and prayers are made, the participants are given the mushrooms, which they consume in pairs while prayers are being offered. The shaman then begins a series of songs that make it possible for her and the group to enter trance and explore the psychedelic universe of the entheogenic mushroom (Wasson et al. 1974**;
Estrada 1980**;
Hofmann 1979*; Liggenstorfer and R  tsch 1996**).

Setting a date for the nocturnal event already implies that the patient, the healer, and perhaps even the group are going to deal with the situation at hand. The problems that are to be solved (the illness or other reasons for holding the meeting) are placed at center stage. Do  a Julieta explained that each and every one of the participants must clearly understand the questions that he wishes to ask the “santitos.” It often happens that the “velada” will not focus on the healing of one single, clearly “defined” patient, but that the various participants also announce their interest in a cleansing (“limpia”) or healing. (Donati 1991, 86 f.**)

“The mushrooms give me the power to see everything completely. I can look back to the beginning. I can go to where the world originated. The sick become healthy, and the relatives then come and visit me to tell me that relief has come. They give me thanks and bring me alcohol, cigarettes, and a little money.”

MARIA SABINA

IN *MARIA SABINA* (ESTRADA 1980, 72 f.**)

For many musicians (e.g., The Allman Brothers), the universe was created in a divine mushroom trip. Consequently, the psychedelic paradise in which these musicians (the techno-pop band Deeelite) are shown frolicking is a garden of gigantic mushrooms. (CD covers: 1994, Sony Music; 1994, Elektra Records)

* = literature listed on pages 878–907

** = literature listed on pages 689–93

“This mushroom is a transdimensional doorway which sly fairies have left slightly ajar for anyone to enter into who can find the key and who wishes to use this power—the power of vision—to explore this peculiar and naturally occurring psychoactive complex.”

TERENCE MCKENNA *TRUE HALLUCINATIONS* (1993, 41*)

Even the truffle (*Tuber* spp.), that culinary delicacy, has a type of psychoactive effect. It produces an odoriferous substance that is an analog of human pheromones, thereby eliciting a specific sexual search behavior in humans. For this reason, truffles enjoy a reputation as an aphrodisiac. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

In Europe, the American Indian model for entheogenic mushroom rituals has been adapted for use with mushrooms (*Psilocybe cubensis*, *Psilocybe cyanescens*, *Psilocybe semilanceata*) and other psychoactive substances (e.g., LSD, MDMA; cf. **herbal ecstasy**) in group settings (M  ller-Ebeling and R  tsch n.d.**). These sessions are known variously as ritual circles, ceremonial circles, healing circles, and mushroom circles. This ritualized use has led to the emergence of a new movement

(Rätsch 1996**). Today's entheogenic mushroom culture is decentralized, both anarchic and partnership oriented, and it transcends religious, cognitive, and political boundaries. It resembles, in fact, the manners in which the mushrooms themselves grow: an underground network of interlaced roots. The fruiting bodies appear at the proper time and the proper place, often in a circle ("fairy ring"), at which time they disperse their spores throughout the world. In order to be introduced or initiated into the mushroom culture, one needs only to ritually consume some mushrooms in a circle of like-minded individuals and "be accepted" by them. Many people have experienced the ritual circle as an initiation into the mysteries of the mushroom. In the Western world, entheogenic mushrooms have brought forth a spiritual cult with its own rituals not unlike those of the peyote cult (cf. *Lophophora williamsii*) of the Native American Church and other, similar movements (La Barre 1979b*).

The World of Fairies and Witches

Toward the end of the Middle Ages, it was widely believed that witches and demons caused mushrooms to grow. "Fairy rings," the circular fruiting characteristic of a number of fungi (e.g., the edible wood blewit *Lepista nuda* [Bull.: Fr.] Cooke and *Amanita muscaria*), were regarded as especially dangerous, for they were thought to be the nocturnal meeting places of witches, female magicians, elves, and mushroom spirits (Englbrecht 1994, 8, 56**):

In days gone by, and especially in the Middle Ages, mushrooms stimulated the human imagination. To superstitious individuals, they have always appeared to be strange beings. The most amazing tales have been told about fungi. Various meanings have been attributed to the "elf rings," also known as "elf dancing places" and "fairy rings." They can still be found today; in fields, meadows, and forest clearings, mushrooms often grow in a closed circle. Folk tales about such rings have been passed down in songs, stories, and poems. It was believed that they were the sites where delicate winged and happy elves or lusty groups of goblins would assemble during the night and perform their graceful or turbulent dances in the forest. These folk beliefs were not limited to the enchanting forms of the fairy rings alone, for they also attributed the mushrooms themselves with mystical significance. As a result, those mushrooms that were shaped like umbrellas became the umbrellas and parasols that dwarves and elves used to protect themselves from the rain or the sun, and they also became known as "elf stools." Nymphs were said to sip the cool morning dew from mushrooms that looked like small goblets, and the little magical beings of the forest were said to take refreshing baths in the larger ones. It was also believed that evil witches would use poisonous mushrooms when they were preparing their dangerous magical drinks. (Rippchen 1993, 13**)

Such conceptions are not limited to medieval and modern Europe but are also found in many other parts of the world. In Japan, mushrooms, especially those of the genus *Amanita* (cf. *Amanita muscaria*, *Amanita pantherina*), are thought to be the food of the long-nosed goblins known as *tengus*, or the places where *tengus* dallied. It is not unlikely that these stories of elves, goblins, and fairies arose as a result of the visions that certain mushrooms can evoke (Golowin 1973*). Some authors have even recommended that people desiring to gain access to the fairy world consume mushrooms (Morris 1992, 5**).

"It is reported that Nero said that 'mushrooms are the food of the gods'; perhaps the joke of a madman who wished to express that it is possible to at least enter paradise by being conveyed by the mushrooms into the beyond."

DER MAGISCHE GARTEN [THE MAGICAL GARDEN] (1980, 254*)

“The Mazateco Indians identify the hallucinogenic mushroom with Jesus Christ. They believe that while on earth, Jesus spat onto the ground. The mushrooms grew out of his saliva. They are his speaking tube, through which he speaks when their chemical constituents produce hallucinations.”

EUNICE PIKE AND FLORENCE COWAN *MUSHROOM RITUAL VERSUS CHRISTIANITY* (1959, 145**)

“He [Gwyddion] then resorted to his skills and began to demonstrate the power of his magic. He made appear a dozen stallions, twelve black hunting dogs . . . twelve golden bucklers. These shields were mushrooms that he had transformed.”

MABINOION (CELTIC MYTH) IN *THE DRUIDS* (MARKALE 1999, 143*)

In Celtic mythology, at least as it is represented in modern times, mushrooms are closely related to the “other world” and to the realms of fairies and elves. In Celtic Wales, tradition tells of a mushroom, known as *bwyd-ellyllon* (“elf mushroom”), that “is one of the delicacies of the elves but is feared by man and beast” (Perger 1864, 210*). It is very likely that the pagan Celts partook of the “elf mushroom”:

We can assume with certainty that they used in their rituals various mushrooms, such as the fly agaric, which when dosed carefully evoke visions and trance states. (Markale 1989, 203*)

Today, in such Celtic areas of Great Britain as Wales and Cornwall, neopagans and underground Druids continue to consume “liberty caps” (*Psilocybe semilanceata*) as a sacrament to invoke the elves. Megalithic dolmens, such as the one found at Chûn Quoit (which looks like a gigantic mushroom), are preferred locales. The British geomancer Paul Devereux has called these dolmens “the dreaming stones” and suggested that at such dream-stimulating³⁴⁷ sites, appropriate earth energies can have inspiring effects upon human consciousness—especially when said consciousness has been expanded by mushrooms (Devereux 1990*, 1992a*, 1992b*; Devereux et al. 1989, 117, 180 ff.*). A traditional Celtic belief holds that these dolmens are entrances to the fairy world (Evans-Wentz 1994*). The keys, of course, are the mushrooms.

The Archaeology of Entheogenic Mushroom Cults

Since fungi are very poorly or not able to be preserved as organic material over long periods of time, they and their fruiting bodies are almost never found during archaeological excavations (Gartz 1992). For this reason, it is practically impossible to state definitively whether fungi had any role to play as ritual offerings or grave goods or to find them as remnants of shamanic activities. From an archaeological perspective, both the shamanic use of fungi and religious mushroom cults can be demonstrated only by means of artifacts and pictorial representations. Often, petroglyphs are the only evidence of a lost culture. It was through rock carvings in the Sahara that the “oldest psychedelic mushroom culture in the world” was discovered (Samorini 1992). Scandinavian petroglyphs have been taken as evidence of mushroom use among the Vikings (Kaplan 1975). Similarly, many Indian petroglyphs have been interpreted as indicating the shamanic use of psychoactive plants (cf. *Datura wrightii*) and as representations of these plants (Wellmann 1978*, 1981*).

Mushrooms and Petroglyphs

In the Tassili plain of northern Africa (Algeria), a now barren Saharan landscape, rock paintings and petroglyphs dated to between 9000 and 7000 B.C. have been discovered. The illustrations portray a flourishing hunting and pastoral culture (Mori 1974). One group of rock drawings appears to be

related to entheogenic mushrooms:

The polychromic scenes of harvest, adoration, and the offering of mushrooms, and large masked “gods” covered with mushrooms . . . lead us to suppose we are dealing with an ancient hallucinogenic mushroom cult. . . . [T]hese mushrooms can be distinguished by means of a complex system; every type having its own mythological representation. . . . [T]hey could indeed reflect the most ancient human culture as yet documented in which the ritual use of hallucinogenic mushrooms is explicitly represented. (Samorini 1992, 69)

In addition to *Psilocybe cubensis*, the rock images apparently depict other psychoactive fungi, including *Psilocybe cyanescens* and *Panaeolus* spp. (Gartz 1992). The most impressive of the Tassili images feature running or dancing figures that look like anthropomorphized mushrooms and are shown holding a mushroom in their hands. In the entheogenic mushroom culture, a bee-shaped god, out of whose body mushrooms are sprouting, is now regarded as a kind of “primordial deity” (Rätsch 1996**).

A large number of petroglyphs are located in the Southwest of North America. Both the Indians who now live in this region and the archaeologists and ethnologists who study these artifacts interpret them as shamanic scenes (Schaafsma 1992). Some petroglyphs portray “shamans” holding mushrooms or mushroomlike objects in their hands (Rätsch 1994; Samorini 1995a*). While no mushrooms are used for ritual or shamanic purposes in the Southwest today, it is possible that they were used in prehistoric times, when there was a lively cultural exchange between Mexico and the Southwest. Trade routes connected Mexico to the Southwest, and ritual objects (e.g., the sacred *Spondylus princeps* shells) were known to move north. Dried psilocybin mushrooms may also have traveled along these routes to the cultures of the north (cf. McGuire 1982**).

Some of the “mushroom” petroglyphs may represent the fly agaric mushroom, which was used in shamanic contexts by other North American Indian peoples. The fly agaric (*Amanita muscaria*) and a subspecies or variety (*A. muscaria* var. *formosa*), as well as the even more potently hallucinogenic *Amanita pantherina*, do occur in the Southwest and are not considered rare (States 1990, 57 f.**). Perhaps the shamans of the prehistoric Pueblo Indians ritually consumed fly agarics in remembrance of their Asian origins (Rätsch 1996).

Entheogenic Mushrooms in Antiquity

The Hittites were known to have possessed idols that had the appearance of anthropomorphized mushrooms (Morgan 1995, 112**). The Mycenaeans were originally of Asian descent, and they etymologized their “new home” Mycenae from *mykes*, “fungus,” to remind themselves of the entheogenic cult that stood at the beginning of their history (Ruck 1995, 32*). When seen from inside, the so-called Treasury of Atreus in Mycenae is a perfect reproduction of a *Psilocybe semilanceata* cap. According to legend, Perseus, the founder of Mycenae, discovered and apparently ate a mushroom at the site, whereupon he received a vision of his city.

The fact that mushrooms had a special religious or ritual importance in ancient Greek cultures can also be seen in the mushroom chains, strings of beads that are clearly shaped like mushrooms, that were produced in both Minoan and Hellenistic times (one such example of the jeweler’s art can be seen in the museum of Iráklion, Crete). The Bronze Age has yielded characteristic ceramic figures that are now known as *kourotrophos* (“wet nurses”). Both the wet nurses and the children they suckled have the shape of mushrooms (Ripinsky-Naxon 1993*). An Etruscan bronze mirror features an image of the Thessalian hero Ixion, an uncle of the legendary Asclepius, as he dances over a mushroom with eagle wings. An amphora from the fourth century

B.C. shows Perseus and the decapitated Medusa, she “who has lost her head.” Above the hero float long-stemmed mushrooms with small, roundish heads. If something looks like a mushroom, it is a mushroom. And all of these images bear strong resemblances to psilocybin mushrooms.

The Greek scholar Carl Ruck interpreted a very enigmatic scene in Aristophanes’ *Birds* as an allusion to a mushroom cult surrounding the philosopher Socrates:

Amidst the shade-foots,
there is a certain swamp
where Socrates, unwashed,
summons up souls.
Amongst his clients came Peisander,
who begged to see a spirit that had forsaken him
while he remained alive. (1553 ff.)

“Shade-foot,” or *monocoli*, was a paraphrase for anthropomorphic mushrooms.³⁴⁸ The “pond” was the sacred swamp of Dionysos in Athens. The “unwashed” Socrates was impure because he had profaned the lesser Eleusinian mysteries, i.e., had carried them out in his own home. This is the reason why he was regarded as a summoner of souls, because he had induced the youth, represented here by Peisander, to consume the sacred drug. That the latter would search for the soul that had slipped out of his living body (a thoroughly shamanic motif) during an appropriate mushroom ritual can be understood only in this way. According to Ruck, the main mysteries at Eleusis, during which **kykeon** was administered, were contrasted by these “lesser rites” in which entheogenic mushrooms were cultically consumed (Ruck 1981**).

Support for this assertion comes from a late ancient relief found in Eleusis that dates to the fourth century A.D. On the relief are Demeter and Persephone; the Great Goddess is shown holding a mushroom in her hand, which she is presenting to Persephone (Stamets 1996, 14**).

The Mesoamerican Mushroom Stones

A number of stone artifacts have been found in southern Mesoamerica, primarily in Chiapas and Oaxaca (Mexico), Guatemala, and El Salvador. Around 30 cm in height, they have become known by the name *mushroom stones* in both the academic and the popular literature (Ohi and Torres 1994; Rose 1977; Trebes 1997). Some of these artifacts are well over two thousand years old. Most are small objets d’art (stone sculptures) depicting animals or humans, from whose backs or heads mushroom-shaped objects emerge. Many of these objects have been found and documented (Mayer 1977, 1979). Recently, a mushroom stone was discovered in the region occupied by the Maya (Trebes 1997).

The German geographer Carl Sapper (1898) regarded these stones as “mushroom-shaped images of idols.” The American scholar Daniel G. Brinton (1898) was of the opinion that these objects are moon symbols. In contrast, the American archaeologist Thomas W. Gann (1911) viewed them as phallic symbols (cf. also Bruder 1978). R. Gordon Wasson (1961**) saw the mushroom stones as symbols of an archaic entheogenic mushroom religion. The German pre-Columbian scholar Ulrich Köhler (1976) argued that the mushroom stones are forms for making pottery (see the criticism in Lowy 1981). The Mexican mycologist Gastón Guzmán (1984) has argued that the mushroom stones are representations of culinary mushrooms, e.g., the edible “porcini mushroom,” *Boletus edulis* Buillard ex Fries (cf. ***Boletus spp.***). The most commonly held view is that the mushroom stones are ritual objects that were associated with the ingestion of psilocybin mushrooms.

The ancient “mushroom stone” of Delphi looks like a naturalistic representation of a *Psilocybe semilanceata* cap. Classical archaeologists, however, have interpreted it as a model of the *omphalos*, “navel of the world.” It does make sense that the navel of the world should be sought in the cap of a psychedelic mushroom.

A Central American mushroom stone (Maya, El Salvador, ca. 300 B.C. to 200 A.D.), in which the spirit of the mushroom appears to be emerging from the stem. (Illustration: Sebastian Rätsch)

A *monocoli* or one-foot, which R. Gordon Wasson sees as a symbol of the sacred mushroom. (From *Schedels Weltchronik*, 1493)

“Then, indeed, as you lie there bemushroomed, listening to the music and seeing the visions, you know a soul-shattering experience, recalling as you do the belief of some early peoples that mushrooms, the sacred mushrooms, are divinely engendered by Parjanya, the Aryan God of the Lightning-bolt, in the Soft Mother Earth.”

R. GORDON WASSON *THE ROAD TO ELEUSIS* (1984, 34)

A running mushroom shaman from Tassili. (Illustration: Christian Rätsch)

A petroglyph from the American Southwest (Dry Fork Valley, Utah) may be a depiction of a shaman with a mask and a sacred mushroom. (Illustration: Christian Rätsch.)

The discovery of nine small mushroom stones (14 to 18 cm in height) together with small, easy-to-use grinding stones (*metate* and *mano*) in a ritual depot at Kaminaljuyú (Guatemala) suggests that the mushroom stones were venerated as idols and the other stones were used to grind dried mushrooms as part of a mushroom cult (Borhegyi 1961; Lowy 1971). Ethnohistorical sources (Lowy 1980**) from the area where the stones were recovered bear witness to the ritual use of the mushroom stones:

The “Titulo de Totonicapán,” which dates to the colonial period, confirms that during their enthronement, the rulers of the Quiché received the insignia of their kingly power as well as *nanakat abaj beleje*, “nine mushroom stones.” Although these text passages refer to practices from the post-Classic period, they clearly demonstrate the continuation of a sculptural tradition that is rooted in pre-Classic times. Mushroom stones may have already been a part of the insignia of kingly power in the pre-Classic period, because only the princes enjoyed the special privilege of consuming mushrooms with hallucinogenic effects. (*Die Welt der Maya*, 1992, 314)

In western Mexico (Nayarit), a number of ceramic objects have been found that may be representations of ritual mushroom consumption (Furst 1965; Kan et al. 1989, 82 f., 91). Ceramic figures discovered in Jalisco depict drumming men with strange, mushroomlike growths on their heads (Kan et al. 1989, 126 f.). Are these representations of shamans in a mushroom-induced trance state?

The contemporary Maya regard artifacts from pre-Columbian times as divine objects or gifts of the gods. These artifacts are considered to be especially powerful and are used as amulets and images of gods. The Lacandon Maya occasionally find artifacts while working their fields or in the forest. They call these ceramics *u pat k’uh*, “pottery of the gods.” Ceremonial axes are known as *u baat k’uh*,

“axes of the gods.” Artifacts and stones of spherical shape are referred to as *kuxun tun*, “mushroom stones” or “living stones.” The usual word for stone is *tunich*, while *tun* tends to be used to refer to precious stones. Perhaps the term *kuxun tun* is a last linguistic reminder of the pre-Columbian mushroom stones.

Today, *Psilocybe* mushroom fans from around the world collect reproductions of these mushroom stones. Both reproductions and forgeries have been on the market since the 1960s (Mayer 1977, 2). Those tourists who visit Mexico in search of mushrooms have led enterprising souvenir makers to produce small mushroom stones (*hongitos*) and amulet-like pendants. These are made from stone (onyx, marble, chalcedony, obsidian), black coral, amber, ceramic, and even papier-mâché. Many of these souvenirs have landed on the house altars of mushroom lovers throughout the world (Rätsch 1996**).

The Golden Mushrooms of the Tairona

In pre-Hispanic Colombia, a number of cultures flourished that were well versed in the manufacture of gold jewelry. Of these, the goldwork of the Tairona incorporates obvious shamanic elements (Reichel-Dolmatoff 1981, 1988). It is probable that the Tairona knew of and ritually used psychoactive mushrooms. A large number of the figured gold objects known as the Darien pectorals display unequivocal mushroom ornamentations (Schultes and Bright 1979). Reichel-Dolmatoff has described the ritual use of psychoactive mushrooms among the Kogi, the descendents of the Tairona (Reichel-Dolmatoff 1977, 285*). From a mycological perspective, the “blue puffball” (cf. *Lycoperdon*) is completely unknown; the other species, which is not described, may be a *Psilocybe*. After all, *Psilocybe yungensis* Sing. et Smith [syn. *Psilocybe acutissima* Heim, *P. isauri* Singer; cf. ***Psilocybe* spp.**] is found throughout South America (Singer 1978, 59**). There also are reports of visionary experiences produced by *Psilocybe* species collected near the village of San Agustín (Mandel 1992).

The Dolmens of India

In Kerala (southern India), there are a number of prehistoric stone structures (dolmens) that belong to the megalithic culture and date to the period between 1400 B.C. and 100 A.D. In the Malayalam language of Kerala, they are known as *kuda-kallu*, “umbrella stones”³⁴⁹; the interiors are called *garbba-gripa*, “uterus chambers” (Rippchen 1993, 99**). The structures are 1.5 to 2 meters in height and are built of five stones that are put together in such a way that they resemble a mushroom: “In the indigenous tradition, they are typically interpreted as parasols and regarded as archaic symbols of power, authority, and sacredness” (Samorini 1995, 33). In modern India, it is thought that these dolmens, known as umbrella stones, are a symbol for ***Psilocybe* spp.** (Jain 1991, 151*). It has also been suggested that these stones are related to an archaic cult of the dead or to the Vedic **soma** cult:

If the *kuda-kallu* represented mushrooms, then these were psychoactive mushrooms, i.e., mushrooms that were much more suitable than others—e.g., culinary mushrooms—for associating with a cult of the dead. There appears to be no direct connection between the *kuda-kallu* and the Vedic soma, in the sense that these monuments do not appear to be emblems of a cult which may have emerged because of or been influenced by the soma cult, for the cult associated with the *kudakallu* developed in a period which certainly predated the contact with the Aryans in South India. (Samorini 1995, 33)

The appearance of the Kerala mushroom stones does not so much recall species from the genera ***Psilocybe*** and ***Paneolus*** as it does those from *Amanita* and *Boletus* (cf. **nonda**). Both the fly agaric (***Amanita muscaria***) and the panther cap (***Amanita pantherina***) are found in Kerala. It is possible that

the *kuda-kallu* were associated with an *Amanita* cult. In the village of Ambalathara, near Thiruvananthapuram in modern Kerala, there is a temple to Devi, the radiant goddess of the plant devas (Storl 1997, 21 ff.*), that appears to have been built to resemble the *kuda-kallu* and which looks like a gigantic mushroom (Samorini 1995, 36). The Naga of this region are said to still consume fly agaric mushrooms for psychoactive purposes.

There are several megalithic dolmens in Cornwall (e.g., Chûn Quoit) that strongly resemble the Indian *kuda-kallu*. In the barren landscape, these giant mushroomlike objects are visible over great distances (Devereux 1990, 154 f.*; 1992, 182 f.).

These Mesoamerican seals from prehistoric times look like mushroom-covered mandalas.

Mushroom-shaped petroglyphs on a stone from Stonehenge—evidence of a psychoactive mushroom cult? (From Samorini)

“The mushrooms were moist, looked greenish, and were very dirty. As I bit into the first one, I had to choke. . . .

I noticed that my husband’s red-checked shirt was intensely colorful.

I stared at the rough wooden furniture. The cracks and knotholes in the wood seemed to change form. Suddenly Masha cried: ‘I am a chicken!’ We both broke into resounding laughter. This comment was just too funny. . . . Then the walls shrank back, and I was carried off—up and away—on swaying waves of light turquoise. I do not know how long I was under way. I came to France, to the caves of Lascaux in Dordogne. We had been to France once, and I immediately recognized the giant stone vault above me and the beautiful primitive paintings of the former cave dwellers, the horses, bison, and deer on the walls. The paintings were even more beautiful than in reality. They appeared to be covered in a crystal-clear light. . . . Now I knew what the shamans meant when they say: ‘The mushroom carries you to a divine place.’ ”

(RIPPCHEN 1993, 128 f.**)

Cultivating Mushrooms

In a comic story by Gilbert Sheldon, his heroes, the Fabulous Furry Freak Brothers, decide that they would like to grow psilocybin mushrooms. Fat Freddy collects a wheelbarrowful of cow dung from a nearby pasture, which he then tips into the bathtub. Because the mushrooms sprout every time it rains, he sprays the dung thoroughly with water. The following day, Fat Freddy goes in to gather his harvest. He finds no sign of mushrooms but does find millions of cockroaches. Disturbed in the midst of their feast, they quickly flee for other parts. . . .

Growing mushrooms at home can have results such as these. Although it appears simple in principle, it can entail almost insurmountable difficulties. Some methods for growing mushrooms for culinary or medicinal purposes have long been in use, e.g., growing mushrooms on straw, a practice that comes from ancient China (Chang 1977).

The simplest way to grow mushrooms is outdoors, e.g., in one's own garden. The psychoactive mushroom species most suited for this purpose are *Psilocybe azurescens* and *Psilocybe cyanescens*. Both species grow wild in forests and are excellent for the climate of central Europe.

First dig a pit 20 to 25 cm deep. Fill the bottom with a layer of small pieces of wood (approximately 5 to 10 cm thick). Mix each mycelium with wood chips or mulch, moisten the mixture thoroughly, and spread it over the bottom layer. Spread a layer of wood shavings over this. Cover the site with leaves and small branches. The bed should never dry out, lest the mycelia stop growing. To prevent moisture loss, foil or wooden boards may be laid over the bed. When the mycelia feel at home and have spread, a rich harvest will erupt when the weather conditions are right (in central Europe, this usually occurs in October, after a period of some ten days with much precipitation and temperatures under 10°C). Since the mushrooms require nutrients after the fruiting bodies have been harvested, the upper layer of mycelium-filled wood should be replaced with fresh wood chips or mulch. Sometimes the mushrooms will spread outside of the bed and may suddenly appear in neighbors' gardens, much to their delight.

Some methods of laboratory cultivation were developed for the mycological and chemical investigations of *Psilocybe mexicana*. In the mid-1970s, mushroom hobbyists discovered a method for growing *Psilocybe (Stropharia) cubensis* ("the mushroom that comes from the stars") at home and published their findings (Oss and Oeric 1976). This book has been translated into a number of languages and has been banned more than once. To date, more than five hundred thousand copies have been published (not to mention the illegal copies). Many people have successfully followed these cultivation methods. With time, other books on growing mushrooms have appeared, some of which make no mention of magic mushrooms or refer to them only cryptically. Nevertheless, these too have provided home growers with useful information (Harris 1989; Meixner 1989; Pollock 1977; Stamets 1993; Stamets and Chilton 1983). In recent years, the species *Psilocybe cyanescens* and *Panaeolus cyanescens* have also been successfully grown in home laboratories.

Ethnobotanical specialty stores are increasingly offering spore prints and mycelia of psilocybin mushrooms (the trade in spores is still legal in many countries). Kits for growing mushrooms, together with detailed instructions, are also available. Growing spores on a substrate is actually quite easy and usually fails only when the petri dishes are not sterilized properly and other wild molds settle on the substrate. Substrates such as agar and rye are available in specialty shops. It is also worthwhile to consult the specialized literature on the subject. The books by Paul Stamets and the articles by Jochen Gartz are especially useful.

The methods of mushroom cultivation are continually being improved and simplified for home use (Gartz 1993a, 1993b; Stamets 1993). Some methods that can increase the psilocybin content have been discovered (Badham 1985). When tryptamine is added to the substrate, the mushrooms are able to quickly metabolize it into **psilocybin** and psilocin. Phosphates can also aid in this process (Gartz 1991).

A homegrown culture of *Psilocybe cyanescens* with mature fruiting bodies.

A culture of *Psilocybe azurescens* that is just beginning to fruit.

Mushrooms and the Law

Psilocybin and psilocin, the active compounds in many psychoactive mushrooms (but not the mushrooms themselves!), are listed in Section I of the German drug laws of 1982 (*Betäubungsmittelgesetz*) as drugs, trafficking in which is prohibited (Geschwinde 1990, 110*; Körner 1994, 40*):

As “plants,” mushrooms are not subject to the German drug laws, for they simply contain psilocybin. The cultivation of mushrooms is not punishable, so it is not a question of the growth stage. The harvesting and preparation of mushrooms, however, can constitute a manufacturing offense. Consequently, trafficking in spores is not illegal. In the same way, a setup for cultivating mushrooms is not illegal. (Böhm 1993, 174)

Psilocybin mushrooms thus thrive in a legal limbo. If the active constituents psilocybin and psilocin were not proscribed as “narcotics,” dried mushrooms and/or Galenic preparations made from them would be available in German pharmacies as medicines requiring a prescription.

The legal situation in the United States is similar, although the laws are applied much more frequently and with much greater severity than in Germany (Boire 1995; Shulgin 1992*). In Mexico, mushrooms of the genera *Panaeolus* and *Psilocybe* are illegal (the Conquest and the Inquisition have not yet ended!).

In the Netherlands, it is permitted to sell freshly cultivated mushrooms (*Psilocybe cubensis*, *Psilocybe cyanescens*, *Panaeolus cyanescens*).

Fly agaric (*Amanita muscaria*) and panther cap mushrooms (*Amanita pantherina*) are legal in

Germany (Körner 1994, 1572*).

Böhm, Rüdiger. 1993. Zauberpilze im Recht. In *Zauberpilze*, ed. R. Rippchen, 173–74. Löhrbach: MedienXperimente.

Boire, Richard Glen. 1995. *Sacred mushrooms and the law*. Davis, Calif.: Spectral Mindustries (P.O. Box 73401, Davis, CA 95617–3401).

“‘MEXICAN MUSHROOMS!’ Meanwhile, psiloc(yb)in mushrooms are being sold openly at some Goa open-air parties. Outside of these ‘temporary autonomous zones,’ the uncertain legal situation means that people are not quite as courageous as in the Netherlands. In the summer of 1994, the owner of the Amsterdam smart drug shop ‘Conscious Dreams’ was the first to dare to sell cultivated psiloc(yb)in mushrooms of the species *Psilocybe cubensis* openly across the counter. It did not take long for the police to show up. The case went before the court. There, as here, the almost identically functioning constituents of the mushroom, psilocin and psilocybin, are forbidden by the opium and narcotic laws. The mushrooms, however, are not explicitly forbidden. The court’s decision noted that the amount of active constituents becomes highly concentrated only when the mushrooms are dried (namely, by about a factor of 10 compared to fresh mushrooms), and only then could one speak of an illegal substance. In no time, only fresh mushrooms were being offered.”

ACHIM ZUBKE “SPASS ATTACKS” [“FUN ATTACKS”] (1997, 21 f.**)

The Genera and Species from A to Z

Psychoactive fungi are found not only in Mexico—as is so often assumed—but throughout the world, on all continents and almost all of the islands of Oceania (Gartz 1995**; 1996**; Stamets 1996**; Stijve 1995**), as well. On the basis of the active compounds they contain, psychoactive fungi can be divided into three groups:

Psilocybin type:

with species from the genera *Conocybe*, *Copelandia*, *Galerina*, *Gymnopilus*, *Inocybe*, *Panaeolus*, *Pluteus*, and *Psilocybe*; possibly also *Agrocybe*, *Gerronema*, *Hygrocybe*, *Mycena*, *Naematoloma*, *Panaeolina*, *Pholiotina*, *Psathyrella*, and *Stropharia*

Ibotenic acid/muscimol (isoxazole) type:

with species from the genus *Amanita*; possibly also *Boletus*

Ergot alkaloid (ergoline) type:

with species from the genera *Balansia* and *Claviceps*; possibly also *Aspergillus* and *Cordyceps*

In addition, there are many fungi that are purported to or may be psychoactive but whose constituents are largely unknown. These genera include *Boletus*, *Heimiella*, *Laetiporus*, *Lycoperdon*, *Piptoporus*, *Polyporus*, *Russula*, and *Scleroderma*.

Of all the psychoactive fungi, those species of the genus *Psilocybe* that contain **psilocybin** have had the greatest cultural significance. Moreover, of all naturally occurring psychoactive substances, these fungi are generally considered to be the best, safest, and most free of side effects. *Psilocybe* mushrooms that contain psilocybin generally require no extensive preparation techniques and can be eaten fresh (“straight from the meadow,” so to speak) or dried and ingested at a later time. The dosage depends upon the concentration of psilocybin (plus psilocin and baeocystin) present in the mushroom material. Between 20 to 30 mg of psilocybin suffices for a psychedelically effective dosage. The classic “psychedelic,” “visionary,” or “entheogenic” effects begin some ten to sixty minutes after ingestion and continue for almost exactly four hours. The first report of an experience with a *Psilocybe* species that appeared in Western literature came from R. Gordon Wasson, the founder of ethnomycology:

[T]he visions came whether our eyes were opened or closed. . . . They were in vivid color, always harmonious. They began with art motifs. . . . Then they evolved into palaces with courts, arcades, gardens—resplendent palaces all laid over with semiprecious stones. Then I saw a mythological beast drawing a regal chariot. Later it was as though the walls of our house had dissolved, and my spirit had flown forth, and I was suspended in mid-air viewing landscapes of mountains, with camel caravans advancing slowly across the slopes, the mountains rising tier above tier to the very heavens. . . . The visions were not blurred or uncertain. They were sharply focused, the lines and colors being so sharp that they seemed more real to me than anything I had ever seen with my own eyes. . . . I was seeing the archetypes, the Platonic ideals, that underlie the imperfect images of everyday life. (Wasson 1957, 102, 109**)

Few people who have tried *Psilocybe* mushrooms will be surprised to learn that both ancient peoples and the American Indians lovingly referred to the species of this genus as divine mushrooms, food of the gods, flesh of the gods, sacred mushrooms, ambrosia, *amrita*, and magic mushrooms. Only people who have no knowledge of them may describe them as the “bread of the devil” or the “devil’s mushroom” (Graves 1957**).

Magic mushrooms—whether *Psilocybe* spp. or *Panaeolus* spp.—cannot be consumed on a daily basis, for they would quickly cease to be effective. According to one common aphorism, “Marijuana is our daily bread, mushrooms the uncommon feast.” The pharmacodynamics of the mushroom make it impossible to use it on a daily, recreational basis:

Rock art from Rio Chinchipe, Peru, which may depict anthropomorphic mushrooms, mushroom spirits, or mushroom shamans.

Psychoactive mushrooms can be found on all continents and in almost every climate zone. In many places, they are esteemed for their visionary effects and are portrayed in appropriately loving ways. (Balinese carving, ca. 1996)

Psilocybin-containing mushrooms of the genus *Psilocybe* are often confused with species from the closely related genus *Hyphaloma*. (*Hyphaloma fasciculare*, photographed in Olympia, Washington)

Spore prints from freshly collected mushrooms often help in identification. The mushroom cap is placed on a piece of paper with the lamellae (gills) facing down. Covering the mushroom with a plastic bowl or a glass may help. After a short time, the mushroom spores will accumulate on the paper. Most of the species that contain psilocybin produce a radial print that is brownish violet in color. The spores give the lamellae their characteristic color when dried. (Cap of *Psilocybe cubensis*)

If psilocybin is ingested more frequently than once a week, this can quickly lead to the development of a considerable tolerance. As with LSD-25, a dosage twice as high will be needed to produce the same effects. Abstention from the drug, as with LSD-25, will just as quickly result in a disappearance of the tolerance effects. (Geschwinde 1990, 110*)

Identifying Mushrooms That Contain Psilocybin

Many people in Western cultures are afraid of mushrooms (an attitude known popularly as mycophobia). They believe that all mushrooms are toxic and that many of them are lethally poisonous. In fact, there are really very few truly dangerous mushrooms, the most lethal of which is the destroying angel (*Amanita phalloides* [Vaillant ex Fries] Secretan) (Graves 1957**). It contains amatoxins that can lead to death within three days. To date, no true antidote has been found for this mushroom. While the destroying angel is very easy to recognize, it can under some circumstances be confused with *Amanita muscaria* or *Amanita pantherina*.

Species of the genus *Psilocybe* can be mistaken for dangerously poisonous *Inocybe* spp. (cf. Gartz 1996):

Since psychoactive mushrooms are typically self-collected, the danger of confusing these with “true” poisonous mushrooms should not be underestimated. There has been a report of a case of mistaken identity between *P. semilanceata* and the muscarinic *Inocybe geophylla*, which looks quite similar at first glance. (Bresinsky and Besl 1985, 115**)

In order to avoid such mistakes, it is advisable to prepare a spore print when an identification is in doubt. Every mushroom that produces a brown-violet spore print and whose stem turns blue when squeezed is a psilocybin-containing mushroom of the genus *Psilocybe* or *Panaeolus*. However, the blueing discoloration alone is not a sure sign of mushrooms of the genus *Psilocybe* or *Panaeolus* (cf. Stamets 1996**). The possibility of mistaken identity is especially acute with species from the genus *Galerina*, all of which, however, produce an orange-colored spore print (cf. ***Galerina steglichii***).

In order to avoid danger when consuming mushrooms, it is advisable to carefully consult the literature on mushroom identification (e.g., Winkler 1996).

Amanita muscaria (L. ex Fr.) Persoon ex Hooker

Fly Agaric

Family

Agaricaceae; Subfamily Amanitaceae, Amanita Section

Forms and Subspecies

The following varieties of fly agaric are generally accepted (Ott 1996):^{[350](#)}

Amanita muscaria var. *alba* (Peck) Saccardo—is completely white and is found primarily in Idaho

Amanita muscaria var. *aureola* Kalchbr.—rare!

Amanita muscaria var. *formosa* (Fr.) Saccardo—has a yellow cap

Amanita muscaria var. *muscaria*

In addition, a subspecies with an orange-yellow cap has been described for Central America (Mexico):

Amanita muscaria ssp. *flavivolvata* Singer

Synonyms

Agaricus muscarius L.

Agaricus muscarius Pers.

Amanita formosa Gom. et Rab.

Amanita mexicana Reko nom. nud.

Amanita muscaria var. *mexicana* Reko nom. nud.

Folk Names

Agaric au mouches (French), agaric moucheté (French), äh kib lu’um (Lacandon Mayan, “the light of the earth”), aka-haetori (Japanese, “red flycatcher”), amanite tue-mouches, amoroto (Basque, “the toadlike thing”), ampakhaw (Igorot), ashitaka-beni-take (Japanese, “long-legged mushroom”), beni-tengu-take (Japanese, “red tengu mushroom”), bolg losgainn (Irish, “toad mushroom”), bolond gomba (Hungarian, “fool’s mushroom”), bunte poggenstool, caws llyffant (Welsh), crapaudin (French, from *crapaud* “toad”), düwelsbrûet, escula, fanká’am (Tawgi), fausseorange, fleugenschwamm, fliegenkredling, fliegenpilz, fliegenschwamm, fliegenschwemme, fliegenteufel, fluesop (Norwegian), fluesvamp (Danish), flugsvamp (Swedish), flugswampt, fly agaric, fly amanite, flybane, fly fungus, fungus muscarius, giftblaume, grapudin, grzyb muszy (Polish), ha-ma chün (Chinese, “toad mushroom”), hango (Celtic), how k’an c/uh (Chuj, “poisonous yellow squash skin”), itzel ocox (Quiché, “diabolical mushroom”), kabell tousec (Breton), kaqualjá (Quiché), kaquljá (Quiché), kaquljá okox (Quiché, “thunderbolt mushroom”), kärbseseene (Estonian), karpässieni (Finnish), kässchwamm, krötenpilz, krötenstuhl, matamosques (Catalan, “fly killer”), migeschwamb, miggeschamm, miskwedo (Ojibwa), moucheté, mousseron, muchomor (Polish), mucho-more, muchumor, mückenpfeffer, muckenschwamm, mückenschwamm, muckenschwemme, muhamor, muhovna goba (Slovenian), mukamor, mukhomor (Russian, “fly death”), mukkenswam, muscinery,

History

There is no debate about the fact that the psychoactive fly agaric mushroom is associated with shamanism. Over the past decades, it has become ever clearer that this mushroom was or is used throughout the world. In spite of all the efforts that have been made to prove it, Wasson’s thesis that the fly agaric was the renowned **soma** of the Aryans is still unproved (Wasson 1968, 1972), as is the question of whether the fly agaric was the tree of knowledge. The suggestion that the fly agaric was in fact a secret means for Buddhist monks to induce states of enlightenment remains speculation as well (Hajicek-Dobberstein 1995). Moreover, it is uncertain when the mushroom was first used for shamanic purposes. However, it has been possible to confirm that it had a shamanic significance in the Germanic regions. And it is possible that the fly agaric found ritual use among the prehistoric Beaker people, who used Stonehenge as a ritual site (Burl 1987, 106 f.).

Although the shamanic use of the fly agaric in Siberia was discovered only in the eighteenth century, it has been suggested that its use is rooted in the Stone Age and that it was used throughout Europe. Wasson (1961**; 1986, 78 f.***) has suggested that the fly agaric and its effects were well known and its shamanic usage was common throughout Asia before the Bering Straits were crossed. When the Paleoindians migrated into North America, they brought the fly agaric cult with them and continued it in the Americas. However, because of the availability of psilocybin mushrooms (*Psilocybe* spp.), which are more easily tolerated and produce more intense visions, the cult was largely forgotten. Traces of the fly agaric cult have been found in Mesoamerica (Rätsch 1995b), and it still exists (at least in part) in North America (Navet 1993; Wasson 1979). The Siberian use of the fly agaric bears many similarities to the North American fly agaric cult of the Ojibwa Indians (Kutalek 1995).

“If we do not want to admit that the reason why this poisonous mushroom was used was to produce a sacred inebriation, then we can ask what other purpose it was used for? And here there is only one possible answer, namely that when the grain failed, and under the pressure of the desire for stimulating agents, the natives turned to every kind of plant material. . . . And certainly nothing merited the religious veneration with which such plants were regarded more than this amazing poisonous plant—*Amanita muscaria*.”

JOHN GREGORY BOURKE *DER UNRAT IN SITTE, BRAUCH, GLAUBEN, UND GEWOHNHEITSRECHT DER VÖLKER* [FILTH IN THE CUSTOMS, TRADITIONS, BELIEF, AND COMMON LAW OF PEOPLES] (1913) (1996, 63**)

The skin of the fly agaric mushroom (*Amanita muscaria*) acquires a velvety sheen when dried. It can be smoked either alone or mixed with other plants (e.g., hemp, thorn apple, tobacco, belladonna, peppermint, angel’s trumpet).

The fly agaric (*Amanita muscaria*) in the three stages of its development, each of which can be interpreted mythologically: the world egg, the divine phallus, and Eros with wings spread. (Photographed near Seattle, Washington)

In his book *The Sacred Mushroom and the Cross* (1970), John Allegro, a former Jesuit who

apparently had access to certain ancient writings that are preserved in the Vatican but unavailable to the public, advanced the theory that Jesus was actually a fly agaric mushroom and that the so-called original Christianity was a secret fly agaric cult. The fly agaric was the flesh of Christ that was consumed at the evening meal—a nocturnal cult circle—together with the blood of Christ, red wine (cf. *Vitis vinifera*). If Allegro is correct, then the original Christianity would have been a direct continuation of the cult of Dionysos, in which the adherents apparently consumed a **wine** that contained mushrooms (Allegro 1971).

Robert Graves (1957**, 1960**) has argued that ambrosia, which the centaurs used to honor Dionysos in the autumn, was in fact fly agaric.³⁵¹ He has also suggested that the maenads did not merely consume **beer** or **wine** (cf. *Vitis vinifera*) to which ivy had been added (cf. *Hedera helix*), but that they also were inebriated from fly agarics.

Wohlberg (1990) views the Thracian Dionysos Sabazios as the analog of the Indian **soma** and the Persian **haoma** (cf. *Peganum harmala*) and has propounded the theory that the Thracian god is identical to the fly agaric mushroom.³⁵² Carl Ruck has suggested that the secret offering of the Hyperboreans to the Delian Apollo was a fly agaric mushroom and was thus the last reminder of the Indo-Germanic soma (Ruck 1983**). He views the leopard, the sacred animal of Dionysos, as a symbol for the fly agaric, which was consumed ritually and used for entheogenic purposes, because the marks on the leopard's coat resemble those on a dried fly agaric cap (Ruck 1995, 133**). In general, Ruck regards the fly agaric as the original entheogen of the Greek culture(s), which over the course of time was replaced by a variety of (placebo) agents (olives, *Viola odorata* L., *Consolida ajacis* [L.] Schur. [syn. *Delphinium ajacis* L.; cf. *Delphinium consolida*], *Apium graveolens* L., *hippomanes*,³⁵³ *Aconitum napellus*, *Crocus sativus*, *Conium maculatum*) and ultimately forgotten (Ruck 1995*). The pine (*Pinus pinea* L.) and spruce (*Pinus pinaster* L., *Pinus nigra* Arnold, *Pinus* spp.) were sacred to Dionysos because they are the trees with which the fly agaric lives in a symbiotic relationship (Ruck 1995, 137*). The Golden Fleece and the golden apples of the Hesperides³⁵⁴ have also been interpreted as fly agarics (Allegro 1971; Hajicek-Dobberstein 1995). Vestiges of this ancient or archaic fly agaric cult may have been preserved among the Basques and in Catalonia (Fericgla 1992, 1994).

It is possible that the fly agaric was known in Egypt by the name *raven's bread*.³⁵⁵ Because some legends say that Saint Anthony (cf. *Claviceps purpurea*) nourished himself in the wilderness on bread that had been brought to him by ravens or similar birds, it has been suggested that fly agarics produced the visions that tempted Saint Anthony (Klapp 1985). It has also been proposed that the fly agaric was the “elixir” of the alchemists of the late ancient and subsequent periods; it has even been interpreted as the Grail (Heinrich 1995).

Pliny was apparently aware of the fly agaric. But like so many after him, he erroneously thought it to be a deadly poison:

With certain [mushrooms], the toxicity can be easily seen in the pale red color; the disgusting appearance, the bluish coloration of the inside, the furrowed lammellae, and the pallid border that surrounds it. These features are not found on some; dry, and similar to the truffle [cf. *Lycoperdon*], these bear more or less whitish drops from their skin on the cap. (22.93)

The name *fungus muscarius* appeared in 1256 in the work *De Vegetabilibus*, written by the monk Albertus Magnus (Neukom 1996, 390). One of the oldest sources to mention the fly agaric by name is the *Kräuterbuch* [Herbal] of the physician Johannes Hartlieb, published in 1440:

The rare yellow North American subspecies of the fly agaric, *Amanita muscaria* var. *formosa*. (Photographed near Olympia, Washington)

The dried cap of the fly agaric (*Amanita muscaria*) has been used as a shamanic inebriant since the Stone Age.

There is also the sort of fungus that is impure, broad and thick and red with white spots on the top, when mixed with milk, it will kill the flies that are around, this is why it is known as the fly fungi, *muscinery* in Latin. (folio 16)

After Hartlieb, the fly agaric received only sporadic mention or description in later herbals, including those of Gerard (1633) and Lonicerus (1679). Those that did remark on the fly agaric noted its use as a fly poison, but they made no mention of its psychoactive effects! These psychoactive effects were first described in modern times by travelers to Siberia (Bauer et al. 1991, 121–64; Rosenbohm 1991, 26–60). Around 1880, during a period of widespread **wine** shortages, an Italian physician suggested that the populace turn to fly agaric as an inebriant (Samorini 1996).

In some areas, fly agarics are eaten for food. In the region around Hamburg, which is very rich in fly agarics, mushrooms with their red skin removed were made into soups. In some Alpine valleys, fresh fly agarics are still sliced and made into an appetizer with vinegar, oil, salt, and pepper (cf. *Piper* spp.). In Japan, fly agarics are one of the culinary specialties of the rural population. In Russia, fresh fly agarics are added to vodka (cf. **alcohol**) to improve its effects.

Distribution

The fly agaric mushroom grows only in symbiosis with birch (*Betula* spp.) and/or pine (*Pinus* spp.) trees. But in those places in which these trees occur, it is found throughout the world. It can be found in arctic, temperate, and even tropical climate zones (Alaska, Siberia, Scandinavia, central Europe, North America, Australia, Mexico, the Philippines). It sometimes occurs in the form of fairy rings.^{[356](#)}

Cultivation

To date, attempts to grow or cultivate fly agaric mushrooms have been unsuccessful.

Appearance

The mycelium is white in color. The fruiting body can grow as tall as 25 cm and form caps as large as 20 cm in diameter. The remnants of the velum remain on the cap in the form of white spots. The fly agaric fruits in central Europe from August until the beginning of November and in North America usually in October.

Although the fly agaric is the most easily recognizable of all the fungi, confusion can sometimes occur. The fly agaric is most commonly confused with a related species, *Amanita regalis* (Fr.) Michael [syn. *Amanita muscaria* var. *umbrina* Fr.], which is found primarily in mountains at altitudes above 400 meters. The fly agaric can also be confused with the panther mushroom (*Amanita pantherina*) or Caesar's amanita (*Amanita caesarea* [Scop. ex Fr.] Pers. ex Schw.), a delicious culinary mushroom (cf. Roth et al. 1990, 42**). In the button stage, the fly agaric bears a certain resemblance to puffballs: "Very young fly agarics that are not yet showing any red on the outside can also be confused with the common puffball (*Lycoperdon perlatum*) [cf. **Lycoperdon**]" (Bresinsky and Besl 1985, 104**).

Psychoactive Material

—Fruiting body (fungus muscarius)

Preparation and Dosage

The fruiting bodies can be used both fresh and dried. When the fresh mushrooms are to be used for culinary purposes, they must be soaked in cold water for at least one hour before they are prepared (this dissolves the active substances). The soaking water can be drunk to produce psychoactive effects. Fresh mushrooms are well suited for use with **alcohol**. One to three specimens can be added to a bottle of vodka (or any other type of alcohol) and placed in a warm location or, preferably, on a windowsill in the sun. After one week, the fly agaric schnapps will be ready for use. Often, one glass is sufficient to produce psychoactive effects. Fresh mushrooms can also be sautéed in butter and eaten (they are delicious).

To dry the mushrooms, place them in the sun or on a rack in an oven set at low heat (30° to 40° Celsius). The dried results can be smoked (either alone or in **smoking blends**), crumbled into a drink (e.g., **beer** or **wine**), or simply eaten as they are. Synergistic effects, typically with aphrodisiac sensations, can be produced by smoking mixtures that include, e.g., henbane (*Hyoscyamus niger*), thorn apple (*Datura stramonium*), and hemp (*Cannabis indica*). Fly agaric prevents the mucous membranes from drying out, a side effect that can occur with both nightshade plants and hemp.

In Siberia, dried fly agaric mushrooms are mixed for consumption or use with freshly pressed bog bilberries (*Vaccinium uliginosum*) or rose bay willow herb (*Epilobium angustifolium* L.) (Hartwich 1911, 257*; Saar 1991, 168; Schultes 1969, 246*). The mixture is either used as is or diluted with water, fermented, and made into a kind of fly agaric **beer**. The urine from people inebriated by fly agarics also can be drunk (Bourke 1996, 55 ff.*).

It is also possible to drink rainwater that has collected in fly agaric caps when they are in the goblet stage (in which the caps are turned upward). This is essentially a cold-water extract, and it has distinct psychoactive effects. This naturally occurring extract has been called “dwarves’ wine” (Bauer 1995).

It has been suggested that fly agarics were an ingredient in **witches’ ointments**.

The literature provides varying information about dosages, ranging from one mushroom to more than ten (Festi and Biachi 1992):

The lethal dose lies above 100 grams of fresh mushrooms. In some locations, however, the quantity of toxins can be very low and the fly agaric may be eaten without side effects. Fly agaric intoxications make up 1–2% of all cases of mushroom poisoning. (Roth et al. 1990, 42**)

Fly agarics are usually not as effective fresh as when dried. The fresh material can produce mild sensations of nausea. The effective dosage of fly agaric is individually extremely variable, and probably more so than with any other entheogen. Approach with care!

Petroglyphs from Yenisei (Russia), apparently depicting shamans covered with fly agaric or panther mushrooms.

Ritual Use

Siberian shamans eat dried fly agarics in order to enter a clairvoyant trance state and mobilize their shamanic powers of healing. According to Koryak tradition, the fly agaric grew from the saliva of the highest god; for this reason, it is regarded as a sacred plant (Bauer et al. 1991, 147 f.). The shamans ingest the mushroom especially when they wish to communicate with the souls of the ancestors or to contact spirits, when a newborn is to be given a name, to find a way out of threatening

situations, to see into the future and peer into the past, and to be able to journey or fly to other worlds. Among the Khanty (Siberian Ostyak), shamans in training are tested with high dosages of fly agaric to see whether they can master the mushrooms and are fit for their future office. In Siberia, fly agaric mushrooms are consumed fresh, cooked, and dried (Saar 1991).

The Siberian usage provided the basis for Wasson's proposal that fly agaric mushrooms were the **soma** of the Aryans (Wasson 1968, 1972, 1995). In the Vedic tradition, however, it is said that soma grows in the high mountains, that is, the Himalayas. No evidence of *Amanita muscaria* has yet been found anywhere in the Himalayan region. According to the current state of ethnopharmacological knowledge, the identification of soma with the fly agaric is untenable. However, there are remnants of a ritual consumption of fly agaric in the Hindu Kush, where the mushroom is known as *tshashm baskon*, "eye opener" (Gholam M. and Geerken 1979). While it was thought that the Siberian use of fly agaric had vanished, it was recently discovered that the mushroom is still used for shamanic and divinatory purposes on the Kamchatka peninsula (Salzman et al. 1996).

In Germanic mythology (as recorded in modern times), several stories associate Wotan (also known as Wodan or Odin), the shamanic god of ecstasy and knowledge, with the fly agaric. According to legend, the fly agaric would appear after the Wild Chase, when Wotan rode through the clouds on his horse at the winter solstice with his followers. The following autumn—exactly nine months later—fly agarics would sprout from the impregnated earth in those very spots where the foam from the mouth of Wotan's horse fell onto the ground (Haseneier 1992**). In the common parlance, the fly agaric is known by the name *raven's bread* (Klapp 1985). Ravens not only are ancient shamanic and power animals but also are the messengers of Wotan, who is also known as the raven god. In pagan times, it is entirely possible that the fly agaric also found use in ecstatic rituals (cf. **mead**). It has been suggested that the berserkers ("bear skinners"), warriors who were sacred to Wotan, may have used fly agaric mushrooms in the rituals of their secret society (Thorsen 1948).³⁵⁷

In Styria (Austria), a tradition has been passed down that illustrates the mushroom's relationship to the fertility-bringing wild storm god Donar, the son of Wotan. Fly agarics are sought out at the beginning of the "mushroom season" (which of course takes place on a Donnerstag (= Thursday), after the first *donner* (= thunder). The seeker will hold the mushroom first out toward the forest, then against him- or herself, and address it: "If you do not show me the good mushrooms, then I will cast you onto the ground, so that you will decay into dust and ashes!" (*Handwörterbuch des Deutschen Aberglaubens* [Hand Dictionary of German Superstitions], 7:30).

It is also entirely within reason that Santa Claus, who always appears dressed in red and white and flies through the air with his team of reindeer, is simply an anthropomorphized fly agaric mushroom or a fly agaric shaman (van Renterghem 1995).

In contemporary neopagan circles, the fly agaric is now used as a psychoactive sacrament:

Another pagan custom that has come down to us is that of drinking on Samhein [November 1] a special tea brewed from the peeled-off skin of a fly agaric that was picked during the full moon. This is probably based on traditions of Siberian and Norwegian shamans, in which the fly agaric was repeatedly referred to as a psychoactive working plant. (Magister Botanicus 1995, 186*)

One family described a traditional ritual that they still conduct on this ancient Celtic holiday (cf. *Atropa belladonna*):

For this—and only on this night—we prepare a fly agaric tea according to the following recipe from my grandmother: On the full moon preceding Samhain, the heads of the family go into the forest and search for a few fly agarics, with whom they establish contact. The healthy

mushrooms (those that have not been infested by worms or eaten by snails!) are cut off at the stipe and placed in a wicker basket; at the place where we harvested the mushrooms, we usually leave some tobacco [*Nicotiana tabacum*] and an apple as an offering. After this, the red skin of the cap is pulled off and quickly dried; the dried skin is kept in a red linen cloth in a dark and cool place until Samhain. During that night a cold [water] extract is made that all of the members of the family drink before they go to bed. The next morning, the resulting dreams are described and interpreted in the family circle. (Magister Botanicus 1995, 197*)

In the pre-Columbian fly agaric cult of the Americas, the fly agaric (known as the light of the earth, the flower of the earth, the underworld mushroom, or the thunderbolt/lightning mushroom) was regarded as a being that was in contact with the underworld (*xibalba*, *metlan*) (Rätsch 1995b). It was symbolically associated with toads and flies (helping spirits) and formed a door to the realm of the dead. It was also associated with the *bolon ti kuh*, the nine gods of the underworld, which were represented in the form of mushroom stones. It was a ritual inebriant with unique effects that shamans, oracular priests, and healers consumed (either eating it or smoking it together with tobacco [*Nicotiana rustica*, *Nicotiana tabacum*]) in order to enter a desired altered state of consciousness in which they would carry out necromantic rites (*uay xibalba*),³⁵⁸ liberate the souls of sick people from the underworld, and generally improve their visionary abilities.

Caves were typically regarded as entrances to the underworld and were often used for necromantic rituals and sacrificial offerings. The mushroom was used for shamanic initiation (the journey into the underworld). Only a few initiates were granted knowledge of the uses of the fly agaric. In order to protect (monopolize) this knowledge, the mushroom was publically portrayed as poisonous or dangerous. Since fly agarics were not available in all places and at all times, they were collected in pine groves and airor fire-dried, which improved their effects. The mushrooms were sold by special merchants together with other ritual paraphernalia (“Transcendental Interaction Model”). There were three important centers of the ancient American fly agaric cult: the northeastern forests of North America (Algonquian, Ojibwa, Dogrib; cf. Keewaydinoquay 1979; Larsen 1977), central Mesoamerica (Mayan peoples, Aztecs, Purépecha; cf. Rätsch 1995b), and western Peru (Mochica).

The Tzeltal still make use of the fly agaric mushroom, which they call *tzajal yuy chauk*, “red thunderbolt mushroom.” They remove the reddish skins from the fresh caps, dry the skins, and smoke them together with *may*, wild tobacco (*Nicotiana rustica*). It is said that smoking this mixture helps the Tzeltal shamans become clear-sighted so that they may recognize diseases in their patients, track down lost or stolen objects, and utter prophecies. The shamans of the Chuj, a Mayan people of the southern Selva Lacandona and northern Guatemala, smoke dried pieces of fly agarics mixed with wild tobacco (Müller-Ebeling and Rätsch 1986, 96–97*; Rätsch 1992, 78*). In the high valley of Puebla, Timothy Knab found an indigenous *curandero* (= healer) who smoked dried fly agarics mixed with tobacco (*Nicotiana tabacum*) in order to make ritual diagnoses (Díaz 1979, 86*). Among the Tzutujil, a figure of a deity named Maximon that is made from the wood of *palo de pito* (*Erythrina rubrinervia*; cf. *Erythrina* spp.) is associated with the fly agaric (Lowy 1980, 102**).

“In the birch forest
The wind whispers and runs softly
Through the heart-shaped leaves.
The trunks glow as white as snow.

“From the grass
sprouts a magical egg,
its grows round redly, spots itself white
and jumps asunder.

“I wished for a witch,
fourteen years old.
I rode with her
through the fly agaric forest.

“Smeared with ointment, she flies
swiftly like the swallow
through the green forest.
Tender skin, smooth fur.

“That which she lightly
touches with magical power,
loses its weight and is
carried off into the air.

“Stick, stem, or ledge,
it is all the same. She lifts, lifts
tenderly around the body.
She flies gently and floats.

“I can see that the forest is enchanted.
He who eats of the fly agaric,
becomes mad, he dances
sings, flies, and forgets.”

FRIEDRICH GEORG JÜNGER *FLIEGENPILZE* [FLY AGARIC MUSHROOMS]

Toad and stool, an ancient mythological pair. *Toadstool* is another name for the fly agaric. (Illustration from a nineteenth-century children's book)

Japan is rich in mushrooms that were or still are used for culinary or shamanic purposes. The genus *Amanita* is represented by a number of species, many of them endemic (Imazeki et al. 1988, 140–71**). All three psychoactive *Amanita* species (cf. *Amanita pantherina*) of the Japanese mycoflora are included in the taxon *tengu take*, “*tengu* mushroom” (Wasson 1973, 15**). The *tengu* is the spirit of the fly agaric and is one of the most popular figures in Japanese mythology and folklore (De Visser 1908; Fister 1985). *Tengus* appear sometimes as birdlike demons and at other times as wild and reclusive monks of the mountains. Occasionally *tengus* are regarded as transformed shamans. At times it is said that there is only one *tengu*; other reports speak of many *tengus*, who even have a king. *Tengus* are seen sometimes as gods and at other times as demons, but they are usually regarded as *kami*.³⁵⁹ *Tengus* can change their form; they can be humans or birds,³⁶⁰ fly through the air, make themselves invisible, and create phantoms. The male *tengus*, which have a bright red skin and a phallic nose, are regarded as tricksters and sexual demons, but also as benefactors. Mountain shrines were erected in their honor. Fossil shark teeth are thought to be visible reminders of their passing. The teeth are known as the “claws of *tengu*” and are sold as talismans. They are even venerated in temples and shrines and guarded as religious relics (Rätsch 1995). *Tengus* have a magical leaf or an enchanted fan that they use to carry out their tricks and magical acts. In some traditional illustrations, this leaf clearly resembles a hemp leaf (*Cannabis indica*).

Although normally invisible, *tengus* reveal themselves as spooks or speak through the mouths of people whom they have possessed. Japanese who are praying on mountain peaks and in mountain shrines fall into possession states particularly often; while possessed, they lend the *tengus* their voices and utter prophecies (Lowell 1894, 1–15). *Tengus* are known for their unlimited thirst for **sake**, which is why people are advised to offer them the beverage. *Tengus* also are excellent with the sword. They

sometimes abduct children or youngsters and teach them sword fighting or impart some other knowledge. People make offerings to the *tengus* so that they will protect them and teach them the wisdom of nature (Rätsch 1995a).

Artifacts

A number of petroglyphs discovered in Asia appear to be connected with a shamanic fly agaric cult.

The Italian ethnomycologists Giorgio Samorini and Gilberto Camilla recently proposed the theory that certain Greek depictions of wine grapes (*Vitus vinifera*) are actually epithetic representations of the fly agaric (or other psychoactive mushrooms) that were kept secret, and that these were related to the cult of Dionysos (Samorini and Camilla 1995**).

There are a large number of anthropomorphic mushroom representations in the pre-Columbian ceramics of the Peruvian Moche. The reference to shamanism is especially apparent in depictions that show mushrooms growing directly out of the head of a seer (Furst 1976a, 82*). A Mochican stirrup vessel (ca. 500 A.D.) at the Peabody Museum at Harvard University has the shape of a human head. In the middle, above the forehead, is a very realistic depiction of a fly agaric mushroom that is more or less growing out of the hat. Other examples of Mochican ceramic work also appear to contain representations of fly agaric mushrooms (Ripinsky-Naxon 1993, 180 f.*).

In Nayarit (western Mexico), a number of small ceramic objects have been found that depict fly agaric-like figures, beneath which a person is sitting (Furst 1974*; Schultes and Hofmann 1992, 82*; Wasson 1986, 51**). A ceramic piece in the Remojada style from Tenenexpan (Veracruz, ca. 300 A.D.) depicts an oversized object, which looks like a fly agaric, together with a human figure in the throes of ecstasy. The person is shown touching the mushroom or mushroom stone (?) with the left hand while pointing the right hand toward the sky (Heim et al. 1966, plate 2**). In Michoacán, a small stone figure was recovered from a pre-Spanish site of the Purépecha culture that Guzmán has interpreted in the following manner: “The one side resembles a fly agaric cap, the other a death skull” (1990, 100 f.**).

The fly agaric is a popular figure in German literature, appearing in fairy tales, legends, songs, and poems (Bauer 1992). One German folk song³⁶¹ about the fly agaric, “Ein Männlein steht im Walde” [A Little Man Stands in the Forest], is quite well known. Engelbert Humperdinck (1854– 1921) even included the song in his children’s opera *Hänsel und Gretel* (1893).

Fly agaric mushrooms are common in illustrated children’s books (e.g., *Wir fahren ins Zwergerland!* [We’re Going to the Land of the Dwarves!], *Hochzeit im Walde* [A Forest Wedding], *Wichtelmanns Reise* [Wichtelmann’s Journey], and *Alice in Wonderland*), where they are usually the dwellings of dwarfs or elves. In one children’s book, *Mecki bei den 7 Zwergen* [Mecki and the Seven Dwarfs], the hero of the story smokes dried fly agarics together with his friends. While under the influence of the mushrooms, they realize that the seven dwarfs are actually fly agaric spirits:

The dwarfs shook their heads back and forth and back and forth. As they did so, their funny hats slowly turned into red caps with white spots. Their legs and little tummies grew together or sank into the ground. At the same time, their white necks grew longer and longer, so that they finally stood there like large, strange fly agarics and stared at me. (Rhein n.d., 45)

The life story of a Siberian shaman is told in the novel *Der Herr des Feuers* [The Lord of the Fire] (Braem 1994). During his training, he must have several experiences with fly agaric mushrooms. The author, who has also written nonfiction works on shamanism (Braem 1994*), describes these as though he himself had had such experiences:

The folk literature in particular has helped make the fly agaric a “dangerous fellow.” (From Usteri, *Pflanzenmärchen und -sagen*, 1926)

Then there was the new seeing, an overly clear vision, that had been brought about by the frequent use of raw fly agarics. Shorting after eating the aromatic flesh of the mushroom, the effects began: Initially, the accelerated pulse and heartbeat were the sure messengers of the coming changes. Then the colors began to light up, a burning green, longingly deep blue, rich brown, and gleaming silvery gray of the rock. The room, the forest, expanded every time he exhaled, and contracted with every inhalation. Breath and forest and vision became one single act. The power of the helping spirits in the mushroom revealed how nature vibrated in a rhythm, illuminated the big pattern, imparted the smallest detail with an unimagined importance. . . . If the fly agaric was good and the helping spirit within it powerful, then his hearing would also change. He perceived the slightest snap in the woods, the rustle of a mouse, he heard crackling in the moss, the movement of the leaves in the wind. And the most astonishing thing was that he could sometimes also understand the language of the animals. (Braem 1994, 149)

Fly agarics often appear in comic books. In the book *Asterix at the Olympic Games* (Uderzo and Goscinny, 1968), Methusalix, the oldest of the unruly Gauls, collects fly agarics for his soup. The Druid Miraculix tells him that the fly agarics should be “sautéed in butter, for only in that way will they retain their typical flavor.” Moebius, in his comic story *A True Wonder of the Universe*, transports the fly agaric to a planet a million light-years away. It speaks to a cosmonaut, who then tries a piece of it, whereupon he becomes a supernova. The volume *Soluna* (1996), from the series John Difool vor dem Incal [John Difool Before the Incal] by Janjetov and Jodorowsky, features a utopian city, the center of which is a gigantic mushroom-shaped temple. The entire fantasy comic cycle Alef-Thau, by Jodorowsky and Arno (1986–1991), takes place in a forest of fly agaric mushrooms. In the three volumes of the cycle *Die Gefährten der Dämmerung* [The Fellowship of the Dawn] (1984–1990), François Bourgeon artistically portrays a fly agaric trip. The second volume, *Die drei Augen der blaugrünen Stadt* [The Three Eyes of the Blue-Green City], contains detailed instructions for using fly agarics and tips about their effects:

This red and white cap contains more colors than your poor human eyes have ever seen! . . . If you dry this and chew it, you will be able to uncover terrible secrets in your dreams. You can go to the earliest times in the world . . . in the times before your gods . . . before my gods. (p. 13)

The comic *Fliegenpilz* [Fly Agaric], by Christian Farner (1993), depicts a fly agaric trip that is both haunting and oppressive.

Fly agarics are not featured as frequently in paintings, perhaps because they are too popular a symbol. The pen-and-ink drawing *Die Hexe* [The Witch] (ca. 1900) by Heinrich Vogeler (1872–1942) depicts a witch passing through the forest, fly agarics sprouting at her feet. In *Brekkekkwakkwak*, an oil painting by Johan Fabricius (1899–1981) from 1926, fly agaric mushrooms are shown growing alongside a fantastic pond. The illustrator Alan Lee contributed several pictures of fly agarics and elves to *Das große Buch der Geister* [The Big Book of Spirits] (Fronde and Lee 1979).

Because fly agarics are symbols of good luck in Europe, they are often portrayed on greeting and congratulatory cards. Fly agaric spirits appear on many decorative items and are common motifs on Easter eggs and Christmas ornaments (perhaps because Santa Claus himself is simply an anthropomorphized mushroom). Countless images of fly agarics are used for decorative purposes, ranging from plastic Smurf figures with fly agarics (cf. *Veratrum album*) to fireworks for New

Year's Eve parties (these fireworks are known as *glückspilzen*, which is usually translated as “lucky dogs” but which literally means “lucky mushrooms”). These pretty mushrooms are also commonly reproduced in the form of Easter cakes, chocolate (cf. *Theobroma cacao*), and marzipan (Bauer et al. 1991).

In the 1990s, fly agaric mushrooms were frequently featured as emblems on handbills advertising raves (Rätsch 1995d; 1995, 12**). They are also found on the covers of CDs of psychedelic trance music (e.g., *Holy Mushroom*, *Ironic Beat*) and of other musical styles. The cover of the LP *Granny Takes a Trip*, by the Purple Gang (1968), shows fly agarics in an alchemical context. Another album, *Early One Morning*, by the band Mushroom (1973), has a picture of a mushroom whose colors are reversed: it has a white cap with red spots. The German combo Witthüser and Westrupp gave expression to the theories of John Allegro (1970) on the cover of the record *Der Jesuspilz—Musik vom Evangelium* [The Jesus Mushroom—Music from the Gospels] (1971) (cf. *Cannabis indica*). Mani Neumeier, founder of the band Guru Guru and the godfather of “kraut rock,” is depicted on the cover of his solo CD *Privat* (ATM Records, 1993) as a six-armed Shiva holding a fly agaric in one hand. OM Records, a San Francisco-based company, selected the fly agaric mushroom as the symbol for its series *Mushroom Jazz*. And the cover of the avant-garde/psychedelic CD *Venus Square Mars*, by Mark Naussef and Dave Philipson, features a *tengu* “fractalizing out of” a fly agaric (M·A Records, 1995).

“According to the view of the natives, however, the fly agaric mushroom, in contrast to alcohol, has an innate power of revealing the future to those who consume it; namely when the wish to be able to look into the future is uttered over the mushroom in a specific form before it is eaten, whereupon the wish will come true in a dream.”

J. ENDERLI

“ZWEI JAHREN BEI DEN TSCHUKTCHEN UND KORJAKEN” [“TWO YEARS AMONG THE CHUKCHEE AND KORYAK”] (1903, 185)

The cosmopolitan fly agaric on stamps from the Southeast Asian countries of Laos and Cambodia.

In Japan, masks of long-nosed *tengus*, the fly agaric spirits, are still made out of wood and other materials and sold in the paraphernalia shops located near shrines. The masks are hung on houses during the Japanese New Year's festival.

Medicinal Use

It is likely that the fly agaric was originally a ritual medicine (Rosenbohm 1995). In Siberia, it was ingested to treat psychophysiological states of exhaustion.³⁶² For snakebites, a fly agaric tea (a cold-water extract made from dried fruiting bodies) was massaged into the affected area of the body (usually the legs). This was said to neutralize the toxins (Saar 1991, 177**).

In the nineteenth century, the fly agaric was used as a home remedy and was also prescribed by physicians as a medicine. It was used internally, for example, to treat epilepsy and fever and externally to treat ulcerated fistulae:

It is officinal under the name *fungus muscarius*. Only the lower portion of the stalk is chosen. . . . The fly agaric, in powder form (for which it must be dried as quickly as possible without destroying it), is administered internally (with care) in small doses (10 to 30 grains) against falling sickness, et cetera, and is sprinkled externally onto malignant tumors, gangrene, et cetera. Meinhard gives a tincture to treat favus and other persistent eruptions. (W. Schneider 1974, 1:80*).

In homeopathy, the preparation *Agaricus muscarius* is an “agent to treat complaints of the entire nervous system” (Bremness 1995, 286*). Depending upon the symptom picture, it is used in homeopathic dilutions (D4, D6, D30, D200) for problems associated with menopause, overexcitability, and bladder and intestinal cramps. One physician who frequently utilizes the mother tincture in his practice reported:

One portion (15–20%) of the patients I have treated with *Agaricus muscarius* had altered dreams during or after their therapy. Especially: dreams of flying with positive contents, dreams reminiscent of Alice in Wonderland, and other pleasant dream experiences. In no case did nightmares occur, although one must consider that the majority of dosages used in therapy are small. Even with higher dosages, on the following day the patients were normally found to be well and to exhibit a strong eagerness to work, without negative side effects or symptoms of a hangover. . . . Following the prescription of fly agaric, almost all of the patients exhibited increased motivation, improved mood, and improved mental and physical well-being. Here again it is the dosage that determines that something is not a poison! (Waldschmidt 1992, 67)

Constituents

Fresh fly agaric mushrooms contain choline, acetylcholine, muscarine, muscaridine, muscazone (empirical formula $C_5H_6O_2N_2$), large amounts of **ibotenic acid** (= prämuscimol, “pilzatropin”; Ott 1996), very little **muscimol**, and the rare trace elements selenium and vanadium. As a result of the decarboxylation of ibotenic acid, dried fly agarics contain high amounts of muscimol, which is responsible for the psychoactive effects (Festi and Bianchi 1992). The pigment is a derivative of ibotenic acid (Talbot and Vining 1963). The amount of muscarine is 0.0003% at most (Roth et al. 1990, 42**). The amount of ibotenic acid in fresh specimens from Germany and Switzerland averaged 0.03% but can run as high as 0.1% (Eugster 1969). Traces of **bufotenine** (Schultes and Farnsworth 1982, 155*) and the **tropane alkaloid** L-hyoscyamine (Salemink et al. 1963) have also been reported.

Muscimol is regarded as the actual psychoactive constituent, although this view (from Eugster 1967a and 1967b) is not without controversy (Cosack 1995). Nevertheless, muscimol can be detected in the urine of people who have ingested fly agarics. Several experiments have demonstrated that the urine from a person who has consumed fly agaric will produce psychoactive effects in other people (McDonald 1978; Ott 1976). Theodore Schurr, an anthropologist and molecular biologist, has summarized our current pharmacological understanding of Siberian fly agaric shamanism:

Once ingested, the psychoactive alkaloids and substances in [*Amanita muscaria*] acted as agonists of normal brain neurotransmitter function, disrupting the coordinate action between the catecholaminergic and serotonergic systems and producing hallucinogenic effects similar to those generated by LSD and harmine. (Schurr 1995, 31)

Effects

Most people in the German- and English-speaking countries—regardless of their level of education—believe that fly agaric mushrooms are deadly poisonous and should be avoided at all costs. Paracelsus’s rule, which says that the dosage is the factor that determines whether something is a poison or a medicine, has apparently not become widely known. If the fly agaric was evaluated according to this criterion, then people would have to leave their cherished black-and-white thinking

behind—for many, a very painful or difficult task.

“Because a feeling of flying often occurs after the consumption [of fly agaric mushrooms], this may be the origin of the Scandinavian and English version of Santa Claus, in which he flies through the air on a sleigh drawn by reindeer.”

LESLEY BREMNESS HERBS (1994, 286*)

Ibotenic acid

Muscimol

This flyer for a psychedelic trance party features a fly agaric mushroom. (Switzerland, ca. 1995)

“Sometimes [in Kamchatka] people also eat the fresh [fly agaric] mushroom in soups and broths, and then it loses much of its inebriating properties. When dipped into the juice of berries of *Vaccinium uliginosum*, it acts like strong wine. One large or two small mushrooms will usually suffice to induce a proper state of inebriation for the entire day, especially if water is consumed as well, which increases the narcotic properties.

“The desired effects begin one or two hours after the mushroom is ingested. Dizzy spells and drunkenness manifest themselves in the same way as with wine or schnapps; at first one feels a happy mental stimulation, the face turns red, then follow involuntary words and movements, and finally complete unconsciousness sometimes occurs.”

DR. GEORG HEINRICH VON LANGSDORF (1809)

IN *DER UNRAT IN SITTE, BRAUCH, GLAUBEN, UND GEWOHNHEITSRECHT DER VÖLKER* [FILTH IN THE CUSTOMS, TRADITIONS, BELIEF, AND COMMON LAW OF PEOPLES] (BOURKE 1996, 57**)

In recent years, many reports and descriptions of the effects of fly agaric have appeared (cf. Cosack 1995; Festi and Bianchi 1992; Ott 1976, 1993). In general, the symptoms of fly agaric inebriation include a strong parasympatholytic stimulation, wavelike shifts between sleepiness and wakefulness, illusions, hallucinations, and delirium. (Leuner 1981, 54*). The effects are often described as unpleasant, and inexperienced users may easily interpret them as signs of a “toxic ecstasy” (Leuner). In the older literature, fly agaric is portrayed as a deadly poison, and people were urgently warned against its use. This notwithstanding, the toxicological literature does not contain a single case of lethal fly agaric poisoning: “there is no evidence of fatalities” (Garnweidner 1993, 41**). The more recent literature also notes: “If the mushroom is consumed with the expectation of hallucinogenic effects, then it tends to produce a pleasant outcome” (Roth et al. 1990, 42**). Once again we see that the expectations a person brings into the experience (the set) exert a powerful influence upon the experience of an altered state. If the fly agaric is believed to be poisonous, horrible apparitions may arise; if it is regarded as a pleasurable inebriant, enjoyable visions and feelings will result.

Some people report temporary sensations of nausea after ingesting fly agaric mushrooms, after which most are overwhelmed by sleep. The visionary effects, which are often characterized by synaesthesia, begin after they awaken and can last for several hours. Reports of visions of giants in the world of dwarfs are remarkably common (Cosack 1995). The effects are more subtle when fly agarics are smoked and are manifested primarily as a heightened perception and increased sensitivity in the musculature. Regardless of the manner in which the mushrooms are consumed, auditory perception is heightened, refined, or altered.

Commercial Forms and Regulations

All homeopathic preparations (including the mother tincture) may be sold only by pharmacists but do not require a physician's prescription. Neither collecting the mushroom nor consuming it is illegal.

“Once a year, the tradition of these nomads [the Koryak of Kamchatka] takes them back to the beginnings of time. This occurs when they slaughter the reindeer. The festival is celebrated according to ancient custom, and playing a special role is a mushroom: the fly agaric. Dried and ground to a powder, it is mixed, so I was told, with fresh reindeer blood that has been filled into vessels. The Koryak who have come to dance drink this. Along with the rhythms, which sound strange to our ears, the dancing becomes ever more intense, the stamping of the feet grows harder and faster. It almost has no end. The inebriation of drink and rhythm can last for three or four days. . . . Only those who have tried the fly agaric themselves can understand this custom of the Koryak.”

Amanita pantherina (DC. ex Fr.) Krombh.

Panther Cap

Family

Agaricaceae; Subfamily Amanitaceae, Amanita Section

Forms and Subspecies

Three varieties are usually distinguished:

Amanita pantherina var. *abietinum* (Gilb.) Ves.—fir panther cap

Amanita pantherina var. *multisquamosa* (Pk.) Jenkins

Amanita pantherina var. *pantherina*

Synonyms

Agaricus pantherinus Fr.

Amanita cothurnata Atkinson

Folk Names

Agarico panterino, amanite panthère, crapaudin gris, fausse golmelle, fausse golmotte, fongo rospèr (Treviso, “toad mushroom”), haitori (Japanese, “fly catcher”), haitori-goke, haitori-kinoko, haitori-take, hyô-take (Japanese, “panther mushroom”), panther cap, panther fungus, panther mushroom, pantherpilz, tengudake (Japanese, “*tengu* mushroom”), tengutake,³⁶³ tignosa bigia, tignosa bruna

The panther cap is similar in appearance to the fly agaric (*Amanita muscaria*) but has a brownish or brown cap. It yields a white spore print and is easily confused with the nonpoisonous and nonpsychoactive pearl mushroom (*Amanita rubescens* [Pers. ex. Fr.] S.F. Gray [syn. *Amanita rubens* Scop. ex Fr.]), also called the blusher because of its tendency to turn red when bruised (Roth et al. 1990, 48**). The panther cap is found almost exclusively in deciduous and fir woods. In Europe, it fruits from July to October, while in North America it usually fruits in early spring. Although many people avoid the panther cap as poisonous, it actually has a long tradition of culinary use:

It is remarkable that the panther cap is characterized as inedible in some books on mushrooms. Many of our patients who were relatively knowledgeable about mushrooms told us with conviction that they have been eating these mushrooms for years without any harm. (Leonhardt 1992, 127)

And yet the panther cap is clearly psychoactive and normally even more potent than *Amanita muscaria*. In Russia, the panther cap is preferred over the fly agaric because the effects of the former are thought to be more pleasant. The shamans of central Asia and Siberia apparently consumed it ritually as an alternative to the fly agaric. It is said that the Russian panther cap induces beautiful visions. The dosage is given as one to four mushrooms.

Today, the panther cap is used for psychoactive purposes wherever it is found:

Amanita pantherina is also a widespread “recreational and party drug” whose effects are stronger than those of *Amanita muscaria*. Pleasant sensations are more likely to arise when the mushroom is ingested with an expectation of hallucinogenic effects. In many areas of the U.S., Russia, France, and Italy, the panther cap is also consumed for culinary purposes. These may be varieties that are relatively devoid of toxins. The psychotropic effects can also be elicited by smoking the dried skins of the caps or mushroom bodies. For adults, the lethal toxic dose is contained in more than 100 grams of fresh mushrooms. (Roth et al. 1990, 43 ff.**)

This old English illustration of *fungi lethales*, “deadly mushrooms,” may depict a group of panther cap, fly agaric, or other amanita mushrooms (*Amanita* spp.). (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

In northern Asia, dried panther caps (*Amanita pantherina*) are popular inebriants.

“Teetotalers must be afraid of the tengu-dake [= panther cap].”

A *Cyperus* species grass known as *piripiri*. (Photographed in Peru)

Amanita Species

Species of the genus *Amanita* that are regarded as psychoactive or are used as psychoactive substances (from Beutler and Der Marderosian 1981; Ott 1978**; Weil 1977**):

Amanita citrina Schaeff. ex St. Gray [syn. *Amanita mappa* (Batsch. ex Lasch) Quélet.]—false death cap; contains up to 7.5 mg **bufotenine** in 1 gram of dry mass (Beutler and Der Marderosian 1981, 423)

Amanita cothurnata Atkinson [syn. *Amanita pantherina* var. *multisquamosa* (Pk.) Jenkins]—booted amanita

Amanita gemmata (Fr.) Gill—contains **ibotenic acid/muscimol**

Amanita gemmata (Fr.) Gill x *A. pantherina* hybrids—contain **ibotenic acid/muscimol**

Amanita parcivolvata Pk.—contains traces of isoxazole

Amanita porphyria (Alb. et Schw. ex Fr.) Secretan—contains **bufotenine** (trace amounts)

Amanita strobiliformis (Paul) Quélet—ibo-tengu-take (Japanese, “warty *tengu* mushroom”); contains **ibotenic acid/muscimol**

Amanita tomentella Krombholz—contains some **bufotenine**

The effects subside no later than ten to fifteen hours after consumption (Roth et al. 1990, 44**). In contrast, the older literature speaks of euphoric and psychotic states lasting as long as eight days (Leonhardt 1992).

Panther caps, at least those of North American origin, have been found to contain **ibotenic acid** and **muscimol**. When dried and stored, the quantity of ibotenic acid declines proportionately as the quantity of muscimol increases (Beutler and Der Marderosian 1981, 423, 427; cf. Benedict et al. 1966). Panther caps also contain stizolobic acid and stizolobinic acid (amino acids), which are also found in *Stizolobium* and *Mucuna* species (cf. *Mucuna pruriens*) (Bresinsky and Besl 1985, 107 f.**).

Balansia cyperi Edgerton

Cyprus Grass Fungus

Family

Clavicipitaceae; Subfamily Balansiae

The *Balansia cyperi* fungus is closely related to ***Claviceps*** and is parasitic exclusively on Cyprus grasses (Cyperaceae; Edgerton 1919). In Ecuador, it infests chiefly *Cyperus prolixus* H.B.K., a grass known locally as *piripiri* that the women of the Jívaro use to aid in birthing (Lewis and Elvin-Lewis 1990). *Piripiri* is also used as an **ayahuasca** additive (cf. ***Cyperus* spp.**) and as a folk medicine for treating snakebites (Plowman et al. 1990).

Balansia cyperi is a parasite that preferentially infests the following species of Cyprus grasses (Clay 1986, Lewis and Elvin-Lewis 1990, Plowman et al. 1990):

Cyperus articulatus L.

Cyperus articulatus L. var. *nodosus* (H. et B. ex Willd.) Kuek.

Cyperus prolixus H.B.K.—piripiri

Cyperus pseudovegetus Steudel

Cyperus rotundus L.—nut grass

Cyperus surinamensis Rottb.

Cyperus virens Michx.

Two of the **ergot alkaloids** found in Cyprus grasses infested with *Balansia* (Plowman et al. 1990), ergobalansine and ergobalansinin, were recently detected in the vine *Ipomoea piurensis* (cf. ***Ipomoea* spp.**) (Jnett-Siems et al. 1994).

Ergot alkaloids are also present in the following *Balansia* species: *Balansia claviceps* Speg., *Balansia epichloë* (Weese) Diehl, *Balansia henningsiana* (Moell.) Diehl, *Balansia strangulans* (Mont.) Diehl (Plowman et al. 1990, 459).

Claviceps paspali Stevens et Hall

Paspalum Ergot

Family

Class Ascomycetes, Order Clavicipitales, Family Clavicipitaceae

Synonyms

Claviceps fusiformis-paspali (also refers to a type group)

Claviceps rolfsii Stev. et Hall.

Folk Names

Ergot of paspalum, paspalum ergot, paspalummutterkorn, paspalum staggers

Paspalum ergot is a parasitic fungus that infests and forms its sclerotia exclusively in the spikes of wild grasses of the cosmopolitan genus *Paspalum* (approximately two hundred species; Gramineae; Poaceae) (cf. ***Claviceps purpurea***, ***Claviceps* spp.**). Infected paspalum grains contain psychoactive or hallucinogenic **ergot alkaloids** (lysergic acid amide and its derivatives; Aaronson 1988; Acramone et al. 1960, 1961; Petroski and Kelleher 1978). The bioactive, antibiotic, and nontoxic substances paspaline, paspalinine, and paspalicine are also present (Gallagher et al. 1980; Springer and Clardy 1980). For cattle breeders, *Paspalum* grasses that have been infected with ergot represent a certain threat for their animals (Hindmarsh and Hart 1939). Ergot-infected grains of the North American Dallis grass (*Paspalum dilatatum* Poir.), which are dangerous to cattle, have also been found to contain paspalinine (Cole et al. 1977).

The ergot fungi of the following *Paspalum* species have acquired a certain significance as psychoactive substances:

***Paspalum distichum* L. [syn. *Paspalum paspaloides* (Michx.) Scribn.]—knotgrass**

Common in North America, knotgrass is now a common wild grass in the Mediterranean region³⁶⁴ as well (Wasson et al. 1985). Ergot infesting this grass produces the **ergot alkaloids** lysergic acid amide (= ergine, LSA) and lysergic acid hydroxyethylamide, both of which also occur in ***Ipomoea violacea*** and ***Turbina corymbosa***. Since it contains only hallucinogenic alkaloids, Wasson et al. advanced the hypothesis that *Paspalum* ergot was the secret ingredient in **kykeon**, the Eleusinian initiatory drink (cf. ***Claviceps purpurea***):

“Early Man in ancient Greece could have arrived at an hallucinogen from ergot. He might have done this from ergot growing on wheat or barley [***Claviceps purpurea***]. An easier way would have been to use the ergot growing on the common wild grass Paspalum. This is based on the assumption that the herbalists of ancient Greece were as intelligent and resourceful as the herbalists of pre-Conquest Mexico. (Wasson et al. 1998, 44)

The cosmopolitan Cyprus grasses (*Cyperus* spp.) are often infected with the fungus *Balansia cyperi*, which produces psychoactive alkaloids as metabolites. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

If this grass was in fact not introduced into Europe until the modern era—as all of the sources suggest—then *Paspalum* ergot must be eliminated as a possible candidate for the active constituent in **kykeon**.

***Paspalum plicatulum* Michx. and *Paspalum unispicatum* (Scribn. et Merr.) Nash**

In Paraguay, these two grasses are apparently often infested with *Claviceps paspali*. As a result, a sweet secretion (= honeydew) forms on the spikes and is consumed by wasps and bees. Bees that have visited these grasses inoculate their honey with this secretion. In the language of the Makai Indians, the resulting **honey** is called *fic'e* and is recognizable by its pungent aroma. Consumption of large amounts is dangerous, for it can produce dizziness, headaches, and drunkenness; it is said that it can be lethal. This honey is used to brew a **beer** or **mead**, certainly a beverage with potent effects. The grass *Elionurus muticus* (Spreng.) Kunth is used as an antidote for poisoning from this honey or drinks made from it. A cold-water extract made from the lower portions of five plants is drunk both to counteract the effects of the honey and to treat poisoning caused by manioc (*Manihot esculenta* Crantz) (Arenas 1987, 289 f.*).

***Paspalum scrobiculatum* L. [syn. *Paspalum commersonii* Lam.]—koda millet, kodrava, kodo**

The indigenous people of India, where this grass is common, used it as a type of millet (*kodo*) for food (cf. DeWet et al. 1983). It is mentioned in the Vedic scriptures, the Puranas, and the Ayurvedic classics (e.g., *Sushruta Samhita*) under the name *kodrava*. Ayurvedic writings note that the seeds are “sweetish and bitter, tonic, and antidotal to poisons, useful in the treatment of ulcers; it caused constipation and flatulence, upset the physiological balance of the body and led to hallucinations and dysuria” [painful urge to urinate] (Aaronson 1988, 346). The effects and symptoms described are produced not by the grass itself but rather by *Paspalum* grains that have been infected with ergot³⁶⁵ (Bhide and Aimen 1959). In India, ergot-infected *Paspalum* was used to treat postpartum pain (Aaronson 1988, 347).

In ancient India, the sclerotia were also used in religious contexts; unfortunately, little is known about such use:

It is said that the monks ate the spikes with the husks, whereupon they displayed symptoms of inebriation and were no longer able to stand. It is said that these effects lasted for several days. (Chauduri and Pal 1978)

During the rice shortage of 1946, many Indians collected and ate spikes of kodo millet. This resulted in numerous cases of LSD-like inebriation. Ergot-infested grains of this *Paspalum* species were found to contain 0.003% **ergot alkaloids** (dry weight): D-lysergic acid, methylcarbinol amide, D-lysergic acid amide (= ergine), and ergometrine (= ergobasin, ergotocine, ergostetetrine) (Aaronson 1988, 345 f.; Arcamone et al. 1960).

The Lodha of West Bengal either collect the wild grass or harvest the cultivated grass. The seed coats are used as a “ritual hallucinogen” (Pal and Jain 1989, 468). Unfortunately, we have no details about this ritual. Seeds that have had their coats removed are used to distill a type of **alcohol** (Aaronson 1988, 346).

The ergot fungus (*Claviceps*) can assume quite different forms on different host plants. Left: *Claviceps purpurea* from rye (*Secale*

cornutum); middle: *Claviceps paspali* from a Mediterranean *Paspalum* grass; right: a spike from a *Paspalum* species. (Photograph: F. Ratek, with permission of LEK, Slovenia)

Claviceps purpurea (Fries) Tulasne

Ergot

Family

Class Ascomycetes (Sac Fungi), Order Clavicipitales (Ergot Fungi), Family Clavicipitaceae

Forms and Subspecies

This species is composed of numerous races, which are distinguished primarily by their constituents and the differing composition of their alkaloids (Hofmann 1964, 5). Varieties, e.g., *Claviceps purpurea* var. *glyceriae*, are occasionally listed; these are not, however, botanically accepted (Teuscher 1992, 912).

Synonyms

Clavarius clavus nom. nud.

Claviceps microcephala (Wallr.) Tul.

Claviceps sesleriae Staeger

Claviceps setulosa Quél.

Clavis secalinus nom. nud.

Cordyceps purpurea Fries

Fusarium heterosporum nom. nud.

Sclerotium clavus DC.

Secale cornutum nom. nud.

Spacelia segetum Leveillé

Folk Names

Achterkorn, acinula davus, afterkorn, blé, bléavorté, blé cornu, blé noire, bockshorn, brandkorn, calvi siliginis, centeio espigado (Portuguese), charbon de seigle, chiodo segalino, clavaria clavus, clavus, clavus secalinus, cockspur, cockspur rye, conichuelo, cornadillo (Spanish), cornezuelo del centeno, cornichos, cravagem de centeio, cuernecillo de centeno, dürrkorn, ergot, ergota, ergot de seigle, ergot of rye, ergotum secale, esparo de centeio, espolón de centeno, esporão de centeio, faux seigle, fungus secalis, giftkorn, grano allogliato, grano cornuto, grano speranota, grano sperone, hahnensporn, horned rye, horn seed, hungerkorn, kindesmord, kornmuhme, kornmutter, kornzapfen, krähenkopf, kriebelkorn, krielkorn, madre segal, mascarello, mater secalis, mehl-mutter, meldrøje, mjjöldrya, mother of rye, mutterkorn, mutterkornpilz, mutterzapfen, rey ergot, rockenmutter, roggenbrand, roggenmutter, roter keulenkopf, rye smut, schwarzkopf, schwarzkorn, sclerotium clavus, secale clavatum, secale corniculatum, secale cornutum, secale luxurians, secale maternum, secale temulentum, secale turgidum, secalis mater, segala alloglioto, segale cornuta, seigle ergoté, seigle ergotisé, seigle ivre (French, “drunken grain”), spawn, spermoedia clavus, sperone di gallo, spiked rye, spur, spurred rye, tizón de centeno, totdenkorn, tollkorn, wolf(s)zahn, zapfenkorn

History

The history of ergot is presumably as old as that of rye (*Secale cereale* L.), which is the primary host for this parasitic fungus. Rye seems to have been largely unknown in ancient times (Germer 1985*).

Apparently it was cultivated in central Europe in the first millennium B.C., during the Hallstatt (early) Iron Age. It first arrived in Greece in the fourth century A.D. (Renfrew 1973, 83*). For this reason, neither rye nor ergot is mentioned by the authors of antiquity (cf. the discussion in Rätsch 1995a, 250 ff.*).

The ancient Hebrews knew of a *son* or *sonin*, a “degenerate wheat of black color and bitter taste.” Consuming this was said to have both inebriating and lethal effects, depending upon the dosage. Berendes (1891, 108*) has interpreted this as grain infected with *Claviceps purpurea*. The Bible makes mention of “rust-infected grain”; some (e.g., Moldenke 1986*) have suggested that this “rust” was the uredinial species *Puccinia*, while others have pointed to ergot.

Shelley (1995) has attempted to demonstrate that ergot was the **soma** of the Aryans, the **haoma** of the Parsis, the initiatory drug of the Mithraic mysteries (cf. *Peganum harmala*), and the elixir or philosopher’s stone of the alchemists. Gordon Wasson believed that ergot was the secret psychoactive ingredient in **kykeon** (cf. *Claviceps paspali*).

In his work *On Nature*, the Roman poet Lucretius (ca. 94–55 B.C.) described a disease that can be interpreted as ergotism:

Grains on an ear of rye (*Secale cereale*) are infected with ergot (*Claviceps purpurea*).

Saint Anthony, the patron saint of those afflicted with ergotism, with his attributes: the *ignis sacer* (“holy fire”), the swine, and the tau-shaped walking stick. (Woodcut, fifteenth century)

Suddenly this new and devastating air of plague descended
down upon the water, or it nested in the fruits of the field . . .
the entire body was reddened by burning sores,
as when the “sacred fire” [*ignis sacer*] spread over the limbs.
Throughout the inside of a person, so that it burned all the way down to the bones, burned in the
stomach as brightly as the fire in the interior of the earth. . . .
Completely confused condition with fear and melancholia,
darkened brow and a sharp, even angry look in the eyes;
moreover, a fearfully excited hearing and buzzing in the ears.

(6.1125, 1166 ff., 1183 ff.)

During the Middle Ages, a devastating epidemic called *ignis sacer*, “holy fire,” struck. The French physician Gay Didier, who worked in the service of the Antonite hospital in Saint-Antoine du Viennois, wrote about Saint Anthony’s “fire” in his *Epitome Chirugieae*:

The fire consists of a mortifying gangrene of a limb, it is also known as Saint Antonious’s or St. Martialis’s fire. It is remarkable to note that such pain and such heat arise with this disease that it is tantamount to a real burn. (In Bauer 1973, 22)

Saint Anthony’s fire (ergotism) was an epidemic disease that swept through central and southern Europe in the sixteenth century (Ruffie and Sournia 1993). The etiology of this devastating disease, which is the result of ergot poisoning, was not discovered until the seventeenth century. Since *Claviceps purpurea* infests primarily rye, the disease usually appeared in those areas where the populace lived primarily on rye and were constantly forced to eat the “bread of dreams” or “devil’s

bread” (Camporesi 1990; Gebelein 1991, 298 f.*; Matossian 1989). It was not until the seventeenth century that the connection between Saint Anthony’s fire and ergotism was recognized. At the time, it was believed that ergot was a creature of the devil. Those afflicted by ergot regarded Saint Anthony as their patron saint, for he himself had once successfully resisted the hallucinatory temptations of the devil—which the victims now faced themselves—in the Egyptian desert (Athanasius 1987). Saint Anthony was long venerated as the healer of ergotism (Kolta 1987; Müller-Ebeling 1985).

The German common names *rockenmutter* [rye mother], *afterkorn* [anal grain], *todtenkorn* [death grain], *tollkorn* [mad grain],³⁶⁶ and *mutter-korn* [mother grain] are all indicative of the effects and usages of this fungus. Since the Middle Ages, midwives have used ergot to induce labor. The first written source that directly referred to ergot in this context was Lonicerus’s *Kräuterbuch* (seventeenth century). During the late modern era, ergot was the most important agent for inducing contractions (Schneider 1974, 1:335*). The first scientific report on ergot as a uterotonic agent appeared in 1808. In 1824, the American physician David Hosack recommended ergot to accelerate childbirth.

In 1918, Arthur Stoll isolated and described ergotamine, the first **ergot alkaloid** to be identified. Later analyses of ergot by Albert Hofmann uncovered the structures of numerous other ergot alkaloids and also resulted in the “accidental” synthesis of LSD. These studies also produced several preparations that are still in use today (e.g., methergine and hydergine).

Distribution

Claviceps purpurea occurs worldwide as a parasite on grasses (June grass [*Poa pratensis* L.], orchard grass [*Dactylis glomerata* L.], meadow foxtail [*Alopecurus pratensis* L.]), and cereal grains (rye, barley, wheat). The fungus is found as a parasite on four hundred species of the Family Gramineae (= Poaceae) (Teuscher 1992, 912).

Cultivation

Ergot is reproduced through a process known as rye inoculation:

To effect this, the blossoming rye spikes are infected using a conidial [spore] suspension obtained through in-vitro culture. This can occur by spraying or by injection, the latter being more effective. Today, inoculating machines that make it possible to efficiently infect large fields using the injection method are used for large-scale industrial production. (Hofmann 1964, 7)

To produce ergot for pharmaceutical purposes, large fields of rye are now inoculated in Chechnya, Hungary, and Portugal (Teuscher 1992, 914).

Appearance

The sclerotium of *Claviceps purpurea* is dark purple. On rye (*Secale cereale* L.), the conelike sclerotium is dark violet to black, can grow up to 6 cm in length, and resembles a long, slender tooth.

Botanical illustration of ergot sclerotia. (Engraving from Pereira, *De Beginselen der Materia Medica en der Therapie*, 1849)

Ergot, or *secale cornutum*, is an ancient agent for inducing labor and still finds use today in homeopathy.

“The ‘sacred fire’ ate into the flesh of the people, so that it fell from the bones in burning shreds, made the earth delirious, and turned humans into beasts.”

STANISLAV PRZYBYSZEWSKI *DIE SYNAGOGE SATANS* [THE SYNAGOGUE OF SATAN] (1979, 43)

Psychoactive Material

—*Secale cornutum* (ergot)

Only the sclerotia (fruiting bodies) of ergot infecting rye (*Secale cereale* L.) are used (Teuscher 1992, 912).

Preparation and Dosage

The sclerotia are collected when the rye is ripe and dry and are then dried and crushed. The resulting powder can be used to produce alcoholic extracts and cold-water infusions. Because ergot preparations are almost impossible to standardize and exhibit considerable variations in alkaloid concentration and in the proportions of the constituent alkaloids, one seldom finds information about dosages. The older literature often notes that four ergot grains are sufficient to speed up the process of labor. Such statements, however, should not necessarily be taken at face value. Alcoholic extracts can be very dangerous, as they dissolve the toxic alkaloids. It is only with cold-water extracts that the poisonous alkaloids remain undissolved. *There is no data available concerning cold-water extracts. Self-experimentation is absolutely not recommended!*

It has been conjectured that ergot was an ingredient in the Delphic **incense** (cf. *Hyoscyamus albus*, *Laurus nobilis*) and in **witches’ ointments**. The recipe for a “lotion for prophetic dreams” (from Piobb) contains ergot (as the primary agent) as well as turpentine, the yolk from the egg of a wild duck, diascordium (?), red roses, goat’s or mare’s milk, ivy (*Hedera helix*), alchemilla, ironweed (*Verbena*?), shavings from deer antlers, monkshood (*Aconitum* spp.), and whale blubber. All of the ingredients are boiled in alcohol with camphor (cf. *Cinnamomum camphora*); mixed with coral syrup, black salisify (radix consolid.), balsam, and ammoniac; and finally dissolved in Malvasian wine. Three drops are added to a liter of water. The resulting solution is smeared onto the hands, feet, head, and abdomen before sleep (Spilmont 1984, 142 f.).

Ergot is also a component of many homeopathic preparations, e.g., *Secale Pentarkan*, which consists of *secale cornutum*, glonoine, Ignatius bean (see *Strychnos* spp.), magnesium phosphate, and *nux-vomica* (*Strychnos nux-vomica*).

A variety of plants were utilized to treat Saint Anthony’s fire, including mandrake (*Mandragora officinarum*; cf. Gebelin 1991, 299*). The precious spice saffron (*Crocus sativus*) was also regarded as a magical antidote. Plants used to treat the epidemic are depicted on the Isenheim Altar together with Saint Anthony (Seidl and Bauer 1983, 64). They are easily identified as common plantain (*Plantago major* L.) and aconite (*Aconitum napellus*). During the Middle Ages, plantain was known as *herba proserpinacia*, “plant of Proserpina [= Persephone]” (Storl 1996, 101*). Persephone, the daughter of Demeter, was kidnapped by Pluto/ Hades, as a result of which the Great Goddess ultimately established her mysteries (cf. **kykeon**).

Most (1842, 457*) lists rhubarb (*Rheum* spp.) as a remedy for ergot poisoning. Rhubarb is one of the many plants associated with **soma**.

Ritual Use

If ergot was in fact an ingredient in **haoma**, **soma**, or **kykeon**, then its ritual use as a psychoactive substance is rooted in prehistoric times.

In ancient central Europe, it may have been used in the ritual transformation of a person into an

animal: “The werewolf crouches amidst the grain,” it was said, and “amidst the grain” is where ergot grows. Here again, the best we can do is to speculate.

Ergot or preparations containing ergot appear to have been used for divinatory purposes in French occultism (Spilmont 1984).

Today, ergot-infected grains are used in Peru by Indian soothsayers in conjunction with the coca oracle (cf. *Erythroxyllum coca*).

Artifacts

An ancient Celtic coin features what may be the oldest representation of an ergot-infected grain (Lengyel 1976). A woodcut in the *Kräuterbuch* of Lonicerus (1679) is usually regarded as the earliest illustration of a grain of ergot-infected rye.

It has frequently been suggested that the pictures of Hieronymus Bosch (ca. 1450–1516) were inspired by ergot-induced hallucinations (Brod 1991; Dixon 1984; cf. *Datura stramonium*). In particular, those pictures that have the temptation of Saint Anthony as their theme have been interpreted as representations of the ghastly visions induced by Saint Anthony’s fire (Müller-Ebeling 1983). The famous Isenheim Altarpiece of Matthias Grünewald (ca. 1470–1528) is directly related to ergot:

On the contrary, this altar stood in an isolated place, before a strange and isolated community: in a hospital church in Isenheim (Alsace) belonging to a cloister of the order of Saint Anthony. Saint Anthony was the patron saint of the lepers, those unfortunates who were afflicted by an epidemic known at the time as “hell fire” or “burning sickness.” This devastating epidemic, from which thousands died, had been moving through the West since the tenth century. The cloister at Isenheim was a house for the afflicted, a hospital for people suffering from this disease. The altar was intended for those wretched individuals who were doomed to this slow, suppurating death. It was the great shrine of their church. (Fraenger 1983, 11 f.)

The right wing of the second opening of the retable depicts the temptation of Saint Anthony. A “human figure, upon whose body fester all of the devastations of the epidemic” (Fraenger 1983, 46), is visible on the bottom left (Seidel and Bauer 1983). The afflicted person is unconscious and appears to be hallucinating the wild scene. On the bottom right of the same panel is a tree stump, from which polypores (cf. “*Polyporus mysticus*”) are growing. Paul Hindemith (1895–1963) dramatized the creation of the altar in his opera *Mathis der Maler* [Matthias the Painter] (1935) by having his painter experience visions like those that had once tempted Saint Anthony.³⁶⁷ The scene was also set to music in “The Temptation of St. Anthony” by the psychedelic rock group The Sensational Alex Harvey Band (1972).

This illustration of an ear of grain infected with ergot is from an antique Celtic coin and may be the oldest representation of its kind. (From Lengyel, *Das geheime Wissen der Kelten*, 1976)

In later centuries, the pictorial motif of the temptation of Saint Anthony was a popular device for depicting hallucinatory states or visionary experiences (Müller-Ebeling 1989, 1997). A poem of the same name by Gustave Flaubert (1821– 1880), which appears very “trippy” from today’s perspective, should also be mentioned in this context. In his horror novel *Die Elixiere des Teufels* [The Elixirs of the Devil] (1815), E. T. A. Hofmann (1776–1822) described a “wine of Saint Anthony,” the consumption of which produced extreme hallucinations (Hofmann 1982*; cf. *Vitis vinifera*). The novel *The Day of St. Anthony’s Fire* (Fuller 1968) is based upon a purported epidemic of ergotism in

Pont-St.-Esprit (France) that produced mass hysteria and collective hallucinations (Latimer 1981, 119).

In his novel *St.-Petri-Schnee* [Saint Peter's Snow] (1933), Leo Perutz (1882–1957) strangely anticipated the discovery of LSD from ergot (cf. **ophiussa**). He describes an experiment in which a chemist is attempting to isolate from a cereal fungus a drug of the gods that would make mystical experiences possible:

This Dionysos [Areopagita] relates in his writings that he imposed a two-day fast on the members of his community who longed for the true presence of God, after which he served them “bread prepared from sacred flour.”—“For this bread”—he wrote—“leads to union with God and enables one to comprehend the infinite.”—... Like all priests, the Roman priests of the fields knew the secrets of the drug that placed humans into that state of ecstasy in which they “became able to see” and “recognized the power of God.” The white frost—this was not a type of grain, but a disease of the grain, a parasite, a fungus that penetrates into the grain plant and nourishes itself on its substance. . . . In Spain, it is known as “the Magdalena lichen,” in Alsace as “the dew of poor souls.” The “doctor's book” of Adam of Cremona described it under the name “misericordia grain”; it was known in the Alps as “St. Peter's snow.” In the area around St. Gallen, it was called the “mendicant,” and in northern Bohemia “St. John's rot.” Among us here in Westphalia, where it occurs particularly often, the farmers call it “the fire of the mother of God.” (Perutz 1960, 119, 120, 121)

The American Beat poet Dale Pendell (b. 1944) immortalized the discovery of LSD from ergot in a poem (Pendell 1997; cf. Pendell 1995*).

The internationally famous American author Marion Zimmer Bradley (b. 1930) is known especially for her romantic fantasy and sciencefiction novels. Psychoactive drugs are featured remarkably often in her novels and stories. In a recent novel, Bradley demonstrates that she has carefully considered Gordon Wasson's thesis that ergot was used in Eleusis.³⁶⁸ This historical novel, titled *The Firebrand*, tells the tale of the Trojan War from the (feminist) perspective of the young seeress Cassandra (Bradley 1987). She was consecrated to Apollo, raised in Colchis, and trained by Penthesilea, the queen of the Amazons. At the conclusion of her training among the Amazons, Cassandra was initiated into the mysteries of the Great Goddess. The ritual, presided over by older women, is conducted in a temple. The female initiates are given a drink made of ergot:

She thought, till she touched her lips to the brew, that it was wine.

She tasted a curious slimy bitterness which made her think of the smell of the blighted rye Penthesilea had bidden her remember; as she drank she thought her stomach would rebel, but with a fierce effort she controlled the queasiness and brought her attention back to the drums. (1987, 135)

The drink quickly manifests its effects, which are described as follows:

Strange colors crawled before her eyes, and it seemed for a moment that she was walking through a great dark tunnel. (135)

After this typical psychedelic tunnel experience, Cassandra perceives the voice of the Great Goddess:

Share with Earth's Daughter the descent into darkness, a voice guided her from afar; whether a

real voice or not she never knew. *One by one you must leave behind all the things of this world which are dear to you, for now you have no part in them. . . . This is the first of the gates of the Underworld; here you must give up that which binds you to Earth and the realms of Light.* (135, 136)

“On the grain cone, Latin Clavi Siliginis: One often finds in the heads of rye or grain long, black, hard, narrow cones growing out betwixt and between the grain, that is in the heads, and which stand out and look like long little nails; they are white on the inside like the grain, and they are entirely harmless to the grain. Such grain cones are regarded by the women as a great aid and proven medicine for the rise and cramping of mothers when one ingests and uses three of these several times.”

LONICERUS KRÄUTERBUCH [“HERBAL”] (1679)

Cassandra passes the test and walks through the gate. A second psychedelic tunnel now opens up to her:

This is the second Gate of the Underworld, where you must give up your fears or whatever holds you back from traveling this realm as one of those whose feet know and tread the Path in My very footprints. (136)

After experiencing her death, she reaches the third gate, whereupon she is reborn. The culmination is the discovery of the Great Goddess:

She hung senseless in the darkness, shot through with fire, surrounded by the rushing sound of wings.

Goddess, If I am to die for You, at least let me once behold Your face!

There was a little lightening of the darkness; before her eyes she saw a swirling paleness, from which gradually emerged a pair of dark eyes, a pallid face. She had seen the face before, reflected in a stream . . . it was her own. A voice very close to her whispered through the drumming and the whining flutes:

Do you not yet know that you are I, and I am you?

Then the rushing wings took her, blotting out everything. Wings and dark hurricane winds, thrusting her upward, upward toward the light. (137)

At the conclusion of the ritual, Penthesilea warns her:

Hush; it is forbidden to speak of the Mystery. (138)

As of 1994, 440,000 copies of the German translation of *Firebrand* had been sold. Assuming that every copy sold is read by at least two people, this means that the book has been read by almost one million people in Germany alone. Certainly, more people have learned of the ergot mysteries from this book than from all of the scientific or nonfiction discussions in the academic literature (Rätsch 1996).

The experimental music group Psychic TV released a song titled “Eleusis” on its album *Dreams Less Sweet*. It was clearly influenced by Wasson’s theory (Sony/Some Bizarre, SBZ CD 011, 1992).

Medicinal Use

Since medieval times, ergot-infested grains have been used in folk gynecology as a means of inducing contractions, hastening childbirth, and treating postpartum complications (Mühle and Breuel 1977). In the eighteenth century, ergot was used in Thuringia (Germany) as a hemostatic agent. In the

nineteenth century, ground grains of ergot were known as *pulvis parturiens*; they were administered to treat palsy and to induce abortions (Most 1843, 457*).

Today, ergot is no longer used in allopathic medicine, as it is almost impossible to standardize the drug (Teuscher 1992, 918). Preparations made from it are used only in homeopathy (*Secale cornutum* hom. *HAB1*, *Secale cornutum* hom. *HPUS78*) to treat particular symptom pictures, such as uterine cramps, spasm disorders, and migraine headaches (Teuscher 1992, 921).

Some of the substances that have been derived from **ergot alkaloids** (e.g., methergine, dihydergot, and hydergine) are still prescribed frequently.

Constituents and Effects

Depending upon the host plant, climate, and location, the ergot fungus can produce alkaloids (the **ergot alkaloids** ergotamine, ergotine, ergocristine, ergokryptine,³⁶⁹ ergocornine, ergometrine; also ergoclavine, histamine, tyramine, choline, acetylcholine) that have varying effects (cf. Horwell and Verge 1979). Some of these are toxic; others are psychedelic. The harmful alkaloids produce two different forms of ergotism (ergot poisoning, Saint Anthony’s fire):

Gangrenous ergotism began with vomiting and diarrhea, with itching in the fingers and inflamed appearances that were accompanied by severe burning pains. After a few days, the symptoms of gangrene then appeared. Starting with the fingers and toes, the limbs began to take on a blue-blackish color and to mummify. In cases of severe poisoning, it could even occur that the arms and legs would fall from the body without any loss of blood whatsoever. The gangrenous form of ergotism was referred to by such names as “mal des ardents,” “ignis sacer,” and “heiliges feuer” [sacred fire]. The convulsive form, which began with symptoms similar to those of the gangrenous, was characterized primarily by severe nervous disturbances. Painful muscle contractions, especially in the extremities, occurred, which ultimately led to epilepticlike spasms. (Hofmann 1964, 8)

Ergot from wheat, barley, and rye contains essentially the same alkaloids (ergotamine and ergotoxine groups, ergonovine, and occasionally traces of lysergic acid amide). In contrast to the dangerous toxins, the hallucinogenic substances lysergic acid amide, lysergic acid hydroxyethylamide, and ergonovine are water soluble and can therefore be separated from one another. Unfortunately, reports about the effects of ergonovine and methylergonovine are quite unsatisfactory (Ripinsky-Naxon 1993*). Further ethnopharmacological research is required.

Plantain (*Plantago*), the “plant of Persephone,” was used to treat Saint Anthony’s fire (ergotism). (Woodcut from Tabernaemontanus, *Neu Völkommen Kräuter-Buch*, 1731)

Ergometrine

“‘I will bring you the strong tea. Drink it quickly. The ergot has overwintered. It is dissolved.’ Taking small, hasty sips, Medea hurried to wash down the fungus. The pustules on the ears of rye were dark violet. The color of her flowers. Pain and happiness. The parasite rushed into her body and worked its way through her. Not a convolution was neglected. Medea lay with her legs and arms spread out, so that the poison could quickly find its way.”

Commercial Forms and Regulations

In Germany, pharmaceutical preparations of ergot may be obtained only from a pharmacy. All preparations of **ergot alkaloids** require a prescription from a physician (Teuscher 1992, 920). Only homeopathic dilutions of D3 and below are freely available.

Claviceps spp.

Ergot Fungi

Family

Class Ascomycetes (Sac Fungi), Order Clavicipitales (Ergot Fungi), Family Clavicipitaceae

There are thirty-five to fifty species of ergot fungi (*Claviceps* spp.). The name *ergot* refers to the overwintering stage (sclerotium) of sac fungi that parasitically infest various cereal grains (rye, wheat, barley, millet), wild sweet grasses (Gramineae = Poaceae; e.g., bearded darnel, *Lolium temulentum*; *Paspalum* species), and rushes (Juncaceae) and sedges (Cyperaceae; cf. *Cyperus* spp.) (Dörfelt 1989, 92**).

It is possible that sleepy grass (*Stipa* spp.) is also infested with *Claviceps* species and consequently may be psychoactive. All ergot fungi produce psychoactive and/or toxic alkaloids (**ergot alkaloids**, **indole alkaloids**).

Claviceps gigantea Fuentes—diente de caballo (“horse’s tooth”), giant ergot

This fungus apparently infests only maize (*Zea mays*), a New World grass (Moreno and Fucikovsky 1972). It contains **ergot alkaloids** of unknown composition and is regarded in Mexico as poisonous (Guzmán 1994, 1438**). Many Indians regard this fungal infestation as a disease of the maize plant (Rätsch 1989).

When the Yucatán peninsula of Mexico was conquered by the Spanish in the sixteenth century, Franciscans came into the country, compiling various reports and dictionaries. One of the three most important lexicons that have been preserved is now known as the *Wiener Wörterbuch* [Vienna Lexicon] (Andrews Heath de Zapata 1978). Compiled around 1625, it contains several extremely unusual and interesting comments related to Saint Anthony and to Saint Anthony’s fire, the malady named after him (cf. *Claviceps purpurea*):

—*metnalil kak: fuego de San Antón*, “ ‘Hell’ fire: Saint Anthony’s fire”

—*he metnalil kake humpati uinic lic yulel: Esta enfermedad mata sin remedio*, “This hell fire burns all people in the same manner: This affliction kills without remedy.” (WW 306)

These entries clearly indicate that the author of the *Wiener Wörterbuch* interpreted certain manifestations and terminology of the Indians as Saint Anthony’s fire (ergotism), which he knew from Europe. Since the link between the disease and ergot had not yet been discovered, and because it is possible that the ergot fungus was not present in the Yucatán at that time, *fuego de San Antón* may have referred to another, similar phenomenon (cf. *Datura innoxia*). However, the entries in the *Wiener Wörterbuch* suggest that in the Yucatán there may also have been epidemics of some types of affliction that resembled gangrenous ergotism. The reports of two Spaniards, Diego Lopez de Cogolludo and Fra Diego de Landa, demonstrate that Saint Anthony was being venerated in Yucatán during the early colonial period (Hermanns and Probst 1994). It may be that *fuego de San Antón* was exactly that which it refers to, a form of poisoning due to the giant ergot that infests maize, *Claviceps gigantea*.

Giant ergot (*Claviceps gigantea*) infests chiefly ears of maize. (Photographed in southern Mexico)

The spikes of the dune grass *Ammophila maritima*, which lives in a symbiotic relationship with *Psilocybe azurescens*, are often infested with ergot (*Claviceps* sp.).

***Claviceps glabra* Langdon**

Infests numerous wild grasses.

***Claviceps nirgicans* Tul.**

Infests numerous wild grasses.

Claviceps paspali

Infests only grasses of the genus *Paspalum*.

Claviceps purpurea

Infests preferentially rye but also wheat and barley.

***Claviceps* sp.**

Infests the dune grass *Ammophila maritima*, which lives in a symbiotic relationship with *Psilocybe azurescens* (Stamets 1996, 95**).

Conocybe spp.

Cone Caps

Family

Agaricaceae: Bolbitiaceae (cone caps)

The cone caps are small, thin mushrooms of pale color and with conic to bell-shaped caps. The lamellae turn rusty brown as the spores form. Cone caps prefer open forest areas. Some species of the genus contain **psilocybin** and are psychoactive. A rudimentary cult based around *tamu*, a *Conocybe* species known as the mushroom of knowledge, was recently discovered in the Ivory Coast (Samorini 1995). The Mazatec used the species *Conocybe siligineoides* Heim, which they referred to as *ta'a'ya*, as an entheogen. Chemical analyses are lacking (Ott 1993, 313*; Stamets 1996, 176**).

***Conocybe cyanopus* (Atkins) Kühner (= *Conocybe cyanopus* (Atkins) Sing.) [syn. *Pholiotina cyanopus*]—blue-footed cone cap**

This mushroom grows in grassy areas and mossy locales from summer to fall. It forms an obtusely convex cap 0.5 to 2.5 cm in diameter. The whitish stem is blue-green at its base and turns blue when squeezed. This mushroom is found in Germany and Switzerland as well as in North America. Generally regarded as poisonous, it contains 0.93% **psilocybin** (dry weight) and some baeocystin but no psilocin (Gartz 1985, 1992).

The following species also contain **psilocybin** (Allen et al. 1992, 93**; Gartz 1985):

Conocybe kuehneriana Singer

Conocybe siligineoides Heim—*ta'a'ya*

Conocybe smithii Watling (also contains baeocystin; Repke et al. 1977)

The tiny fruiting bodies of *Conocybe cyanopus* contain 0.33 to 0.93% psilocybin. (Photograph: Paul Stamets)

Copelandia spp.

Ink Caps

Family

Coprinaceae (Ink Caps)

Some of the psychoactive mushrooms originally assigned to this genus are now classified in the genus *Panaeolus*: *Panaeolus cambodginiensis*, ***Panaeolus cyanescens***, *Panaeolus tropicales* (cf. ***Panaeolus* spp.**).

The following species of the genus *Copelandia* contain **psilocybin** (Allen et al. 1992, 93**; Ott 1993, 309*):

Copelandia anomalus (Murr.) Sacc. et Trott.

Copelandia bispora (Malencon et Bertault) Sing. et Weeks

Copelandia chlorocystis Sing., Weeks et Hearn

Copelandia mexicana Guzmán

Copelandia westii (Murr.) Sing.

None of these species is known to have or to have had a traditional use (cf. Weeks et al. 1979).

Galerina steglichii Besl

Steglich's Galerina

Family

Cortinariaceae

This tiny mushroom, which suddenly appeared in Regensburg, Germany, in 1993, develops a bluish color when pressed or squeezed. An extract of the mushroom was found to contain **psilocybin**, psilocin, and baeocystin. This was the first discovery of these psychoactive alkaloids in a species of the genus *Galerina* (Besl 1993). The dried fruiting bodies contain 0.21 to 0.51% psilocybin, 0.02 to 0.07% baeocystin, and 0.08 to

0.21% psilocin (Gartz 1995, 304). This species is relatively easy to cultivate on an agar substrate.

Beware! Many other species of the genus *Galerina* are very poisonous and may be lethal.

“The genus *Galerina* contains dangerously poisonous mushrooms in which the same deadly amatoxins are present as in the death cap [*Amanita phalloides* (Vaill.) Secr.]. These toxins manifest their effects after a latency period of 12 hours and are typically lethal in spite of therapy. *Galerina autumnalis* (Peck) Singer et Smith is a common North American species that, like some *Psilocybe* species, grows on remnants of wood in parks and forests. At first glance, it is very similar to *Psilocybe stuntzii* Guzman et Ott and can grow directly next to this. But the *Galerina* species do not blue.”

JOCHEN GARTZ *NARRENSCHWÄMME* [FOOLS' FUNGI] (1993, 67 f.**)

Gymnopilus spp.

Gyms

Family

Cortinariaceae

Gyms are typically small to medium in size and have convex to plane caps and yellow- or orange-colored lamellae. They thrive on trees from summer to fall. Most species have a bitter taste and are usually regarded as poisonous or inedible. Several species are said to have hallucinogenic effects.

The following species have been demonstrated to contain **psilocybin** (Allen et al. 1992, 93**; Hatfield et al. 1978):

Gymnopilus aeruginosus (Peck) Singer [syn.

Pholiota aeruginosa Peck]

Gymnopilus braendlei (Peck) Hesler

Gymnopilus intermedius (Sing.) Singer

Gymnopilus leteoviridis Thiers

Gymnopilus liquiritae (Fr.) Karst.

Gymnopilus luteus (Peck) Hesler

Gymnopilus purpuratus (Cooke et Mass.) Sing. [syn. *Flammula purpurata* Cooke et Masee]—purple gym

The purple gym apparently originated in South America but also occurs in Germany. It contains **psilocybin** as well as psilocin (Gartz 1993, 55**). This mushroom may once have been used for inebriating purposes (cf. “*Polyporus mysticus*”).

Gymnopilus validipes (Peck) Hesler (cf. Hatfield et al. 1977)

Gymnopilus viridans Murrill

The following species may contain psychoactive substances:

Gymnopilus luteofolius (Peck) Singer [syn. *Pholiota luteofolia* (Peck) Saccardo]

Gymnopilus ventricosus

Only one species of the genus *Gymnopilus* has attained any cultural significance:

Gymnopilus spectabilis (Fries) Singer [syn.

Gymnopilus junonius (Fr.: Fr.) P.D. Orton, *Pholiota spectabilis* (Fries) Gillet]—big gym, giant laughing mushroom

Gymnopilus spectabilis grows on deciduous wood and, less frequently, coniferous wood. Its cap can attain a diameter of 5 to 15 cm. It has a very bad taste and is low in active components. It is commonly regarded as poisonous.

The yellow variety *Gymnopilus spectabilis* var. *junonius* (Fr.) J.E. Lange is one of the largest mushrooms known. It can develop stems as tall as 60 cm (Gartz 193, 55 f.**).

The big gym also occurs in North America and Japan; psychoactive effects have been reported from both regions (Walters 1965). An experiential report is now available from Canada:

I tried three grams of *G. spectabilis*. Slight optical changes, but (together with my meditation techniques) enough to drive me into an intense convulsive trembling. When I gave in to this, I found that this was a memory of the room in which I had found myself after my birth. I was very cold there, I was afraid and needed my mother. The culmination came 3 to 3 1/2 hours after ingestion. . . . *Psilocybe* always takes away my clarity; this mushroom increases it. . . . The effects are markedly different. (In *Entheogene* no. 2 [1994/1995]: 23 f.)

In Japan, this mushroom is known as *owaraitake*, “giant laughing mushroom,” a name with a long history. A story recorded in the *Konjaku monogatari* [Stories from Ancient Times] (eleventh century) indicates that psycho-active fungi must have been known in Japan at a very early date. In this story, woodcutters meet a group of nuns who are singing and dancing. The woodcutters regard the nuns as manifestations of demons or goblins. The nuns explain that they had eaten certain mushrooms, and that these had caused them to sing and dance. The woodcutters eat some of the same mushrooms, and they too then dance and sing. After this event became known, the mushroom was given the name *maitake*, “dancing mushroom.” One old dictionary identified this mushroom as *Grifola frondosa* (Dicks. ex Fr.) S.F. Gray [syn. *Boletus frondosus* Vahl., *Cladomeris frondosa* Quél., *Polyporus frondosus*] (cf. “***Polyporus mysticus***”); it was noted, however, that the *maitake* of the *Konjaku* story was actually known as *waraitake*, “laughing mushroom.”³⁷⁰ In the *Daijiten*, on the other hand, *waraitake* is identified as *Panaeolus papilionaceus* (cf. ***Panaeolus* spp.**) or *Gymnopilus spectabilis* (Sanford 1972, 174**). The *Daijiten* has the following to say about this mushroom:

Illustration of a *Gymnopilus* species (*Pholiota adiposa*) on a Korean stamp.

A species of the genus *Gymnopilus* that grows on trees. (Photographed near Astoria, Oregon)

The cap of a *Gymnopilus* species as seen from below.

People who eat this mushroom become inebriated. They can become extremely excited, dance and sing, and see different visions. Other names for it are *odoritake* [“jumping mushroom”] and *maitake*. (In Sanford 1972, 175**)

A Taoist source from the eleventh or twelfth century states that an elixir of life (known as “earth drink”) was obtained from the “laughing mushroom” (Sanford 1972, 178**).

It is possible that *Gymnopilus spectabilis* contains indole derivatives; the analysis of Hatfield et al. (1978, 142) found that it contains **psilocybin** (cf. Benjamin 1995, 326**). Styrylpyrone, bisnoryangonine, and bitter principles (gymnopilins) have also been detected (Aoyagi et al. 1983; Tanaka et al. 1993). The psychoactivity, on the other hand, is unquestioned (Buck 1967; Romagnesi 1964; Sanford 1972**).

“You should try to give King Emma several of the ‘laughing mushrooms.’ ”

HAIKU BY KOBAYASHI ISSA IN “MUSHROOMS IN JAPANESE VERSE” (BLYTH 1973, 11**)

Inocybe spp.

Inocybe Mushrooms

Family

Cortinariaceae

These small- to medium-size mushrooms form first conic and later slightly convex caps with a slightly incurved margin. Their German name, *risspilze*, means “ripped or cracked fungi,” referring to their typically fissured surface. They grow from summer to fall in forests, on pastures and moors, and in alpine settings. Of the approximately 160 species, several are feared as poisonous. The brick red *Inocybe erubescens* Blytt. [syn. *Inocybe patouillardii* Bres.] contains muscarine and can produce serious and even deadly poisonings. The few species that color blue-green (*I. aeruginascens*, *I. corydalina*, *I. haemacta*) contain **psilocybin** and baeocystin (Stivje et al. 1985). These are nonpoisonous and occur in central Europe (Germany, Switzerland) (Gartz and Drewitz 1985). They have no traditional use.

Inocybe aeruginascens Babos

This mushroom was first found in 1965 in Hungary, spread from there, and suddenly appeared in 1975 in Berlin. In 1980, it came to Holland, and in 1984 it even made it to the Rhône valley of Switzerland. It can be assumed that this species is a new one that arose only a few years ago (Gartz 1992).

The cap is only 2 to 3 cm across; the stem colors heavily bluish green all the way to the swelling base. This mushroom grows from spring to fall near deciduous trees in the grassy areas of parks. It contains **psilocybin** and has unequivocal psychoactive effects (Gartz 1986a). To produce visions, 2.4 g of dry weight suffice (Gartz 1995). None of the samples tested has yielded the toxic muscarine, which does appear elsewhere in the genus (Gartz 1986b).

The blueing mushroom *Inocybe calamistrata* is psychoactive and may contain psilocybin.

“The mushrooms [*Inocybe aeruginascens*] taste like ordinary culinary mushrooms. After some 30 minutes, while lying relaxed with no other somatic effects, there gradually appeared an extremely pleasant neutralization of the sense of weight. Abstract hallucinations in the form of sparkling colors and lights slowly developed. When the sense of weight had completely disappeared, there arose a very lively perception of a flight of the soul with corresponding euphoric feelings.”

JOCHEN GARTZ *NARRENSCHWÄMME* [FOOL’S FUNGI] (1993, 51**)

The mushroom *Inocybe patouillardii* on a Cuban stamp

Inocybe coelestium Kuyper

Inocybe corydalina Quélet

This species occurs in two varieties:

Inocybe corydalina var. *corydalina* Quélet

Inocybe corydalina var. *erinaceomorpha* (Stangl et Veselsky) Kuyper—brown cap, more than 5 cm across

This mushroom grows from summer to fall, primarily in deciduous forests.

***Inocybe haemacta* (Berkeley et Cooke) Saccardo**

This mushroom grows in the fall in deciduous forests and parks.

Copelandia papilionacea (Bull.) Bres. non Fr.

Copelandia westii (Murr.) Sing.

Panaeolus anomalus (Murr.) Sacc. et Torr.

Panaeolus westii (Murr.)

Folk Names

Blauender düngerling, blue meanies, faleaitu (Samoan, “spirit house” or “comedy”), falter-düngerling, Hawaiian copelandia, jambur, jamur, pulouaitu (Samoan, “spirit hat”), taepovi (Samoan, “cow patty”), tenkech (Chol)

In the early 1960s, reports emerged from southern France of strange “intoxications” produced by mushrooms that grew on horse dung. The mushrooms were identified as the tropical species *Copelandia cyanescens* and were analyzed by Albert Hofmann. He found high concentrations of psilocin in the fruiting bodies and only slight quantities of **psilocybin** (Heim et al. 1966). The reason these mushrooms had so suddenly appeared in France was also discovered. The mushroom grows on horse dung, i.e., in a kind of symbiotic relationship with horses. When horses from Indonesia were brought to southern France to take part in a horse race, the mushroom became established in the wild via their feces (Gerhardt 1987). This species clearly comes from Southeast Asia and occurs in Indonesia, Australia (Low 1990, 206*), and, since ancient times, Samoa (Cox 1981).

Panaeolus cyanescens is easily confused with *Panaeolus tropicales* and *Panaeolus cambodginiensis* (cf. ***Panaeolus* spp.**). It is possible that the latter species are merely varieties or races and are in fact synonymous with *Panaeolus cyanescens*.

The tropical mushroom *Panaeolus cyanescens* [syn. *Copelandia cyanescens*] prefers to grow on cow or horse dung. (Photographed in Palenque, Chiapas, Mexico.)

The mushroom is cultivated in Bali and purportedly is used both in native festivals and in the tourist trade (Cox 1981, 115). In Java, it may possibly have a long tradition of use as a ritual drug. The Javanese batik artists in Yogyakarta eat jambur mushrooms to obtain inspiration for their artistic

endeavors. Not surprisingly, the mushroom is often featured in their art.

In Samoa, the caps are boiled in water for a long period of time until a black juice is produced. This juice is mixed with coffee (cf. *Coffea arabica*) and drunk. Sometimes the caps are eaten raw and washed down with Coca-Cola. Occasionally, they may be dried and smoked (Cox 1981).

The effects of the mushroom are manifested quite rapidly, as they usually contain a preponderance of psilocin, i.e., the actual active component. It produces strong feelings of euphoria with visual and auditory hallucinations that may last as long as seven hours. Very high dosages can result in loss of muscle control. In Samoa, it is said that regular use of the mushroom will produce a painful red rash around the neck (Cox 1981). This may be due to the presence of urea (Stivje 1987, 1992).

“The blue meanie is the perfect alchemist: it transforms dung into gold, into the golden light of enlightenment.”

GALAN O. SEID

DIE NEUE ALCHEMIE [THE NEW ALCHEMY]

This illustration, inspired by the use of mushrooms, clearly depicts jambur mushrooms (*Panaeolus cyanescens*) at work inside the figure's head. (Indonesian batik, twentieth century)

Panaeolus subbalteatus Berkeley et Broome

Dark-rimmed Mottlegill

Family

Coprinaceae (Ink Caps); Subfamily Panaeoloideae

Synonyms

Panaeolus cinctulus Bolt.

Panaeolus subbalteatus (misspelling!)

Panaeolus subbalteatus (Berk. et Br.) Sacc.

Panaeolus venenosus Murr.

Folk Names

Dunkelrandiger düngerling, gezondeerde vlek plaat (Dutch), gezonter düngerling, magusotake (Japanese, “horse pasture mushroom”)

This fungus is common throughout Europe and is also found in the subtropics and tropics (Asia, the Americas). It thrives in fields fertilized with manure, in grassy soil, and especially in horse pastures and in connection with horse manure. Its somewhat convex cap quickly becomes plane and is 2 to 6 cm in diameter. It is initially moist and brown but fades in the center as it dries, so that the margin often appears much darker (which accounts for its German name *dunkelrandiger düngerling* (“dark-banded dung mushroom”). The reddish brown lamellae are emarginate and later turn black because of the spores. This species is easily confused with the changing pholiota (*Kuehneromyces mutabilis* [Schaeff. ex Fr.] Sing. et Smith) (Roth et al. 1990, 95**).

No traditional uses of this mushroom are known. It is possible that it was used as an additive to the **mead** or **beer** of the Germanic peoples. The mushroom does have a symbiotic connection to the horse, the sacred animal of Wotan, the Germanic god of ecstasy.

Panaeolus subbalteatus contains approximately 0.7% **psilocybin** and 0.46% baeocystin along with large amounts of serotonin and 5-hydroxytryptophan, but it does not contain psilocin (Gartz 1989). It is questionable whether serotonin can in fact reach the brain when the mushrooms are ingested. Experimental pharmacology has demonstrated that serotonin is not absorbed by the brain when ingested orally. Nevertheless, according to all reported experiences, the effects of *Panaeolus subbalteatus* differ from the effects of mushrooms that contain only **psilocybin**; they are more empathogenic and aphrodisiac and yet still visionary. The individual visions can be observed for longer periods of time and contemplated at a leisurely pace. Psychoactive effects are produced by as little as 1.5 g dry weight (Stein 1959); a visionary dosage is 2.7 g. The psychoactivity of this mushroom was discovered following its accidental ingestion (Bergner and Oettel 1971).

Panaeolus subbalteatus is found chiefly in the immediate vicinity of horse stud farms. (Photographed near the Externsteine, a series of standing stones)

The cover of this CD by Shaw Blades, with the telling title *Hallucination*, features specimens of *Panaeolus subbalteatus* in the right foreground. (Warner Bros. Records, 1995)

“*Panaeolus subbalteatus* is the classic Druid mushroom.”

DANIEL DELANEY (4/1996)

“Horse manure also has a chance in the time of the giant mushrooms.”

HAIKU BY KOBAYASHI ISSA

Panaeolus spp.

Panaeolus Mushrooms

Family

Coprinaceae (Ink Caps); Subfamily Panaeoloideae The cosmopolitan genus *Panaeolus*, with more than twenty species, forms fragile fruiting bodies that are small to medium in size. The caps are usually hemispheric to campanulate. The pale lamellae become increasingly dark as the black spores develop. *Panaeolus* mushrooms grow on nutrient-rich, grassy soils or dung.

Panaeolus acuminatus (Schaeffer) Quélet sensu Ricken [syn. *Panaeolus rickenii* Hora]

Found in North America; said to be psychoactive, although no analyses have detected **psilocybin** or psilocin.

Panaeolus africanus Ola'h—African panaeolus

Found from central Africa to Sudan; thrives in rhinoceros and elephant dung. It contains various quantities of **psilocybin** and psilocin.

Panaeolus antillarum (Fries) Dennis sensu Dennis [syn. *Panaeolus phalaenarum* (Fr.) Quélet, *Panaeolus sepulcralis* Berk., *Anellaria sepulchralis* (Berk.) Singer]—Antilles panaeolus

While this mushroom is regarded as psychoactive, it does not always contain active substances (Merlin and Allen 1993**).

This old English illustration of “poisonous mushrooms or those that are usually not eaten” may represent a *Panaeolus* species with a wavy cap. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

Panaeolus ater (Lange) Kühner et Romagnesi—black panaeolus

Now considered to be a synonym for *Panaeolus fimicola*.

Panaeolus cambodginiensis Ola'h et Heim [syn. *Copelandia cambodginiensis* (Ola'h et Heim) Singer]—gold top

Contains 0.55 to 0.6% **psilocybin** and psilocin (Merlin and Allen 1993).

Panaeolus castaneifolius (Murrill) Ola'h [syn. *Panaeolina castaneifolius* (Murr.) Smith]

Contains traces of active compounds.

Panaeolus cinctulus Bolt.

Regarded as a synonym for *Panaeolus subbalteatus*.

Panaeolus fimicola (Fries) Gillet [syn. *Panaeolus ater* (Lange) Kühner et Romagnesi]

Found in Africa, the Americas, and Europe; contains only trace amounts of **psilocybin** and psilocin (Roth et al, 1990, 95**). This small, reddish to brown-black mushroom (cap 2 to 4 cm across) thrives

in grassy forest areas.

***Panaeolus foenisecii* (Fries) Kühner [syn. *Panaeolina foenisecii* (Pers.: Fr.) Maire = *Panaeolus foeniseci* (Pers.: Fr.) Schroeter]—haymaker’s panaeolus**

This cosmopolitan mushroom grows in central Europe from spring until fall on freshly mown meadows, along roadsides, and in pastures. Not all samples have been found to contain **psilocybin** (Allen and Merlin 1992; Gartz 1985a).

***Panaeolus olivaceus* Møller**

A Finnish sample was found to contain **psilocybin**.

A tropical *Panaeolus* species that thrives on cow dung and has psychoactive effects. (Photographed in Belize)

It is uncertain whether *Panaeolus papilionaceus* [syn. *Panaeolus campanulatus*, *Panaeolus sphinctrinus*] is psychoactive. (Photographed near the Externsteine, a series of standing stones)

***Panaeolus papilionaceus* (Bull. ex Fries) Quélet [syn. *Agaricus callosus* Fr., *Agaricus (Panaeolus) sphinctrinus* Fries, *Panaeolus campanulatus* (Fries) Quélet, *Panaeolus retirugis* (Fries) Quélet, *Panaeolus sphinctrinus* (Fries) Quélet]**

This mushroom is quite variable, which is why it was formerly divided into different species that are now regarded as synonymous. It apparently occurs in different chemical races; some of these contain **psilocybin**, while others are lacking in psychoactive substances. Serotonin has also been detected (Gartz 1985b). It grows in pastures, in nutrient-rich meadows with dung deposits, and directly on dung. It is found throughout the world, including central Europe.

In Japan, this mushroom is known as *warai-take*, “laughing mushroom” (cf. *Gymnopilus* spp.). In ancient China, it was called *hsiao-ch’ün*, which has the same meaning. Consumption of the mushroom was known to result in “excessive laughter” (Li 1975, 175*).

During his attempts to find the Mexican magic mushroom, Richard Evans Schultes identified as *teonanacatl* a variety of this species: *Panaeolus campanulatus* L. var. *sphinctrinus* (Fries) Bres. [syn. *Panaeolus papilionaceus*] (Schultes 1939**). The psychoactivity of this species, however, is doubtful.

In addition to the fly agaric mushroom (*Amanita muscaria*), Graves regarded *Panaeolus papilionaceus*, which is “still used by Portuguese witches,” as an additional candidate for the divine ambrosia and nectar (1966, 45*). To support his hypothesis, he cited a number of myths and works of art, including an Attic vase that depicts Nessus, the centaur. A mushroom can be seen sprouting from between his hooves. This fungal ambrosia later became the sacrament of the Eleusinian and Orphic mysteries. Graves even etymologically associated the word *kekyon* (= **kykeon**; cf. *Claviceps purpurea*) with the word *mykon* (“mushroom”). In Greek folklore, mushrooms are still referred to as the “food of the gods” (Ripinsky-Naxon 1988, 5*).

***Panaeolus semiovatus* Fries (Lundell) [syn. *Panaeolus separatus* Gillet, *Anellaria separata* Karst.]**

Found throughout North America; may contain **psilocybin**.

***Panaeolus tropicales* Ola’h [syn. *Copelandia tropicales* (Ola’h) Sing. et Weeks]—tropical panaeolus**

Found in tropical regions of Hawaii, central Africa, and Cambodia (cf. *Panaeolus cyanescens*).

Panaeolus papilionaceus is a common species found throughout the world. (From Winkler, 2000 *Pilze selber bestimmen* [Identify 2000 Fungi Yourself], 1996**)

Pluteus spp.

Pluteus Species

Family

Pluteaceae (Pluteus Mushrooms)

The small- to medium-size pluteus mushrooms have more or less plane to convex caps. They are well represented in Europe (Singer 1956). Many species are considered edible. Some have been found to contain **psilocybin** and baeocystin (Allen et al. 1992**; Gartz 1986; Stamets 1996**).

Pluteus cervinus (Schaeff.) P. Kumm.

This species, the fawn pluteus, is now seen as synonymous with *Pluteus atricapillus* Singer. In Europe, the fawn pluteus is regarded as edible. It is doubtful whether the fruiting bodies of *Pluteus cervinus* contain psychoactive substances. According to Allen et al. (1992, 93**), the species does contain **psilocybin**.

Pluteus cyanopus Quélet

This small species is found throughout central Europe. It develops a greenish blue color at the base of its stem. The mushroom is regarded as “somewhat poisonous” because it contains **psilocybin**.

Pluteus nigriviridis Babos

This pluteus species has been found to contain **psilocybin** (Stijve and Bonnard 1986).

Pluteus salicinus (Persoon ex Fries) Kummer—willow pluteus

This somewhat uncommon grayish mushroom, which usually appears alone, has a convex cap that later becomes plane. The center of the cap is scaly. In Europe, it grows from early summer to fall on deciduous wood. It contains the psychoactive substances **psilocybin** and baeocystin (Gartz 1987). North American samples have yielded psilocybin and psilocin (Saupe 1981).

A nonblueing variety is known by the name *Pluteus salicinus* var. *achloes* Sing. (Saupe 1981, 783).

Pluteus villosus Bull. [syn. *Pluteus ephebeus* (Fr.: Fr.) Gillet, *Pluteus murinus* Bres., *Pluteus lepiotoides* A. Pearson, *Pluteus pearsonii* P.D. Orton]

In central Europe, this species thrives on decaying deciduous wood from early summer to fall. It purportedly contains **psilocybin**.

The fawn pluteus (*Pluteus cervinus*). (From Winkler, 2000 *Pilze selber bestimmen*, 1996**)

“*Polyporus mysticus*”

Polypore Species

“The delicious aroma of the polyporus of the birch tree (*Polyporus betulinus*) increases the smoker’s enjoyment, which is why it is mixed into the tobacco.”

LIPPINCOTTS MAGAZINE (PHILADELPHIA, 1888)

IN *DER UNRAT IN SITTE, BRAUCH, GLAUBEN UND GEWOHNHEITSRECHT DER VÖLKER* [FILTH IN THE CUSTOMS, TRADITIONS, BELIEF, AND COMMON LAW OF PEOPLES] (BOURKE 1996, 68**)

Classification

- Order Poriales (Aphyllophorales):
- Family Polyporaceae (Pore Fungi)
- Family Ganodermataceae (Lacquer Fungi)
- Family Poriaceae

A variety of evidence and numerous hypotheses suggest that there may be at least one as yet unidentified psychoactive polypore. Here, I have given this polypore the nickname *Polyporus mysticus*. But there is also evidence that well-known polypore species, such as the birch polypore and the larch polypore, have psychoactive effects and have found use in shamanic contexts.

The sensational and still somewhat controversial discovery of Ötzi, a 5,300-year-old mummy found in a glacier (known popularly as Glacier Man, Adam of the Alps, Frozen Fritz, and Homo tyrolensis), indicates that polypores may have played a ritual or shamanic role among pre-Germanic peoples (Heim and Nosko 1993; Rätsch 1994). With him, Ötzi carried two dried mushrooms attached to a string. The mushrooms have been identified as either the birch polypore (*Piptoporus betulinus* [Bull. ex Fr.] Karst. [syn. *Polyporus betulinus* Karst., *Ungulina betulina* Pat.]) or the larch polypore (*Laricifomes officinalis* [Vill. ex Fr.] Kotl. et Pouz. [syn. *Polyporus officinalis* Fr., *Boletus laricis* Jacq.]) (cf. **silphion**). They were initially interpreted as “tinder fungi”:³⁷¹

The two specimens from the Hauslabjoch were cut from the fruiting body of the birch polypore [*Piptoporus betulinus*]. The result was very surprising to us, as we had actually assumed that this was tinder material. The birch polypore, however, is not suitable for this purpose, as its tissue is difficult to set afire. We must thus look for the solution of this problem on another level. (Spindler 1993, 132)

Then a sensational press release made its way through the newspapers. A mycologist from Innsbruck, Reinhold Pöder, told the science editor of the weekly newsmagazine *Stern* that he had found LSD-like substances, i.e., **indole alkaloids**, in the first of the mushrooms he had studied:

The newest evidence for the shamanic thesis was discovered by Dr. Reinhold Pöder of the University of Innsbruck. . . . The microbiological analysis . . . revealed: the two tree fungi that Ötzi was carrying were not for making fire at all. “The fungi are hallucinogenic,” Dr. Pöder stated over the marble-size pieces from the genera of the larch and birch polypores. Among Ötzi experts, the discovery of this Stone Age relative of LSD is regarded as a minor sensation. (Scheppach 1992, 22)

Following this news, the yellow press (e.g., the *Hamburger Morgenpost*) stamped Ötzi as a junkie. The psychedelic scene celebrated him as a primordial shaman (Rätsch 1994):

There are several things that suggest that he may have been a shaman . . . , especially the dried pieces of birch polypore that, strung onto a strip of leather, he also carried with him. The latter is a tree fungus that is used for medicinal and spiritual purposes (“spirit bread”) in a number of shamanistic cultures, e.g., among the Haida Indians. The assertion that this tree fungus could contain a hallucinogen, i.e., an inebriating substance (which would fit the shamanic hypothesis without a problem), is plausible but is avoided in the scientific report on the fungal finds. (Scheidt 1992, 100)

The official scientific report on the mushrooms ignored the sensational news of the presence of a “Stone Age LSD” and degenerated into a trivial discussion:

What could have led a person 5,000 years ago to collect birch polypores and tie these to a strip of leather? At this time, it is hardly possible to suggest an appropriate answer to this question. The . . . evidence for the “medicinal and spiritual use of polypores,” however, suggests that the discussions about such a use may be merited. The investigation of the second piece of “tree fungus” may provide additional information. (Pöder et al. 1992, 318)

Later, the head of the Innsbruck research project cautiously wrote:

A few apocryphal places in the literature on this matter have drawn attention to a purported hallucinogenic effect of the birch poly-pore. To date, however, this supposition has not received either medical or pharmaceutical support. Therefore, at the present time, they should not yet be taken into consideration in discussions pertaining to the meaning that the tree fungi had for the man in the ice. (Spindler 1993, 133)

Among the Indians of the Pacific Northwest, polypores were directly related to shamanism. They are said to have been used as a **snuff** for healing rituals, and shamans are said to have carved the fruiting bodies of *Fomitopsis officinalis* into the shapes of protective spirits to watch over graves (Blanchette et al. 1992). The Indians of the northwestern coast used birch polypores, which they called “spirit breads,” in shamanic contexts as a trance-inducing snuff (Andrew Weil, pers. comm.).

The larch polypore (*Laricifomes officinalis* = *Fomitopsis officinalis* [Vill. ex Fr.] Bond. et Sing.) formerly was made into an *elixier de longue vie*, “elixir of long life,” together with aloe (*Aloe* sp.), gentian (*Gentiana lutea* L.), Levantine saffron (***Crocus sativus***), rhubarb (*Rheum officinale* Baill.), and **theriac** (Chapuis 1985, 111).

In the seventeenth century, Jesuits reported that the Yarimagua Indians of the Peruvian Amazon prepared an inebriating drink from “fungi that grow on fallen trees”:

These appear as reddish, pungent-tasting growths on fallen trees. It was so strong that no man who took three draughts of the brew was able to resist its effects. The fungus was considered to be *Psilocybe yungensis* Singer and Smith [cf. ***Psilocybe* spp.**]. But because gym species are reddish and also settle on compact trunks, they are more likely candidates for this ominous tree fungus. . . . The red tree species was probably a close relative of *Gymnopilus purpuratus*. (Gartz 1993, 57 f.**)

The Indians of the Pacific Northwest (e.g., the Haida) used the polypore *Fomitopsis pinicola* for medicinal and shamanic purposes. (Photographed near Seattle, Washington)

The birch polypore (*Piptoporus betulinus*) was once used as a medicinal drug. It was one of the few objects found with the glacier mummy known as Ötzi. According to a statement by a mycologist from Innsbruck, it was a type of “Stone Age LSD.” The statement was later retracted. (Photographed at Duvenstedter Brook, Hamburg)

“The earth came forth from a tree fungus, ‘as from an egg.’ More precisely: The egg-shaped tree fungus parted in the middle: the upper part ascended and became the heavens, the lower became the earth. From the two halves of *alonkok*, as the tree fungus was called, came all the things that are visible: the stars, the sun, mountains, rivers, plants, animals, and the ‘primordial mother,’ which was also called *alonkok*. In a separate egg lay the lightning; this is how the primordial mother came to have fire. She bore two pairs of twins, the first were called ‘Mud Hill’ (Nkombodo) and ‘Great Mountain’ (Odangemeko), the second was Mebere [‘Highest Being’] and his sister.”

MYTH OF THE PANGWE OF THE AFRICAN CONGO IN *DIE GÖTTER SCHWARZAFRIKAS* [THE GODS OF BLACK AFRICA]

(BONIN 1979, 193 f.*)

The polypore *Ganoderma lucidum* has been identified with the legendary Chinese mushroom of immortality. (From an old Chinese herbal)

Ott (1993, 316*) also considers it possible that this tree fungus was a *Gymnopilus purpuratus* that thrived on wood (cf. ***Gymnopilus spp.***). But it may also have been a polypore. Ian Watson (1983) has written an outstanding science-fiction novel about an Indian mushroom cult in Amazonia. His description is based upon the Jesuit accounts.

Many travelers and researchers have reported psychoactive mushroom use in the Amazon, often in connection with **ayahuasca** (Leginger 1981*; McKenna 1989*; McKenna and McKenna 1994*; Ott 1993, 316*). One indication that these reports may indeed be based in truth comes from the Paumari Indians of central Amazonia, who refer to polypores as *badiadimurobuni*, “the ear of the spirit” (Pance et al. 1977, 129*).

It was recently discovered that in Amazonia (Ecuador), the powdered fruiting body of a *Ganoderma* species is mixed with tobacco (***Nicotiana tabacum***) and smoked. According to the descriptions of indigenous shamans, this **smoking blend** has an **ayahuasca**-like effect (Paul Stamets, pers. comm.).

The Makai Indians of Paraguay use the fruiting bodies of various polypores (*Dedalea elegans* Fries, *Polyporus guaraniticum* Speg., *Pycnoporus sanguineus* [Fries.] Murr.) as **incense** to pacify crying children (Arenas 1987, 287*). The Siberian Khanty (= Ostyak) used a mixture of tinder fungus (*Fomes fomentarius* [Fr. ex L.] Kichx.) and the bark of the silver pine (*Picea obovata* Ledeb. or *Abies sibirica* Ledeb.) as a ritual **incense** when a person had died, burning the incense until the corpse had been removed from the house (Saar 1991, 177**).³⁷² The Khanty also used the polypore *Inonotus obliquus* (Fr.) Pilát as an incense. They burned the fruiting bodies of the polypore *Phellinus nigricans* (Fr.) Karst., which thrives on birches (*Betula* spp.), and mixed the ashes with ground wild tobacco (***Nicotiana rustica***) to produce a narcotic chewing tobacco (Saar 1991, 178**).

In Alaska, the polypores *Fomes igniarius* (Fr. ex L.) Kichx. and *Fomes fomentarius* (Fr. ex L.) Kichx. allegedly are smoked or sniffed in combination with ***Nicotiana spp.*** for their narcotic properties (Ott 1978, 234**).

In Chignahuapan (Puebla, Mexico) is a church known as the Iglesia de Neustro Señor del Honguito

(Church of Our Lord, the Mushroom). Built especially for the *honguito*, this church preserves as a relic the fruiting body of a mushroom that is said to bear the mark of the hand of Jesus. This mushroom, which has been identified as *Ganoderma lobatum* (Schw.) Atk., is believed to have miraculous and healing powers. It has been suggested that this folk church cult may preserve elements of entheogenic mushroom rituals from the pre-Spanish period (Guzmán et al. 1975).

Paul Stamets has suggested that **soma** may have been a psychoactive polypore that has not yet been discovered and described.

Many ancient Chinese myths and traditions concerning the *ling-shih* (also *ling chih*, *lingzhi*), or the mushroom of immortality, now usually identified mycologically as the lacquer fungus (*Ganoderma lucidum* [Fr.] Karst.),³⁷³ suggest that this mushroom has potent psychoactive effects (Camilla 1995a, 1995b; Rätsch 1996). It is said to grow on a mysterious island in the East (probably the South Korean shaman's island of Chejudo). The effects of this magic mushroom have been described as fantastic:

The Isle of Tsu lies close by, in the eastern sea. It is there that the plant that does not die grows, shaped like a piece of seaweed with leaves that are up to four feet in length. A man who has already been dead for three days will immediately awaken to a new life if he is touched by it. If you eat of it, it will extend your life. . . . When dead bodies lay around on the side of the road, birds like ravens or crows would fly by with the miraculous plant in their beaks, which they laid upon the faces of the corpses. These immediately stood up and became alive once more. (*Shih chou chi*)

The Taoist alchemists later numbered the *lingzhi* among a group of “five wondrous fungi of immortality”—corresponding to the five signs of happiness (Imazeki and Wasson 1973, 6**). The mysterious elixir of immortality was prepared from these fungi, which probably included the fly agaric (*Amanita muscaria*) and other psychedelic magic mushrooms (such as the “nine stemmed, purple-red mushroom”), together with cinnabar and jade. Those recipes that have come down to us have not yet been tested (Michel Strickman, pers. comm.; cf. **han-shi**).

Ganoderma lucidum has been very well studied but has not yet yielded any evidence indicating any possible psychoactive effects or psychoactive constituents (Laatsch 1992). It does contain bioactive triterpenes and ganodermic acids (Lin et al. 1988).

The Japanese furry polypore *Inonotus hispidus* (Bull. ex Fr.) Karst. [syn. *Polyporus hispidus* Bull. ex Fr.], also known as the Japanese laughing mushroom (cf. *Gymnopilus* spp.), contains hispidin, a substance that is chemically closely related to the kavains (see *Piper methysticum*) and the longistylines (see *Lonchocarpus violaceus*) (H. Laatsch, pers. comm., July 1, 1986). *Polyporus berkeleyi* Fries has been shown to contain the β phenethylamine hordenine, which is also found in many psychoactive cacti (*Ariocarpus fissuratus*, *Coryphantha* spp., *Pelecypora aselliformis*, *Trichocereus* spp.) (Ott 1978, 234**).

One species of polypore, the sulfur fungus (*Laetiporus sulphureus* [Bull. ex Fr.] Bond et Sing. [syn. *Boletus sulphureus* Bull., *Boletus caudicinus* Scop., *Cladomeris sulphurea* Quél., *Polyporus caudicinus* Köhl., *Polyporus sulphureus* Fr.]),³⁷⁴ has become known for having induced strong tryptamine-like hallucinations in at least one clinically documented case (Appleton 1988). Otherwise, it has been said that “used as a snuff, [it] can be described as a weak disinfectant” (Chapuis 1985, 111).

“Once an ancient peach tree stood for many years in a marsh in the deep mountains. It eventually became rotten and died. I am a mushroom that sprouted from its trunk. For many years I grew on a tree trunk, becoming larger and larger, until I had truly become an important mushroom. One day a beautiful small bird flew by and sat in the branches of the tree, where it sang with its beautiful chirping voice. Watching it, I at first found it to be simply pretty, but then I felt an urge to eat it. I had such a terribly great desire to eat, eat, eat it that while I was looking at it, I suddenly had eyes and a mouth and gulped it down and swallowed it. . . . With time the tree decayed and crumbled. I broke off from its stump and crawled around, then I grew arms and legs and I could walk.”

Psilocybe azurescens Stamets et Gartz

Indigo Psilocybe

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe, Caerulescentes or Cyanescens Section

Synonyms

Psilocybe astoriensis nom. nud.

Psilocybe cyanescens Ossip nom. nud.

Folk Names

Astoriensis, azureus-kahlkopf, blue runner, flying saucer mushroom, indigo psilocybe

The history of *Psilocybe azurescens* is very new and mysterious. This mushroom was only recently discovered:

In 1979, Boy Scouts found an unusually large and strongly blueing *Stropharia* near the city of Astoria in the state of Oregon, close to the mouth of the majestic Columbia River. Stem lengths of up to 20 cm (!) and caps as broad as 10 cm were no rarity. By 1981, the mushroom was being grown outdoors on wood chips or cow mulch, methods that were originally developed for *Psilocybe cyanescens* and have been described in detail elsewhere (Gartz 1994). Soon these “new” mushrooms, which proved to be potently psychoactive, were called “*Psilocybe astoriensis*” (Gartz, in Rippchen 1993[**]), although no mycological description with a valid Latin diagnosis was published. (Gartz 1996, 189)

The initial description by Paul Stamets and Jochen Gartz was not published until 1995. This largest species of the genus *Psilocybe* grows on the remains of wood in the coastal region of Oregon and Washington, where it fruits in the fall (from the end of September to the beginning of November). Of all the *Psilocybe* species, this one spreads the most aggressively. “The mushroom even grew spontaneously on wooden clothespins that were lying about” (Gartz, in Rippchen 1993, 72**).

This mushroom is quite similar to *Psilocybe cyanofibrillosa* Stamets et Guzmán (cf. ***Psilocybe* spp.**) but is also easily confused with the sulfur tuft (*Hypholoma fasciculare* [Hus.: Fr.] Kummer).

The spore print can germinate on an agar surface within three days. Cultivating the mycelium is best done on a substrate of rye. Unfortunately, in Germany the cultivated mushrooms commonly do not fruit (B. Schuldes 1995).

Psilocybe azurescens can develop caps that are 10 cm in diameter and stems that are as long as 20 cm. Because it was discovered only at the end of the 1970s, it has been speculated that this is a new species that only recently evolved. It grows in a habitat that is very untypical for members of the *Psilocybe* genus. It thrives on sandy soil close to the ocean, usually in association with the grass *Ammophila maritima* (cf. ***Claviceps* spp.**). The mushroom quickly spread from Astoria and will certainly soon be common in the entire Pacific Northwest. It is the most potent member of the genus *Psilocybe*.

The indigo psilocybe (dry weight) contains 1.29 to 1.78% **psilocybin**, 0.18 to 0.37% baeocystin, and

0.27 to 0.5% psilocin. The alkaloid concentration is almost consistently the same among mushrooms that have been collected in the wild, those that have been cultivated in Washington state, and those that have become feral in Germany (Stamets and Gartz 1995, 23).

An experiential report written by a mycologist clearly demonstrates the potent effects of *Psilocybe azurescens*:

Psilocybe azurescens, which resembles a flying saucer (photographed in its type locality [natural habitat] near Astoria, Oregon)

To my surprise, the mushroom powder (1 gram) in the mixture of orange juice was tasteless, which I found positive in comparison to earlier experiments with *Psilocybe semilanceata* and *Psilocybe cubensis*. After some 20 minutes, the effects suddenly began in such a way that my body immediately dissolved into pure energy. This sensation of a remaining, isolated soul without a Christian/ church context that existed somewhere and sometime was extremely impressive. There began a journey through historical periods that was without precedent for me. The coarse structure of the white ceiling of the room dissolved completely, as when cobwebs are brushed aside, and a stage opened up. A multitude of historical events and experiences that my soul experienced as totally real alternated in quick succession. Once, the room was transformed entirely into the style of an ancient Egyptian tomb, and I lay in the center, which provoked a moment of sudden terror, for it had an absolute character of being real. But generally this flight through historical times took place in an essentially peaceful and meditative mood with many experiences of a transpersonal nature, as [Stanislav] Grof has described in detail. Personal problems no longer existed.

After some 5 hours, this journey beyond time and space ended with the rather abruptly developing sensation that my body and its union with the free-floating soul had been created anew. Aside from a certain tiredness, no other aftereffects were observed. During the following day, there was a very pleasant sensation of a special freshness of spirit that then slowly dissipated. (Gartz 1996, 91)

“A cold weather–tolerant species, *P. azurescens* is one of the most potent species in the world and exhibits one of the strongest bluing reactions I have seen.”

Psilocybe (Stropharia) cubensis (Earle) Singer

Magic Mushroom, Divine Dung Mushroom, Golden Cap

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe, Cubensae Section

Forms and Varieties

The recently described species *Psilocybe subcubensis* may possibly be merely a subspecies or variety of *P. cubensis* (cf. ***Psilocybe* spp.**). Three varieties have been described:

Psilocybe cubensis var. *caerulescens* (Murr.) Singer et Smith

Psilocybe cubensis var. *cubensis*

Psilocybe cubensis var. *cyanescens* (Murr.) Singer et Smith

Synonyms

Hypholoma caerulescens (Pat.) Sacc. et Trott.

Naematoloma caerulescens Pat.

Psilocybe cubensis var. *caerulescens* (Murr.) Singer et Smith

Stropharia cubensis Earle

Stropharia caerulescens (Pat.) Sing.

Stropharia cyanescens Murr.

Stropharia subcyanescens Rick.

Folk Names

Champiñon, derrumbe de estiércol de vaca (Spanish, “abyss of the cow patties”), di-ki-sholerraja, dishitjolerraja (Mazatec, “divine dung mushroom”), divine dung mushroom, golden top, gold top, göttlicher düngerpilz, hed keequai (Thai), hongo de San Isidro, hongo maravilloso, honguillos de San Isidro Labrador (“mushroom of Saint Isidro the Farmer” [= the saint of agriculture]), hysteria toadstool, kubanischer kahlkopf, kubanischer träuschling, lòl lú’um (Yucatec Mayan, “flowers of the earth”), magic mushroom, nocuana-be-neeche (Zapotec), nti-xi-tjolencha-ja (Mazatec, “mushroom like that which grows on cow patties”), San Isidro, San Isidro Labrador, tenkech (Chol), tenkech (Chol: Panlencano), teotlaquilnanácatl (modern Nahuatl, “the sacred mushroom that paints in colors”), zauberpilz

The tropical *Psilocybe cubensis* (= *Stropharia cubensis*) prefers to live on cow dung. (Photographed in Palenque, Chiapas, Mexico)

“Ample evidence supports the notion that *Stropharia cubensis* is the Ur plant, our umbilicus to the feminine mind of the planet, which, when its cult, the Paleolithic cult of the Great Horned Goddess, was intact, conveyed to us such knowledge that we were able to live in a dynamic equilibrium with nature, with each other, and within ourselves. Hallucinogenic mushroom use evolved as a kind of natural habit with behavioral and evolutionary consequences. This relationship between human beings and mushrooms had to have also included cattle, the creators of the only source of the mushrooms.”

TERENCE MCKENNA *FOOD OF THE GODS* (1992, 39)

History

Psilocybe cubensis (Earle) Sing. (= *Stropharia cubensis* Earle), known internationally by the names magic mushroom and golden cap, is originally from Africa. It thrives on cattle dung and in meadows with deposits of dung. In symbiosis with African cattle, it has spread around the world, although it grows only in tropical or subtropical areas. Terence McKenna believed that this psychoactive mushroom exerted an important influence upon human evolution. According to his theory, consuming these mushrooms resulted in a “mental quantum leap” that transformed our apelike ancestors into “intelligent beasts” with a greater ability to survive. This psychedelic “primordial experience” led to the development of the first mystical mushroom rituals, which formed the basis for shamanism, mythologies, and religions (McKenna 1996*). It has even been suggested that this mushroom was the original **soma**.

This mushroom was first found in Cuba (hence its species name *cubensis*, “Cuban”). The Englishman S. Baker provided the first description of its traditional use in Ceylon (Sri Lanka) (*Eight Years in Ceylon*, London, 1855 [1884]). The shamanic use of *Psilocybe cubensis* in Mexico was discovered during research into the magic mushrooms of Mexico (cf. ***Psilocybe mexicana***). There, it is known as *hongo de San Isidro*, “mushroom of Saint Isidro.” Among the Mazatec Indians, Saint Isidro is the patron saint of fields and meadows, the same locales in which this mushroom—which is exclusively coprophilous—is found (Heim and Hofmann 1958a).

Because this mushroom is frequently found in Palenque (Mexico), it has been suggested that the ancient Maya may have used it as an entheogen. Before the Spanish, however, there were no cattle in the Americas, and the mushroom requires their dung to grow. All of the evidence suggests that *Psilocybe cubensis* was introduced into Mexico during the late colonial period (Coe 1990).

In Thailand, *Psilocybe cubensis* is now the most commonly offered mushroom on the vacation islands of Koh Samui and Koh Pha-Ngan (Allen 1991; Allen and Merlin 1992a, 1992b). The omelets made with this mushroom are renowned. It is also common in Bali (Wälty 1981).

The fruiting bodies of *Psilocybe cubensis*, growing from the head of a mushroom user who has been enlightened from within. (Indonesian batik, twentieth century)

Appearance

The mushroom forms relatively large fruiting bodies with slightly convex caps that can grow as large as 8 cm in diameter. The caps usually have a yellow or golden color at their center.

Psilocybe cubensis can be distinguished from *Psilocybe subcubensis*, a Central American species known as *suntiamá*, only on the basis of the size of its spores (Guzmán 1994, 1472**).

Distribution

Psilocybe cubensis is found throughout the tropics wherever there is cattle or water buffalo breeding or ranching, including Mexico (Oaxaca, Chiapas), Cuba, Guatemala, Colombia, Bolivia, Brazil, Argentina, Florida, Thailand, Vietnam, Cambodia, Indonesia, the Philippines, and Australia. In tropical areas, the mushroom can fruit throughout the year. The mushrooms usually sprout from cow dung after it has rained.

Cultivation

Of all species of *Psilocybe*, this is the easiest to grow. The mushroom produces more **psilocybin**

when grown on malt agar (Gartz 1987). Fruiting occurs most readily when air humidity is high and the temperatures are tropically warm (24 to 34°C).

Harvest, Storage, and Consumption

In the tropics, the fruiting bodies of *Psilocybe cubensis* are easy to collect. During the harvest, however, certain things should be taken into consideration:

Although many people eat the fresh mushrooms right from the field, this unhygienic practice is to be discouraged. Some mushrooms grow directly on the dung and may possibly have particles of dung adhering to their flesh. For reasons of safety, the wise user should select only fresh, healthy specimens that are free of insects and avoid those that are rotting. Before consumption, [the mushrooms] should be washed thoroughly with water; the conscientious consumer will also cut off the lower end of the stem.

To store, the mushrooms are dried in the air at more or less room temperature (devices for drying food are also suitable; they can also be dried on a grate near a source of warmth). Overly long drying processes and high temperatures should absolutely be avoided. When the mushrooms are crispy, they should be filled into airtight containers. They can then be placed in a freezer. In this way, they can be stored for months with only a very slight loss of effectiveness. The mushrooms should not be frozen until they are completely dry (otherwise, they will quickly lose their effectiveness). They also should not be preserved in honey while fresh (this will result in a disgusting fermented mass). If the mushrooms are going to be stored for only a few days, it will suffice to place them in the refrigerator. . . .

The dried mushrooms are clearly not very easy to digest, especially when they have not been sufficiently mixed with saliva. Mixing the mushrooms with juice or chocolate breaks up the tissue and allows the psilocybin to more easily enter into solution. It goes without saying that the mushrooms should be mixed with these carrier substances only immediately prior to consumption. Some users prefer mushrooms that have been sautéed in butter and are eaten with toast or potato chips. Lightly sautéing them over a low flame will not seriously lower the psilocybin content (it may be better to fry fresh mushrooms, so that any toxic components that may be present, e.g., gyromitrine and other methylhydrazines, will be destroyed). (Ott 1996, 191 f.)

An effective dosage of *Psilocybe cubensis* is regarded as 3 to 5 g of dried mushrooms. The user may want to use different dosages for different purposes, ranging from mild psychostimulation produced by a small mushroom to a “full blast” or a psychedelic breakthrough (Terence McKenna’s famous “heroic” recipe calls for 5 g “on an empty stomach in total silent darkness”). *Psilocybe cubensis* is the psilocybin mushroom that is most commonly available on the black market (Turner 1994, 27*).

Magic mushrooms are usually consumed in fresh or dried form. With time, certain specific forms of ingesting the mushrooms have been developed: Dipped in **honey** or powdered, the mushrooms may be drunk with cacao (cf. *Theobroma cacao*). From time to time, the mushrooms are also eaten with chocolate (cf. Remann 1989, 248*).

In Thailand, the mushroom is dried and then smoked or baked into cookies together with hemp (*Cannabis indica*) (Allen and Merlin 1992b, 213). The fresh mushrooms are incorporated into dishes in the same way that normal culinary mushrooms are used.

Ritual Use

In central Europe, cultivated mushrooms are used in ritual circles in the same manner as ***Psilocybe semilanceata***. In Mexico, wild mushrooms growing on cow dung are used in shamanic rituals in the same manner as ***Psilocybe mexicana***.

In central Europe, this mushroom has also been used with success in private healing rituals (Strassmann 1996).

Artifacts

On the Thai “mushroom island” of Koh Samui, an entire T-shirt industry has arisen that offers tourists hand-painted T-shirts with mushroom designs (Allen 1991; Allen and Merlin 1992a). The mushroom is also frequently depicted on Indonesian batiks (cf. ***Panaeolus cyanescens***).

Constituents

The fruiting body contains a maximum of 1% **psilocybin** by dry weight. An analysis by Gartz (1994, 19**) found an average of approximately 0.6% psilocybin, 0.15% psilocin, and 0.02% baeocystin by dry weight. The quantity of active constituents is greater in the caps than in the stems (Gartz 1987).

Effects

As with all psilocybin mushrooms, *Psilocybe cubensis* produces strong visions that often feature shamanic characteristics:

The effects of the mushrooms [*Psilocybe cubensis*] began by manifesting themselves as waves of energy that ran through my body. I found the beauty that was proffered to my eyes to be even more valuable.

Suddenly a large snake glided toward me from the desert that surrounded us and slipped into my body. The next thing I noticed was that I myself had become the snake. No sooner had I gotten used to this condition than a large eagle descended and snatched me with its talons. My body shook from the blow, but I did not feel any pain. The eagle held me firmly in its clutches, ascended again, and flew directly into the sky until it had become one with the sunlight. My personal identity as a separate consciousness dissolved. The only thing that remained was the unity with the light. (Pinkson 1992, 144)

The American heavy-metal band The Big F was obviously inspired by the visionary powers of *Psilocybe (Stropharia) cubensis* when it named its album *Is*. Or is there another way to interpret this apparently mycological picture of magic mushrooms? (CD cover, 1993, Chrysalis Records)

“Did you know that it has been suggested that some ancient Indian brahman was unable to properly get his metaphor together, so that instead of declaring the mushroom that grows on the dung holy, he proclaimed holy the cow that produces the dung? Did you know that such misunderstandings also make it clear why it is indeed idolatrous to dance around the golden calf?”

Psilocybe cyanescens Wakefield emend. Kriegelsteiner

Wavy Caps

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe, Semilanceata = Cyanescens Section

Synonyms

Geophila cyanescens (Maire) Kühner et Rom.

Hypholoma coprinifacies (Rolland ex Herink) Pouzar

Hypholoma cyanescens Maire

Psilocybe bohémica Sebek (cf. ***Psilocybe* spp.**)

Psilocybe mairei Sing.

Psilocybe serbica Moser et Horak

Folk Names

Blaufärbender kahlkopf, blauwwordend kaalkopje (Dutch), blue halos, böhmischer kahlkopf, oink, wavy caps, zauberpilz, zyanescens

This mushroom is most easily recognized on the basis of its peculiar wavy cap. It lives not on dung but on the remains of plants, rotting wood, and humus-rich soils. In older mushroom guides, it often appears under the name *Hyphaloma cyanescens* (Cooper 1980, 18**). It is native to North America and central Europe and is found even in Hamburg (Findeisen 1982):

This species settles on wood chips, which are often lying directly on the ground, so that the mushroom appears to sprout directly out of the earth. It is found primarily in parks in the Pacific Northwest, often in fairy circles, in amounts of up to 100 pounds. These mushrooms are one of the most potent species known and contain psilocybin and psilocin in amounts of up to 2% dry weight. (Gartz in Rippchen 1993, 70*)

Gartz (1994, 19**) found that specimens grown in Germany contain approximately 0.3% **psilocybin**, 0.5% psilocin, and 0.01% baeocystin by dry weight.

In central Europe, *Psilocybe cyanescens* is used in rituals in precisely the same manner as ***Psilocybe semilanceata*** (Liggenstorfer 1996). Here, cultivated mushrooms that contain a very high concentration of psilocybin are consumed. A visionary dosage is regarded as 1 g dry weight.

This painting by the Swiss artist Fred Weidmann was inspired by *Psilocybe cyanescens*.

The very potent *Psilocybe cyanescens* is easily recognized by its undulating cap.

“Studying the surface structure of the mushroom, this wave-shaped cap with the skin of an elephant, I know that this must be an Oink. Of course, an Oink, it could not be anything else. Explaining to the ‘tour guide’ what these mushrooms are really called, he agrees that this

could only be an Oink! Since that time, this name for *Psilocybe cyanescens*, which was conceived of in a bemushroomed state, has been spreading like mycelia.”

ROGER LIGGENSTORFER

OINK, DER KOSMISCHE KICHERFAKTOR [OINK, THE COSMIC LAUGH FACTOR]

Psilocybe mexicana Heim

Mexican Magic Mushroom, Teonanacatl

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe, Mexicanae Section

Forms and Varieties

The following forms have been named (all nom. nud.!; Ott 1996):

Psilocybe mexicana f. *angulata-olivacea* Heim et Cailleux

Psilocybe mexicana f. *distorta-intermedia* Heim et Cailleux

Psilocybe mexicana f. *galericulata-convexa* Heim et Cailleux

Psilocybe mexicana f. *galericulata-viscosa* Heim et Cailleux

Psilocybe mexicana f. *grandis-gibbosa* Heim et Cailleux

Psilocybe mexicana f. *navicula-viscosa* Heim et Cailleux

Psilocybe mexicana f. *reflexa-conica* Heim et Cailleux

The variety *Psilocybe mexicana* var. *longispora* Heim, first proposed by Roger Heim, is now regarded as a synonym for *Psilocybe aztecorum* Heim (cf. ***Psilocybe* spp.**).

Folk Names

Alcalde, amokia, a-mo-kid (Chinantec), amokya, angelito (Spanish, “little angel”), a-ni, atkat, atka:t (Mixe), chamaquillo (Spanish, “little boy”), cuiya-jo-to-ki (Chatino), di-chi-to-nize (Mazatec), di-nize, hongo sagrado, kong, kongk (Mixe), konk, little bird, mbey-san (Zapotec), mexikanischer kahlkopf, mexikanischer zauberpilz, Mexican liberty cap, Mexican magic mushroom, nashwinmush (Mixe, “earth mushroom” or “world mushroom”), ndi-shi-tjo-ni-se (Mazatec), nize (Mazatec, “little bird”), pajarito (Spanish, “little bird”), piitpa, pi-tpa (Mixe), pi-tpi, pi:tpi, piule de churis,³⁷⁵ teonanacatl, teonanácatl (Aztec), teotlaquilnanácatl (Nahuatl)

History

Ethnohistorical sources indicate that *teonanacatl*, the “divine mushroom” or “flesh of the gods” (*Psilocybe mexicana* and other species of the genus *Psilocybe*), was being ritually consumed and used in religious ceremonies in Mexico before the arrival of the Spanish. During the colonial period, the indigenous use of the mushroom was forbidden and brutally suppressed by the Spanish Inquisition. In spite of this, the mushroom cult has survived underground even into the present day. The psychoactive use of *Psilocybe mexicana* in Indian shamanism was rediscovered at the end of the 1930s. In the late 1950s, it was found that the Mixe Indians of Coatlan, Oaxaca, also used *Psilocybe mexicana* for shamanic purposes (Hoogshagen 1959).

Psilocybe mexicana was the first mushroom in which Albert Hofmann discovered the LSD-like substances **psilocybin** and psilocin (Heim et al. 1958; Hofmann 1958, 1959).

Distribution

Psilocybe mexicana is found exclusively in Mexico (Michoacán, Morelos, Jalisco, Oaxaca, Puebla,

Xalapa, Veracruz) and Guatemala (Stamets 1996, 129 f.**). It grows in subtropical forests at altitudes of 1,000 to 1,800 meters and is found in the vicinity of liquidambar (*Liquidambar styraciflua* L.), oak (*Quercus* spp.), alder (*Alnus* spp.), and plane (*Platanus lindeniana* Mart. et Gall.) trees.

The historic culture of the Mexican magic mushroom (*Psilocybe mexicana*), photographed in the laboratory by Albert Hofmann. (Photograph: Brack)

Appearance

Albert Hofmann noted that *Psilocybe mexicana* can be recognized by its cap, which resembles a typical Mexican sombrero. It can grow up to 10 cm tall and has small bell- or hat-shaped caps (3 to 5 cm in diameter). In Mexico, it fruits from June to September.

Psilocybe mexicana can be confused with poisonous muscarinic *Inocybe* mushrooms, e.g., *I. geophylla* (Sow. ex Fr.) Kummer (cf. ***Inocybe* spp.**). It is also very similar to the species ***Psilocybe semilanceata*** and *Psilocybe pelliculosa* and is often confused with them (cf. ***Psilocybe* spp.**).

Psilocybe mexicana can be easily grown on a substrate of a *Lolium* species (cf. ***Lolium temulentum***).

The fruiting bodies can be consumed fresh or dried. Mexican Indians often ingest the mushroom together with **honey** or chocolate (cf. ***Theobroma cacao***). In former times, the mushrooms were steeped in pulque and drunk (cf. ***Agave* spp.**).

Carlos Castaneda's claim (1973*, 1975*) that these mushrooms are dried and then smoked for their psychedelic effects has been the subject of considerable controversy and is highly doubtful (Clare 1988**; Siegel 1981, 330*).³⁷⁶

Nanacatl, the Mexican magic mushroom (*Psilocybe mexicana* and *Psilocybe aztecorum*), shown here in the Florentine Codex, the Azteclanguage chronicle of Sahagun (Paso y Troncoso edition).

Ritual Use

The literature from the colonial period contains numerous texts that provide information concerning the mushrooms, their effects, and their ritual and/or medicinal uses. The Florentine Codex, an early colonial chronicle by the Franciscan missionary Fra Bernardino de Sahagun, written in Aztec, reports:

Nanacatl. They are called teonanacatl, “flesh of the gods.” They grow in the flatlands, in grass. The head is small and round, the stem long and thin. It is bitter and scratches, it burns in the throat. It makes one foolish; it confuses one, it distresses one. It is a remedy for fever, for gout. Only two, three are eaten. It makes sad, depressed, distressed; it makes one run away, become afraid, hide. He who eats many of them sees many things that scare him and that make him happy. He runs away, hangs himself, throws himself from a cliff, screams, is afraid. It is eaten with honey. I eat mushrooms; I take mushrooms. It is said of one who is haughty, impertinent, vain that: “He has bemushroomed himself.” (Sahagun, Florentine Codex 11.7*)

Another Aztec text by Sahagun provides a rudimentary description of the mushroom ritual:

The first thing that one ate at such meetings was a black mushroom that they called nanacatl. It has inebriating effects, produces visions, and incites to obscene acts. They already take the thing

early on the morning of the festival day and drink cacao before they arise. They eat the mushrooms with honey. When they have made themselves drunk with these, they begin to become excited. Some sing, others cry, others sit in their rooms as if they were deep in sorrow. They have visions in which they see themselves die, and this hurts them bitterly. Others see scenes in which they are attacked by wild animals and believe that they are being eaten up. Some have beautiful dreams in which they believe they are very rich and possess many slaves. But others have quite embarrassing dreams: they have the feeling of being caught while committing adultery or of being wicked forgers or thieves who are now facing their punishment. They all have their visions. When the inebriation that the mushrooms produce is over, they speak of that which they have dreamed, and one tells the other about his visions. (Sahagun 9)

In his *Historia de las Indias de Nueva Espana*, the missionary Diego Duran noted several times that mushrooms were ingested at festivals and were “drunk like wine” (= pulque; cf. *Agave spp.*), although they were mixed with chocolate (cf. *Theobroma cacao*) (Wasson 1980**). Today, *Psilocybe mexicana* is still used by shamans of the Mazatec, Mixe, Zapotec, and Cuiclatec in a manner that is quite similar to its pre-Spanish use (Hoogshagen 1959; Lipp 1990; Miller 1966; Ravicz 1961).

Among the Mixe, the most important deity is the Earth Mother Naaxwin or Na:shwin (literally, “the eye of the earth”). The earth is regarded as the source of wisdom; the Earth Mother is omniscient and can see the past, present, and future. Since the mushrooms grow from the earth, they are regarded as extremely wise and full of knowledge. The Mixe originally believed that the mushrooms were born from the bones of primordial shamans and prophets. According to a different version of that belief, which was influenced by Christianity, the mushrooms are regarded as soothsayers because they are equated with the blood of Christ. It is said that as Jesus hung on the cross, blood flowed from his heart to the ground. Numerous flowers and edible mushrooms grew from this blood. Finally, the magic mushrooms emerged and supplanted the plants that had previously turned green. For this reason they are called *na:shwin mux*, “mushrooms of Mother Earth” (Lipp 1991, 187*). Accordingly, the messages of the mushrooms are known as the “voice of the Earth” (Mayer 1975, 604**).

Magic mushrooms are used primarily in ritual contexts by the mostly female shamans. They are eaten for divinatory purposes.³⁷⁷ They are used to recognize the causes of diseases, to predict the death and loss of family members, to localize lost objects, to uncover thieves and magicians, and to search for answers to familial problems. The mushrooms can also help in finding hidden treasures, discovering ruins, and experiencing ritual knowledge. The mushrooms normally speak Mixe, although they occasionally speak Zapotec as well (Lipp 1991, 187). Among the Mixe, the old pre-Spanish *tonalámatl* divination calendar is still in use. Some shamans use the mushrooms in conjunction with the calendar divination (Miller 1966).

Magic mushrooms³⁷⁸ can be harvested only in summer. It is said that they grow only on sacred ground. When a person encounters a mushroom, he should offer it three candles, kneel before it, and speak the following prayer:

Tum’Uh. Thou who art the queen of all there is and who was placed here as the healer of all sicknesses. I say to you that I will carry you from this place to heal the sickness I have in my house, for you were named as a great being of the earth. Forgive this molestation, for I am carrying you to the place where the sick person is, so that you make clear what the suffering is that has come to pass. I respect you. You are the master of all and you reveal all to the sick. (Lipp 1991, 189*)

The collected mushrooms are carefully placed on the house altar or stored in the village church for

three days. Incense (copal; cf. **incense**) is offered to them. They are consumed either fresh or sundried. For three days before ingesting the mushrooms, a person must remain abstinent from sex and refrain from eating poultry, pork, eggs, and vegetables. It also is forbidden to drink **alcohol** (mescal; cf. **Agave spp.**) or to use other drugs or medicines. During this time, a person should also refrain from agricultural activities. On the morning of the fourth day, he or she takes a bath and eats a light breakfast (of only foods made from maize; cf. **Zea mays**). He or she fasts for the rest of the day. On the morning after the session, the person must eat a large quantity of chili peppers (**Capsicum spp.**); he or she should abstain from meat and alcohol for the following month.

The mushrooms are always eaten in pairs and also dosed in pairs: three pair for children, seven pair for women, nine pair for men (Lipp 1991, 189 f.*). Sometimes only the caps are eaten (Mayer 1975, 604**). In each session, a person should eat mushrooms of just a single species, because mixing the species can result in unpleasant, i.e., threatening, visions. Two eggs are laid next to the mushrooms before they are eaten. At the same time, “copal”³⁷⁹ (incense; the resin of the palm *Acrocomia mexicana* Karw., from which **palm wine** is also obtained) is burned and a candle is lit. A prayer is offered to the mushrooms before they are eaten:

Thou who art blessed. I am now going to swallow you so that you heal me of the illness I have. Please give me the knowledge I need, thou, who knows all of what I need and of what I have, of my problem. I ask of you the favor that you only tell me and divine what I need to know but do nothing bad to me. I do not wish an evil heart and wickedness. I only wish to know of my problems and illness and other things that you can do for me. But I ask you, please do not frighten me, do not show me evil things but only tell all. This is for the person with a pure heart. You can do many things, and I ask you to do them for me. I now ask your forgiveness for being in my stomach this night. (Lipp 1991, 190*)

After the mushrooms are swallowed whole with water, one should be quiet. It is said that the mushrooms, like all other magical plants, do not like noise and will not speak if they feel disturbed. Normally the person who has eaten the mushrooms is accompanied by one or two friends or family members. They should pay attention to the things that the “bemushroomed” person says and fumigate him or her with copal smoke if problems arise. The visions that appear are shaped by culture. First one sees snakes and jaguars. After these have disappeared, the sun and the moon appear as a boy and girl, the children of the wind and the Earth Mother. Often, the “bemush-roomed” person only hears voices that give advice, provide diagnoses, or ask about the reasons for ingesting the mushrooms. In these visions, most people obtain profound insights into their state of health and learn how they may become healthy and complete (Rätsch 1996).

Artifacts

Some pre-Columbian Aztec manuscript illustrations (*tlacuilotli*) depict scenes that are usually interpreted as mushroom rituals (Caso 1963). In particular, several pages in a manuscript that has become known as the *Codex Vindobonensis Mexicanus I* give the impression of an entheogenic ceremony. A number of figures, each holding two mushrooms (pairs!) in their hand, are shown sitting in a ritual arrangement (cf. Rätsch 1988a, 174 f.*; Wasson 1983**).

In the comic *Azteken* [Aztecs], by Andreas (1992), Mexican magic mushrooms are ingested in order to solve problems.

Medicinal Use

The Aztecs used *teonanacatl* as a medicine to treat fever and gout (Rätsch 1991a, 267*). Today,

Mexican magic mushrooms are still used as a remedy for a number of illnesses, including stomach and intestinal disturbances, migraines and headaches, swelling, broken bones, epileptic seizures, and acute and chronic ailments. Most Indians who are not shamans avoid the mushrooms and ingest them in low (subpsychedelic) dosages only in cases of illness. They fear confrontation with the mushrooms, which speak to them and can reveal things that may be unpleasant (Lipp 1991, 187 f.*).

“No one said that anyone had partaken of any kind of wine, not to mention had become inebriated; they spoke only of mushrooms of the forest that they ate raw and that made them become happy and beside themselves, but not wine. The only thing they spoke of was the tremendous quantities of chocolate that were drunk during these festivals.”

THE MISSIONARY DIEGO DURAN, REPORTING ON THE FESTIVITIES SURROUNDING THE CORONATION OF THE AZTEC EMPEROR AHUITZOTL (CA. 1496)

Psilocybin

Psilocin

“I saw Mexican scenes. Although I attempted to see things in the normal manner, this did not happen, everything was simply Mexican. I had the feeling that the physician who was supervising this experiment was a Mexican priest who had come to remove my heart. I thought that I was imagining this only because I knew that these mushrooms were from Mexico.”

ALBERT HOFMANN, REPORTING ON A SELF-EXPERIMENT³⁸⁰

Constituents

In his “classic” analysis, Albert Hofmann found concentrations of 0.25% **psilocybin** and 0.15% psilocin by dry weight (Heim and Hofmann 1958; Hofmann 1960b). Fresh mushrooms contain more psilocin (Stamets 1996, 130**).

Effects

Timothy Leary (1920–1996), a consciousness researcher and former Harvard professor, took his first “trip” with the magic mushrooms of Mexico. He encountered the “divine mushroom” while he was staying in Cuernavaca, Mexico, in 1960. This event did not simply change his life and thought but also led to profound changes in society and in the ways that science looks at the world. One of the first effects that Leary noted during his historical experience was that famous “cosmic laughter,” especially about one’s self and science:

I laughed about my daily pomposity, that narrow-minded arrogance of the scientist, the impertinence of the rational, the glib naïveté of words in contrast to the unadulterated, rich, eternally changing panoramas that flooded my brain. . . . I surrendered to the joy, as mystics have done for centuries when they looked through the veil and discovered that the world—as plastic as it might appear—is actually a small stage setting that is constructed by our mind. There was a flood of possibilities out there (in here?), other realities, an infinite arrangement of programs for other scenarios of the future. (Leary 1986, 33 f.*)

At the peak of his mushroom encounter, Leary had a profound and mystical experience of the world:

Then I was gone, off to the department for fantastic optical effects. The palaces of the Nile, the temples of the Bedouins, shimmering jewels, finely woven silk garments that breathed colors, of muso-emerald glistening mosaics, Burmese rubies, sapphires from Ceylon. There were jewel-encrusted snakes, Moorish reptiles whose tongues flickered, turned and reeled down into the drain in the center of my retina. Next there followed a journey through evolution that everyone who travels through their brain is guaranteed to experience. I slipped down the channel of recapitulation into the ancient production rooms of the midbrain: snake time, fish time, big-jungle-palm time, green time of the ferns.

Peacefully I observed how the first ocean creature crawled onto the land. I lay next to it, the sand crunching under my neck, then it fled back into the deep green ocean. Hello, I am the first living creature. (34)

This initiatory experience permanently changed the academically trained scientist:

The trip lasted somewhat more than four hours. Like most everyone who has the veil lifted, I came back a changed person. . . . In four hours at the pool in Cuernavaca, I learned more about the mind, the brain, and its structures than I was able to during the preceding fifteen years as a busy psychologist. (35)

As they did for so many people before and after him, the mushrooms taught Leary something important (or would it be more appropriate to say that he discovered it through the mushrooms?):

I experienced that the brain is an unused biocomputer that contains billions of unexplored neurons. I learned that normal waking consciousness is a drop in the ocean of intelligence. That the brain can be programmed anew. The knowledge about the functioning of our brain is the most pressing scientific task of our time. I was beside myself with enthusiasm, convinced that we had found the key we had been looking for. (35)

For many scientists and psychonauts, the Mexican mushrooms—and later the European and North American species as well—became keys to other worlds, realities, and conceptions of life that opened the normally locked doors to an expanded, visionary, or cosmic consciousness. Since that time, many have passed through these “doors of perception” and allowed the overwhelming adventures of consciousness to flow into their thoughts and actions, their scientific theories and philosophical treatises.

An ithyphallic shaman with magical staff and mushroom, above which a soul bird flies. (Petroglyph in the Petrified Forest National Park, Arizona)

Psilocybe semilanceata (Fries) Quélet

Liberty Cap

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe, Semilanceatae = Cyanescens Section

Forms and Subspecies

There are color variants that have white, brown, and bluish caps (cf. Dähncke 1993, 614 f.**):

Psilocybe semilanceata (Fr.) Quélet f.—brown caps

Psilocybe semilanceata (Fr.) Quélet var. *semilanceata*

Psilocybe semilanceata var. *caerulescens* (Cke.) Sacc.—the margin of the cap and the base of the stem turn blue

Two varieties that have been described are now regarded as constituting a separate species (*Psilocybe strictipes* Singer et Smith; cf. ***Psilocybe* spp.**):

Psilocybe semilanceata var. *obtusata* Bon.

Psilocybe semilanceata var. *microspora* Singer

Synonyms

Agaricus glutinosus Curtis

Agaricus semilanceatus Fr.

Coprinarius semilanceatus Fr.

Geophila semilanceata Quélet.

Panaeolus semilanceatus (Fr.) Lge.

Psilocybe semilanceata Fr.

Psilocybe semilanceata (Fr.: Secretan) Kummer

Folk Names

Blue leg, halluzipilz, kaalkopje (Dutch), kleiner prinz, kleines zwergenmützchen, lanzenförmiger düngerling, liberty cap, magic mushroom, meditationsspilz, narrenschwamm, paddlestool, pilzli, pixie cap, psilo, psilocybinpilz, puntig kaalkopje, sandy sagerose, schwammerl, spitzkegeliger kahlkopf, traumpilz, witch cap, zauberpilz, zuckerpuppe von der wasserkuppe, zwergenhut, zwergenmützchen

History

The liberty cap is the most common psychedelic mushroom in Italy. It is thought to have grown there for ten thousand to twelve thousand years. A number of late Neolithic rock paintings in northern Italy (Monte Bego, Valcamonica) depict mushrooms in shamanic contexts (Ripinsky-Naxon 1993, 154*).

The liberty cap (*Psilocybe semilanceata*) can be recognized by its cap, which resembles a dwarf's hat. (From Winkler, 2000 *Pilze selber bestimmen*, 1996**)

□

Dried fruiting bodies of the liberty cap (*Psilocybe semilanceata*); this amount corresponds to approximately one psychedelic dose.

Toward the end of the Middle Ages, women in Spain who were accused of being witches apparently used liberty caps as a visionary inebriant (Fericgla 1996*).

After numerous Mexican species (*Psilocybe* spp.) were collected, described, and chemically analyzed (Heim and Wasson 1958; Wasson 1961**), the Swiss chemist Albert Hofmann, who had first discovered the active substances **psilocybin** and psilocin in *Psilocybe mexicana*, was informed by an inhabitant of the Alps that there were mushrooms in the Alps that had effects like those from Mexico. He said that he had often eaten these mushrooms and had a very precise knowledge of their effects. Hofmann then received a sample of the mushrooms, which belonged to the species *Psilocybe semilanceata*, and was able to detect psilocybin in them as well. The original work was published in a small scientific journal (Hofmann et al. 1963). Nevertheless, knowledge of the indigenous magic mushroom, which Alpine nomads had apparently once consumed in ritual contexts (Golowin 1991*), spread very quickly (Gartz 1986):

Today, it can be said that *Psilocybe semi-lanceata* is **the** psychotropic mushroom of Europe with regard to its distribution, study, and use. (Gartz 1993, 23**)

In Switzerland, collecting and ingesting *Psilocybe semilanceata* has been an established tradition for over twenty years (Venturini and Vanini 1995, 38 f.*). In Germany, the collecting and eating of *Psilocybe semilanceata* began somewhat later. The ritual consumption of the indigenous magic mushroom was first described by Linder (1981).

The mushroom can be collected from the end of August until the middle of January (Leistenfels n.d., 22**). It is either eaten while fresh or dried and stored. Occasionally, dried mushrooms are powdered and then ingested together with fruit juices, cacao, or chocolate (cf. *Theobroma cacao*). A handful of fresh mushrooms (30 to 40 g) or 2 to 3 g of dried mushrooms is regarded as a high dosage. In Switzerland, chocolate and 0.5 g of powdered liberty caps are mixed together to make cookies (“the genuine Swiss chocolate”). It is possible that the mushroom was once used as a **beer** additive.

Distribution

Liberty caps do not occur in Europe and the Americas alone but instead are now found throughout the world (even in Australia) (Gartz 1986; Jokiranta et al. 1984). Although the mushroom is now cosmopolitan, it has not yet been found in Mexico. This has led to the suggestion that *Psilocybe mexicana* may be simply a subspecies or variety of *Psilocybe semilanceata*, which is regarded as the most common and most widely distributed of all members of the genus *Psilocybe*.

Liberty caps prefer to grow in meadows with old dung deposits and in grassy, nutrient-rich locales (pastures). It is equally at home in the flatlands of northern Germany, the meadows of the low mountains of central Germany, and the pastures of the Alpine countries. It has not yet been found in forests. It thus appears to be an anthropophilous species that has spread through human activity. Its fruiting bodies mature by late summer and early autumn. In the United States, temperate zones in the Northwest (Oregon, Washington) are especially good areas to collect the mushroom (Weil 1975**); similarly good European areas include the Swiss Alps, Valcamonica (Fest and Aliotta 1990**), the Rhône valley, and Wales (cf. Remann 1989, 247, 262*).

□

Appearance

The cap (1 to 2 cm in diameter) is campanulate and acutely umbonate and often has a distinct papilla; it usually feels moist or slimy to the touch. The pellicle is easily removed. The narrow lamellae are olive to red-brown in color, while the spores are dark brown or purple-brown.

Liberty caps can be confused with some muscarinic fungi, e.g., *Inocybe geophylla* (Sow. ex Fr.) Kummer (cf. ***Inocybe spp.***). It is very similar to the closely related species ***Psilocybe mexicana*** and *Psilocybe pelliculosa* (cf. ***Psilocybe spp.***) and is often confused with them.

Ritual Use

Alpine nomads are said to have referred to *Psilocybe semilanceata* as the “dream mushroom” and to have used it traditionally as a psychoactive substance. Unfortunately, we have no details concerning this use (Golowin 1991, 63*).

The first description of a modern European mushroom cult appeared in 1981 in the catalogue *Rausch und Realität—Drogen im Kulturvergleich* [Inebriation and Reality—Drugs in Cross-Cultural Perspective], which was published on the occasion of a museum exhibition of the same name:

I [was able to take part] in a solstice ceremony in Canton Bern from Dec. 21–23, 1979, in which the little mushroom that I identified as *Psilocybe semilanceata* was used in the context of a cult that had existed for some seven years and that featured complicated sweat-bath rituals, prayers, pipe ceremonies (without psychoactive substances), mandatory fasting, fumigations, offerings, and music in a specially furnished room with a central altar. All of the people who were present (5 women and 6 men) were required to strictly avoid all drugs, including alcohol, sexual contact, eating meat, and “bad thoughts” for four days prior to and following the ceremony. During the meeting, strict fasting was required, although only two of the men ate twenty mushrooms each on the second evening following rituals of purification. This use clearly served an oracular function for the group. It was supported by intensive, hours-long drumming of all the participants. . . . For the group, whose ideology was shaped by a broad “pagan”-Christian-Buddhist-Hindu syncretism . . . the mushroom does not appear to fall into the category of “drugs” but was said to be a component of “the primordial religion.” (Linder 1981, 727)

Most participants in these modern mushroom rituals regard them as a form of “psychedelic shamanism” (DeKorne 1994*) related to American Indian rituals. However, they feel that they are practicing a revived primeval form of an entheogenic ritual that is accessible to all people as a result of the “collective unconscious” or the “morphogenetic field.”

Harvesting of the mushrooms is often preceded by a prayer to the Earth Goddess Gaia or an ominous mushroom deity; offerings such as small crystals may be placed on the borders of the pasture or meadow to give thanks to the spirit of the mushroom. The collector should eat the first two mushrooms so that he or she will then be able to recognize the right species and find it everywhere. Some mushroom collectors told me that the mushroom can be found only when the collector is in a “good mood”; people who are “weird or in a bad mood” will not be able to locate them. In Switzerland, a ritual method of collecting the mushrooms was observed in the 1970s:

The mushrooms are collected on native meadows while adhering to avoidance taboos, they are purified with sage smoke, dried, and stored in vessels that are also ritually purified. They are regarded as a “gift from God” or “from nature,” and only a limited number are collected. The

largest specimens in each group are allowed to remain as the “leaders,” which are thanked and offered flour and other gifts. Songs are sung for the mushrooms so that the mushrooms that are hidden in the grass will show themselves. (Linder 1981, 727)

In Italy, a small booklet that provides easy-to-understand instructions for the sacramental use of the indigenous *Psilocybe semilanceata* has been published in an enormously large press run (Pagani 1993).

In modern rituals in central Europe, the mushroom is used in groups consisting of six to twenty participants. The rituals take place outdoors in especially beautiful settings or power places, in special rooms, or in tepees. Sweat baths, meditations, walks in the forest, and other such preparations precede the communal ingestion. Most rituals begin in the evening and last for about four hours, corresponding to the duration of the mushroom’s effects.

By far the most important ritual device is the talking stick, which is modeled after that of the North American peyote cult (cf. *Lophophora williamsii*) and plays an extremely important role in the rituals. It is a stafflike object that may be individually chosen and modified. After he or she receives the talking stick, each person is urged to communicate to the circle (by singing, speaking, silence, rattling). The other participants remain silent and offer their complete attention to the person holding the stick. The stick is passed around during all three phases of the ritual (always in a clockwise direction). Because each person can hold the stick as long as he or she pleases, individuals are able to ensure the ritual attention they desire. By using the talking stick, the communal circle, and the power of the mushroom, collective visions, ecstatic laughter, and individual insights occur. After the circle has ended, an evening meal is shared.

The next morning, the group meets for a communal breakfast. Most of the participants are hungry and have a healthy appetite. Much joking and laughter accompanies the meal, and sometimes people describe and discuss the dreams of the preceding night. After breakfast, the participants gather in the ritual room and assume their places in the circle. Sage (*Artemisia spp.*) is burned as an **incense**. The follow-up or integration of the experience is actually the most important part of the ritual. It is said that visions are valuable only when they have been communicated. The visions are to be taken seriously, for they provide guidelines for the future. The talking stick is then passed around for the final time, and the participants are urged to speak of their experiences. Often, it is only at this time that they realize that their question has been answered and that the mushroom has taught them much. Strong emotional reactions and expressions of thanks are common. Almost all of the participants leave the ritual with deep feelings of gratitude and with the sense that they have been initiated into the mysteries of the entheogenic mushroom and have recognized their own place in the cosmos. A ritual leader once noted:

“I . . . have come to celebrating with mushrooms the presence of all the Gods and Goddesses. Gods and Goddesses are my name for forces that move me. . . . Teo-Nanacatl was yesterday’s visitor, and having entered this abode of soul called Jeannine Parvati, is now written as first in my heart on the list of plant allies for healing.”

JEANNINE PARVATI *HYGIEIA*
(1978, 85*)

An English group known as the Magic Mushroom Band took its name from *Psilocybe semilanceata*, which is common in Great Britain. The free-floating eye in the cosmos depicted on the cover illustrates the visionary look into the infinite universe provided by magic mushrooms. It appears that the lettering can be deciphered only while under the influence of the mushroom (the album is titled *RU Spaced Out 2*). (CD cover 1993, Magick Eye Records)

You can always depend on the mushrooms. No matter what happened while the effects were

being felt, whether people completely flipped out, experienced pure horror, were shamanically dismembered, or fell into paranoia, in the end the mushroom illuminates and disseminates its legendary healing power. (In Rätsch 1996**)

Psilocybe semilanceata in the heart chakra. (Embroidery on a T-shirt from Kathmandu, Nepal)

A computer-generated picture of liberty caps in the modern design of the techno/rave culture. (Detail from a postcard, ca. 1997)

Artifacts

For several years, naturalistic wooden models of *Psilocybe semilanceata* have been produced in Switzerland on lathes.

In the United States and England, it is especially common to see T-shirts decorated with mushrooms of the genus *Psilocybe*, and often with *Psilocybe semilanceata*. One T-shirt even features a guide to identifying *Psilocybe semilanceata* (Rätsch 1996**).

Liberty caps also appear in the iconography of the techno and rave cultures. They are sometimes found on the album covers, posters, and admission tickets of psychedelic rock groups (e.g., Grateful Dead, *Aoxomoxoa*, 1971; The Golden Dawn, *Power Plant*, 1988; Merrell Fankhauser and H.M.S. Bounty, *Things Goin' Round In My Mind*, 1985; Phish). There is even a Magic Mushroom Band, which took its name from the native fungus.

In the Jugendstil and art deco movements, numerous lamps that look like naturalistic representations of the liberty cap were manufactured (Uecker 1992).

Constituents

Psilocybe semilanceata often contains high concentrations of **psilocybin**, some psilocin, and baeocystin. This species is one of the most potent *Psilocybe* species. According to an analysis by Gartz (1994, 19**), German specimens contained 0.97% **psilocybin**, no psilocin, and 0.33% baeocystin by dry weight. Mushrooms collected in the wild usually exhibit a higher concentration of psilocybin (up to 1.34% by dry weight has been measured) than is found in cultivated mushrooms. Total indole concentrations as high as 1.9% have been found (Gartz 1986). Swiss collections have been found to contain as much as 2.02% total alkaloids (Brenneisen and Borner 1988). In dried material, the active constituents can be preserved for quite some time:

The length of time in which the psilocybin remains in the mushroom material is astonishing. A mushroom exsiccation from 1869 that was in a Finnish herbarium was found to still contain 0.014% psilocybin. On the other hand, a sample from 1843 was found to not contain any more alkaloids. However, it is of course no longer possible to determine the manner in which drying was performed at that time. Temperatures above 50° C. effect the breakdown of psilocybin and its derivatives. In laboratory experiments, dried mushrooms and freeze-dried fruiting bodies were examined at room temperature. Here it should be pointed out that because of the porous structure of the freeze-dried mushrooms, a relatively rapid breakdown of the alkaloids will occur when they are stored for an extended period of time (months) at 20°C. For this reason, exsiccates that are produced for the analysis of natural products should be stored in a dry state at -10°C until extraction and chromatography are performed. (Gartz 1993, 31**)

Psilocybe spp.

Psilocybin Mushrooms

Family

Agaricaceae: Strophariaceae; Stropharioideae Tribe

The genus *Psilocybe* is divided into eighteen sections and includes at least 150 species (Brenneisen and Stalder 1994; Guzmán 1983 and 1995). The genus is represented in all areas of the world. Most species are rather small and have thin stems and more or less conic caps. In all species, the spore print ranges from purplish to violet to dark violet/blackish. Most species live on dung or prefer nutrient-rich soils with old dung deposits.

Some species have attained great cultural significance as traditional entheogens (see *Psilocybe cubensis*, *Psilocybe mexicana*). Some species play a role primarily in the modern Western mushroom cult (*Psilocybe azurescens*, *Psilocybe cyanescens*, *Psilocybe semilanceata*). In contrast, most psychoactive species are not used in traditional contexts. New species, some of which represent very potent entheogens, are being discovered and described at an increasing rate (Gartz 1995; Gartz et al. 1994, 1995; Guzmán 1995; Guzmán et al. 1993, n.d.; Marcano et al. 1994).

The following species of the genus *Psilocybe* contain **psilocybin**. Most also contain psilocin, and some contain baeocystin (Allen et al. 1992**). Only a few of the potent species have any ethnopharmacological significance.

Psilocybe acutipilea (Speg.)

Psilocybe aeruginosa (Curtis: Fr.) Noordeloos [syn. *Stropharia aeruginosa* (Curtis: Fries) Quélet] —verdigris cap

Psilocybe angustispora Smith

Psilocybe argentipes Yokoyama

Psilocybe armadii Guzmán et Pollock

Psilocybe atrobrunnea (Lasch) Gillet

This small species is found in central European marshlands and grows on peat and peat moss (*Sphagnum*).

Psilocybe aucklandii Guzmán, King et Bandala

Psilocybe augustipleurocystidiata Guzmán

Psilocybe australiana Guzmán et Watling—Australian psilocybe

Psilocybe aztecorum Heim emend. Guzmán—Aztec psilocybe

This mushroom occurs in at least two varieties:

Psilocybe aztecorum var. *aztecorum* (Guz.) Guzmán
Psilocybe aztecorum var. *bonetti* (Guz.) Guzmán

It is used in Mexico in the same manner as ***Psilocybe mexicana*** (Guzmán 1994, 1462**).
Folk names: Nahua, apipiltzin, tejuinti, teunanácatl, teyhuinti nanácatl; Spanish, dormilón (“long sleeper”), niño de las aguas (“child of the waters”), niños (“boys”)

***Psilocybe baeocystis* Singer et Smith emend. Guzmán**

***Psilocybe banderiliensis* Guzmán**

***Psilocybe barrerae* Cifuentes et Guzmán**

***Psilocybe bohémica* Sebek [syn. *Hypholoma coprinifacies* (Roll.) Herink]—Bohemian psilocybe**
Now regarded as a synonym for ***Psilocybe cyanescens***, as the species is confused with *Psilocybe mairei* (Sebek 1983).

***Psilocybe brasiliensis* Guzmán—Brazilian psilocybe**

***Psilocybe brunneocystidia* Guzmán**

Psilocybe baeocystis, common in the Pacific Northwest, contains psilocybin and the psychoactive constituent it is named for, baeocystin (approximately 0.1%). (Photograph: Paul Stamets)

This small and strongly blueing mushroom from the genus *Psilocybe* is found near Astoria, Oregon. According to reports of local mushroom collectors, its effects are primarily aphrodisiac.

Baeocystin

***Psilocybe caerulea* (Kriesel) Noordeloos [syn. *Stropharia caerulea* Kriesel, *Stropharia cyanea* (Bolt. ex Secr.) Tuomikoski]—blue psilocybe**

***Psilocybe caeruleoannulata* Sing.: Guzmán**

The Mixtec god Seven Flowers is depicted here holding entheogenic mushrooms in his hand. In cross section, these look exactly like *Psilocybe caerulescens*. He is listening to the music of the wind god Nine Wind (= Ehecatl), a manifestation of Quetzalcoatl, the feathered serpent. (Codex Vindobonensis, p. 24)

***Psilocybe caerulescens* Murrill [syn. *Stropharia caerulescens*]—derrumbe**
This mushroom occurs in several varieties:

Psilocybe caerulescens var. *albida* Heim

Psilocybe caerulescens var. *caerulescens* Heim—derrumbe (Spanish, “abyss”), di-chi-te-ki-sho (Mazatec), cañadas (Spanish, “canyons”), razón-bei, teotlaquilnanácatl (modern Nahuatl, “the sacred mushroom that paints in colors”)

Psilocybe caerulescens var. *mazatecorum* Heim—ntixitho ntikixo (Mazatec, “abyss”)

Psilocybe caerulescens var. *nigripes* Heim—cui-ya’-jo’-o-su (Chatina, “mushroom of great understanding”), derrumbe negro (Spanish, “the black abyss”), kong (Mixe, “lord/ruler”), ko:ng-mus (Mixe, “ruler mushroom”), ndi-kisho (Mazatec), ndi-shi-tjo-ki-sho (Mazatec, “the small, dear things that shoot out”)

Psilocybe caerulescens var. *ombrophila* (Heim) Guzmán

This species is used in Mexico (Oaxaca) in the same manner as *Psilocybe mexicana* (= *P. mixaeensis*) (Guzmán 1994, 1441**), known in the Mixe language as *atkat*.

***Psilocybe caerulipes* (Peck) Saccardo**

***Psilocybe carbonaria* Singer**

***Psilocybe collybioides* Singer et Smith**

***Psilocybe columbiana* Guzmán—Colombian psilocybe**

***Psilocybe coprinifacies* (Roll.) Pouz. [syn. *Hypholoma coprinifacies* (Roll.) Herink]**

***Psilocybe coprophila* (Bulliard ex Fries) Kummer [syn. *Psilocybe mutans* McKnight]—dung psilocybe**

This mushroom is very similar to *Psilocybe subcoprophila* (Britz.) Sacc., although the latter has larger spores. It grows on dung throughout most of the year in central Europe.

***Psilocybe cordispora* Heim—atka:t (Mixe/Coatlán), dulces clavitos del señor (Spanish, “sweet cloves of the lord”), enedi:z (Mixe, “thunder teeth”), pitpi (Mixe), pi:tpimus (Mixe)**

This species is used in Mexico in the same manner as *Psilocybe mexicana*.

***Psilocybe crobula* (Fries) Kühner et Romagnesi [syn. *Geophila crobula* (Fr.) Kühner et Romagnesi, *Psilocybe inquilina* var. *crobula* (Fr.) Holland]**

Sometimes regarded as a synonym for *Psilocybe inquilina*.

***Psilocybe cyanofibrillosa* Stamets et Guzmán [syn. *Psilocybe rhododendronensis* Stamets nom. prov.]**

***Psilocybe dumontii* Sing.: Guzmán**

***Psilocybe eucalypta* Guzmán et Watling—eucalyptus psilocybe**

***Psilocybe fagicola* Heim et Callieux**

This mushroom occurs in at least two varieties:

Psilocybe fagicola Heim et Callieux var. *fagicola* Guzmán

Psilocybe fagicola Heim et Callieux var. *mesocystidiata* Guzmán

Both are known as *señores principales* (Spanish, “the principal lords”)

Psilocybe farinacea Rick.

Psilocybe fimetaria (Orton) Watling [syn. *Psilocybe fimetaria* (Orton) Singer, *Psilocybe caesioannulata* Singer, *Stropharia fimetaria* Orton]

Psilocybe fuliginosa (Murr.) Smith

Psilocybe furtadoana Guzmán

Psilocybe galindii Guzmán

Psilocybe gastoni Sing. (?)—di-nizé-te-aya (Mazatec)

Psilocybe goniospora (B. et Br.) Singer

Psilocybe graveolens Peck

Psilocybe heimii Guzmán [syn. *Psilocybe hoogshagenii* Heim var. *hoogshagenii*]—atkadmus (Mixe, “mushroom judge”), atka:t, cihuatsinsintle (Nahuatl), Heim’s psilocybe, los chamaquitos (Spanish, “little boys”), los niños (Spanish, “children”), pajarito de monte (Spanish, “little bird of the forest”)

Psilocybe herrerae Guzmán

Psilocybe hoogshagenii Heim sensu lato [syn. *Psilocybe caerulipes* var. *gastonii* Singer, *Psilocybe zapotecorum* Heim sensu Singer, *Psilocybe semperviva* Heim et Callieux]

Psilocybe hoogshagenii Heim var. *convexa* Guzmán [syn. *P. semperviva* Heim et Callieux]

Psilocybe hoogshagenii Heim var. *hoogshagenii* Guzmán

A wooden shamanic staff in the form of a *Psilocybe* species, found in a prehistoric context of the Hopewell culture (Mound City, Ohio), approximately 40 cm long. (From Devereux)

Psilocybe hoogshagenii Heim [var. *hoogshagenii*] [syn. *Psilocybe gastoni* Sing. (?)—atkadmus (Mixe, “mushroom judge”), atka:t (Mixe), cihuatsinsintle (Nahuatl), di-nizé-te-aya (Mazatec), los chamaquitos (Spanish, “little boys”), los niños (Spanish, “children”), teotlaquilnanácatl (modern Nahuatl, “the sacred mushroom that paints in colors”)

This species is used in Mexico in the same manner as *Psilocybe mexicana*.

Psilocybe inconsicua Guzmán et Horak

Psilocybe inquilina (Fries ex Fries) Bresadola [syn. *Psilocybe ecbola* (Fries) Singer]

This species, which is common in Europe and grows on small branches, decaying wood, and sawdust, is best recognized by its pellicle, which is sticky and easy to remove. A variety of this species, *Psilocybe inquilina* var. *crobula* Fr. [syn. *Psilocybe crobula* (Fr.) Lange ex Sing.], also occurs in central Europe.

Psilocybe jacobsii Guzmán—Jacob’s psilocybe

***Psilocybe kashmeriensis* Abraham—Kashmiri psilocybe**

***Psilocybe kumaenorum* Heim**

***Psilocybe liniformans* Guzmán et Bas.**

There are two or more varieties:

Psilocybe liniformans Guzmán et Bas. var. *americana* Guzmán et Stamets

Psilocybe liniformans Guzmán et Bas. var. *liniformans*

***Psilocybe lonchopharus* (Berk. et Br.) Horak: Guzmán**

***Psilocybe luteonitens* (Peck) Saccardo [syn. *Stropharia umbonatescens* (Peck) Saccardo]**

***Psilocybe magnivelaris* (Peck apud Haariman) Noordeloos [syn. *Psilocybe percevalii* (Berkeley et Broome) Orton, *Stropharia percevalii* (Berkeley et Broome) Saccardo, *Stropharia magnivelaris* Peck apud Harriman]**

***Psilocybe mairei* Singer [syn. *Psilocybe maire* Singer sensu Guzmán, *Hypholoma cyanescens* Maire]**

This species is now regarded as a synonym for *Psilocybe cyanescens*.

***Psilocybe makarorae* Johnston et Buchanan**

***Psilocybe mammillata* (Murrill) Smith**

***Psilocybe merdaria* (Fries) Ricken—dung psilocybe**

This little mushroom, which thrives on dung, has a cap that is 1 to 4 cm in diameter. In central Europe, it grows from spring until fall.

***Psilocybe moellerii* Guzmán [syn. *Stropharia merdaria* Fr. sensu Rea, *Stropharia merdaria* var. *macrospora* (Moller) Singer]**

***Psilocybe montana* (Fries) Quélet [syn. *Psilocybe atrovufa* (Schaeffer ex Fries) Quélet]**

This small mushroom feels dry to the touch. It lives in sandy soil, among short mosses, and at elevations well above the tree line. In Europe, it is found in the Alps.

***Psilocybe muliericula* Singer et Smith [syn. *Psilocybe wassonii* Heim, *Psilocybe mexicana* var. *brevispora* Heim]—cihuatsinsintle (modern Nahuatl), mujercita, mujercitas (Spanish, “girls”), nano-catsintli (modern Nahuatl), netochhuatata (modern Nahuatl), ne-to-chutáta (Matlazinca, “[dear] little sacred lord”), niñas (Spanish, “daughters”), niño (Spanish, “son”), quauhtan-nanácatl (?) (modern Nahuatl), siwatsitsintli (Nahua, “little girls”)**

This species is used in Mexico in the same manner as *Psilocybe mexicana*.

***Psilocybe natalensis* Gartz, Reid, Smith et Eicker—Natal psilocybe**

The discovery of this potentially psychoactive African species in Natal is of great ethnopharmacological significance:

It is the first blueing and entheogenic species that has been demonstrated to exist in this land. The

comparatively large and entirely white mushrooms grow in pastures in the summer, although not directly on dung. . . . Germinating the spores on agar yielded a fast growing mycelium that also turned blue. (Gartz et al. 1995, 29)

The fruiting bodies contain up to 0.6% **psilocybin**, up to 0.04% baeocystin, and up to 0.21% psilocin by dry weight (Gartz et al. 1995).

***Psilocybe ochreata* (Berk. et Br.) Horak**

***Psilocybe papuana* Guzmán et Horak—Papuan psilocybe**

***Psilocybe pelliculosa* (Smith) Singer et Smith [syn. *Psathyra pelliculosa* A.H. Smith]—liberty cap**

***Psilocybe physaloides* (Bull. ex Merat) Quélet [syn. *Psilocybe caespitosa* Murrill]**

Found throughout central Europe, where it lives on nutrient-rich soils.

Psilocybe pelliculosa, a North American species, is easily confused with *Psilocybe semilanceata* and can have the same effects. It contains, however, considerably less psilocybin. (Photograph: Paul Stamets)

“True overdoses with psilocybin mushrooms appear to be almost impossible. Psilocybe intoxications are usually considered harmless. Between 1978 and 1981, 318 cases of psilocybe intoxication were registered in England, but none of them were fatal. The amount ingested ranged between a few mushrooms and 900 to 1360 grams and did not normally correlate with the symptoms of intoxication.”

RUDOLF BRENNISEN AND ANNA-BARBARA STALDER

PSILOCYBE

(1994, 293)

“The contact with Christianity and with modern ideas has had little influence upon the reverence the mushroom ritual is accorded in Mexico. The mushroom ceremony lasts the entire night and often includes a healing ritual. Most of the celebration is accompanied by songs. Depending upon the species, between 2 and 30 mushrooms are eaten. These may be eaten fresh or crushed and drunk as a hot-water infusion. The choice of the species of mushroom depends upon the personal taste of the shaman, the purpose it is being used for, and what is seasonally available.”

RUDOLF BRENNISEN AND ANNA-BARBARA STALDER

PSILOCYBE

(1994, 293)

***Psilocybe pintonii* Guzmán**

***Psilocybe pleurocystidiosa* Guzmán**

***Psilocybe plutonia* (B. et C.) Sacc.**

***Psilocybe pseudobullacea* (Petch) Pegler**

***Psilocybe pseudocyanea* (Desmazieres: Fries) Noordeloos [syn. *Stropharia pseudocyanea* (Desm.) Morgan, *Stropharia albocyanea* (Des.) Quélet]**

***Psilocybe quebecensis* Ola’h et Heim—Quebec psilocybe**

***Psilocybe rzedowski* Guzmán**

***Psilocybe samuensis* Guzmán, Allen et Merlin—Samoan psilocybe**

***Psilocybe sanctorum* Guzmán—sacred psilocybe**

***Psilocybe schultesii* Guzmán et Pollock—Schultes’s psilocybe**

***Psilocybe semiglobata* (Batsch: Fries) Noordeloos [syn. *Stropharia semiglobata* (Fries) Quélet]**

***Psilocybe serbica* Moser et Horak—Serbian psilocybe**

Now regarded as a synonym for *Psilocybe cyanescens*.

***Psilocybe silvatica* (Peck) Singer et Smith**

***Psilocybe singeri* Guzmán—Singer’s psilocybe**

***Psilocybe squamosa* (Persoon ex Fries) Orton**

***Psilocybe strictipes* Singer et Smith [syn. *Psilocybe callosa* (Fries ex Fries) Quélet sensu auct., sensu Guzmán (1983), *Psilocybe semilanceata* var. *obtusa* Bon., *Psilocybe semilanceata* var. *microspora* Singer]**

***Psilocybe stuntzii* Guzmán et Ott [syn. *Psilocybe pugetensis* Harris]—Stuntz’s psilocybe**

***Psilocybe subaeruginascens* Hohnel [syn. *Psilocybe aerugineomaculans* (Hohnel) Singer et Smith; *Psilocybe subaeruginosa* Cleland]**

Two varieties have been described:

Psilocybe subaeruginascens Hohnel var. *septentrionalis* Guzmán

Psilocybe subaeruginascens Hohnel var. *subaeruginascens*

***Psilocybe subcaerulipes* Hongo**

***Psilocybe subcubensis* Guzmán (see *Psilocybe* (*Stropharia*) *cubensis*, soma)**

***Psilocybe subfimetaria* Guzmán et Smith**

***Psilocybe subviscida* (Peck) Kauffman**

***Psilocybe subyungensis* Guzmán**

***Psilocybe tampanensis* Guzmán**

***Psilocybe tasmaniana* Guzmán et Watling—Tasmanian psilocybe**

***Psilocybe thrausta* (Schulzer ex Kalchbremer) Orton [syn. *Psilocybe squamosa* var. *thrausta* (Schulzer ex Kalchbremer) Guzmán, *Stropharia thrausta* (Schulzer et Kalchbremer) Bon]**

***Psilocybe wrightii* Guzmán—Wright’s psilocybe**

***Psilocybe xalapensis* Guzmán et Lopez**

***Psilocybe yungensis* Singer et Smith [syn. *Psilocybe acutissima* Heim, *Psilocybe isauri* Singer]—atkad (Mixe, “judge”), derrumbe negro (Spanish, “the black abyss”), di-nezé-ta-a-ya (Mazatec), di-shi-to-ta-a-ya (Mazatec), hongo genio (Spanish, “genious mushroom”), pajarito de monte (Spanish, “little bird of the forest”), piitpa (Mixe), si-shi-tjo-leta ja (Mazatec)**

This species is used in Mexico in the same manner as *Psilocybe mexicana*.

Like most species of *Psilocybe*, the dung psilocybe (*Psilocybe coprophila*) “loves” to live on dung, which it alchemically transforms into the so-called food of the gods. (From Winkler, 2000 *Pilze selber bestimmen* [Identify 2000 Fungi Yourself], 1996)

***Psilocybe zapotecorum* Heim emend. Guzmán [syn. *Psilocybe bolivari*, *P. candidipes* Singer et Smith, *P. zapotecorum* forma *elongata*]—crown of thorns** This mushroom is known in Mexico as *hongo de la corona de cristo*, *badaoo*, *piule de barda*, *hongo santo*, et cetera, and is used in the same manner as *Psilocybe mexicana* (Guzmán 1994, 1450**).

Folk names: Zapotec, badao zoo, badoo, bei, be-meeche, beya-zoo, beneechi, mbey san, njte-jé, patao-zoo, paya-zoo, peacho, pea-zoo; Chatina, cuiya-jo-otnu (“the great mushroom saint”); Mazatec, di-nizé-ta-a-ya, nche-je; Spanish, corona de cristo (“crown of Christ”), derrumbe de agua (“abyss of the water”), derrumbe negro (“the black abyss”), hongos de la razón (“mushrooms of reason”), piule de barda (“inebriating plant of the crown of thorns” [cf. *Rhynchospia pyramidalis*]), razón guiol (“the guiding reason”), razón viejo (“old reason”)

“It should be mentioned that the rich fungal flora of Japan also includes a number of psychotropic mushroom species. Reports from the

eleventh century already spoke of the renowned ‘laughing mushroom,’ and cases of unintended ingestion are noted. In our century as well, many involuntary intoxications are known from Japan, resulting from confusing psychotropic species with edible mushrooms. In addition to dung mushrooms, *Stropharia venenata* Imai, a close relative of *Psilocybe cubensis* that can also be classified in the genus *Psilocybe*, also grows there. Other mushrooms that contain the active constituent psilocybin are *Psilocybe argentipes* Yokoyama, *Psilocybe subcaerulipes* Hongo, and *Psilocybe subaeruginascens* Höhnelt . . . the demarcations between the species are the subject of debate. To date, however, there are no definitive reports about a possible subcultural use of such species in Japan.”

Discography of “Bemushroomed” Music

Allman Brothers Band, *Where It All Begins* (Sony Music, 1994)

Awkana, *Earth’s Call* (Wergo, 1993)—the cover features a Huichol yarn painting with a glowing mushroom

The Big F, *Is* (Chrysalis, 1993)—features a photograph of laboratory-raised *Psilocybe cubensis*

Braindub, *In Your Brain* (Sun Records, 1995)—a techno-mushroom-trip

Deee-Lite, *Dewdrops in the Garden* (Elektra, 1994)—the band is shown sitting in a garden with an oversized *Psilocybe cubensis* and fly agaric mushrooms

Merrill Fankenhauser & H.M.S. Bounty, *Things Goin ’Round My Mind* (1968)

The Golden Dawn, *Power Plant* (Independent Artists, 1967)

Harald Grosskopf, *World of Quetzal* (CMS Music, 1992)—musical version of an Aztec myth in which the god Quetzalcoatl ingests the magic mushroom

Hans Hass, Jr., *Magic Mushroom—Strong* (Aquarius Records, 1996)

Holy Mushroom (Efa Records, 1997)—a psychedelic trance sampler

Ironic Beat, *Move on Groove On* (Rough Trade Records, 1995)

Jefferson Airplane, *Surrealistic Pillow* (RCA Records, 1967)

Dr. Timothy Leary, *Turn On, Tune In, Drop Out* (The Original Motion Picture Soundtrack, 1967)

Magic Mushroom Band, *RU Spaced Out 2* (Magic Eye Records, 1993)

Ministry, *Filth Pig* (Warner Bros. Records, 1996)

Mushroom, *Early One Morning* (1973)

Mushroom Trail, *My Medicine* (LSD/A&M Records, 1993)—opening the cover reveals textbook illustrations of a fly agaric and *Psilocybe semilanceata*

Mark Nauseef & Dave Philipson, *Venus Square Mars* (M•A Recordings, 1995)

Nevermore, *The Politics of Ecstasy* (Century Media Records, 1996)—mushrooms are praised as a sacrament

Phunk Junkeez (Naked Language Records, 1992)—the cover art includes psychedelic mushrooms

Porno For Pyros, *Good God’s Urge* (Warner Bros. Records, 1996)—the lyrics refer to Balinese mushrooms

Robbie Robertson & The Red Road Ensemble, *Music for the Native Americans* (Capitol Records, 1994)—“We ate the sacred mushroom / And waded in the water / Howling like coyotes / At the naked moon”

Sacred Mushroom, *same* (Parallax, 1969)

Shamen, *Boss Drum* (Rough Trade, 1992)

Shaw & Blades, *Hallucinations* (Warner Bros. Records, 1995)—the cover shows the musicians sitting in a field of psychoactive mushrooms

Space Time Continuum, *Alien Dreamtime* (Caroline Records, 1993)

Space Tribe, *Sonic Mandala* (Spirit Zone Records, Hamburg, 1996)

Stereo MC’s, *Connected* (Island Records, 1992)—the cover depicts several psychoactive mushrooms

The Tassilli Players, *Outer Space* (Universal Egg Records, 1996)

Tiamat, *Wildhoney* (Magic Arts, 1994)—“Honey tea, psilocybe larvae / Honeymoon, silver spoon / Psilocybe tea”

Tribu, *IN Mixkoakali* (Cadamac Records, 1996)—includes a song titled “Teonanakatl (Hongo Divino)”

Rick Wakeman, *Journey to the Centre of the Earth* (A& M Records, 1974)

Yo La Tengo, *May I Sing With Me* (Slang 017/EFA, 1992)—includes “Mushroom Cloud of His”

Zuvuya & Terence McKenna, *Dream Matrix Telemetry* (Delirium Records, 1993)

Zuvuya & Terence McKenna, *Shamania* (Delirium Records, 1994)

“Bemushroomed” Literature

Boyle, T. Coraghessan. 1979. *Descent of Man*. New York: Penguin Books. Includes the psilocybin-inspired story “Quetzalcoatl Lite.”

Bradley, Marion Zimmer. 1982. *The mists of Avalon*. New York: Alfred A. Knopf. In this international best seller, psychedelic mushrooms are said to produce a different state of consciousness.

“He knew about the mushrooms. Carlos also offered me some, and since I was starving, I ate quite a few as well. They tasted better than the coca, and I gained a little weight again. We often sat in the stubbly grass of an Indian savanna with a basket of hallucinogenic mushrooms, munching and looking up into the infinite starry sky. We both had visions. Carlos floated and conversed with dead magicians, while I always saw a woman as large as the heavens who was wearing a white doctor’s coat and who longingly held out her arms toward me.”

URS WIDMER

MEINE JAHRE IM KOKA-WALD [MY YEARS IN THE COCA FOREST]
(1995, 65)

On the cover of the album of the film music to *Turn On, Tune In, Drop Out* (1967), Dr. Timothy Leary (1920–1996) is depicted as a psychoactive mushroom. Leary’s life changed dramatically after his first encounter with Mexican magic mushrooms in 1960.

Braem, Harald. 1994. *Der Herr des Feuers: Roman eines Schamanen*. Munich: Piper. See **Amanita muscaria**.

Carroll, Lewis. 1946. *Alice in Wonderland*. New York: Grosset & Dunlap. See Carmichael 1996.**

Geerken, Hatmut. 1988. mappa. Spenge: Klaus Kramm. A literary mushroom trip; see the review by Martin Hanslmeier in *Integration* 2/3 (1992): 137–40.

———. 1992. fliegen pilze? merkungen und anmerkungen zum schamanismus in sibirien und andechs. *Integration* 2/3:109–14. According to the author’s own statement, the text was written while he was under the influence of fly agaric.

Huxley, Aldous. 1962. *Island*. New York: Harper & Row. In his novel *Island*, Huxley helped psychedelic mushrooms gain literary renown as “moksha-medicine,”³⁸¹ the “reality revealer,” and the “truth-and-beauty pill” (p. 157). He wrote the following about the value of using mushrooms once a year in a ritual context: “The fact remains that the experience can open one’s eyes and make one blessed and transform one’s whole life” (p. 160). For Huxley, this ritual “mycomysticism” was a way to use the power of the

mushrooms for a positive purpose: “And all that the moksha-medicine can do is to give you a succession of beatific glimpses, an hour or two, every now and then, of enlightening and liberating grace. It remains for you to decide whether you’ll cooperate with the grace and take those opportunities” (p. 197).

Lloyd, John Uri. 1895. *Etidorpha or the end of the Earth: The strange history of a mysterious being and the account of a remarkable journey*. Cincinnati: self-published. The mycologist John Uri Lloyd (1849–1916), after whom the journal *Lloydia* is named, worked his experiences with English mushrooms into this fantasy story, which had a considerable influence on *Alice in Wonderland*: “In any case, it seems clear that John Uri Lloyd’s bizarre hollow-earth novel *Etidorpha* was for him a kind of labyrinth at whose center he wished to place the apotheosis he had personally experienced in his own peregrinations in the realm of gigantic fungi” (McKenna 1990, 169**).

Moers, Walter. 1992. *Schöner Leben mit dem Kleinen Arschloch: Sex, Drogen und Alkohol*. Frankfurt/M.: Eichborn Verlag. The author provides clear instructions for using mushrooms: “Mushrooms. The mildest results are achieved with champignons, the wildest with fly agarics. Psilocybin mushrooms, small, inconspicuous fellows that sometimes have magical effects, lie somewhere in between. But don’t be afraid—if LSD is the Porsche among consciousness-expanding drugs, then psilocybin is the bicycle. This means that the limits of perception are never opened so drastically that you believe that you have five lips—three lips is the maximum. If you have taken the proper dosage, you will soon feel a love for all forms of life that you have never felt before: for people, for animals, for plants, and especially for mushrooms” (p. 32 f.).

Remann, Micky. 1989. *SolarPerplexus: Achterbahn für die Neunziger*. Basel: Sphinx. Contains a chapter titled “Glücks-Pilze” [Happiness Mushrooms], a report on an experience with Psilocybe.

Shea, Robert. 1991. *Shaman*. New York: Ballantine Books. This best seller, which has appeared in numerous editions, begins with a mushroom trip. A young man destined to be a shaman goes to a cave and eats magic mushrooms. In this way, he is initiated into the secrets of the shamanic universe and obtains great visions that are full of both significance and consequences.

Wells, Herbert George. 1904. *The food of the gods and how it came to Earth*. London: Macmillan and Co. In this novel, scientists develop a drug, “the food of the gods,” that causes enormous growth.

Widmer, Urs. 1995. *Meine Jahre im Koka-Wald*. NZZ-Folio (June 1995): 64–65. A satirical tale about Castaneda and his experiences with mushrooms.

“Bemushroomed” Comics

Mushrooms appear frequently in comics, usually as *Psilocybe* species or fly agarics (see *Amanita muscaria*). They also take on fantastic shapes. Sometimes mushroom trips are depicted (e.g., Jürgen Mick, *Träume*; Seyfried + Ziska, *Space Bastards*; Travel/Aoumri, *Das Volk der Wurzeln*; Jodorowsky/Arno, *Alef-Thau*). Some of the stories illustrate the use and effects of the mushrooms (Andreas, *Azteken*; Gilbert Shelton, *The Fabulous Furry Freak Brothers*; Howard Cruse, in *Dope Comix* no. 2, 1978). Magic mushrooms even appear in the *Abenteuer des kleinen Spirou* [Adventures of the Little Spirou]. The volume *Der geheimnisvolle Stern* from Hergé’s Tim und Struppi series (1947) deals with strange mushrooms that are both red and white. Similar mushrooms appear in *Gazoline und der Rote Planet* (1991) by Jano. At the beginning of *Die Zeit der Asche* (1987), by Chevalier and Segur, the hero swallows a mushroom egg and goes on a fantastic trip. Mali and Werner, in *Der grüne Planet*, show the “path to the troll oracle”: fly agaric mushrooms. In *Gon 3*, by Tanaka (1995), a small dinosaur eats psychoactive mushrooms and almost laughs itself to death.

Purported Psychoactive Fungi

A number of fungi are alleged to be psychoactive. Some species or genera are thought to contain the active constituent **psilocybin** (see the box below); the information contained in the literature, however, is contradictory. Other genera or species have a reputation of being psychoactive. Here again, the reports and other information contained in the literature are decidedly contradictory or incomplete.

In Australia, species from the genera *Aspergillus*, *Hypomyces*, *Hygrocybe*, and *Psathyrella* (Bock 1994*) may be psychoactive. The mold fungus *Aspergillus fumigatus* Fres. is known to produce **indole alkaloids** (Moreau 1982; Roth et al. 1990, 174**).

The caterpillar fungus *Cordyceps taylori*, shown adhering to a larva. (From Kerner and Oliver, *The Natural History of Plants*, 1897)

Genera and Species That May Contain Psilocybin

(from Ott 1993, 309, 313, 317*)

Agrocybe farinacea Hongo

Hygrocybe psittacina (Schaeffer ex Fr.) Wunsche—parrot mushroom

Hygrocybe psittacina var. *californica* Hesler et Smith

Hygrocybe psittacina var. *psittacina* Hesler et Smith

Mycena amicta (Fries) Quélet

Mycena cyanescens Velenovsky

Mycena cyanorrhiza Quélet

Naematoloma popperianum Singer

Panaeolina spp. (cf. ***Panaeolus*** spp.)

Pholiotina spp.

Stropharia *coronilla* (Bull. ex Fr.) Quél. (cf. Roth et al. 1990, 112**)

Cordyceps spp.

Clavicipitaceae

This parasitic genus of the Order Hypocreales (Class Ascomycetes) is found throughout the world (Jones 1997). In Mexico, two species are reputed to be psychoactive:

Cordyceps capitata (Holmskjöld) Link—hombrecitos, soldaditos

Cordyceps ophioglossoides (Fries) Link—hombrecitos, club head fungus

Cordyceps ophioglossoides and *C. capitata* infest the fruiting bodies of truffles (*Elaphomyces* spp.),³⁸² which are found in oak and pine forests. In the area around Toluca (Mexico), these parasitic fungi were or are still used in nocturnal healing rituals. They are mixed with *Psilocybe muliericula* (cf. ***Psilocybe*** spp.), *Elaphomyces granulatus* Fr. [syn. *Elaphomyces cervinus* (Pers.) Schroeter, *Hypogaeum cervinum* Pers.], and *Elaphomyces muricatus* f. *variegatus* and then powdered and ingested (Guzmán 1994b, 1446**). This fungus has been found to contain an **indole alkaloid**, the structure of which has not yet been clarified (Hobbs 1995, 86**; Ott 1993, 397*). *Cordyceps ophioglossoides* contains the antibiotic substance ophiocordine.

The two Mexican species are closely related to and hardly distinguishable from the species

Cordyceps sinensis (Berk.) Sacc., which occurs in Tibet and southwestern China—especially in the highlands of Tibet—and is used for medicinal purposes. Rutting yaks sniff out the fungus and eat it as an aphrodisiac. The substance was praised as an aphrodisiac in the very oldest Chinese herbals, a reputation that continues to echo in the Chinatowns of our time (Davis 1983, 62–64). Attempts to cultivate the fungus, which is difficult to collect, have only recently proved successful. Extracts (alcoholic tinctures) are drunk as tonics and aphrodisiacs and are ingested even by athletes (not yet forbidden!) as doping agents. The effects are similar to those of ginseng (*Panax ginseng*). The tincture is also used as an antidote for opium overdoses and to treat opium addiction (Hobbs 1995, 82**). The coveted Chinese aphrodisiac *dong chong xia cao* is composed of the dried larvae of a moth (*Hepialus armoricanus* Oberthür) in which *Cordyceps sinensis* has grown. Six to 12 g is powdered and ingested as a tea (or mixed with other substances) in order to strengthen the body for erotic adventures and to overcome impotence. The drug contains cordycepinic acid, quinic acid, cordycepin, proteins, saturated and unsaturated fatty acids, D-mannitol, and vitamin B₁₂. Cordycepin has been demonstrated to have antibiotic effects (Paulus and Ding 1987, 114 f.*). Tinctures made from the powdered raw fungus are reported to have strong aphrodisiac effects as well as mild psychedelic effects that are primarily mood-improving in nature.

In Asia, dried larvae that live in symbiosis with the fungus *Cordyceps sinensis* are sought as aphrodisiacs and tonics. Some *Cordyceps* species are also attributed with psychoactive effects. (Dried larvae, collected in Tibet)

Dictyophora

Phallaceae (Stinkhorns)

The Chinantec use *Dictyophora indusiata* (Vent.: Pers.) Desv. [syn. *Dictyophora phalloides* Desv.], a species distributed widely throughout the tropics (Americas, Southeast Asia, Seychelles, et cetera), together with *Psilocybe mexicana* for ritual purposes. The shamans of Chinantla use the mushroom for divinatory purposes. They dry the mushroom and grind it. Two to three hours before the planned divination, they drink the powder with water (Guzmán 1994b, 1478**; McGuire 1982, 231**). The Lacandon Maya call this ritually important mushroom *u ba'ay äh och*, “the carrying net of the opossum.” The Lacandon and other peoples of Mexico consider the opossum³⁸³ a rascally trickster that is also associated with fertility and birth. The mushroom is regarded as inedible; its Spanish name is *vela de novia*, “bridal veil.” In Thailand, this mushroom or another species of the same genus is used in magical rites. Chemical studies of the genus are lacking (Ott 1993, 399*).

Hydnum repandum L.: Fr.

Hydnaceae (Hedgehog Mushroom)

Some Swiss mushroom enthusiasts have reported that the hedgehog mushroom, which is quite common and well known in Jura, is psychoactive. The mushroom is generally regarded as edible (Dähncke 1993, 1036**). The red-yellow hedgehog mushroom (*Hydnum repandum* var. *rufescens* [Fr.] Barla [syn. *Hydnum refescens* Fries]) is also considered edible (Dähncke 1993, 1036**). It is interesting to note that in Japan, mushrooms of the genus *Hydnum* are known as *yamabushi-take*, “mushrooms of the mountain priests” (Imazeki 1973, 37**).

Gerronema

Tricholomataceae

An analysis by Gartz (1986) detected the presence of **psilocybin** in two East German species of this

genus:

Gerronema fibula (Bull.: Fr.) Singer [syn. *Rickenella fibula* (Bull. ex Fr.) Raith., *Omphalia fibula* (Fr.) Kummer]

Gerronema solipes (Fr.) Singer [syn. *Gerronema swartzii* (Fries ex Fries) Kreisel]

A subsequent analysis found neither psilocybin nor any other active substances (Stijve and Kuyper 1988).

Psathyrella

Coprinaceae

This genus, in the Order Agaricales (Class Basidiomycetes), encompasses approximately one hundred species. It is closely related to ***Panaeolus***. **Psilocybin** was reportedly found in a Japanese sample of *Psathyrella candolleana* (Fr.) Maire [syn. *Agaricus violaceus-lamellatus* DC., *Agaricus appendiculatus* Bull.], which is found throughout the world. This mushroom is attributed with psychoactive effects (Gartz 1986; Ott 1993, 310*).

The tropical stinkhorn *Dictyophora phalloides* has acquired a certain significance as a shamanic magical agent. (Photographed in the Seychelles)

Some species of the genus *Psathyrella* are attributed with psychoactive properties. (A *Psathyrella* species, photographed in Washington state)

In one old English herbal, the fruiting bodies of a *Psathyrella* species were described as “deadly poisonous fungi.” (Woodcut from Gerard, *The Herball or General History of Plants*, 1633*)

Lycoperdon

Puffballs

Family

Lycoperdaceae (Puffballs)

In 1962, during research into the Mexican magic mushrooms (cf. *Psilocybe mexicana*), it was discovered that Indians used two species of this genus that are attributed with psychoactive properties:

Lycoperdon marginatum Vitt. ex Morris et De Not. [syn. *Lycoperdon candidum* Persoon; cf. Guzmán 1994b, 1452**]

Lycoperdon mixtecorum Heim [syn. *Lycoperdon qudenii* Bottom., *Vascellum qudenii* (Bottom.) Ponce de Leon]—Mixtec puffball

These fungi appear to have narcotic or dream-inducing effects. People under their influence are said to hear voices. One Indian reported, “I fell asleep for an hour or an hour and a half and the puffball spoke to me then, saying that I would become ill but would recover from the sickness” (in Schultes and Hofmann 1980, 41 f.*).

The Mixtec apparently use these fungi for divinatory purposes. In the region of the Tara-humara, the fungi are known as *kalamota* and are associated with witchcraft (Bye 1976*; 1979b, 39*). Additional research into their ritual use is needed. It is possible that they were used as peyote substitutes (see *Lophophora williamsii*).

Most puffballs are edible when young. The Mexican species *Lycoperdon umbrium* Pers. is known among the Tepehuan Indians as *ju’ba’pbich nakai*, “excrement of the stars fungus,” and it is a popular edible fungus when it is young (Gonzalez E. 1991, 170). It may be that only older specimens are psychoactive.

Some allegedly psychoactive Mexican species of puffball (*Lycoperdon* spp.) are used in Mazatec shamanism.

A number of species (including some from the related genera *Astraeus*, *Scleroderma*, and *Vascellum*) have been studied to determine whether they have any psychoactive effectiveness. No psychoactive effects have been observed, nor has any psychedelic component³⁸⁵ been detected (Díaz 1979, 93*; Ott et al. 1975). However, it is possible that ingesting a puffball may result in subtle effects upon dreaming. Because most Indians have been trained to consciously experience their dreams and to analyze them for divinatory contents, it is entirely possible that non-Indian researchers have not been able to notice these effects.

In North America, puffballs possess a certain ritual and medicinal importance that may indicate a possible psychoactivity. The Blackfeet call them *ka-ka-toos*, “falling stars” or “dusty stars.” They used the pleasantly scented species to make necklaces and decorated their tepees with representations of these fungi, considering them symbols of the life that arose from the earth. They sniffed the spores to treat nosebleeds (Johnston 1970, 303 f.*). They burned *Lycoperdon* species as magical **incense** to

drive off spirits (Burk 1983, 55). The Cherokee used the common puffball (*Lycoperdon perlatum* Pers. ex Pers.)³⁸⁶ as a remedy for treating chafed areas. The amino acid lycoperdic acid has been isolated from *Lycoperdon perlatum* (Rhugenda-Banga et al. 1979). The North American stump puffball (*Lycoperdon pyriforme* Schaeff. ex Pers.) is reputed to have sleep-inducing effects (Morgan 1995, 127**).

The following North American puffballs have also been attributed with psychoactive effects (Burk 1983, 60; Guzmán 1994, 1452**):

Lycoperdon pedicellatum Peck [syn. *Lycoperdon candidum* Pers. ex Pers.]

Scleroderma verrucosum Bull. ex Pers.—warted devil’s snuffbox

Vascellum pratense (Pers.: Pers.) Kreisel [syn. *Lycoperdon hiemale*]

The Mapuche Indians of Chile refer to various *Lycoperdon* species as *pëtremquilquil*, “tobacco of Chunchu” or “powder of the devil” (Mösbach 1992, 52*). Chunchu or Chonchon is a bird with a human head that is sometimes regarded as an incarnation of a sorcerer, that is, a shaman (Brech 1985, 7). It is entirely possible that the fungus known as the tobacco of Chunchu, which has unfortunately not yet been identified, was smoked to effect the transformation into an animal and the ability to fly.

Reichel-Dolmatoff wrote that the *mamas* (shaman priests) of the Colombian Kogi used a number of psychoactive fungi, including a “bluish puffball,” in ritual contexts. Unfortunately, the identity of this “bluish puffball” is unknown (Reichel-Dolmatoff 1977, 285*; 1996b, 167, 297*).

Before leaving his body for all time, the Buddha ate a piece of a fungus known as *pâtika* (*Scleroderma* sp. or *Lycoperdon pusillum*). *Pâtika* is said to have been a substitute for **soma** (Wasson 1983). The Santala, a Dravidian group of India, refer to *Lycoperdon pusillum* as “toad” and believe that the fungus possesses a soul (Morgan 1995, 148**). This belief may be a relic of an earlier psychoactive use.

“One view that is widely held geographically but is inaccurate claims that the spore dust of *Lycoperdon* is harmful to the eyes and can even lead to blindness. This may be connected to the mistrust of the puffballs and of fungi in general and to the general fear of getting dust in one’s eyes.”

Nonda

In Papua New Guinea, a number of mushrooms from the genera *Boletus*, *Russula*, and *Heimiella* are generally referred to by the name *nonda*. They reportedly are consumed by the Kuma tribe and produce a temporary state of “mushroom madness”³⁸⁷ that is characterized by manic, wild behavior (Reay 1960). The mushrooms are eaten for culinary purposes throughout the year; it is only at a particular time (during moderate rainfall) that they are said to elicit these psychoactive effects. The fruits (*nong’n*) of a ***Pandanus* sp.** are said to be able to produce the same effects (Reay 1959, 188).

The Kuma once used the effects of *nonda* mushrooms to induce a wild and uninhibited aggressiveness before undertaking acts of warfare (Heim 1972, 170). Occasionally, the “mushroom madness” was also said to produce hallucinations of a terrible or pleasantly cheerful nature. Some Papuans describe the condition as a “bad trip” (Nelson 1970, 10).

This “mushroom madness” is strongly reminiscent of the “wild man” behavior that is so well known on Papua New Guinea (Newman 1964) as well as of the Balinese phenomenon of amok. Running amok, however, is not induced by any psychoactive substances but, rather, appears to be a traditional pattern of behavior within the culture (cf. Kertonegoro 1991, 61–102). In the same way, the “wild man” behavior, which is known as *long-long*, also appears to be learned and culturally patterned. It can appear without any pharmacological stimuli, at least among the Gururumba:

It begins when a person simply stops reacting to words. Because of this, he is also unable to understand anything, and his speech consists solely of inarticulate babbling or shrieking. Often, this condition leads to a violent shaking of the body, shortness of breath, and uncontrolled movements. In this state, the afflicted person may then take up his weapon and run through the village. (Rätsch and Probst 1985, 305 f.)

The French mycologist Roger Heim identified the following fungi as *nonda* (Heim 1972; Heim and Wasson 1965):

***Boletus* (Boletaceae)**

This genus includes the delicious porcini mushroom or king bolete (*Boletus edulis* Bull.: Fr.), as well as *Boletus luridus* Schaeff.: Fr., which is toxic when taken in combination with **alcohol**, and the very toxic Satan’s mushroom (*Boletus satanas* Lenz).

Boletus manicus, the largest and supposedly most effective species of *nonda*, closely resembles the Satan’s mushroom (*Boletus satanas* Lenz) of Europe. A powder produced by grinding the dried fruiting bodies is said to be able to induce colorful visions. *Boletus manicus* has been found to contain traces of **indole alkaloids** (Heim 1972, 173; Ott 1993, 422*). One *Boletus* species from the New Guinea highlands that is known as *namanama* was found to contain only amino acids and steroids, none of which is known to have any psychoactive effects (Gellert et al. 1973).

In Papua New Guinea, species of mushrooms that are closely related to the coveted king bolete (*Boletus edulis*) are said to induce a temporary state of insanity.

Boletus (Tubiporus) flammeus Heim nondo ulné kobi

<i>Boletus (Tubiporus) kumaeus</i> Heim	nonda ngamp kindjkants
<i>Boletus (Tubiporus) manicus</i> Heim	nonda gegwants ngimbigl
<i>Boletus (Tubiporus) nigerrimus</i> Heim	nondo kermaipip
<i>Boletus (Tubiporus) nigroviolaceus</i> Heim	nonda tua-rua
<i>Boletus (Tubiporus) reayi</i> Heim	nonda ngam ngam

“Cerdier told us that [the natives] of the African West Coast have elevated a certain type of mushroom to the sacredness of a god and bow deeply before it in veneration; for this reason, Afzeltus has given this variety the name *Boletus sacer*.”

JOHN GREGORY BOURKE

DER UNRAT DER UNRAT IN SITTE, BRAUCH, GLAUBEN UND GEWOHNHEITSRECHT DER VÖLKER [FILTH IN THE CUSTOMS, TRADITIONS, BELIEF, AND COMMON LAW OF PEOPLES] (1913)
(1996, 67**)

Heimiella (Boletaceae)

This genus is composed of just two or three species and is found only in Asia. It is characterized by long, fleshy stems and small caps.

Heimiella anguiformis Heim nonda mbolbe
Heimiella retispora Heim

To date, no psychoactive compounds have been discovered in the genus *Heimiella* (Schultes and Hofmann 1992, 44*).

Russula (Russulaceae)—brittle caps

Brittle caps are found throughout the world. Some species are coveted as culinary mushrooms, some are regarded as inedible, and some are attributed with a certain degree of toxicity. The taste can be used to estimate the toxicity of a specimen. Species that have a mild taste are edible, while pungent varieties tend to be inedible or poisonous. Because the pungent taste is often not immediately apparent, a sample should be retained in the mouth for at least two minutes. Two species of *Russula* have been found to contain stearic acid. Some varieties also contain **ibotenic acid** and **muscimol**, both of which are also present in the fly agaric (*Amanita muscaria*) (Schultes and Hofmann 1992, 55*).

The following brittle caps have been described for Papua New Guinea and are classified as nonda:

<i>Russula agglutinata</i> Heim	nonda mos
<i>Russula kirinea</i> Heim	kirin
<i>Russula maenadum</i> Heim	nonda mos
<i>Russula nondorbingi</i> Singer	nonda bingi
<i>Russula pseudomaenadum</i> Heim	nonda wam

Nonda mushrooms from the genus *Russula* are said to induce the mushroom madness (*ndaadl*) in women but not in men (Heim 1972, 177).

Some brittle caps (*Russula* spp.) are purported to have psychoactive effects.

Self-experiments with nonda mushrooms (ingestion) conducted by various ethnographers and mushroom enthusiasts have not detected any type of psychoactive effects (D. McKenna 1995, 102*). It is of course possible that the nonda mushrooms contain substances that react only in the context of some specific chemical properties of the Kuma (cf. Nelson 1970). All of the information that is available indicates that the mushroom madness represents a traditional and learned pattern of behavior that is integrated into the Kuma culture in a complex manner. Mushroom madness is a cultural institution that makes it possible for individuals to “flip out” on a temporary basis, thereby enabling them to undergo a social catharsis and enact a ritual drama (Heim and Wasson 1965).

In the area inhabited by the Maya, objects have been found that have been interpreted as phallus stones but are nevertheless associated with mushroom stones. (From Theobert Maler, ca. 1895)

Psychoactive Molds

A number of species of mold fungi produce **indole alkaloids** (lysergic acid, elymoclavine, agroclavine, fumigaclavine, fumitremorgine, ergokryptine, ergosine, costaclavine, ergosinine, noragroclavine, and others), some of which have psychoactive as well as highly toxic effects (from Samorini 1997a, 41):

Ascochyta imperfecta Peck
Aspergillus clavatus Desmaz.
Aspergillus conicus Bloch.
Aspergillus flavus Link.
Aspergillus fumigatus Fres.
Aspergillus nidulans (Eidam) Wint
Aspergillus versicolor (Vuill.) Tirab.
Dematium chodati Nechitsch
Geotrichum candidum Link.
Isariopsis grieseola Sacc.
Mucor subtilissimus Berk.
Penicillium chermesinum Biourge
Penicillium expansum Link.
Penicillium granulatum Bain.
Penicillium roqueforti
Penicillium rugulosum Thom.
Rizopus arrhizus Fischer
Rizopus nigricans Ehramb.

“While researching *Psilocybe*, I became accustomed to meeting great resistance from professional mycologists, many of whom had an instant distrust of anyone expressing a passion for *Psilocybe*. There were some mycologists who stated publicly that it would be better for people to die from mistakes in identification than to provide them with the tools for recognizing a *Psilocybe* mushroom. This bizarre attitude towards *Psilocybe* mushrooms and the people who used them reflected a chasm between generations.”

“And thus, as is still told here and there in Bavarian and Austrian states, their [the mushrooms’] growth depends upon higher and lower gods of growth. Once it depended upon Donar and Wodan, later upon their Christian equivalents, upon God and his saints, especially St. Peter, who controls the weather, and St. Veit, the successor to the Slavic sun god Svantevit, and upon St. Procopius and Anthony the hermit. On the other hand, some claimed that it was the devils, witches, elves, and good or evil fungi spirits that enabled the race of fungi to grow, or mushroom souls, mushroom dwarves, or perhaps a dwarflike mushroom prophet. All of them are offered small gifts and ‘mushroom prayers.’ ”

LINUS ZEITLMAYER
KNAURS PILZBUCH [KNAUER’S BOOK OF FUNGI]
(1976, 10**).

“The secret of the castle ghosts has been solved! In Great Britain, which is rich in castles, microbiologists investigated moist, mildewed, and moldy cellars, in which thrive tiny little fungi with psychoactive effects. Breathing in their spores induces hallucinations—in other words, people get ‘high’ and believe that they are seeing things that in actuality do not exist.”

FRANZ AUF DER MAUR
(IN *NATÜRLICH* 16/11:30, 1996)

An Amazonian shaman prepares the psychoactive and purgative ayahuasca drink from the leaves of *Psychotria viridis* and the stems of *Banisteriopsis caapi*. Drinking ayahuasca enables the astral body, which is composed of colorful lights, to leave the shaman's body and travel to the stars. (Painting by Pablo Amaringo, detail, ca. 1994)

The psychoactive effects of many plants can be improved, modified, or even simply made possible by preparing or processing the plants using both traditional and pharmaceutical methods or by combining them with other plants and substances. The resulting products typically are culturally significant, whether as agents of pleasure (**betel quids, chicha, palm wine, sake, wine**), shamanic tools (**ayahuasca, cimora, snuff**), or sacred drugs (**balche', mead**). These products bear witness to humanity's amazing powers of invention and creativity. Some (**beer, pituri, incense, honey**) have been produced and used since the Stone Age. However, precise details about many of the recipes for or ingredients in some ancient products (**hanshi, haoma, witches' ointments, kykeon, soma**) are not well known, whether because of a desire for secrecy, because that knowledge was suppressed, or because the ingredients were simply forgotten over time. Other products (**ayahuasca analogs, energy drinks, herbal ecstasy**) are more recent developments. Today, more and more people are searching for new psychoactive substances and products. Countless closet shamans in North America and Europe have been experimenting with new combinations, extracts, and possibilities for preparing such products. Considerable research into **ayahuasca analogs** and **smoking blends** is currently under way.

Combination Preparations

Some products (such as **alcohol**) can be produced only through elaborate techniques, while others are distinguished by a skillful and deliberate combination of various substances. At times, plants or certain parts of plants become psychoactive only when combined with other ingredients. Sometimes various admixtures can be used in combination to produce a synergistic effect, that is, the two effects shape one another, resulting in a new effect that is different from that of the individual substances (as is the case for **madzoka medicine** and **zombie poison**). In some cases, a particular substance is more easily tolerated when mixed with another. At other times, combining substances can potentiate a constituent's primary effects or steer them in a particular direction (as can be seen in **Oriental joy pills, kinnikinnick, enemas, soporific sponges, and theriac**).

The sugarcane plant (*Saccharum officinarum* L.) originated in Melanesia but is now found in all the tropical regions of the world as a result of human activity. The fresh juice of the plant is used to brew beerlike beverages and to produce potent alcoholic spirits (firewater). Many plants can be used to produce psychoactive products such as beer and alcohol. (Woodcut from Tabernaemontanus, *Neu Völkomen Kräuter-Buch*, 1731)

Alcohol (Distilled)

Other Names

Alcohol, alk, aqua vitae, bourbon, brandy, branntwein, cañaza, dharu, ethanol, ethyl alcohol, gola, moonshine, pox, rakshi, schnapps, schnaps, spirits, spiritus, sprit, soju, whiskey, whisky

Since humans first became acquainted with sweet substances and the various sugars, we have been making them into alcohol by using yeast as a fermenting agent (Bush 1974). The resulting products can be either consumed as **wine** or distilled into alcoholic spirits. Because alcohol evaporates more readily than water, it can be distilled from a fermented product by heating it with care. And because alcohol is strongly hygroscopic, i.e., it attracts water, a portion of the water in which it is contained will be carried into the distillate during distillation. The final distillate product contains approximately 38% alcohol, along with the water and the **essential oils** that are also distilled during the process.

Ethanol

“You can easily take this literally. Alcoholic thrushes really do exist. So do other animal drinkers, who are absolutely wild about alcohol and other drugs. They are all of them all too human: it appears that inebriation also produces feelings of happiness in animals.”

LOTHAR FRANZ

DIE GRÖSSTEN TRUNKENBOLDE DES TIERREICHS [THE GREATEST DRINKERS OF THE ANIMAL KINGDOM] (1995, 14)

The medieval distillation of alcoholic spirits. (Woodcut from *Von allen geprannten wassern* [Of All Distilled Waters], 1498)

An apparatus for distilling palm wine on Amboina Island. (From Hartwich, *Die menschlichen Genußmittel*, 1911)

The origin of the distilling arts lies far back in the mists of time. Distilling equipment has been discovered at the temple of Memphis. The ancient Egyptians had allegedly been distilling wine and apple wine since around 4000 B.C.E. (Bosi 1994, 11). Distilling alcohol to manufacture cosmetics has been practiced in Egypt since the eighth century B.C.E. Whether or not a distillate with a high percentage of alcohol was also being distilled during this period, however, remains uncertain. In Wales, various distillation procedures were experimented with during the fourth century C.E. The Saracens brought the Arabian art of distillation to Spain in the eighth century C.E., and from there it quickly spread across Europe (Höschel n.d.). The word *alcohol* is derived from Arabic (cf. *Catha edulis*, *Coffea arabica*). The Arabs believed that the distillate of wine was a “medicine that could soothe both physical and spiritual pain” (Bosi 1995, 13). The Arabian art of distillation exerted a powerful influence on the alchemical practices of medieval Europe. In Germany and Italy, a rich

tradition emerged in which not only fermented alcohol but also practically every herb and every animal was distilled (Braunschweig 1610). For these reasons, distilled alcohol also became known by the names *spiritual drink*, *spirits*, and *alchemical elixir*.

The root of yellow gentian (*Gentiana lutea*), which grows in the Alps, is used to distill a schnapps known locally as *enzian* (= gentian). Unfortunately, the plant is sometimes confused with white hellebore (*Veratrum album*), a plant capable of producing a powerful and toxic state of inebriation.

The starchy root-balls of the yucca plant are used to distill alcohol. (*Yucca* sp. from North America)

The sugarcane plant (*Saccharum officinarum* L.) is originally from Melanesia. From there, humans have carried it to all the tropical regions of the world. The freshly pressed juice of the plant can be used to brew beerlike beverages and can also be distilled into potent alcoholic beverages (firewater).

Distilling equipment from the early modern era. (Woodcut from Lonicerus, *Kreuterbuch*, 1679)

The number of plants that contain starch or sugar constituents that can be mashed and fermented with yeast is beyond count. Numerous other ingredients may be combined with these plants before, during, or after the fermentation period. Most of these additives are aromatic plants whose active constituents are distilled along with the alcohol. For this reason, herbs such as wormwood (***Artemisia absinthium***) and juniper are often added to the mash. During the production of some palm alcohols (*arrack*, *kolwater*), the bitter bark of the large *muna-mal* or *mukalai* tree (*Mimusops elengi* L.) may be added to the **palm wine** either before or during the distillation process (Macmillan 1991, 424*).

Alcohol is a very effective solvent for herbs. The active constituents or extracts not only are absorbed into the solution but also are simultaneously preserved by the high alcohol content (cf. **theriac**). Many different kinds of alcohol can be aromatized by adding either herbal extracts or **essential oils** (Mayr 1984). For example, Scandinavian aquavit, “the water of life,” is actually a grain alcohol to which the essential oil of caraway (*Carum carvi* L.) has been added. An absinthe substitute can be made by adding worm-wood (***Artemisia absinthium***) to alcohol:

Place the upper parts of the flowering herb in alcohol and allow the mixture to sit in a sunny location for two weeks. Shake often. Allow to sit undisturbed for another two weeks, strain, and store for a long time before drinking. (Mayr 1984, 96)

Many psychoactive plants are suitable for adding to alcohol. ***Cannabis*** may be added to tequila, ***Mandragora officinarum*** to brandy, ***Ephedra*** to brandy, ***Brugmansia*** to light rum, ***Datura innoxia*** to tequila, peyote (***Lophophora williamsii***) to mescal, and fly agaric (***Amanita muscaria***) to vodka.

This traditional *rakshi* container features the face of Bhairab, the god responsible for alcohol inebriation. (Nepal, twentieth century)

A Mexican bottle of cheap sugarcane alcohol. Shamans drink copious quantities of this during their healing ceremonies.

Ritual Use

Like all other alcoholic beverages (**beer**, **balche'**, **palm wine**, **wine**, pulque [cf. *Agave spp.*]), distilled alcohol is used throughout the world for ritual purposes (Babor 1988). Surprisingly, some kinds of alcohol are used as shamanic drugs to induce trance and are offered to mountain spirits, gods, and Mama Coca (cf. *Erythroxylum coca*). Alcohol is also consumed ritually in many modern societies, such as when one shares a drink with a guest. Similar modern rituals are initiating communal drinking by clinking glasses or proposing a toast, the drinking binges of fraternities, et cetera.

In Nepal, Parvati, the divine wife and shakti of the Hindu god Shiva, is usually regarded as the creator of *rakshi* (a distilled alcohol typically made from a mash of millet). *Rakshi*, which is typically made at home, is both offered and drunk at the Buddhist sacrificial rites of the Newari and other Nepalese ethnic groups. The Newari say that it is good to drink some *rakshi*, but never so much that one becomes drunk.

Shiva, in his terrifying form as Bhairab, is a great lover of **beer** and alcohol. Because of this, his followers often drink (great amounts of) alcohol so that they may better identify with him (Fouce and Tomecko 1990, 19). In Darjeeling and Sikkim, millet alcohol is sometimes made more potent by adding the seeds of *Datura metel*, a plant that is also sacred to Shiva/Bhairab (Biswas 1956, 70*).

The Aghoris, Tantrists who follow the left-hand path, are able to consume enormous amounts of distilled alcohol without becoming drunk. They use the alcohol to train and sharpen their minds, which they can then use to transform the inebriating effects of the alcohol (Svoboda 1993, 173; cf. *Aconitum ferox*, *Cannabis indica*).

The North American Iroquois have long allowed unusual dreams to guide them in their lives. In later times, they used the “firewater” that the Europeans introduced to produce such dream states (Carpenter 1959).

The Indians of Mexico offer and drink great amounts of alcohol (*aguardiente*, *refino*, *yolixpa*, *pox*) during many of their rituals and prayer ceremonies. They frequently consume such large quantities that the sacred events often culminate in a state of collective drunkenness (cf. Knab 1995, 160*; Loyola 1986).

The shamans (*nahualli*) of the modern Nahuat offer *aguardiente* to the soul eaters of Talocan, the underworld, who hold captive the lost soul-parts (*tonalli*) of humans. The *aguardiente* is intended to make these otherworldly beings drunk, as it is then easier for the shamans to pull the lost *tonal* away from the soul eaters (Knab 1995*). A close connection between alcohol and witchcraft is found in other Mexican Indian cultures as well (Viqueira and Palerm 1954).

In the highlands of Chiapas, *aguardiente* is one of the most important shamanic drugs (Siverts 1973). In Zinacatán (Chiapas), a special *pox* prepared for the feast of San Lorenzo consists of sugarcane alcohol, sugarcane, pineapple juice, and an extract of *Ipomoea violacea* (Dawn Delo, pers. comm., 1996). The renowned shamans (healers) of the village of Masao, near Cuzco (Peru), drink large quantities of *cañazo* (homemade sugarcane alcohol) during their healing rituals, offering ceremonies (*t'inkupas*), and coca oracles. They usually also ingest equally substantial amounts of coca (cf. *Erythroxylum coca*).

Postcard, Ireland, ca. 1993

A nineteenth-century observer provided the following description of the use of alcohol by the Siberian Samoyed and eastern Yakut shamans:

The shaman is familiar with his own kind, and yet he lives in enmity with the evil shamans. The shaman practices his art without compensation. Shamanism is passed down from father to son, although there are also female shamans. All of these shamans have their own specialty. One may be able to find lost objects, while another knows how to find the best places to fish. Others know how to reveal the site where a disease is located in the human body (worms on the heart for example!) or to locate stolen property. The shaman requires a glass of cognac, a knife, and a cross for this purpose. The latter object is needed especially by Christian, i.e., baptized shamans, for the power of the shaman has in no way been limited by Christianity and the cross. During the conjuration, the thief is struck in the eye with the knife. (Brutsgi 1987, 215)

When the Siberian people were forbidden to use the fly agaric mushroom for shamanic and hedonistic purposes during the Soviet era, many turned to vodka as a substitute. The shamans were able to utilize the alcohol, but many others became alcoholics.

Alcohol, and especially the associated problem of addiction, has been the subject of numerous autobiographical novels (famous examples include *John Barleycorn: Alcoholic Memoirs*, by Jack London, and *Der Trinker* [The Drinker], by Hans Fallada).

The Effects of Alcohol

The euphoric effects of certain amounts of alcohol may result from the release of endorphins or the activation of the endorphinergic system induced by alcohol (Verebey and Blum 1979). It has been speculated that acetaldehyde, the initial metabolite of alcohol, reacts with dopamine and enzymes to produce **morphinelike** substances, and that it is these that lead to alcoholism (Davis and Walsh 1970). It is possible that alcohol consumption may cause psychoactive **β -carboline**s (tetrahydroharmane, harmane; cf. **harmaline** and **harmine**) to be created in the body, and that these in turn are responsible for certain euphoric effects of the alcohol. Recent experiments have demonstrated that acetaldehyde and tryptamine are converted in vivo into tetrahydroharmane via an enzymatic process (Callaway et al. 1996). Elevated concentrations of harmane have been detected in the bodies of alcoholics (Susilo 1994).

The effects of alcohol can be changed, suppressed, or intensified by combining it with other substances. The effects may be suppressed by coca (*Erythroxylum coca*, *Erythroxylum novogranatense*), *Ephedra* species, **ephedrine**, **mescaline**, **cocaine**, henbane (*Hyoscyamus niger*), **nicotine**, LSD, and **psilocybin**. Both *Ledum palustre* and *Piper methysticum* can potentiate the effects of alcohol. Synergistic effects (interactions) can result when alcohol is used in combination with MAO inhibitors (**β -carboline**s), **diazepam**, and numerous medicines (psychopharmaceuticals).

Hallucinogenic Salamander Brandy

In the mountains northwest of Ljubljana, Slovenia, a distinctly hallucinogenic alcohol is still being distilled today according to ancient (alchemical) recipes. Following the distillation of a fruit mash, living European fire salamanders (*Salamandra salamandra*) are placed in the distillation vessel. The salamanders are then slowly heated to a very high temperature. It is said that the more the animals suffer, the more the desired alkaloids are exuded into the distillate. The salamanders' skin contains the psychoactive steroidal alkaloids samandarin³⁸⁸ and samandaridin. Samandenon is also present. The effects of salamander brandy are said to be similar to those of **ibogaine** or **strychnine**. In Slovenia, it is legal to distill live salamanders (Ogorevc 1995). An alternative method consists of simply adding living salamanders to high-percentage spirits (Valenčič 1998).

“I would say that the drug that gets you knocked up, blindly and unconsciously, is alcohol. Alcohol does reduce inhibitions—people become aggressive, indiscriminately loving *or* hostile, weepily self-pitying or self-expansive. Alcohol stimulates the social emotions.”

TIMOTHY LEARY

THE POLITICS OF ECSTASY

(1998, 213*)

“Salamanders have been known to be poisonous since the most ancient of times. Like toads, for thousands of years salamanders have played an important role as animals with magical powers. In ancient Persian mythology, the salamander was the animal that extinguishes fire, just as it did for the alchemists of the Middle Ages.”

GERHARD G. HABERMEHL

GIFT-TIERE UND IHRE WAFFEN [POISONOUS ANIMALS AND THEIR WEAPONS]

“The other type of drinker has imagination, vision. Even when most pleasantly jingled he walks straight and naturally, never staggers nor falls, and knows just where he is and what he is doing. It is not his body but his brain that is drunken. He may bubble with wit, or expand with good fellowship. Or he may see intellectual specters and phantoms that are cosmic and logical and that take the forms of syllogisms. It is when in this condition that he strips away the husks of life's healthiest illusions and gravely considers the iron collar of necessity to be welded about the neck of his soul. This is the hour of John Barleycorn's subtlest power.”

Ayahuasca

Other Names

Ambihuasca, ambiwáska, ayawáska, biaxíi, brew (“the brew”), caapi, cají, calawaya, camaramti (Shipibo), chahua (Shipibo), cipó, daime, dapa, dapá, djunglehuasca, djungle tea, doctor, dschungelambrosia, el remedio, hoasca, honi, iyaona (Zapara), jungle ambrosia, jungle-huasca, jungle tea, kaapi, kahi, kahpi, la droge (Spanish, “the drug”), la purga (Spanish, “the purgative”), la sogá, masha (Shipibo), metí, mihi, mii (Huaorani), moca jene (Shipibo, “bitter brew”), muka dau (Cashinahua, “bitter medicine”), natem (Achuar), natema, natemá, natemä, nepe, nepi, nichí cubin (Shipibo, “boiled liana”), nishi sheati (Shipibo, “liana drink”), nixi honi, nixi paé, notema, ohoasca, ondi (Yaminahua), pilde, pildé, pinde, pindé, rao (Shipibo, “medicinal plant”), remedio, sachahuasca, santo diame, uni (Conibo), vegetal, yagé, yajé, yaxé

The psychoactive drink known as ayahuasca has been used by shamans and medicine men in the Amazon region for healing rituals and shamanic experiences since pre-Columbian times (Naranjo 1979). Such use is probably as ancient as South American civilization itself and apparently was first discovered in the western regions of the Amazon basin (now Ecuador) (Naranjo 1979). In the coastal regions of Ecuador, so-called witches’ pots—used for brewing ayahuasca—have been discovered in archaeological excavations. These pots are estimated to be about 3,500 years old (Andritzky 1989, 57*).

How the beverage was first discovered is still a mystery. But it certainly was more than just an accidental discovery made by primitive Indians:

A long time ago, a skilled hunter lived in the rain forest. One day, when he was far from his home, he heard a liana speaking to him. The hunter, who knew many things about making arrow poisons from roots, barks, and seeds for hunting, understood the power of plants. He returned to his house with his new find.

Banisteriopsis caapi stems are the basis of all ayahuasca preparations.

The leaves of *Psychotria viridis*, which contain DMT, are the most popular ayahuasca admixture.

During the following night, he had a dream in which the spirit of the liana explained to him how to prepare it into a brew that one could use to heal many diseases.

Today, shamans still use the “drink of true reality” to determine the origins of diseases, travel into the normally invisible world of the forest, communicate with the lords of the animals and plants, and accompany the participants of tribal rituals into the world of myths.

The beverage is a unique pharmacological combination of the ***Banisteriopsis caapi*** liana, which contains harmaline, and chacruna leaves (***Psychotria viridis***), which contain DMT. Harmaline is an MAO inhibitor—it inhibits the excretion of the endogenous substance monoamine oxidase, which breaks down the psychoactive substance ***N,N-DMT***. It is only through this combination of active

ingredients that the drink is able to produce its consciousness-expanding effects (Rivier and Lindgren 1972). Because of the powerful and often three-dimensional visions, ayahuasca is sometimes jokingly referred to as “Amazonian television” (“the Nature Channel”) or “jungle cinema.”

The shamans attribute the effects of ayahuasca not to any active constituent but to the plant spirits who reveal themselves as master-teachers to humans when they are under the influence of ayahuasca. The plant spirits make it possible for humans to discover the origins of a disease, obtain the recipe for a medicine, and find out where the wild game is hiding deep in the forest. The shamans have been using their magical drink for a long time, and clearly with great success. As former rain-forest regions have become increasingly urbanized, more and more non-Indians have come into contact with the magical drink, which has led to the development of an urban shamanism. Now, many Catholic mestizos have set themselves up as urban shamans and use the drink to treat the afflictions of city dwellers. Their rituals are a colorful mix of Indian and Catholic customs during which Christian songs are sung and the spirits of the forest invoked (Dobkin de Rios 1970, 1972, 1989, 1992; Luna 1986). Numerous ayahuasca churches and sects have emerged, as has a vigorous ayahuasca tourism.

Recipes

In the past, methods for preparing ayahuasca were well-protected secrets of the shamans. Only they knew the ingenious recipes. Only they knew which plants to use, where to find the lianas and herbs, which protective spirits needed to be invoked, and how to prepare the brew.

Banisteriopsis caapi stems are the basis for all ayahuasca recipes. To prepare ayahuasca, manageable-size stems of this liana must be boiled, after which chacruna leaves (***Psychotria viridis***) are added. The mixture is allowed to sit on the fire until a black, thick, horrible-tasting liquid results. The drink should never be prepared in aluminum pots, as it will corrode the aluminum and may in some cases produce inedible aluminium salts. Although cold-water extracts of *Banisteriopsis caapi* and *Psychotria viridis* will also produce the desired effects, they are only rarely made.

In the recipes of the Amazonian Indians, the liana itself is typically the main ingredient. Tests of different samples have found 20 to 40 mg, 144 to 158 mg, and even 401 mg of **β-carbolines** as well as 25 to 36 mg of ***N,N*-DMT** per dose. The ayahuasca prepared by the urban mestizos contains consistently higher concentrations of alkaloids (especially *N,N*-DMT) than are found in the Indian preparations. The highest concentrations are said to be found in the preparations of the Barquinha Santo Daime church (Luis Eduarda Luna, pers. comm., 1996).

Natema Recipe of the Shuar

The Shuar shamans (*uwishin*) split a 1- to 2-meter-long piece of ***Banisteriopsis caapi*** stem into small strips. They place the strips in a pot along with several liters of water. They then add leaves of ***Diplopterys cabrerana***, a *Herrania* species, ***Ilex guayusa***, *Heliconia stricta*, and an unidentified Malpighiaceae known as *mukuyasku*. The resulting mixture is boiled until most of the water has evaporated and a syrupy fluid remains (Bennett 1992, 486*). The Kamsá, Inga, and Secoya make similar preparations (Bristol 1965, 207 ff.*).

Ecuadoran Recipe

The bark of the ***Banisteriopsis caapi*** liana is peeled off and placed beneath a certain tree in the forest.

A Shipibo man inspects his chacruna plant (*Psychotria viridis*).

Ayahuasca prepared from *Banisteriopsis caapi* and *Psychotria viridis*.

A Tukano ayahuasca vessel and drinking bowls. (From Koch-Grünberg, *Zwei Jahre bei den Indianern Nordwest-Brasiliens* [Two Years among the Indians of Northwest Brazil], 1921)

These paintings on the community house (*maloca*) were inspired by the use of ayahuasca. (From Koch-Grünberg, *Zwei Jahre bei den Indianern Nordwest-Brasiliens* [Two Years among the Indians of Northwest Brazil], 1921)

The bare stems are then split into four to six strips and boiled together with fresh or dried ***Psychotria viridis*** leaves. A piece of liana approximately 180 cm long and forty *Psychotria* leaves represent a single dosage, although a piece of stem just 40 cm long and 3 cm thick is also said to be sufficient. In general, the less vine that is used, the easier the ayahuasca is on the stomach.

Preparation of the União do Vegetal (UDV), Brazil

Pieces from the ***Banisteriopsis caapi*** vine are pounded, mixed with leaves from ***Psychotria viridis***, and boiled for 10 to 12 hours in rust-free steel pots until all that remains is a thick liquid with globules of fat on the surface that shimmer in all colors of the spectrum.

Recipe of the Shipibo of San Francisco/Yarinacocha

A fresh piece of ***Banisteriopsis caapi*** bark is boiled together with a handful of chacruna leaves (***Psychotria viridis***) and a *flor de toé* (***Brugmansia suaveolens*** flower) until a thick liquid decoction is produced. This preparation is said to have especially strong effects and to produce many visions.

Indigenous ayahuasca preparations exhibit considerable variation. Numerous plant admixtures can be used to induce psychoactive effects, and stimulating or medicinal drinks can also be produced. An Ecuadoran preparation of ***Banisteriopsis caapi*** and ***Ilex guayusa*** is purported to be a strong purgative. Recipes that cause delirium often contain tobacco and angel's trumpets (***Brugmansia***). Experienced ayahuasca shamans possess a vast wealth of knowledge about the effects of many plants and may utilize more than one hundred different admixtures in order to achieve the effects they desire.

These traditional preparations are often devoid of ***N,N*-DMT**. However, it is precisely those drinks that do contain high concentrations of DMT and that do produce visionary effects that have exerted such a powerful attraction on legions of Western enthnobotanists, psychedelic cognoscenti, artists, New Age tourists, and seekers of the esoteric (Leginger 1981*; McKenna 1989*; McKenna and McKenna 1994*; Perkins 1995). For most outsiders, experiences with Amazonian ayahuasca have tended to be rather disappointing (McKenna 1993). Westerners seeking “highs” or healing experiences are often duped by the pranks of *curanderos* or self-proclaimed shamans. As early as 1953, William Burroughs reported, “. . . I had been conned by medicine men ”(Burroughs and Ginsberg 1963, 15). But there are also examples of more positive experiences (Pinkson 1993; Wolf 1992).

A very ancient, presumably pre-Columbian petroglyph found on a granite cliff in Nyi on the lower Río Piraparaná (Colombia). The Tukano believe that it was at this sacred place that the Sun-Father wed the first earth woman, thereby creating the Tukano people. The Desana (one of the Tukano tribes) interpret the triangular face as the cosmic vagina and the stylized human figure below it as a winged phallus. They say that ayahuasca was created at the beginning of history when the two poles were united. (Redrawn by C.

Traditional Ayahuasca Admixtures

(from Ayala Flores and Lewis 1978; Bennett 1992*; Bianchi and Samorini 1993; Faust and Bianchi 1996; Luna 1984b, 1986; Ott 1993, 269 ff.*; Ott 1995; Pinkley 1969; Schultes 1972; modified and expanded)

“The natives use ayahuasca in ceremonies for healing and to obtain visions and describe the liquid as their ‘university.’”

OLAF KRAEMER

LUZIFERS LICHTGARTEN [LUCIFER’S GARDEN OF LIGHT]

(1997, 142*)

“Gradually, faint lines and forms began to appear in the darkness, and the shrill music of the *tsentsak*, the spirit helpers, arose around him. The power of the drink fed them. He called, and they came. First, *pangi*, the anaconda, coiled about his head, transmuted into a crown of gold. Then *wampang*, the giant butterfly, hovered above his shoulder and sang to him with its wings. Snakes, spiders, birds and bats danced in the air above him. On his arms appeared a thousand eyes as his demon helpers emerged to search the night for enemies. The sound of rushing water filled his ears, and listening to its roar, he knew he possessed the power of *Tsungi*, the first shaman. Now he could see. Now he could find the truth. He stared at the stomach of the sick man. Slowly, it became transparent like a shallow mountain stream, and he saw within it, coiling and uncoiling, *makanchi*, the poisonous serpent, who had been sent by the enemy shaman. The real cause of the illness had been found.”

MICHAEL HARNER

THE SOUND OF RUSHING WATER

(1973, 15 f.)

“I came to the realization, that all plants which are called the *doctores*, or *vegetales que enseñan* (= plants, the teachers) either 1) elicit hallucinations when they are taken alone, 2) in some way influence the effect of the *ayahuasca* drink, 3) cause dizziness, 4) have strongly emetic and/or cathartic qualities, or 5) elicit very vivid dreams. Often a plant has all of these characteristics or at least some of them.”

LUIS EDUARDO LUNA

“THE CONCEPT OF PLANTS AS TEACHERS”

(1984a, 135–56)

“Every time I took ayahuasca I became dizzy, sometimes I traveled through the air, where I remember seeing the most beautiful views, such as big cities, high towers, wonderful parks, and other incredible things. Other times I found myself lost in the forest, where I was attacked by wild animals.”

M. VILLAVICENCIO

GEOGRAFÍA DE LA REPUBLICA DEL ECUADOR [GEOGRAPHY OF THE REPUBLIC OF ECUADOR]
(1858, 373)

In the Brazilian Santo Daime cult, certain religious songs are sung at worship ceremonies while worshippers are under the influence of ayahuasca. The most important of these songs were released privately on a CD in 1996. (CD cover, ©Richard Yensen, Orenda Institute)

Traditional Uses

To the shaman, ayahuasca is inseparable from the rain forest. The power of the drink enables him to see the spirits that are present in the plants and animals of the forest. He communicates with them and acquires a knowledge of their innermost being. In this way, he comes to know the significance of every individual animal and every single plant and to understand why each species has its necessary place in the “circle of life.” With the aid of ayahuasca, he seeks out the lords of the animals. In the “true reality,” these appear to him in human form, and from them he learns, for example, why the hunters are no longer able to find their children, the animals. The reason might be that an unknown hunter has killed too many animals, leaving the bodies behind in the jungle, unused and rotting. This enrages the lord of the animals, and he demands compensation. The shaman must impregnate the soul of a female animal so that there will again be enough offspring. The shaman returns to everyday life, reports about his experiences, and warns the hunters that they will be able to hunt these animals again only if they give them time to recover. Any hunter who violates this law will be punished by the lord of the animals, perhaps with an invisible magical arrow.

The shamans utilize the visionary effects of ayahuasca to travel to the true reality, often referred to as the “blue zone,” where they are able to explore the secrets of the past, present, and future; to heal sick members of the tribe; or to fight against a harmful sorcerer, a “black shaman” (Reichel-Dolmatoff 1996b*), who typically sends invisible objects (such as arrows, thorns, or crystals) into the body of his victim. In the mundane world, nothing about the victim appears to be different. It is only when the shaman drinks the ayahuasca that he is truly able to see. If he can recognize the alien magical objects, he can suck them out and remove them. To make the invisible healing process manifest to the external, visible world, he proudly shows the patient and the others in attendance a bloody thorn that he had previously placed in his mouth with a clever sleight of hand. This small “deception”—which serves only to make the invisible visible—is essential to the success of the treatment (Ott 1979).

Fiery hot chili pods (*Capsicum* sp.) may be added to the ayahuasca drink.

In Mayan culture, the *kapok* tree (*Ceiba pentandra*) is regarded as the World Tree, which links the different levels of the universe with one another. The shaman can use the tree to climb up to the heavens or to descend to the underworld. The *kapok* is also viewed as a World Tree and shamanic tree in South America, where it is used as an ayahuasca admixture. Although the tree does have a symbolic significance, it probably has no psychoactive effects. (Photographed at Palenque in Chiapas, Mexico)

Chorisia insignis, the sacred Argentinean tree known as *palo borracho* (“drunken tree”), looks like a “pregnant” *Ceiba pentandra*, and the two trees are very easily confused. Its bark is sometimes used as an ayahuasca additive.

Many South American peoples venerate the pink-flowering *Chorisia speciosa* as a shamanic tree or World Tree. The bark of this tree is used as an ayahuasca additive.

The fruit of this rattletree (*Thevetia* sp.) is added to ayahuasca as a powerful magical substance; such use, however, appears to be very dangerous.

In Amazonia, the tropical tree *Couroupita guianensis* is regarded as a medicine that stimulates dreams; for this reason it is added to ayahuasca. Because of the flowers’ unusual beauty and the unusual way in which they grow directly out of the trunk, the tree has spread into all tropical regions as a decorative plant. In Thailand, it is even religiously venerated.

This *Tournefortia* species is used as an ayahuasca additive. (Photographed in northwestern Peru)

Ipomoea carnea, known locally as *toé*, is used as an ayahuasca admixture in the Pucallpa region. (Photographed in Peru)

“*Nixi honi* vision vine boding spirit of the forest origin of our understanding give up your magic power to our potion illuminate our mind bring us foresight show us the designs of our enemies expand our knowledge expand our understanding of our forest.”

AYAHUASCA SONG OF THE AMAHUACA INDIANS

IN *THE NATURAL MIND*

(WEIL 1972, 106)

Amazonian shamans usually travel to the other reality while in a different form. The *payé* has “turned his stomach inside out”—this is how the Tukano describe the condition in which the shaman’s body lies as if dead while his consciousness has taken off into another reality. The shamanic soul has transformed itself into a jaguar and now flies over a rainbow to the Milky Way. The most fantastic colors and forms unfold before the shaman’s inner eye. Honeycomb patterns dance by and change into crystals filled with an otherworldly light. Wavy lines flow out and back together into colorful swirls. The jaguar shaman is irresistibly sucked in. The swirls open into a tunnel made of circling skulls, at the end of which shines a warm, blue light. The jaguar shaman has reached the Milky Way, where he meets the ayahuasca woman who revealed the true reality to humans at the dawn of creation and gave them the secret of the “drink of true reality” (Reichel-Dolmatoff 1971*, 1975*, 1978*).

Although the true reality lies beyond the Milky Way, it is nevertheless a mirror image of the rain forest. To the shamans, the mundane visible world is only a world of appearances; behind its manifestations, the world of myths, gods, and spirits operates. All that happens in the mundane world finds its cause in this true reality. Here is where the causes of diseases, absent wild game, and droughts and floods can be found. The true reality is hidden from the normal eye (Baer 1987; Reichel-Dolmatoff 1996*), and one can attain a glimpse of it only through dreams and visions. The shaman is a specialist in dreams and visions, and he functions as a kind of tour guide in the other

reality. His most important tool for this task is the magical drink ayahuasca (Deltgen 1993). Because the contents of the ayahuasca visions are culturally interpreted, they often become standardized patterns that make it possible for the Indians to swiftly and purposefully arrive in the realm of the all-important visionary world (Langdon 1979).

Shamans often prepare for an ayahuasca session by remaining sexually abstinent for a time (from three days to six months), adhering to special dietary rules, and using purgative and laxative substances, **enemas**, libations, and so on. The ayahuasca diet prohibits the consumption of salt, chili (*Capsicum* spp.), spices, and fat. The Jíbaro drink guayusa (*Ilex guayusa*) to make themselves vomit. The Siona and Secoya drink a cold-water extract of the liana they call *hetu bisi* (*Tournefortia angustiflora* Ruiz et Pav.; Boraginaceae) to purify themselves before the ritual (Vickers and Plowman 1984, 8*).

Ayahuasca rituals are often accompanied by the continuous smoking of tobacco (*Nicotiana rustica* or *Nicotiana tabacum*). The tobacco is said to banish evil spirits, that is, unpleasant and threatening visions. In addition, participants may also drink great quantities of **chicha** or some other type of **alcohol** (Bennett 1992, 486*) and chew *ipadú* (*Erythroxylum coca*). Sometimes, *Brugmansia* leaves will be soaked in rum and drunk as a tonic. The mestizo shamans burn camphor (*Cinnamomum camphora*) as an **incense** during their ayahuasca healing ceremonies, possibly to enhance the psychoactivity (Luna 1992, 246 f.). If a shaman wants to learn about an unknown plant and its healing properties, he may add the plant to an ayahuasca mixture before he drinks it.

Artifacts

A great number of different artifacts are related to ayahuasca (Mallol de Recasens 1963). The Tukanos interpret many Amazonian petroglyphs as ayahuasca images (Reichel-Dolmatoff 1967*). They decorate their houses with the patterns and figures they see during their ayahuasca journeys. These patterns often take on symbolic dimensions and can tell initiates entire stories from the other reality (Reichel-Dolmatoff 1978*). The patterns seen under the influence of ayahuasca are also woven into such everyday objects as baskets (Reichel-Dolmatoff 1985*, 1987*).

Jíbaro artists make many images depicting their ayahuasca experiences (Münzel n.d., 204, 205, 207, 212, 213). Yando Rios, a Peruvian artist who now lives in California, made numerous paintings of his early ayahuasca visions (Andritzky 1989, 191). The paintings of the former *ayahuasquero* Pablo Amaringo are particularly impressive and have become quite renowned. His visionary paintings portray the entire ayahuasca mythology (including the syncretic elements), the jungle pharmacopoeia, and the other reality of the shamanic universe (Luna 1991; Luna and Amaringo 1991). Many Latin American and Western artists, e.g., Alexandre Segrégio, have also painted their ayahuasca visions (Weiskopf 1995).

In 1953, William Burroughs (1914–1997) traveled to the Amazon basin to learn about the ethnopharmacology of the mysterious magical drink of the Amazon Indians and to try it himself. His experiences were published in the book *The Yage Letters* (Burroughs and Ginsberg 1963).

The best-selling novel *The Incas* contains numerous descriptions of ayahuasca experiences (Peters 1991*). The Peruvian poet César Calvo published a magnificent poem, inspired directly by ayahuasca and the story of Bruce Lamb (1974), in his book *The Three Halves of Ino Moxo* (1995).

The Shipibo-Conibo Indians have developed an astonishing method for encoding and decoding the patterns they see under the influence of ayahuasca in songs. When they want to use a certain pattern to paint their face, an article of clothing, or a piece of pottery, they sing the pattern. The person who is doing the painting, usually a woman, will then translate the song into a design (Gebhardt-Sayer 1985, 1987; Illius 1991).³⁹⁵

Ayahuasca songs also play a role in traditional shamanism, where they are used primarily as a map

for the journey into the other reality. Whistled melodies for creating certain standardized visions have an important part in the ayahuasca shamanism practiced by the urban healers of Iquitos (Katz and Dobkin de Rios 1971). The so-called *icaros* (shamanic power songs) are also used for this purpose (Luna 1986, 1992).

A Shipibo ceramic jug (*chomo*) painted with ayahuasca designs.

Ayahuasca designs—originally seen under the influence of the magical drink—on a piece of Shipibo fabric.

The preparation of the ayahuasca drink, as depicted on a painting by Pablo Amaringo, a former *ayahuasquero*.

Ayahuasca Churches

In addition to the true shamanic use of ayahuasca, in recent decades various syncretic churches that use ayahuasca as a sacrament have emerged in Amazonia. Some ayahuasca churches have integrated African orishas into their cult. In Brazil, there are also non-Christian sects that use ayahuasca ritually to venerate spirits (Prance 1970, 67*).

Both in the Santo Daime cult and in the ayahuasca church known as União do Vegetal, regular meetings are held at which the followers—overwhelmingly mestizos from the lower and middle classes—drink ayahuasca communally and sing devotional songs. Guided by a priest, the congregation travels to both the spirits of the forest and to the Christian saints. Many of the cult participants discover a new purpose in life and find healing for their souls. Like the shamans of the forest, the adherents of these Brazilian churches (which have now gained a foothold in Europe as well) are legally permitted to use the magical and ritual drink, which they prepare from *Banisteriopsis caapi* and *Psychotria viridis* (Lowy 1987). The DMT content of their brew is typically higher than that of the more traditional preparations (Liwszyc et al. 1992). At the meetings, pleasant-smelling *breuzinho* (**incense** made from *Protium heptaphyllum* and *Protium* spp.) is burned. Sometimes *Cannabis indica* (Santa María) is consumed as well.

Barquinha Daniel Periera de Matos, the founder of one branch of the Santo Daime cult, was once in

the navy. As a result, his congregations are structured along military lines and the congregants all wear uniforms. Barquinha saw his church as an institution open to the entire world, and the cult has been carried to the Western world with missionary zeal (Bogers 1995). Men, women, and children are all allowed to take part in the ceremony. Even pregnant women drink *daime*. It is said that this has never resulted in problems of any kind!

“The modern *ayahuasca* cult originated in the Amazon when a Christian took this substance and had a vision of Mary, who appeared to him as Our Lady of the Forest. She was clad in green and revealed the outlines of the ritual use of *ayahuasca*—which the devotees call *daime*—as a communion.”

RUPERT SHELDRAKE

IN *CHAOS, CREATIVITY, AND COSMIC CONSCIOUSNESS*

(SHELDRAKE, MCKENNA, AND ABRAHAM 2001, 135–36*)

In the Daime cult, the *Banisteriopsis caapi* liana is regarded as the embodiment of Jesus and the leaves of *Psychotria viridis* as Mary. The finished brew is regarded as the flesh and blood of Christ. During the ceremony, *Cannabis* (which they call Santa María) is smoked as a sacrament. Europeans often report having profound spiritual experiences, during which Jesus, Mary, and the spirits of the forest reveal themselves (Luczyn 1994; Weigle 1995). Often consumed daily, *daime* is considered both healthy and therapeutic (Groisman and Snell 1996), and various types of addictions are now being treated within the context of the Santo Daime cult (Yatra 1995). In Peru, the Takiwasi project is investigating the effects of shamanic therapy with ayahuasca on drug addicts. Initial reports indicate that this method has great promise (Mabit et al. 1986).

The other large ayahuasca church, which was founded by Gabriel da Acosta, is known as the União do Vegetal (UDV). In recent years, this church has attracted increasing numbers of Brazilians, most of whom have been culturally uprooted. Because the effects of the ayahuasca drink are clearly regarded as positive, the Brazilian government has made this psychoactive agent legal when used within the framework of cult and religious ceremonies. This unusual sociopolitical situation has made it possible to carry out interdisciplinary research. Under the direction of Charles Grob, Dennis McKenna, and James Callaway, universities in the United States (California), Finland, and Brazil joined together to investigate the medicinal, pharmacological, and health effects of regular ayahuasca use on the members of the church. The research was carried out on location, that is, in the temples of the UDV. Standardized psychiatric tests accepted throughout the world were administered to a test group before, during, and after the ingestion of ayahuasca. The test subjects were also given standard medical tests while they were under the influence of ayahuasca. The data that was obtained was analyzed at the University of California at Los Angeles. A control group of Brazilian workers who had never taken ayahuasca were given the same tests for purposes of comparison. The pilot study for this large-scale project revealed that the cult members who regularly ingested ayahuasca were on average far more healthy in both body and mind than the group that had never had contact with ayahuasca. This research project will certainly provoke a radical rethinking of the medicinal and psychiatric attitudes about psychoactive substances that are currently accepted in the West (Callaway et al. 1994; Grob et al. 1996; cf. Dobkin de Rios 1996).

Ayahuasca Tourism

The many reports of travelers' experiences with Amazonian shamans have led to a kind of pilgrimage of Westerners to the rain forest. For years, tourists from around the world have been attracted to the magical realm of ayahuasca. Many of these seekers have promised themselves personal insights and mystical experiences. In turn, numerous greedy, self-proclaimed pseudo-

shamans have exploited the hopes of these tourists. They openly offer ayahuasca rituals, but the desired effects typically do not occur. These entrepreneurs are not initiated shamans who know what their recipes can do. In the best cases, the brew they offer simply is ineffective. Sometimes, however, even highly toxic plants may be tossed into the brew, which is then offered at great cost as “genuine Amazonian ayahuasca.” The journey, which should take one to mystical domains, may actually end with the tourist in a coma or at the hospital (Dobkin de Rios 1995).

But those travelers who have the good fortune to encounter real shamans typically report having spiritual, mystical, and healing experiences (Ayala Flores and Lewis 1978; Pinkson 1993; Wolf 1992).

Pharmacology

Unbelievable rumors and amazing reports of the wondrous effects of ayahuasca have been making their way to the West since the nineteenth century. It was said that people under the influence of ayahuasca were able to go through walls, locate hidden treasures, see through mountains, know the future, and take part in events happening in far distant places. Both missionaries and physicians have claimed that the drink could awaken and even increase telepathic abilities.

It was only in recent times that the neuro-chemical secrets of the visionary effects of ayahuasca could be clarified (Rivier and Lindgren 1972). The two main active constituents of ayahuasca are harmaline (= telepathine) and *N,N*-DMT. When ingested, DMT cannot reach the brain because it is broken down by the enzyme monoamine oxidase (MAO). **Harmaline** (as well as harmine and several other **β-carbolines**) inhibits the release of MAO. (It was recently discovered that ayahuasca inhibits only MAO-A [D. McKenna 1996*].) This makes it possible for DMT to pass unhindered through the blood–brain barrier, occupy specific receptor sites, and cause the nervous system to enter into an extraordinary state characterized by brilliant and overwhelming visions (McKenna et al. 1994a, 1994b; McKenna and Towers 1985*).

The effects last for some four hours. The **harmaline** first induces a sedation that sometimes results in immobility. During this phase, in which the effects first become manifest, harmaline can cause profound nausea and frequently induces vomiting. The psychedelic DMT effects set in some forty-five minutes after ingestion of the drink. The main visionary effects last for about an hour and then suddenly cease. The nausea usually disappears when the DMT effects begin. When ayahuasca is used on a regular basis, the body becomes accustomed to the pharmacological action of the harmaline, and many chronic users find that they no longer experience nausea. Because the body does not build up tolerance to *N,N*-DMT, a person can consume ayahuasca several times a day.

The Legal Situation

At the present time, ayahuasca is completely legal in Brazil. The legal situation in other Amazonian countries is less clear. Because the drink contains the prohibited substance *N,N*-DMT, the legal situation is very difficult in Western countries.

Patent No. 5751, which the International Medicine Corporation (represented by Loren Miller) registered at the United States Marks and Patents Office in June 1996, created a perversely odd situation (Fericgla 1996a). In taking the step, this corporation hoped to secure for itself a patent and copyright on ayahuasca, that is, to monopolize the chemical and pharmacological principles of ayahuasca. If the patent had come into force, the Indians—the inventors and guardians of the ayahuasca brew—would have been forbidden to brew their own drink or, more precisely, would have been allowed to make it only if they paid licensing fees to the corporation. In Ecuador, for example, which recognizes American patent laws, the few remaining traditional Indians would have had to pay money to the owners of the copyright on ayahuasca every time they prepared it. As of 2004, however, this patent has not gone into effect.

The heads of some four hundred Amazonian tribes wrote an open letter to then president Bill Clinton protesting this incredible impudence. As Valerio Grefa, the speaker of the Confederation of Indian Organizations of the Amazon Basin, exclaimed: “Patenting our medicine, which we have inherited through many generations, is an attack on the culture of our peoples and on all of humankind.”

“Because the Yebamasa have a theory of reality that differs from ours, they also have a different conception of true consciousness and of the true recognition of reality. The ability that enables the Yebamasa to recognize reality is neither intellectual nor emotional nor intuitive. It encompasses all these kinds of awareness and adds another—the mystical experience, through hallucinations and visions in the state of toxic ecstasy, of a realm of reality that cannot normally be experienced. According to the Yebamasa conception, humans are able to penetrate the foreground of ordinary reality with *caji* [= ayahuasca]. To those who are knowledgeable, this ordinary reality appears as the world of effects, whereas the world of myths is that of causes. . . . The mythological reality experienced in the *caji* visions is just as real and natural as the ordinary world—perhaps even more real.”

FLORIAN DELTGEN *GELENKTE EKSTASE* [GUIDED ECSTASY]
(1993, 125 f.)

“The songs have a special importance during the ayahuasca séances, for through them all the figures of the ayahuasca world manifest themselves as visions. The songs are the activating and formative stimulus that structures and controls the sequence of the mentally preexisting cultural-mythic pattern of the visions.”

WALTER ANDRITZKY “ETHNOPSYCHOLOGISCHE BETRACHTUNG DES HEILRITUALS MIT AYAHUASCA” [“AN ETHNO-PSYCHOLOGICAL CONSIDERATION OF THE AYAHUASCA HEALING RITUAL”]
(1989a, 186)

“The narcotics produced a miracle! My performance is greeted with appreciative comments and deemed to consist of true *natem* songs. But soon my intoxication takes a new turn. Against the serene glow of the night, phosphorescent circles begin to whirl, then merge and separate, forming constantly changing kaleidoscopic designs. One after another all the symmetrical patterns invented by nature pass before me in a subtle continuum: lozenges first red, then yellow, then indigo, delicate traceries, crystalline prisms, iridescent scales, the eyes of butterfly wings, feline pelt markings, reticular carapaces.”

THE ETHNOLOGIST PHILIPPE DESCOLA, WRITING ABOUT HIS PERSONAL EXPERIENCE WITH AYAHUASCA
IN *THE SPEARS OF TWILIGHT*
(DESCOLA 1996, 207*)

Ayahuasca Analogs and Pharmahuasca

Other Names

Anahuasca, ayahuasca borealis

The effects of the pharmacological principle that was discovered during the investigations of traditional **ayahuasca** can be imitated with other plants that contain the same constituents (**harmaline**, **harmine**, **N,N-DMT/5-MeO-DMT**). Today, nontraditional combinations of plants with these ingredients are known as ayahuasca analogs or anahuasca. Combinations composed of isolated or synthesized constituents are referred to as pharmahuasca:

Paradoxically, psychonautic research on *pharmahuasca* . . . , which is so far out of the scientific mainstream that nearly three decades had to pass before unfunded and independent scientists working underground and in secrecy put the enzyme-inhibitor theory of *ayahuasca* pharmacology to the test, may turn out to be at the center of research on the biochemistry of consciousness and the genetics of pathological brain function! Not only is *ayahuasca* research now at the neuroscientific cutting edge, but the reversible MAO-inhibitors in *ayahuasca* may prove to be viable, less toxic alternatives to the noxious compounds currently in use! (Ott 1994, 69)

The term *ayahuasca analog* appears have been coined by Dennis McKenna. The American ethnobotanist Jeremy Bigwood was probably the first person to test pharmahuasca (100 mg each of **harmaline** hydrochloride and **N,N-DMT**) on himself; he reported “DMT-like hallucinations” (Ott 1994, 52). The chemist and chaos theorist Mario Markus used the Heffter technique (self-experimentation) to perform extensive experiments into the optimal proportions for mixing the alkaloids:

Markus reported on the studies that he had carried out several years earlier in which the plant combinations used by Indian peoples in the Amazon region for ritual purposes were simulated experimentally. In those experiments, Markus mixed one sample each of a representative of the β -carbolines (harmine, harmaline, or 6-MeO-harmaline) with a tryptamine (5-MeO-DMT). This yielded a domain of different optimal mixture ratios within which a marked psychoactive productivity with hallucinatory effects occurred. Within quite specific dosage limits, there was a good overall tolerance without serious side effects. (Leuner and Schlichting 1986, 170*)

For Jonathan Ott, the value of the ayahuasca analogs lies in their entheogenic effects, which can help one attain a more profound spiritual ecology and a mystical perspective. **Ayahuasca** and its analogs can induce a state of shamanic ecstasy, but only when used at the proper dosage:

Shamanic ecstasy is the *real* “Old Time Religion,” of which modern churches are but pallid evocations. Our forebears discovered in many times and places that in the ecstatic, entheogenic experience, suffering humankind could reconcile the cultivated braininess, which isolated each individual human being from all other creatures and even from other human beings, with the

wild and feral, beastly magnificent bodies that we also are. . . . There is no need for faith, it is the ecstatic experience itself that *gives* one faith in the intrinsic unity and integrity of the universe, in ourselves as integral parts of the whole; that reveals to us the sublime majesty of our universe, and the fluctuant, scintillant, alchemical miracle that is quotidian consciousness. . . .

Entheogens like *ayahuasca* may be just the right medicine for hypermaterialistic human-kind on the threshold of a new millennium which will determine whether our species continues to grow and prosper, or destroys itself in a massive biological Holocaust unlike anything the planet has experienced in the last 65 million years. . . .

The Entheogenic Reformation is our best hope for healing Our Lady Gaea, while fostering a *genuine* religious revival for a new millennium. (Ott 1994, 89–90)

Recipes

All recipes must contain an MAO inhibitor as well as a source of **DMT**. To date, experiments have been conducted only with ***Banisteriopsis caapi***, ***Banisteriopsis spp.***, ***Peganum harmala***, and synthetic (pharmaceutical) MAO inhibitors. But there are other MAO inhibitors in nature, such as ***Tribulus terrestris***. The ongoing investigations into St. John's wort (*Hypericum perforatum* L.) and other *Hypericum* species³⁹⁶ as possible MAO-inhibiting admixtures are very interesting. Hypericin, the primary active constituent in *Hypericum* spp., "has been proven to be a monoamine oxidase inhibitor" (Becker 1994, 48*). ***Psychotria viridis*** and ***Mimosa tenuiflora*** have been looked at as sources of DMT, but numerous other possibilities also exist (see the tables on the following pages). The dosages are determined by the alkaloid concentrations in the various admixtures (DeKorne 1996; Ott 1994).

Many grasses (from the genera *Arundo*, *Phalaris*, and *Phragmites*) contain DMT and are increasingly being tested for use as ingredients in ayahuasca analogs. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

As with traditional **ayahuasca**, most ayahuasca analogs have a thoroughly disgusting taste and are therefore generally difficult to force down (because they are forced up again from below). Chewing sliced ginger (***Zingiber officinale***) can help counteract the often repulsive taste (DeKorne 1994, 98*).

The following recipes are formulated to yield a single dose.

Classic Ayahuasca Analog

25 g ***Psychotria viridis*** leaves, dried and ground

3 g ***Peganum harmala*** seeds, crushed

Juice of one lemon

Enough water to boil all the ingredients (approximately 200–350 ml)

Place all the ingredients in a steel pot. Slowly bring to a boil, then boil rapidly for two to three minutes. Reduce the heat and simmer for approximately five more minutes. Pour off the decoction. Add some water to the herbs remaining in the pot and boil again. Pour the first decoction back into the pot. After a while, pour out the liquid once more. Add fresh water to the remaining herbs and bring to a boil again. Remove the plant remnants and compost them, if possible. Mix together the three extracts. Carefully heat the mixture to reduce the total volume. The tea should be drunk as fresh as possible (allow to cool first), although it can be stored in the refrigerator for a few days. The effects begin about forty-five minutes after ingestion. The visionary phase lasts about an hour.

Juremahuasca or Mimohuasca

Connoisseurs consider this ayahuasca analog to be both the most easily tolerated and the most

psychoactive preparation.

3 g *Peganum harmala* seeds, finely ground

9 g *Mimosa tenuiflora* root cortex

Juice of one lime or lemon

The crushed Syrian rue (*P. harmala*) seeds may be either swallowed in a gelatin capsule or mixed in water and drunk. The decoction of lemon juice and mimosa root cortex should be drunk fifteen minutes later.

Prairie Ayahuasca

This blend is especially popular in North America. Predominantly pleasant experiences have been reported (Ott 1994, 63; cf. DeKorne 1994, 97*).

3–4 g *Peganum harmala* seeds, finely ground

30 g *Desmanthus illinoensis* root cortex (prairie mimosa, Illinois bundleweed, Illinois bundleflower)

Juice of one lemon or lime

Prepare in the same manner as juremahuasca (above).

Precisely measured ingredients for mimohuasca, an ayahuasca analog made with 9 g of *Mimosa tenuiflora* root cortex and 3 g of Syrian rue (*Peganum harmala*).

The root of the American shrub known as prairie mimosa (*Desmanthus illinoensis*) is rich in DMT and is a popular ingredient in ayahuasca analogs.

Acaciahuasca

This blend is especially popular in Australia and has been used with good success.

3 g *Peganum harmala* seeds, finely ground

20 g *Acacia phlebophylla* leaves, ground (cf. *Acacia* spp.)

Juice of one lemon or lime

Prepare in the same manner as juremahuasca (above).

Phalahuasca

In Europe, various combinations of *Phalaris arundinacea* or *Phalaris aquatica* (see *Phalaris* spp.) and *Peganum harmala* have been investigated. Unfortunately, the experiments have met with little success to date as far as pleasant visionary experiences are concerned. Because of the toxic alkaloid (gramine) that occurs in the reed grasses, these preparations can be very dangerous (Festi and Samorini 1994).

Peyohuasca

This preparation is a combination of *Peganum harmala* and *Lophophora williamsii*. It may be pharmacologically very dangerous.

San Pedro Ayahuasca

The following amounts and ingredients have been reported to produce pleasant effects (in *Entheogene* 5 [1995], 53).

1–3 g Syrian rue (*Peganum harmala*)

20–25 g San Pedro cactus powder (see *Trichocereus pachanoi*)

This blend may be pharmacologically dangerous.

“May the Entheogenic Reformation prevail over the Pharmacratic Inquisition, leading to a spiritual rebirth of humankind at Our Lady Gaea’s breasts, from which may ever copiously flow the *amrta*, the *ambrosia*, the *ayahuasca* of eternal life!”

JONATHAN OTT *AYAHUASCA ANALOGUES*

(1994, 12)

Psilohuasca

This mixture, which is also known as mushroom ayahuasca or soma ayahuasca, consists of:

3 g *Peganum harmala* and 3 g mushrooms (*Psilocybe cubensis*)

or

2 g *Peganum harmala* and 1.5 g *Psilocybe semilanceata* in sage tea

Because the effects of these blends can be extremely unpleasant, people are generally warned against using them (Kent 1995; Malima 1995).

LSA/Desmanthus Ayahuasca

Although the report (in *Entheogene* 5 [1995]: 40 f.) spoke of a quite pleasant experience, this mixture appears to be potentially dangerous.

3 g *Peganum harmala*

1 *Argyreia nervosa* seed

3–4 g *Desmanthus illinoensis* root cortex

Mayahuasca

For several years, there has been considerable speculation that the pre-Columbian Maya may have used a psychoactive ritual drink that was an ayahuasca analog. It has been conjectured that the Mayans used a *Banisteriopsis* species (*Banisteriopsis* spp.) that grows in the Mesoamerican lowlands in combination with a source of DMT to make a “Mayahuasca” (Hyman 1994). It is entirely possible that *Banisteriopsis muricata* was used for this purpose, as its stems contain harmine and its leaves DMT. In other words, it is possible that an ayahuasca analog was made from just one plant.

Pharmahuasca

For pharmahuasca, 100 mg *N,N*-DMT and 50 mg **harmaline** is usually the recommended dosage per person. However, combinations of 50 mg harmaline, 50 mg harmine, and 50 mg *N,N*-DMT have also been tested with success. As a rule, the fewer **β-carbolines**, the less nausea; the more DMT, the more spectacular the visions. The constituents are put into separate gelatin capsules. The capsule with harmaline/harmine is swallowed first and the capsule containing the DMT is taken some fifteen to twenty minutes later. The purely synthetic MAO inhibitor Marplan is also suitable in place of **harmaline and harmine** (Ott 1996, 34).

The summer cypress, *Kochia scoparia* [syn. *Bassia scoparia*], indigenous to Asia, contains substantial amounts of harmala alkaloids and may be useful in ayahuasca analogs as an MAO inhibitor.

5-MeO-DMT can be used instead of *N,N*-DMT, or a mixture of both DMTs can be used.

Endohuasca

The pharmacologist James Callaway has hypothesized that under certain circumstances a kind of pharmahuasca (which he calls endohuasca) is produced in the brain when both endogenous **β-carbolines** and endogenous **DMT** are excreted. This endohuasca produces dreams in a neurochemical manner (Callaway 1995; cf. also Ott 1996).

Tribulus terrestris (known as *burra gokhru*) may be of psychopharmacological interest and urgently merits further research. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

The root cortex of *Desmanthus pulchellus* is rich in DMT and is thus suitable for use as an ingredient in ayahuasca analogs.

Balche'

The Lacandon, a Mayan tribe, prepare the divine balche' drink in a ritual canoe. (Photograph taken in Naha', Chiapas, 1990)

Other Names

Ba'che', ba'alche, balché, pitarilla

The name *balche'* refers to three things: a tree (see ***Lonchocarpus violaceus***), a drink prepared from this tree through fermentation (with *Saccharomyces cerevisiae*), and a religious ritual during which the drink is collectively consumed. The balche' beverage is a ritual drink used by the pre-Hispanic Maya, the Yucatec Maya, and the Lacandon. It is a kind of **mead** made from water, **honey** (or more rarely sugarcane syrup, pineapple juice, or refined sugar), and the fresh or previously used bark of *Lonchocarpus violaceus*. The drink is mildly alcoholic (2 to 5% alcohol), and sometimes other ingredients are added to it.

Numerous so-called *chultunes* (Mayan, “moist stone holes”) have been discovered in archaeological excavations at Petén (Guatemala), e.g., at the ceremonial center of Tikal. Some archaeologists have suggested that these underground, shoe-shaped hollows in the limestone may have been used as storage spaces. Others have speculated that the *chultunes* were used during the Classic Mayan period (300 to 900 C.E.) as vessels for brewing balche' (Dahlin and Litzinger 1986). Chacmol, a reclining god of the post-Classic period, has been interpreted as the god of the balche' drink (Cuéllar 1981).

Both the tree and the ritual drink made from it are mentioned in all of the ethnohistorical sources about the Yucatec Maya (Blom 1928; Roys 1967; Räscht 1986*). The Motul dictionary, prepared during the early colonial period, describes the balche' tree as the tree from which “the ancient wine” was brewed (MS 45r). The translator Gaspar Antonio Chi remarked that balche' was the most important ritual drink of the Maya prior to the Spanish conquest (Blom 1928, 260). The Spanish Franciscan and book burner Fray Diego de Landa wrote about it in his sixteenth-century *Relación de las cosas de Yucatán*:

The Indians were very dissolute, drinking until they were intoxicated. . . . They make wine from honey, water and the root of a certain tree that they cultivated for this purpose. The drink thus produced was strong and smelled foul. (de Landa 2000, 67)

The drink and its ritual and medicinal significance were described in de Landa's early colonial text:

A further reason why these Indians are decreasing in number is that they have been prevented from drinking a wine that they were accustomed to preparing and of which they said it was healthy for them and that they called *balche*. They made it out of honey, water, and a root called *balche*. They filled this into large containers that were like big tubs and held fifty *arrobas* [= 200 gallons] or more of water. There it fermented and frothed for two days, became very strong, and then smelled very bad. At their dances and songs, and when they were dancing and singing, they gave everyone who was dancing or singing a small bowl to drink from. They gave them so much until they became very inebriated from it so that they did strange things and made such faces that their condition did not remain hidden from the spectators. When they were drunk they vomited and emptied themselves. This purified them and made them so hungry that they ate with

a great appetite. Some of the elder men said that this was very good for them, that it was a medicine for them, that it healed them, because it worked like a very good laxative. With it they remained healthy and strong and many grew to be very old because of it. (2.188)

Freshly pressed pineapple juice (*Ananas comosus*) was once used as a fermenting agent for balche'. The use of pineapple to prepare fermented drinks is widespread throughout Central and South America. (Copperplate engraving from Meister, *Der Orientalisch-Indianische Kunst- und Lustgärtner* [The Oriental-Indian Art and Pleasure Gardener], 1677)

Both the balche' tree and the drink of the same name are mentioned repeatedly in the esoteric texts of the *chilam balam*, the shamanic divining priest. In these texts, the drink is metaphorically called *u ci maya* "the exquisite of the Maya." In a passage dealing with the symbolic (secret) Yucatec Maya language of Zuyua, the balche' ritual is metaphorically described as "little woman":

Depiction of the traditional balche' ceremony. (Drawing by K'ayum Ma'ax, ca. 1980)

This is the green blood of the little woman, who is called for, it is the Mayan's exquisite.
These are the entrails of the little woman, they are beehives.
This is the head of the little woman, it is the untouched vessel of the exquisite that is being prepared.
This is the stool of the little woman, it is the honeycomb [?] of the bees.
This is the left ear of Ah Bol [probably the god of inebriation], it is the small *zul* cup [a small tree gourd vessel used in the preparation of the drink] of the exquisite.
These are the bones of the little woman, they are the bark strips of the balche' tree.
These are the thighs—so it is said—, they are the trunk of the balche' tree.
These are the arms of the little woman, they are the branches of the balche' tree.
This—so it is said—is her crying, it is the language of inebriation.
(Chumayel MS 37c; in Räscht 1986, 216*)

The balche' drink is associated with the origin of the world. The first god or gods were Ah Muzencab, "the honey collector(s)" (bee deities). During the creation of the world, the balche' drink was (re)born with the rain gods. In the Mayan creation myth, as related in *The Book of Chilam Balam of Chumayel*, the divine origins of the drink and the plants associated with it are noted:

Then the Lord (of Katun) 11 Ahau released his bees. Then came the word of the Bolon Dzacab (nine descendant) from the tip of his tongue. Then the burden of Katun was searched for. Ninefold is his burden. Then it came from heaven. *Kan* is the day to which his burden is bound. Then water came out, it came out of the heart of heaven, for the rebirth, nine years old is his house. And with it came Bolon Mayel ["nine *mayel*"; from Mayahuel, the Aztec goddess of pulque inebriation; see ***Agave spp.***]; sweet was his mouth and the tip of his tongue. Sweet too was his brain [i.e., they were sexually aroused]. Then came the four Chacs [the rain gods of the four cardinal points], they have pots full of blessings [filled with the balche' drink]. There is the honey of the flowers [of the balche' drink]. Then emerged the red opening vessel and the white opening vessel and the black opening vessel and the yellow opening vessel and the opened water lily and the closed water lily. And with it emerged the five-petaled flower, the five-petaled flower, the toothed cocoa [= *ninichh cacao*] and the *chabil tok* plant [?] and the *bac* flower [probably *Polianthes tuberosa*] and the *macuil xuchit* flower [*macuixochitl* "five flower,"⁴⁰¹ a

manifestation of Xochipilli, the Aztec god of psychedelic plants], the flower with the hollow interior and the laurel flower and the paralyzing (crooked flower). (Smailus 1986, 132 f.)

Both this text and various archaeological sources and other ethnohistorical reports (such as the 1710 report from Thomas Gage [1969, 225]) suggest that a number of ingredients were added to the balche' drink of the pre-Hispanic Maya period (see the table on page 725). The balche' drink of that time thus seems to have been a kind of "witch's cauldron" with quite potent, synergistic effects (Gonçalves de Lima et al. 1977).

There are only a few sparse reports about balche' from the colonial era (Blom 1928). The most interesting of these is contained in the travel journal of the English clergyman Thomas Gage, who visited the New World in the sixteenth century. The tenth chapter contains a "description of an unusual drink of the Indians":

They [the Pokomchi] make among other things a special drink / that is much stronger than wine / in large earthen jugs or pots / that are brought from Spain / in this way: They first add a little sugarcane / or a little honey / so that the drink will be sweet / as well as other roots / that grow in that land / and of which they know / that they have the same effect. I have myself seen at different locations / that they have thrown a living toad into it.

Then the vessel is closed / and they let this all sit together fermenting for fifteen days or a month / until everything is well worked through / the frog totally decayed / and the drink has reached its desired potency.

And then they open the vessel up again / and invite their friends to the feast / which usually takes place at night / so that they are not caught by the village priests / and they do not stop drinking / until they are totally crazy and full.

They call this drink, which smells foul as it comes from the vessel, *chicha* / and it often causes many to die / particularly in those places / where they add toads. (Gage 1710, 307 f.)

The Maya who live in the Yucatán today still consume the balche' drink (Steggerda 1943, 209*; Redfield and Villa Rojas 1962, 38), which they brew from water, **honey** from native nonstinging bees, and four pieces of balche' tree bark per person. There appear to be a number of magical sayings that the Mayan shamans (*h-mèno'ob*) use when they are preparing the drink (Bolles 1982). One Mayan from Campeche informed me that there is a balche' song (*u k'àyil bà'lché*) that invokes many poisonous animals and the bees of the forest.

The magical incantation for brewing balche' invokes Chäk Xok ("red shark"), a water dweller, and asks him for assistance in starting the fermentation. (Drawing by a Lacandon child, Naha', ca. 1982)

Balché is brewed only for non-Catholic ceremonies. The *h-mèn* (shaman) uses the drink, which is stored in gourd containers called *homa*, during pagan ceremonies for divinatory purposes (Redfield and Villa Rojas 1962, 36, 125). Drops of balche' are offered during prayers to Yuntsilob (the lord of the animals) (Redfield and Villa Rojas 1962, 128). Before the *h-mèn* gazes into his *sastun* (quartz crystal; cf. ***Turbina corymbosa***) so that he may divine, he dips the *sastun* into the balche', thereby awakening its powers (Redfield and Villa Rojas 1962, 171). The *h-mèno'ob* also ingest seeds of ***Datura innoxia*** and ***Turbina corymbosa*** with the balche'.

In Valladolid (Yucatán), balche' is also prepared for wedding ceremonies (Aguilera 1985, 131*; Barerra M. et al. 1976, 302*). The Yucatec Maya drink balche' at rain and agricultural ceremonies to honor the rain god Chakó'b (Friedel et al. 1993). They believe that a man who owns chickens that are

currently incubating their eggs should not drink balche', lest the chicks die in the eggs (Steggerda 1943, 209*).

There is also evidence for the use of balche' among the Chol-Lacandon, who lived in Chiapas during colonial times and have since disappeared. They also used sugarcane and pineapple juice for fermentation (Tozzer 1984, 15).

It is remarkable that the classic balche' ritual of the Mayan-speaking Lacandon of Chiapas has been preserved. The earliest ethnographic reports noted that "honey, mixed with the bark of the balche' tree, was fermented into an inebriating drink (balche')" (Sapper 1891, 892). At that time, it was said that the Lacandon still performed their rituals in Yaxchilan, a ruin from the Classic Mayan period:

It seems likely to me that the Lacandon have always had a connection to Manché Tinamit [= Yaxchilan], for otherwise we could not explain why they (until recently) would travel every year from their residences in imprecisely known places in Lacanjá and other areas to Manché in order to celebrate their festivals there with balche' carousals and unusual customs, and to make offerings to their gods in the different buildings, in particular an exceptional three-storied structure (apparently the main temple of the former city). (Sapper 1891, 894)

The balche' ceremony is a ritual circle that is still performed by the Lacandon of Naha'. The gods gave this ritual to the Lacandon primordial ancestors, the "great, ancient people, who still found the paths to heaven." The god of creation himself originally conceived of the ritual, during which the inebriating balche' drink is communally consumed. The brewing of the drink, on the other hand, was the job of Bol, the god of inebriation:

Bol made a balche' drink for Hachäkyum, our true lord. He tried some of it. Bol stood up and gave it to the gods. How many of them were soon lying there! Mensäbäk lay there, and even Hachäkyum; they did not move, they were completely drunk. All of the gods were stretched out there on the ground. They were drunk all at once. They were very drunk, but they were happy and sang. (Ma'ax and Rätsch 1984, 127)

From that time on, the primordial ancestors of the Lacandon as well as their descendants were to imitate the inebriation of the gods in their ritual circle in order to continually relive the drunken state of consciousness that creates harmony between heaven and earth. The drink is prepared in a special ceremonial mahogany canoe (called *u chemi balche'*) from honey (or sugar), water, and the bark of the balche' tree, which is cultivated specifically for this purpose. The solution will ferment, and when the fermentation is finished—usually after two to three days—the drink is ready. It contains 1 to 5% ethanol, which dissolves various other substances from the bark (Rätsch 1985b).

Brewing the balche' is a well-established magical act. Magical incantations and prayers are recited during the brewing process. The brewer identifies himself with Bol, the god of inebriation. Uttering a long incantation (*u t'ani balche'*), he calls the invisible spirits of all the poisonous animals and plants of the forest to him and asks them to add the essences of their poisons to the drink so that it will be especially potent. One after another, the following animals are called forth and asked to add the "juice of their stings/teeth/ nettles" to the brew: wasps, caterpillars, ants, spider killers, bird spiders, scorpions, poisonous lizards, beetles, and snakes. Then the brewer invokes other beings, such as Chäk Xok ("red shark"), the helpful water spirit, and these stir the drink, heat it, and cause it to froth (cf. Ma'ax and Rätsch 1984, 270–82; also Boremanse 1981).

One or two days later, the drink is done fermenting. Now it is time to offer the "soul" of the balche' drink to the gods. The "head of the balche'" is carried in a ceramic jug to the house of the gods. The

gods, in the form of ceramic incense bowls (*u läkil k'uh*), are placed on the ground. As prayers are continuously offered, a palm leaf is used to give every god and every goddess a mouthful of the drink. From the bowls of the gods on the ground, the soul of the drink rises into the heavens, where it manifests as a drink that will inebriate the gods. The gods love to be inebriated, and they sing and dance and amuse themselves with delight for the ritual offerings the humans have provided.

“Stab through, bore through my foot
stab through, bore through my hand
I, were I Bol
I, were I Istal
Here is the green chili pepper
It passes through my canoe
Here is the green *chawa*’ chili
Here is the raging chili pepper With it the heat comes into my canoe
It comes in and bites into my vessel Here is the pot of my solution Here are the wasps
That is the root of my canoe
Here is the nose of my canoe
Here are the wasps
They pass by on the flanks of my canoe
Come, give me the juice of your stingers for my balche’ drink Come and give it to me
Here are the raging wasps
Here are the hard red drinking wasps
Here are the wasps
Here are the branch wasps
Here are the hornets
Here are the bumblebees
Here are the white bumblebees Here are the big bumblebees
Here come here, give me the juice of your stingers for my canoe In my vessel
Here is my balche’ drink
Come, give me the juice of your stingers . . .
Here is the ground chili in my canoe
There they come
Here the bubbles rise
The air bubbles are rising up in my vessel
Here is Chäk Xok, the water man He stands in the middle of my canoe
He stands at the root of my canoe Here is the nose of my canoe
It goes to the ground of the vessel of the solution
He enters and stirs the juice of my balche’ drink
He enters and awakens the fermentation
He makes the bubbles rise
He, Chäk Xok, the water man
So come then . . .
Here are the ch’el birds [*Penelope nigra*]
So come then
Come and light the fire
Beneath my vessel
Come, kindle the fire
With your tails
You ch’el birds . . .
There the ants rise up and pass by Through my vessel
There the tree toads croak
That is their croaking
The tree toads croak in my vessel the wo’ toads croak in my vessel Here are the white salmon
Here are the *bayok*’ fish
They swim through my canoe
They dive into it
These are the things in my canoe . . . It bubbles in my vessel
Here are my tree toads
The crocodiles make noise
Here are the crocodiles of the sea . . . The turtles pass by . . .
There the ants are passing by on the air bubbles
There are the things of my vessel They rumble in my vessel

In my canoe
All came and gave of themselves for my vessel
I, were I Bol
I, were I Itsal.”
A MAGICAL INCANTATION FOR MAKING BALCHE’
IN *Ein Kosmos im Regenwald*
[A COSMOS IN THE RAIN FOREST]
(MA’AX AND RÄTSCH 1984, 270–82)

After the balche’ drink has been offered to the gods, the humans may drink it. This occurs in a ritual, the form of which can be characterized as a ritual circle. The communal drinking, in which the *tu wolol winik*, “whole circle of humans,” takes part, usually begins just before dawn. When the first offering has been made, the brewer blows into a conch trumpet (from *Strombus gigas*, the queen conch) to sound the call and invitation to the ritual. The people come. No one is required to participate in the ritual, but all who have been initiated are allowed to come. The men go into the house of the gods and the women meet in the ceremonial kitchen. The brewer assigns each person a place in the circle around the ceramic jug filled with balche’. Using a measure (*u p’iis*), the brewer fills special drinking glasses (*luch* or *hama’*, made from *Crescentia cujete* L.; cf. Morton 1968). Each participant receives the same amount. Everyone drinks at the same time, and all the participants are supposed to drink the same amount. Within just a few hours, each of the participants will consume approximately 17 liters. The communal inebriation and the corresponding alteration of consciousness rather quickly becomes apparent. It is said that consciousness gets lost or turned around and is exposed to the adventure of inebriation. The Lacandon say that the effects of the drink are determined by the quality of the bark used and the magical abilities of the brewer. They attribute the least part of the effects to the alcohol.

Depiction of a toad (*uo*-glyph) on lintel 48 at Yaxchilan (from the Classic Mayan period).

The effects of balche’ are not like those of **beer** or **wine** or any other inebriant known to us. Balche’ is not hallucinogenic. Its effects may be more precisely described as empathogenic. Consciousness becomes euphoric, perception more acute, the muscles relaxed, and the stomach and intestines emptied, and the heart is brought to laughter. Very strong doses (20 liters) have narcotic and analgesic effects. The effects on mood are especially pronounced. The inebriated people are prone to cramps from laughing and sentimental or affable feelings. As the effects increase, aggressive feelings disappear. Sometimes the drink may also produce a mildly psychedelic effect, particularly when a lot of fresh bark has been used (Rätsch 1985b).

The main purpose of the ritual circle is to heal the sick or to improve the state of the “consciousness of heaven” (as Hachäkyum, the main god, is referred to ceremonially). When humans come together into the circle and imitate the gods’ inebriation, the inebriated gods in heaven develop such a good mood that their magical healing powers are able to heal the sick, counteract ecological catastrophes, and make the rain fall and the corn grow.

One important function of the balche’ ritual is to promote social contact among the Lacandon community, the communal alteration of consciousness, and often a kind of social therapy that appears to be reinforced by the specific effects of the drink. When two men who have been in an aggressive mood toward each other take part in the ritual, one is able to say to the other, “Come, let us drink, for there is something between us.” Then the two quickly and simultaneously drink such an enormous quantity that they can barely keep it down. In this way, they shift their state of consciousness together and, because of the large amounts of liquid, must soon vomit and empty their bladders and intestines

together as well. The drink flushes out their bodies completely, alters their consciousness with its strong inebriation, and cleanses them both of their problem.

The ritual is over when all of the balche' has been consumed. The inebriated participants then typically fall into a dreamless sleep. Several hours later, they awaken with a clear consciousness and a purified body (the drink has diuretic, purgative, and laxative properties). No unpleasant side effects or aftereffects are known.

Balche' Additives

Balche' appears to have had meaning and function in Mesoamerican and Mayan culture similar to that of **ayahuasca** in Amazonia. The archaeo-logical, ethnohistorical, and ethnographic information makes it clear that balche' has long been a drink to which various other, often more potent psychoactive substances were added. There has been considerable speculation about which other substances may have been used.

In the Lacandon creation myth, the gods and goddesses were born enveloped in the sweet scent of night hyacinth (*Polianthes tuberosa*) blossoms. These enchantingly scented flowers are sometimes used to perfume the balche' drink. (Photographed in Naha', Chiapas)

Older Lacandon still remember that the Lacandon who once lived near Piedras Negras (Guatemala) brewed an extremely potent balche'. One small bowlful was said to have induced powerful inebriation and visions. We can only conjecture as to whether these effects were achieved by the addition of turtles, frogs (e.g., *Dendrobates* spp. or *Phylllobates* spp.; cf. Daly and Myers 1967 and Myers et al. 1978), or plants. I assume that the plants and the animals referred to in the magical spell for balche' brewing were once used to flavor or strengthen the drink. Among the plants that are mentioned are some (e.g., **Acacia** spp.) that contain **N,N-DMT** or other tryptamines. It is entirely possible that the longistylines that are present in balche' bark may have MAO-inhibiting properties and could thus have orally activated any ingredients that contained DMT (cf. **ayahuasca**).

It has been asserted in the literature that the Lacandon add psychedelic mushrooms to their balche' (Furst 1976; Greene Robertson 1972). Unfortunately, there is no ethnographic information of any kind to support this conjecture. Today, the Lacandon use only aromatic additives (*Polianthes tuberosa*, *Plumeria* spp., cocoa beans, vanilla pods, balche' flowers).

It is very likely that the Maya of the Classic period added **Nymphaea ampla** to their balche'; it is probable that **Tagetes** spp. and other as yet unidentified plants were also added. A report from the colonial period states that the roots of a maguey agave (perhaps *Agave americana* var. *expansa*; cf. **Agave** spp.) were used as a balche' additive in the northern Yucatán (*Relación de Mérida*, Col. Doc. inéd., 11:49).

Vanilla, a native of the southern Mexican rain forest, is used to flavor the balche' drink. (Wild plant, photographed in the Selva Lacandona region of Chiapas)

The balche' drink was once flavored with chili pods. (A variety cultivated by the Lacandon, photographed in Naha', Chiapas)

The exquisitely aromatic *Plumeria rubra* flowers are used to perfume the balche' drink.

The Maya use frangipani or temple tree (*Plumeria alba*) flowers for love magic and also occasionally add them to the balche' drink.

This image of a turtle (*äh báb*) was carved into a Lacandon balche' drinking vessel. (Drawing: C. Räscht)

Beer

Other Names

Acca, acupe, ahai, akka, ale, asua, badek, bakhar, bier, binburam, birra, biru, bosa, bouza, burukutu, busaa, cangüi, cashirí, cauim, caxiri, caysuma, cerveza, chang, chhang, chica, **chicha**, darassun, dolo, huicú, ikigage, kaffir, kalya, kiwa, kufa, kwass, lugri, masato, mazamorro, mekzu, merissa, mqombothi, munkoya, murcha, nawá, øl, pachwai, paiva, paiwariu, pajuarú, pissioina, pito, sende, sendechó, talla, taroba, tesvino, tesgüino, tizwin, to, toach, torani, tulapi, tulbai, tulpi, utywala, yale

Beer and beerlike drinks are found throughout the world (Bücheler 1934; Fairley 1992; Hürlimann 1984). Beer consists chiefly of water in which starch or sugar has been dissolved (see the table on page 729; cf. **chicha**). By adding cultivated or wild yeast (see the table on page 728), the mixture begins to ferment (for more on fermentation, cf. Hlavacek 1961). This yields a brew with an **alcohol** content of generally between 2 and 5%. However, modern brewing techniques make it possible to increase the alcohol content to around 10% (as in *bock* and strong beer). Today, most industrial beer is made with malted barley (Delos 1994; Jackson 1988); in former times, almost all the various kinds of grain known to man (many of which were also made into bread) were fermented (Gastineau et al. 1979; Lazzarini and Lonardonni 1984; Ziehr and Bühner 1984).

Throughout the world, beer was originally a ritual drink that was drunk during shamanic or religious ceremonies to honor the gods (libations) and in order to establish contact with other realities (Huber 1929). Psychoactive plants were usually added to these ritual beers (see the table on page 730). Some fifty known psychoactive plants have been added to beer at some time and place in the world. Such beers were consecrated to the gods or goddesses (e.g., Thor, Dionysos, Bacchus, Hathor, Bhairab/Shiva, Isis; cf. Golowin n.d.). Some of the more famous of these beers are the mandrake beer of the Egyptians (see *Mandragora officinarum*), the maize beer of the South American Indians—which is flavored with seeds from angel’s trumpets or thorn apple (see *Brugmansia sanguinea*, *Datura innoxia*, *Datura stramonium*)—and the “true pilsner,” the Germanic henbane beer (see *Hyoscyamus niger*). The *porst* beer of the Vikings, which had potent inebriating properties, was brewed with marsh rosemary (*Ledum palustre*) or bog myrtle (*Myrica gale*) (Simpson et al. 1996).

Today, barley (*Hordeum vulgare*) is the most commonly used brewing grain in the world. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Barley (*Hordeum vulgare*) is the most important source of fermentable material for beer brewing.

The root of the cassava bush (*Jatropha multifida*) is used to brew beer in South America.

In Africa and Asia, beer is brewed primarily from true millet (*Panicum miliaceum*).

“The art of brewing beer was revealed to the humans out of a special goodness and grace. When no one yet knew how barley could be used, Dionysos conceived of the drink and taught it to those who had no vineyards, so that they would not have to drink water like the geese and ducks.”

CHRISTOPH WEIGE (REGENSBURG, 1698)

In the Middle Ages, beer brewing was associated with alchemy and witchcraft and was consequently a sometimes disreputable practice. This was often due to the “secret ingredients” (Eckstein 1927). Not only strong, inebriating beers but also aphrodisiac and medicinal beers were made. In Germany, “the land of beer,” beer was brewed with strong psychoactive additives, some of which cannot be botanically identified, well into the early modern era. In 1720, Paul Hönn, a royal councilor of Saxon, wrote in the *Betrugs-lexicon* [Dictionary of Deception]:

Brewers deceive, when they throw so-called cat brains [?], valerian [*Valeriana officinalis* L.], and other such mind-boggling things into the pot, so that they will make the beer strong and the people who drink it stagger, even more so when hops becomes expensive and they instead use wormwood [*Artemisia absinthium*], ox bile, and such things in the beer simply to make it bitter. (In Mathäser 1996, 57)

The so-called Bavarian Purity Law of 1516 was the first German drug law; it specifically forbade the use of henbane (*Hyoscyamus niger*) as a beer admixture. The use of hops (see *Humulus lupulus*) as a flavoring agent in beer is an invention of Christian monks. It has been suggested that the Bavarian Purity Law was intended primarily to suppress the use of pagan ritual plants and thus to finish the work of the Inquisition (Rätsch 1996).

The potato (*Solanum tuberosum* L.) was cultivated in South America; it is one of the most important sources of highly nutritive carbohydrates in the Andes. The entire plant is highly toxic, and only the tubers are suitable for consumption. The native peoples of the Andean region use the tubers to brew beer. Potatoes are also used to make vodka. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“Of the herb margosae [neem tree]. This herb, which the Dutch use instead of hops for flavoring sweet beer, is dried because of its bitterness. Its leaves are almost like those of hemp but grow somewhat smaller, or like cinquefoil, it vines up trees.”

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST-UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER] (1677)

In Asia and Africa, most beer is brewed from many different kinds of millet. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

“In any case, the Chinook of the northwestern coast of North America report an unusual form of alcohol fermentation for the purposes of inebriation. They consume as delicacies acorns that have been allowed to soak in human urine for over five weeks, which causes them to ferment. These *Chinook olives* produce a pleasant state of inebriation.”

ANDREA BLÄTTER

“DROGEN IM PRÄKOLUMBISCHEN NORDAMERIKA” [“DRUGS IN PRE-COLUMBIAN NORTH AMERICA”]
(1996A, 178*)

In the early modern era, beer and beer drinking were often demonized and associated with pagan witches’ cults. Indeed, beer, especially that brewed with henbane (*Hyoscyamus niger*), is an ancient, heathen ritual drink. The caption reads: “A female innkeeper being taken by the devil.” (Illustration of an old English sculpture)

In recent years, home brewing has been gaining in popularity again. At home, of course, people can put anything they want in their beer. In the United States, spices (cinnamon, coriander, ginger, paradise grains, nutmeg and mace, cardamom, pepper, chilies, cumin, turmeric, vanilla) are often added. In Germany, henbane beer (*pilsner*) is being brewed once again, and a Swiss brewery introduced a hemp beer to the market in 1996. A mixture of wheat beer and a guaraná extract (*Paullinia cupana*) is popular in Brazil and is now available in Europe as well. In Belgium, a wheat beer known as Floris Chocolat is made with chocolate (cf. *Theobroma cacao*).

In Central and South America, ritual beers (see **chicha**) with psychoactive ingredients were very common in pre-Hispanic times (Arriaga 1992*; Cobo 1990*). Some tribes, such as the Tarahumara, Huichol, and Quechua, still use varied admixtures to increase the strength of their maize beer. Many of the same plants are also added to **ayahuasca**, **cimora**, and San Pedro drinks (cf. *Trichocereus pachanoi*).

Betel Quids

Other Names

Asia's chewing gum, betel, betelbissen, betele, betelpriem, betelpriemchen, bulath, paan, pan, pán, pan masala, pin-lang, pynan, sirih, supari, tambul, tembul

Betel quids consist of essentially three ingredients: betel nuts (*Areca catechu*), betel leaves (*Piper betle*), and slaked lime, to which other ingredients (*masala*) are almost always added. About half of betel quid preparations call for mixing in specially treated (e.g., limed or fermented) tobacco (*Nicotiana tabacum*) (Gowda 1951, 196), as well as an assortment of spices and other psychoactive substances (see the table on page 735). These mixtures can be varied to change the taste or to produce specific effects.

The oldest recipe that is known to us from the literature was passed down by Sushruta, the first-century founder (or at least one of the founders) of the Ayurvedic system of medicine. He lists as ingredients betel leaves filled with broken betel nuts, camphor (*Cinnamomum camphora*), nutmeg (*Myristica fragrans*), and cloves and adds that intelligent people chew betel after a meal.

In India, there are veritable gardens of betel, in which betel palms are cultivated together with betel pepper. The pepper plants climb up the stems of the palms, and the space between the palms is used to grow the spices added to the quids.

A betel palm plantation. (Copperplate engraving, nineteenth century)

Slaked lime, which is indispensable for increasing the effectiveness and absorption of the active constituents, is obtained by burning mussel shells, conch shells, river snail shells, coral, or limestone and then dousing the ashes with water.

Today, an estimated 450 million people worldwide chew betel (Roth et al. 1994, 141*). Betel chewing is found throughout India, Nepal, Sri Lanka (Ceylon), the Maldives, the Nicobar Islands, Myanmar (Burma), Thailand, southern China, Malaysia, Singapore, Indonesia, Taiwan, the Philippines, Papua New Guinea, and Melanesia.

There is evidence suggesting that people have practiced betel chewing for more than twelve thousand years. Archaeologists excavating the Spirit Cave site (in northwestern Thailand) have unearthed fragments of betel nuts, traces of a *Piper* species, and gourds, all of which suggest the use of betel. Radiocarbon dating has indicated that these finds are between 12,000 and 750 years old (Gorman 1972; Seyfarth 1981, 562).

Betel chewing has a long tradition in India, perhaps one of the longest in the world. In addition to its ritual use, betel is chewed hedonistically for its stimulating effects. Mentions of betel merchants date back to the late Vedic period (Moser-Schmitt 1981).

Great quantities of betel are chewed in Varanasi (Benares). Small betel shops and the stands of betel sellers (*pan vala*) can be found wherever one goes. Both freshly made betel (*pan*)—typically spiced according to the customer's particular wishes—and hygienically packed mixtures (*pan masala*), of which there are many brands and makers, are available. These packages cost between 0.75 and 1.50 rupees each. While it is difficult to predict whether these factory-made betel blends might displace the

traditional betel, it is rather unlikely.

Although the effects of betel were formerly described as narcotic, the opposite is actually the case; betel has stimulating effects (Charpentier 1977) and, in general, a primarily parasympathomimetic action (a “muscarinic character”). It promotes salivation, suppresses hunger and thirst, and can also act as a laxative. Betel has stimulating effects upon the central nervous system. The strongest action (on the central and peripheral nervous systems) begins six to eight minutes after chewing a quid (Chu 1995, 183). The Trobriand Islanders say that betel produces sensations of heat, increased perspiration, and feelings of happiness. These euphoric feelings are more powerful when unripe betel nuts are used in the blend (Jüptner 1969, 371). Internationally, betel is considered not to be “addictive” but to “structure social behavior” (Charpentier 1977, 117). “Betel makes the ears hot, the face red, [and] the eyes blurry and produces a mood like drunkenness, at least that is what the Chinese texts state. It is believed that betel is a remedy for malaria” (Eberhard 1983, 39).

Fresh betel leaves sit on the table of a betel merchant, while the bowls and tins in the foreground contain the other ingredients. (Photographed in Varanasi, India, 1995)

In the eighteenth century, European observers came up with the idea that betel chewing causes cancer. In Sri Lanka, a disease known as “betel chewer’s cancer” was recorded in the literature (Charpentier 1977, 110). Even today, it is often claimed that extensive and regular chewing of betel over years or even decades can increase the risks of or even cause mouth or tongue cancer. Sen et al. (1989) summarized the results of the studies that have been carried out to date. These indicate that only those betel quids that contain tobacco exhibit these characteristics. Among betel chewers who have never used tobacco as an additive, the carcinostatic action of the betel leaves (*Piper betle*) appears sufficient to protect the mucous membranes of the mouth from cell damage, an effect that presumably is due to the formation of cytotoxic *N*-nitrosamines when the leaves are chewed (Sen et al. 1989). The slaked lime and the catechu have also been attributed with carcinogenic effects, although these views are based solely upon animal experiments.

The notorious red coloration that betel chewing imparts to saliva is thought to be a product of areca red, a phlobatannin. This phenol-like substance is a constituent of *Areca catechu* and turns red as a result of the slaked lime (Heubner 1952, 17*; Roth et al. 1994, 140*).

Slaked Lime

(lime, quick lime, calcium hydroxide)

In Sri Lanka, slaked lime is known as *huna* or *chunam* and is produced by burning mussel shells, freshwater snails, coral (*hirigal/hunugal*), and, in rare cases, limestone in large kilns. This lime is used not only for betel chewing but also to build houses, in agriculture, and as a paint pigment. The slaked lime used for betel chewing is sometimes colored with powdered yellow turmeric (*Curcuma longa* L. [syn. *Curcuma domestica*]; Zingiberaceae); coconut oil is added to keep the lime from drying out and becoming hard (Charpentier 1977, 111).

In Nepal and India, pieces of betel nuts (*Areca catechu*) and anise seeds (*Pimpinella anisum*) may be chewed together in place of betel quids. This mixture is used mainly after meals as a digestive aid. (Anise plant; woodcut from Gerard, *The Herball or General History of Plants*, 1633)

“A man went to the pig hunt. He sat down under a tree on which a betel pepper plant was growing. He bit through the stem in order to use it as a rope. Coincidentally, he had at the time a betel nut and lime in his mouth and saw with astonishment how his saliva became red. He

realized that this color was made by mixing the pepper plant with the nut and the lime. He also found that the mixture now tasted better and it took away the biting sharpness. The stem was very tough, but then he discovered the fruit of the betel pepper. He tried them and noticed that they caused the same effect but were much better to eat.”

A TALE FROM THE NORTHERN SOLOMON ISLANDS

IN “BETELKAUEN IN MELANESIEN” [“BETEL CHEWING IN MELANESIA”] (SEYFARTH 1981, 563)

In Melanesia, the third ingredient in betel chewing, lime, is produced primarily by burning conches or mineral limestone. For the coastal inhabitants, mussels and coral species naturally offer themselves, while inland groups use chiefly limestone and, when available, river snails; the Yimar in the southern Sepik region provide an example. They first cook the mussels until the shells can be easily opened and the mussel flesh can be removed [and eaten]. The shells are then air-dried, wrapped in sago leaves, bound with *rotang* [palm fibers], and burned. The burned shells are crumbled by hand and dissolved in water, and the coarse lime powder is wrapped again in leaves to dry, until it is finally put in the lime container. (Seyfarth 1981, 563)

In Taiwan, a so-called red lime, a mixture of lime and catechu, is available and used in betel (Chu 1995, 183).

Paraphernalia

The paraphernalia associated with betel are expressions of specific cultural characteristics and the cultural significance of betel (Beran 1988), and they are often artistically and splendidly produced. Siamese and Thai kings used only betel instruments made of gold.

The following tools are traditionally used to prepare and consume betel (Brownrigg 1992):

- 🌿 Betel scissors (*tong, giraya, girri*).
- 🌿 Betel chopper (*bulath wangediya, wanggedi moolah kaimili*). The betel chopper is a kind of tube with a built-in chopping knife to cut the betel nuts. It is often used by older people without teeth.
- 🌿 Betel presentation plate (*ilah thattuwa, heppuwa*). Presentation plates are used primarily on ceremonial occasions.
- 🌿 Tobacco box (*dumkola heppuwa*). These small, right-angled boxes or chests are made from a variety of materials.
- 🌿 Lime box (*hunu killotaya, yaguma, sunnadu dabbi*). Lime is usually carried in a small bottle with a stopper to which a spatula or spoon is fastened with a band or a chain. Very large lime boxes also exist, but they are used only for ritual occasions. In Melanesia and other areas, lime is stored in bottle gourds (*Lagenaria* spp.). e Lime spatula (*kaiaku*). In Melanesia, the lime spatula is sometimes the only betel-chewing tool. It is usually made of an animal or bird bone (e.g., from a pig or cassowary), but it can also be made from the leg bone of a deceased family member. The spatula is used especially when chopped betel nuts and pieces of betel leaves, rather than a betel quid, are being consumed. In this case the spatula is used to continuously add lime to the mouth (Seyfarth 1981, 564).

On the Trobriand Islands, which are part of Papua New Guinea, the making of lime spatulas has developed into a high art. Here, they are usually carved out of hardwood (ebony) or, less frequently, from tortoise shells, and they bear depictions of snakes, birds, and crocodiles or of ancestors (Jüptner 1969). Betel utensils were once also made from the bones of ancestors:

In former times, it was common for the son to remove individual bones from his dead father’s corpse, to make this into a kind of “reliquary,” and to save it: the skullcap became a lime

container, pieces of the shin or arm bones were used as lime spatulas. Such reliquaries were passed down in the family for a time and then finally placed on a rock overlooking the sea. (Jüptner 1969, 375)

Symbolic and Ritual Use

The Dayak of central Borneo, like nearly all the peoples of the Malaysian archipelago and the islands of Southeast Asia, use betel as an agent of pleasure and as an important element in ritual activities. The Dayak have a detailed conception of what happens to the soul of the dead in the afterlife. After dying, the soul travels on a ghost ship into the next world, which is connected to the world of the gods and ghosts. This ghost canoe is filled with all sorts of status symbols and other valuable objects. The most important of these are the betel utensils (betel scissors) and betel leaves and nuts. If the deceased person chewed betel constantly during his lifetime, then his soul will be able to indulge in this pleasure in the afterlife for all eternity. The betel-laden ghost ship is frequently depicted in the cult drawings of the Dayak (Seyfarth 1981, 560 f.).

Betel chewing often plays a great role in maintaining social dynamics (quite similar to the roles played by *Camellia sinensis*, *Cannabis indica*, *Catha edulis*, *Coffea arabica*, *Erythroxylum coca*, *Nicotiana tabacum*, *Piper methysticum*, alcohol, beer, and wine):

The offering of and the communal chewing of betel can strengthen partnerships, seal negotiations, and end conflicts and is not infrequently a firm component of peace treaties following feuds and wars. The areca nut itself is the very symbol of friendship and peace. (Seyfarth 1981, 566)

The betel pepper vine (*Piper betle*) prefers to climb shade trees. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

“An invitation to chew betel: Here, a small areca nut and a withered betel leaf. Take it, it is from me, *Xuan Huong*, I have just prepared it. If our two fates should join themselves together, then may these betel quids color themselves deep red.

“They should not remain green like the leaf, white like the lime.”

VIETNAMESE LOVE MAGIC IN *AUGEN LACHEN*, *LIPPEN BLÜHEN* [EYES LAUGH, LIPS BLOSSOM] (HUU 1985, 46)

In Ceylon, it was customary for rulers to have a special “royal betel,” which was made by a special betel preparer and was constantly offered to the king (Charpentier 1977, 109). The king had the privilege of enjoying betel quids with pearls that had been powdered or burned to ashes.

The natives of the Trobriand Islands have a betel ceremony called *kakaui* in which many people gather together and, within the span of one to three hours, consume large quantities of betel quids. The amount of betel they share is calculated based on the number of people in attendance and the amount of betel to be consumed by each. Eight, ten, or twelve betel nuts are used per person (Jüptner 1969, 371).

Betel quids, as well the objects used and needed for their preparation and consumption, often have symbolic and ritual significance. In Ceylon, it was customary to carry around a betel presentation plate during wedding ceremonies. The hairdresser who shaved and bathed the groom before the ceremony was rewarded with a roll of seven betel leaves (*Piper betle*), seven silver coins, and seven slices of betel nut (Charpentier 1977, 110). Betel is also a ritual wedding gift among the minorities of southern China (Eberhard 1983, 39). On the Trobriand Islands, a man typically brings a woman he is pursuing or his lover betel nuts or tobacco when he meets her (Jüptner 1969, 376).

Betel quids often carry sexual connotations. In Melanesia, the betel quid or the betel nut alone is given as a sign of sexual desire and is used for love magic. The ground betel mixture is painted onto arrows to enhance their accuracy, rubbed onto fishing lines in order to improve the catch, and smeared onto hunting fetishes in order to utilize the spirits that live in them. When sprayed onto the belly of a pregnant woman, the betel mixture is supposed to induce labor and make the delivery easier. Betel saliva, spat into the wind, is supposed to dispel rain and storms; spat onto the grain, it is supposed to encourage the growth of the soil.

Nepalese betel scissors for chopping the hard betel nuts.

A lime container, one of the traditional betel utensils, from Timor.

Ready-Made Mixtures (*Pan Masala*)

In India, ready-made betel mixtures are increasingly competing with traditional betel quids. None of these industrially packaged betel mixtures contains betel leaf (*Piper betle*). The precise ingredients are listed on the back of each package. Such mixtures contain the following ingredients:

betel nut	<i>Areca catechu</i>
catechu	<i>Acacia catechu</i> (cf. <i>Acacia</i> spp.)
lime	calcium hydroxide
cardamom	<i>Elettaria cardamomum</i>
camphor	presumably synthetic (cf. <i>Cinnamomum camphora</i>)
menthol sandalwood oil	from <i>Santalum album</i>
saffron	presumably <i>Carthamus tinctorius</i>
tobacco	<i>Nicotiana tabacum</i>
perfumes	no precise specification
“permitted spices”	no precise specification ⁴¹⁰

About half of the available products contain tobacco.

Some of these products are exported (primarily to Nepal). Apart from a mild stimulation, a suppression of the effects of hemp, and the promotion of digestion, I have not been able to perceive any particular psychoactive effects (Rätsch 1996).

The packages feature the caution “Betel chewing may be injurious to your health.” A traditional Ayurvedic medicine to cure “betel addiction”⁴¹¹ recommends chewing a few leaves of *tulsi* (= holy basil; *Ocimum sanctum*) after a meal instead of the customary betel quid (cf. *Ocimum micranthum*). These too promote digestion while simultaneously alleviating withdrawal symptoms (Rai 1988, 117).

In Southeast Asia, *tulsi* leaves are sometimes chewed as a betel substitute (Macmillan 1991, 424*).

Substitutes

The seeds of other *Areca* species are occasionally chewed in place of betel quids (see *Areca catechu*). Sometimes the bark, leaves, and roots of entirely different plants (which the literature unfortunately does not botanically specify) may be used as surrogates (Charpentier 1977, 115).

“Betel illuminates the spirit and dispels worries. . . . Whoever uses it will be filled with joy; he will have a perfumed breath and a sound

sleep. . . . Betel takes the place of wine for the Indians, who use it often.”

SHERIFF

(CITED BY ABD ALLAH IBN AHMAD)

“The groom, the bride, and a woman of the barber caste participate in a certain ritual procedure. The barber woman cuts in the little finger of the left hand of the bride with her nail clippers so that blood comes out. This blood is put on betel, which is then put into the mouth of the groom. In this instance betel is the pleasant packaging for another important thing, the blood of the woman, with whom he enters into a fictitious blood relationship.”

ERIKA MOSER-SCHMITT

“SOZIOKULTURELLER GEBRAUCH VON BETEL IN INDIEN” [“SOCIO-CULTURAL USE OF BETEL IN INDIA”]
(1981, 549)

Chicha

Other Names

Akha (Quechua, colonial period), asua (Quichua), cachir, cachiri, catchir, cono (Secoya), corn beer, kashiri, kasuma (Zapara), maisbier, nijiamanch (Achuar/Shuar), tepae (Huaorani), tesguino, tesvino, tizwin, tsetsepa (Kofán), tulpi

Chicha is produced primarily from maize/corn (***Zea mays***), tubers, and fruits. The substance to be fermented is always mashed with water; in other words, chicha is actually a **beer**.

Maize beer is brewed in the American Southwest, for example by the Apaches (Hrdlicka 1904). In Central and South America, chicha made from maize has been known from time immemorial and has long been valued as both a food and an inebriant. Other plants believed to improve fermentation or to protect the grains of maize are sometimes added during the preparation of the drink. In Peru, the leaves of certain ferns (*Thelypteris glandulosolanosa* [C. Chr.] Tyron, *Thelypteris rufa* [Poiret] A.R. Smith) are used for this purpose (Franquemont et al. 1990, 40*). There, chicha is made primarily from the fruit pods of *Prosopis pallida*.

In the Amazon region of Ecuador, the fruits of the chonta palm (*Bactris gasipaës*) are boiled and fermented to make chicha. The tree's extremely hard wood is used to make bows, spears, arrowheads, and the small, magical shamanic arrows that are used mainly for black magic and during shamanic wars.

In Colombia, chicha is made from a type of corn known as *maíz blanda*. The kernels of maize are ground with a stone pestle, soaked in diluted sugarcane molasses (*aguamiel*, "honey water"), and allowed to ferment for twelve days. Magical additives such as ground bones, rat skulls, or cow's skin are often added to the brew (cf. **zombie poison**). During fermentation, the corn gluten can produce ptomaine, a toxic substance that can produce undesired side effects (cf. ***Zea mays***).

In Central and South America, chicha is also prepared from various palms (cf. **palm wine**). The fruits of the following palms are used in the preparation of chicha (after Vickers and Plowman 1984*):

Bactris gasipaës H.B.K.

Jessenia bataua (Mart.) Burret

Mauritia flexuosa L.

Mauritia minor Burret (*chicha de canaguche*)

The palm fruits are first boiled and then usually pressed, soaked in water, and allowed to ferment.

Chile is a veritable land of chicha. In Santiago de Chile, the name *chicha* is now used for freshly fermented apple cider (Seeler 1994, 247). In rural and Indian regions, *chicha* is a catchall term given to all fermented beverages, especially aqueous fruit solutions (see the table on page 740). The *chicha de algarrobo* is very popular. Interestingly, the *algarrobo* tree (*Prosopis chilensis* [Mol.] Stuntz), the sweet fruit pods of which are fermented to prepare the drink, is also called *tacu*, *huancu*, and *huilca* in Peru. These same names are given to *Anadenanthera colubrina* (Mösbach 1992, 84*).

Some Chilean types of chicha are attributed with medicinal qualities; those from *huighan* or *huighnan* (*Schinus dependens* Ortega), for example, have strong diuretic properties and are consumed

by people suffering from dropsy (Schultes 1980, 106*). A chicha prepared from the pepper tree (*Schinus molle*) has potent stimulating and possibly other psychoactive effects, as the **essential oils** of the fruit include β -phellandrene, α -pinene, carvacrol, o-ethylphenol, β -pinene, camphene, myrcene, α -phellandrene, limonene, π -cymene, and β -spatulene (Terhune et al. 1974). The chicha prepared from *Schinus molle* is also used to treat dropsy.

An Indian chicha merchant (drawing from Mortimer, *History of Coca*, 1901).

The hard fruit pods of the Chilean *algarrobo* (*Prosopis chilensis*) contain a large amount of sugar and are thus suitable for preparing fermented drinks.

In southern South America, many species from the genus *Prosopis* are used to brew a drink similar to chicha. (Photographed in southern Chile)

In southern Chile, the starchy, sugary sprouts of the primordial monkey puzzle (*araucarie*) tree (*Araucaria araucana*) are fermented to produce chicha. (Photographed in southern Chile)

The people who live in the oases of the Atacama Desert use the ripe fruits of the unusual *chañar* tree (*Geoffrea decorticans*), which contains large amounts of chlorophyll in its bark, as an ingredient in brewing. (Wild plant, photographed in San Pedro de Atacama, northern Chile)

The fruits of *Gaultheria phillyreifolia* are used on the southern Chilean island of Chiloé for brewing chicha. (Wild plant, photographed near Ancud, Chiloé)

Known as red pepper, the seeds of the molle tree (*Schinus molle*) are used as a fermentation substance and as a spicy beer additive. (Wild plant, photographed in San Pedro de Atacama, northern Chile)

The fruits of the Chilean barberry (*Berberis darwinii*) are used to brew chicha.

The people of Chiloé use the sweet fruits of the Chilean guava (*Ugni molinae*) to make chicha. (Wild plant, photographed near Ancud, Chiloé)

“[W]e drink simply because we like to, and we vomit because it is fun for us.”
AN INDIAN FROM THE RUCUYEN TRIBE IN “KOKA UND CHICHA” [“COCA AND CHICHA”]
(NACHTIGALL 1954)

In South America, several trees from the Family Leguminosae that are widely referred to as *algarrobo* yield fruit pods that are used to make fermented drinks (chicha). (From Pedro de Montenegro, *Materia médica misionera*, seventeenth century)

Sometimes admixtures are used to alter the taste or the effect of chicha. In the Colombian Vaupés region, the dried greenish yellow flowers of *Duguetia odorata* (Diels) Macbride (Annonaceae) are used to perfume (and strengthen?) chicha. The plant is rich in alkaloids (Schultes and Raffauf 1986, 259*). In the same region, the powdered flowers of *Heterostemon mimosoides* Desf. are also used as an aromatic additive to the drink (Schultes 1978b, 231*). The Barasa Indians add the powdered bark of *Vochysia lomatophylla* Standl., known locally as *ka-kwee'-gaw-ya*, as an abortifacient (Schultes 1977b, 117*). A wide variety of other psychoactive plants may also be added to chicha (see the table on page 741).

“When the inhabitants of the river-filled forests and meadows no longer felt like hunting and gathering, they lived from their reserves, drank home-brewed stimulants, and indulged in polygamy. Hate and jealousy began to creep around the Rucas, and depravity raised its ugly face. Then the giant serpent Caicaivilu awoke from its thousand-year sleep and roused up the wind and the sea so that they would destroy the land. Hurricanes laid waste to the forest, earthquakes in the ocean caused tidal waves. Humans and animals fled to the mountaintops and fought each other for a safe haven. The giant serpent Tentenvilu, who slumbered in the ancient cordilleras, was also awoken by the chaotic din. It realized the distress of the besieged and pushed the mountains upward with all its strength as the ocean rose ever higher. The battle of the enemy serpents lasted for moons upon moons. Then the god Ngenechen intervened, neutralized the battle, and brought the wrathful nature to a standstill. The gulfs, fjords, canals, and islands remained from the waters of the evil serpent and the earth masses of the good serpent.”

Cimora

Other Names

Timora

In Peru, the name *cimora* or *timora* is given to a psychoactive drink used for shamanic purposes. This drink consists primarily of *Iresine* species (*Iresine celosia* L. and others; see ***Iresine* spp.**), ***Brugmansia*** species, or a mixture of the following plants (Ott 1993, 409*; Schultes and Farnsworth 1982, 159*; Schultes 1966, 302*):

Trichocereus pachanoi Br. et R.

Neoraimondia arequipensis (Meyen) Backeb. [syn. *Neoraimondia macrostibas* (K. Schum.) Br. et R., *Neoraimondia roseiflora* (Werderm. et Bckbg.) Bckbg., *Pilocereus macrostibas* K. Schum.]

Hippobroma longiflora (L.) G. Don⁴¹⁵ [syn. *Isotoma longiflora* Ducke or (L.) Presl, *Laurentia longiflora* (L.) Peterm., *Lobelia longiflora* L.]

Pedilanthus tithymaloides (L.) Poit. [syn. *Pedilanthus carinatus* Spreng.]

Brugmansia spp. [syn. *Datura*]

Iresine does not appear to contain any alkaloids and presumably does not induce any psychoactive effects. In Peru, *Euphorbia cotinifolia* L. is known as *timora* (cf. ***Trichocereus pachanoi***). Although a related euphorbia, *Pedilanthus tithymaloides* Poit. (cf. ***Pedilanthus* spp.**), is known in Peru by the folk name *cimora misha*, it does not appear to have any psychoactive effects (Müller-Ebeling and Rätsch 1989, 32 f.*).⁴¹⁶

In Peru, different cultivars of ***Brugmansia*** x ***candida*** as well as ***Brugmansia arborea*** are known by the name *cimora*, and it is these, along with *Trichocereus pachanoi*, that presumably represent the actual psychoactive components of the cimora drink. More precise recipes for preparing cimora or timora are lacking, as are precise pharmacological investigations of the purported blend.

Several South American species of *Iresine* provide the basis for preparing the cimora drink.

The euphorbia *Pedilanthus tithymaloides* is known as *cimora misha* in Peru, where it is often added to San Pedro drinks. It is planted throughout South America as a magical protection for houses and farms. It is said that when witches and sorcerers attempt to slip into the house, they see in the plant arrows that are dangerous to them. Whether or not the plant has psychoactive effects is unknown. (Photographed in a Mataco village in northern Argentina)

Enemas

Other Names

Clistere, clyisma, clyster, clysterium, clystiere, eingießungen, einläufe, klistiere, klystier, lavement

The term *enema* refers to a liquid that is administered rectally for medicinal/therapeutic, hedonistic, or ritual/psychoactive purposes. Enemas often consist of nothing more than lukewarm water, but for medicinal purposes, a decoction or infusion of certain plants may be used, e.g., as a laxative. The fluids may also take the form of alcoholic beverages (**beer**,⁴¹⁷ **wine**, **chicha**, **balche**’, pulque [cf. *Agave spp.*]). Many medicines that can cause discomfort to the stomach are often administered in enema form (e.g., opium; cf. *Papaver somniferum*). Cleansing enemas often play a role during ritual preparation for entheogenic rituals.

It has often been asserted that the ancient Egyptians invented enemas after observing the behavior of the ibis. This bird supposedly uses its long, curved, tubelike beak to administer enemas to itself. Because the ibis is the symbolic animal or even the embodiment of the shamanic god Thoth, Thoth became known as the god of enemas (Degenhard 1985, 13). In fact, enema devices have been found in various places around the world (Hallowell 1935; Heizer 1944; Lieberman 1944). Of particular significance are the caoutchouc (rubber) balls that were used to administer enemas that have been found in South America. South American shamans also made enema devices from jaguar bladders and bird bones (Nordenskiöld 1930, 188). Such tools are sometimes also used to ingest dry **snuffs** through the nose.

In Europe, special enema syringes were once popular. Devices known as blowing tubes and also specially designed machines were used to blow smoke, especially from tobacco (*Nicotiana tabacum*), into the rectum (Schäffer 1772; Degenhard 1985, 22 ff.). Enemas of tobacco smoke were administered not only to humans but also to horses (Degenhard 1985, 171).

During antiquity and the Middle Ages, people believed that enemas had been discovered by observing nature: “the stork that purges itself.” (Woodcut, late Middle Ages)

Enema scene on a ritual vessel (drinking glass?) of the Classic Mayan period, showing a diviner or shaman administering either a tobacco decoction or balche’.

“The Indians who live in the interior of Brazil, such as the Caripuna, Murás, Maukés, Pouporó, and the Catanixi, had already hit upon the idea of using an enema to affect consciousness, and they used parica enemas for inebriation. ‘Parica’ is the name of the seeds of the angico tree, which are powdered and mixed with the ashes of the imbauwa tree and then, added to water, were administered as an enema in a rubber syringe with a very long tip made from a hollow bird bone.”

ARMIN VON DEGENHARD *DAS KLISTIER* [THE ENEMA] (1985, 334)

In ancient Mexico, sexual rituals included enemas containing pulque, the fermented juice of *Agave spp.*, to which other psychoactive substances (e.g., *Lophophora williamsii*) were usually added (de

Smet 1985, 20). The Mayans appear to have used enemas made from *Nicotiana spp.* and **balche'** in ritual contexts (de Smet 1981; Furst and Coe 1977). There is also evidence suggesting that the pre-Columbian Mochica administered enemas containing aphrodisiacs to men during ritual anal coitus (cf. Dobkin de Rios 1982*). The ritual use of enemas for purification and/or to administer psychoactive preparations was especially important in South American shamanism.

In the modern period, enemas are often used as part of erotic activities (Degenhard 1985). In the Orient, and especially in the world of the harem, opium was given in enemas that were aphrodisiac and also intended to induce forgetfulness. In contemporary anal-erotic circles, a variety of psychoactive substances (PCP, ketamine, **cocaine**, **scopolamine**) are used in aphrodisiac enemas in orgies (Rätsch 1987).

Different preparations were administered as narcotic enemas in ancient times (cf. **soporific sponges**). In the nineteenth century, narcotic enemas consisting of olive oil and ether were administered for surgical purposes (Degenhard 1985, 333 f.). Enemas have also been abused in the context of Catholic exorcisms and in the persecution and humiliation of women accused of being witches.

In Japan, enema blowing tubes were used to administer different psychoactive substances, especially green tea and opium, for hedonistic and other purposes. (Woodcut, nineteenth century)

Energy Drinks

During the past several years, new types of beverages have been developed in connection with the rave and techno culture. Marketed as “energy drinks,” they are offered to ravers as stimulating, healthy alternatives to **alcohol**, which in the rave culture is becoming increasingly frowned upon as a party drug (Ahrens 1994, Millman and Beeder 1994). Many of the names of these drinks—for example, Mystery (an “official Michael Jackson Product”), Fit for Fun, Flying Horse, Warp 4 Space Drink, Cult Energy Activator, Magic Man, Taurus, and XTC (= ecstasy = MDMA)—suggest improbable psychoactive effects.

The basis of most of these products is guaraná (see ***Paullinia cupana***). They usually also contain various vitamins, DHA (polyunsaturated fatty acids), taurine (a substance that appears to be pharmacologically inactive), propolis, and pure **caffeine**. However, the caffeine concentration typically is not as high as that found in a cup of coffee (cf. ***Coffea arabica***). In other words, these products are as frustrating as **herbal ecstasy**.

A collection of so-called energy drinks. Advertisements for such beverages often claim that they are more stimulating than cocaine and more psychedelic than LSD.

Han-Shi

Other Names

Cold food powder, cold mineral powder, five-mineral powder, han-shih, han-shih san, han-shi powder, medicinal powder made from the five minerals, wu-shi

The Chinese politician He Yan (in office 240–249 C.E.) was one of the most important philosophers of the Wei dynasty. After trying the han-shi powder, he reported enthusiastically, “When one takes the five mineral powder, not only are diseases cured, but the mind is awakened and opened to clarity” (in Wagner 1981, 321).

The purported inventor or discoverer of the drug, Huangfu Mi (215–282 C.E.), commented:

In recent times, He Yan has devoted his time to music and esteemed sex, and when he took the drug for the first time, he attained an additional clarity of consciousness, and his physical strength gradually grew stronger. [Because of this], everyone was soon passing the drug around in the capital city. . . . After his death, the number of those who took it grew even larger, and this did not change over time. (In Wagner 1981, 321)

The poet Su Shi (1036–1101) listed the main ingredients of the drug:

It began with He Yan, that the people took stalactites with aconite and uninhibitedly abandoned themselves to wine [= **sake**] and sex in order to extend their lives. In his youth, He Yan was rich and respected, why should it be such a surprise that he took the *han-shi* powder in order to satisfy his desires? (In Wagner 1981, 321)

Although there is some connection between the efficacious powder and the recipes of Taoist alchemy, han-shi was used chiefly as an agent of pleasure (Strickman 1979, 168). It was generously consumed in circles that were already interested in inebriants:

From the Wei period on [after 220 C.E.], one encounters wine [pressed from grapes] in a totally new context. It was consumed by the feudal class with a consciousness-expanding and potency-promoting drug—the han-shi powder. According to the instructions of the inventor Huang-fu Mi, the drug needed to be taken with hot, high-quality wine in order for its effects to be released. The literature of the time contains various reports of wine societies, which were actually drug parties. The combined effects of wine and drugs sometimes caused things to get out of control. For example, it was said that the wealthy Shi Ch’ung would use so-called beautiful women to encourage his guests to drink wine at his banquets. In the event the guest did not drink to complete excess, the woman would be executed. (Majlis 1981, 318)

Stalactites in a limestone cave; since ancient times, stalactites have been used in traditional Chinese medicine to strengthen *yang* and to move *chi* (= life energy) in the lower abdomen. (Woodcut from *Ben cao gang mu*, 1596)

The Chinese drug called *fu tzu* is made from the roots of different species of monkshood (*Aconitum* spp.). It was once an important ingredient in the psychoactive han-shi powder.

Many han-shi consumers—and not only Taoists and/or alchemists—also experimented with such other drugs as **sake**, **wine**, brandy (**alcohol**), and psychoactive mushrooms (Wagner 1973; Wagner 1981, 322; cf. Strickman 1979 and Cooper 1984, 23, 54, 62*). Unfortunately, we do not yet know the identity of these psychoactive mushrooms (cf. “*Polyporus mysticus*”). It also appears that the han-shi powder was often used in the context of Taoist sexual practices and sexual magic exercises.

Yü Chia-hsi (1938) has conducted research into the recipe or recipes for making han-shi powder, but only imprecise details are known:

The recipe for the drug is known. In addition to various ingredients containing calcium (stalactites [*é guan shí*], oyster shells [*mu lì*], both ground) and numerous herbs, it contains above all the poisonous aconite. Unfortunately, no pharmacologist has studied this complex drug to date, so that we provide no information about experiments or theoretical effects. (Wagner 1981, 321)

Unfortunately, Yü Chia-hsi did not indicate whether the *é guan shí* (literally “gooseneck stones” = stalactites) and oyster shells (most likely *Crassostrea gigas* [Thunberg 1793])⁴¹⁸ were pulverized or burned/slaked. But it seems likely that this was a slaked lime, for the recipes for all known psychoactive products that are mixed with lime require slaked lime (i.e., calcium hydroxide); cf. *Areca catechu*, *Erythroxylum coca*, *Nicotiana tabacum*, and **betel quids**. In addition to stalactites, Shen Kuo names an additional plant ingredient: *Atractylodes macrocephala* Koidz. (cf. **sake**). He considers the effects of the powder to be a product of synergistic interactions between its components:

When a person ingests many minerals in one medicine, then the minerals must be able to work in synergy, and when in addition a person further stimulates them with medicinal plants, then the effect must be very strong. Thus, when the powder of the five minerals is combined with different medicinal plants, one should use only an extremely small amount of mineral powder, for one must produce the effects with only small amounts of additives. (Shen Kuo 1997, 127 f.*)

Shen Kuo then mentions Sun Simajao, who claimed that poison sumac (*Rhus toxicodendron* L. [syn. *Toxicodendron quercifolium* (Michx.) Greene]) and kudzu vine (*Pueraria lobata* [Willd.] Ohwi [syn. *Dolichos lobatus* Willd., *Pueraria thunbergiana* (Sieb. et Zucc.) Benth., *Pueraria hirsuta* (Thunb.) Scheid. non Kurz]) were effective substitutes for the dangerous five mineral powder (Shen Kuo 1997, 129*).

Aconite is the only psychoactive ingredient (cf. *Aconitum* spp.) known to be present in the powder. It is possible that it reacts with the lime and the other herbs in a synergistic manner, although Su Shi claims that the other plants are not significant. In addition, the inebriating effects of alcohol, which was used as a carrier substance, should not be underestimated or forgotten.

It would be truly interesting to reconstruct the recipes and perform pharmacological tests on humans with them. However, caution is advised, for the Chinese literature also contains descriptions of unpleasant side effects, emaciation resulting from chronic use, and death from overdose (Wagner 1981, 322 f.).

Haoma

Other Names

Chaoma, hauma, hom, homa, sauma

The ancient Parsis had a sacred drink known by the name *haoma* (also *hauma*, corresponding to the Indian **soma**⁴¹⁹), which is reputed to have had inebriating effects and to have been a source of divine inspiration. This inebriating drink was consumed during the communal bull sacrifice. It was venerated as a god but was condemned by Zarathustra (= Zoroaster), the founder of the religion that bears his name. According to Pliny, Zarathustra was “the creator of magic” who rejected⁴²⁰ both haoma and the ancient (Indo-Iranian) gods, who were the personifications of the stars, waters, and natural occurrences (fire) (Gaube 1992, 108, 114).⁴²¹ These *daiwas* (“demons, idols”) were primordially related to the devas, the plant spirits of the Indians (cf. Storl 1997*). The god of the inebriating drink was also known as Hauma or Haoma. Today, Iranians still refer to Syrian rue (*Peganum harmala*) as *hom* or *homa*.

In order to extract the sacred juice from the plant, Haoma as a god must in a certain sense be killed, and this happens during the pressing of the juice. During the main ceremony of the Parsis—the sacrifice—not only is haoma drunk, that is, one god is offered to another dying god, but sacred bread is also consumed. By doing this, the priests and the faithful desired to partake in the immortality of the gods and therewith the resurrection of eternal life. (von Prónay 1989, 27)

Not only did the Parsis regard haoma as the primordial plant out of which all other medicinal plants came, but they also viewed it as a powerful medicine in itself:

The haoma inebriation is invigorating. Any mortal that praises haoma like a young son: to him will haoma make itself available and heal his body. Since that time have you been growing on these mountains, the multifarious, milky, gold-colored haoma; your medicines are tied to the blisses of Vohu Manah. (Avesta, Yasna 10)

The Persians considered the haoma plant to be a “miracle tree” or an “all-seed tree” from which the seeds of all trees descended. During the Hellenic period, the ancient Iranian god Mithra became the god Mithras, who was cultically worshipped in a secret male organization. The veneration of the Parsi haoma lived on in the Mithraic mysteries (Cumont 1981; Ulansey 1991). Some cult images depict Mithras as a young god who is grabbing a bull by its nostrils with one hand and stabbing him with the other:⁴²²

It is then that the miracle takes place, that blessings flow from the body of the bull as it is collapsing in death. All of the nourishing and healing plants issue forth from it. This is suggested by the ears of grain that grow out of the end of his tail; the most important is the generative seed that gushes from the bull, and from which comes future life. Diabolic animals, snake, scorpion, crab, attempt to steal this source of life, but the seed is caught in a vessel and brought to the moon. Purified in the light of the moon, from there this seed produces a pair of cattle, and with this pair, from which the entire earthly race of cattle are descended, arise all the useful animals.

As so it is that all plant and animal life on earth is created from the death of the bull. This bull was the first living being to be created, and the brutal and gruesome deed that Mithras was prepared to do against his will upon the command of the highest god, to kill the primordial life, brought forth all that is good in the world, increased life in infinite fashion, the multifaceted all-life of nature comes from a mythical, unified living being that had to be killed for this very purpose . . . this bull is haoma. (Lommel 1949, 212)⁴²³

Haoma was stirred together with the fat of a bull to make the “drink of immortality” (cf. “*Polyporus mysticus*”); the psychoactive plant “wards off death” and symbolizes the energy of life:

This sacred plant is the embodiment or paragon of the plant world or the primordial plant; it encompasses the entire plant world within itself, and its juice represents all of the nutritional and medicinal powers contained in the plant world. It is the symbol of nourishment and healing. . . . Soma-haoma is thus the all-life, which comes from heaven and pulses through all of nature and is given form in all living beings. . . . During the full moon, when the vessel is full with the bright life potion, the gods drink from it. It is from this that they derive their immortality, for the contents of the moon is the drink of immortality, *amrta*, a word related to ambrosia. (Lommel 1949, 213)

Carl Ruck believes that the Parsis remembered the fly agaric mushroom (*Amanita muscaria*) (which has often been construed as ambrosia) as haoma (Ruck 1995, 132*). Unfortunately, the identity of the true haoma plant remains undetermined. The limited sources also make it difficult to reconstruct the method or methods used to prepare the drink. However, it is very likely that haoma, like **soma**, was a plant or preparation that produced potent psychoactive effects. It may have been a kind of **ayahuasca analog**, such as a preparation made from *Peganum harmala* and *Phragmites australis* or *Phalaris arundinacea*. Archaeological finds suggest that *Ephedra* species (*Ephedra* spp.) were consumed ritually in the haoma cult as part of a beerlike preparation.

“A great god is Ahura Mazda, who created this world, who created the high heavens, who created humans, who created happiness for humans, who made Darius king.”

GRAVE INSCRIPTION AT PERSEPOLIS IN *ZOROASTRISMUS (DIE RELIGION DES ZARATHUSTRA)* [ZOROASTRIANISM (THE RELIGION OF ZARATHUSTRA)]
(GAUBE 1992, 109)

The psychedelic or visionary effects of hamoa were described in the Persian text called the Book of Arda Viraf (fourth century C.E.). A holy man named Viraz was inebriated on haoma—his haoma being a drink called *mang* made from “wine and henbane” (cf. *Hyoscyamus niger*, *Vitis vinifera*)—and fell asleep. His soul was led across the bridge that spans the world mountain and binds this world with the one beyond and into heaven. The holy man passed beyond the sphere of the stars and into the realm of the wise lord of the heavens, Ahura Mazda or Ohrmuzd, where he was initiated into the secrets of life after death. After seven days, he descended back to the earth with instructions to tell the people what he had seen (Coulano 1995, 140 f.*):

In Persia, vision into the spirit world was not thought to come about simply by divine grace nor as a reward for saintliness. From the apparent role of sauma [= haoma] in initiation rites, experience of the effects of sauma, which is to say of *menog* existence, must have at one time been required of all priests (or the shamans antecedent to them). (Flattery and Schwartz 1989, 31)

Some rudiments of the ancient haoma cult have been preserved in modern Iran. Today, the ritual drink is brewed either from pomegranate juice (*Punica granatum* L.) and ephedra (***Ephedra spp.***) or from rue (*Ruta graveolens* L.) and milk (Flattery and Schwartz 1989, 80). The fire ritual of the haoma cult has been integrated into the rites of tantric Buddhism and has survived into the present day; it is still practiced in Japan (Saso 1991).

Haoma Candidates

Herbal Ecstasy

Other Names

Cyberorganic ecstasy, herbal XTC, natural ecstasy, nature XTC, thrill pills

The modern techno parties or raves of the 1990s were like a reflowering of the ancient bacchanalias and recalled the medieval dance frenzies. To non-participating observers, they seem like witches' sabbaths, Haitian voodoo dances, Indian powwows, or the trance dances of the San (!Kung Bushmen) of the Kalahari Desert (cf. *Ferraria glutinosa*). In particular, the so-called goa parties, which usually take place outdoors and are attended mainly by aging hippies and neo-hippies, resemble the ecstatic dance rituals of archaic peoples (Saunders and Doblin 1996).

These weekend parties, which usually begin around midnight and last until the following afternoon, seem to be an imitation of what Aldous Huxley described as “experiences of heaven or paradise” in his classic book *Heaven and Hell* (Huxley 1963*). Light shows reveal the mystical “otherworldly” light, and burning sticks of incense (cf. **incense**) evoke the delightful scents of heaven, carried on the “breezes of paradise.” The DJs (disc jockeys) function as the high priests of a cult community, which clothes itself in special (“techno-style”) garb. The DJs have the task of leading their congregation into an altered, ecstatic state—a task similar to that performed by tribal shamans. For this reason, many DJs like to refer to themselves as techno-shamans. These modern shamans employ the latest technology to take themselves and others into different realities. The powerful rhythmic music, called techno, trance, or psychedelic trance music, plays a central role (Cousto 1995).

Most techno-shamans and most of the partygoers agree that the rhythm of the music, especially in combination with psychoactive substances, helps induce trance experiences. A number of studies of the techno scene have shown that the partygoers selectively seek out the sound and rhythm that best functions for them. In general, a longing for ecstatic experience seems to provide the impetus for such party and dance activities (Krollpfeiffer 1995; Böpple and Knüpfer 1996; Rabes and Harm 1997).

One of the many products—sold mainly at raves and techno parties—circulating under the name *herbal ecstasy*.

“Gingko biloba
This tree’s leaf, which from the east in my garden propagates,
On its secret sensations we feast, As the wise ones it elevates.

Is it a living being and single, which in itself divides?
Is it two, which choose to mingle So that one the other hides?
To answer such a question,

I found a sense that’s right and true; Do you see by my songs and suggestions,
That I am both one and two?”

JOHANN WOLFGANG VON GOETHE *WEST-ÖSTLICHER DIVAN* [WEST-EASTERN DIVAN]
(1819/20)

Most partygoers ingest psychoactive substances, such as ecstasy (= MDMA; cf. *Myristica fragrans*), LSD, psilocybin mushrooms (*Psilocybe semilanceata*, *Psilocybe cyanescens*), hashish and marijuana (*Cannabis sativa*), **cocaine**, amphetamines, and guaraná (*Paulliania cupana*). The problems usually associated with MDMA began when the substance was banned internationally (1987). As a result, the black market was flooded with poor-quality preparations containing ingredients that the users often did not know about (Ahrens 1995). Uncertainties about the purity and quality of these products, combined with the development of a tolerance toward MDMA and the need for a “natural” alternative, have led to increasing numbers of plant products (so-called natural drugs) appearing on the party scene (cf. **energy drinks**). Distributors and producers advertise these products, usually sold under the name *herbal ecstasy*, as natural surrogates for MDMA, promising “very similar effects” (Leitner 1995; Saunders and Wright 1995).

The recipes for herbal ecstasy are based on the so-called brain foods and smart drugs coming from the United States. These compounds are made from plant stimulants (**ephedrine**, **caffeine**), vitamins, amino acids, and hormones (Pelton and Pelton 1989; Potter and Orfali 1993) and are reminiscent of traditional Chinese tonics (Teeguarden 1984). Many of them contain *fo-ti-tieng* (*Centella asiatica* [L.] Urban [syn. *Hydrocotyle asiatica* L.]), a tonic and sometimes mildly psychoactive plant (Emboden 1985; Storl 1995). They often include an extract of *Ginkgo biloba* L. [syn. *Salisburia adiantifolia* Sm.] (Gingkoaceae) as well; it is said to stimulate the brain and to strengthen memory⁴²⁴ (Schmid and Schmoll 1994). But the main ingredient is (was) usually ma-huang (*Ephedra sinica*). Sometimes yohimbé bark or extract (*Pausinystalia yohimba*) may also be added (Saunders and Doblin 1996, 157). It is doubtful whether these herbal ecstasy preparations actually do induce psychoactive, not to mention empathogenic, experiences. Even when ephedrine is present, the dosages would typically be too small.

One recipe that is considered to be effective in the European scene contains the following ingredients:

The packaging of the American product Herbal Ecstasy. The “psychedelic” butterfly is intended to symbolize the purported effects (“soul flight”).

The ginkgo tree (*Ginkgo biloba*) is an ancient Asian medicinal plant. Since its positive effects on brain function have become known in the West, there has been renewed interest in this traditional herbal medicine. Because ginkgo is now regarded as a brain tonic, the extract is often added to so-called brain foods and to herbal ecstasy. (Copperplate engraving from Kaempfer, *Amoenitates Exoticae*, 1712)

The recommended dosage is one to three capsules (0.8 g per capsule) per person. Unfortunately, the recipe does not provide any information as to the relative proportions of ingredients. I perceived mild stimulant and aphrodisiac effects after taking three capsules but did not notice any similarities to the effects of MDMA.

Herbal Ecstasy, a trademarked product marketed in the United States as 100% natural, consists of the following ingredients:

The effects of this product are comparable to those of the first (disappointing).

The marketing of Herbal Ecstasy and similar products (Ultimate Euphoria, et cetera) is big business (\$300 million in annual sales; Jolly 1996). In the United States, this has resulted in an FDA investigation into the ingredients and the component that is typically the only one with any activity, namely the ephedrine-containing *Ephedra* extracts. Ultimately, this and other problems led to a ban on ephedra and on all products that contain ephedra (cf. Saunders and Doblin 1996, 160). Since the summer of 1996, the makers of herbal ecstasy (and other preparations) have been advertising ephedra-free herbal ecstasy. The result is a kind of “decaffeinated coffee” or, in other words, “ecstasy-free ecstasy,” a harmless but expensive placebo.

Honey

Other Names

Cab, honig, kab, ksandra (Sanskrit), mel, mella, miel

Honey is a substance produced by the domestic honeybee (*Apis mellifica*) and by wild bees (*Melipona* spp., *Trigona* spp.) from the nectar and pollen of various plants. “Honey is perhaps the only predigested food that humans know” (Root 1996, 127*).

Honey has been used to make **mead** since the Stone Age. The fact that honey can be toxic and/or psychoactive—in other words, inebriating—has long been known and has been demonstrated throughout the world (Palmer-Jones 1965). Honey also has a long history of use as a healing remedy or a “heavenly medicine.” In Hippocratic medicine, honey was used as “a kind of psychopharmacological agent to treat depression and melancholia, and as a geriatric medicine.” It was also used as an antidote for opium overdoses (Uccusic 1987, 38 f.; see *Papaver somniferum*).

There are three categories of plants that are associated with toxic honey: 1) plants whose nectar or pollen kills the bees before they can transform it into honey (e.g., locoweed [*Astragalus lentiginosus*], *Veratrum californicum*, *Vernonia* spp.); 2) plants whose nectar is harmless to bees but when turned into honey becomes toxic/inebriating to humans (e.g., oleander [*Nerium oleander*], thorn apple [*Datura* spp.], angel’s trumpet [*Brugmansia* spp.], mountain laurel [*Kalmia* spp.], false jasmine [*Gelsemium sempervirens*], *Euphorbia marginata*, *Serjania lethalis*); and 3) known poisonous plants that are harmless to bees and yield edible and often exquisite honey (e.g., *Rhus toxicodendron*, *Metopium toxiferum*, *Jatropha curcas*, *Baccharis halimifolia*, *Ricinus communis*) (Morton 1964, 415).

Xenophon (ca. 430–355 B.C.E.) reported in his *Anabasis* that soldiers became inebriated and poisoned by the honey that had been produced from the Pontic rhododendron (*Rhododendron ponticum* L.) and apparently from a red-flowering oleander (*Nerium oleander* L.; cf. Rätsch 1995, 267 f.*) (Roth et al. 1994, 615*). “In modern terms, they ‘got high.’ . . . This condition did not last long amongst the Greeks and quickly abated” (Rüdiger 1974, 93). The toxicological literature refers to this Pontic (Turkish) honey as “mad honey” or “toxic honey of Asia Minor” (Fühner 1943, 203*). This inebriating honey was well known in ancient times (Krause 1926; Plugge 1891), and it may have had been involved with the Dionysian frenzies:

In the district on the Pontus, among the people of the Sanni, there is a kind of honey that is known as *maenomenon* [“mad maker”] because of the insanity it induces. It is thought that this is caused by the flowers of the oleanders [*Rhododendron*], which abound in the woods. (Pliny 21.77)

In ancient times, it was believed that oleander first came from the land of Colchis (on the Black Sea); it was regarded as a plant of the “witch” Medea (who may have been a Scythian shamaness). Apparently, oleander also had something to do with the wines that were drunk during the Dionysian orgies. Oleander was a popular subject in the wall frescoes of Pompeii, a city known for its Bacchic mysteries. Oleander leaves contain the powerful cardiac poison oleandrin, which can be life-threatening for humans and animals because it can paralyze the heart. Also present are digitalis-like glycosides (neriine, nerianthine, adynerin, cortenerin). The milky latex contains salacin and other alkaloids. Although oleander is frequently said to be toxic, the toxicological literature contains no

observations of dangerous intoxications resulting from the consumption of the flowers and leaves (Frohne and Pfänder 1983, 47*).

On Cypress, the island of the great love goddess, honey is still regarded as “Aphrodite’s secret.”

Oleander (*Nerium oleander*) was once used as an inebriating ingredient in wine. The honey yielded by its flowers is also said to have inebriating effects. (Photographed in Delphi, Greece)

In the Yucatán, a liquor made with honey from *Turbina corymbosa* is known by the Mayan name for the vine: *xtabentun*.

The Pontic rhododendron or Pontic oleander (*Rhododendron ponticum* ssp. *ponticum*) is the source of an inebriating “mad honey.”

A violet-flowering *Rhododendron ponticum* var. *variegatum*.

The Japanese azalea (*Rhododendron simsii*) produces a honey that is feared as poisonous.

The honey collected from the flowering alpine rose (*Rhododendron ferrugineum*) is said to have toxic or inebriating effects. (Wild plant, photographed near the Aletsch glacier, Switzerland)

The honey of European ragwort (*Senecio jacobaea*) appears to contain pyrrolizidine alkaloids that can have toxic or inebriating effects.

“The first ceremonial house (*alnáua*, *arhuínese*) was created by the ‘Great Mother’ in the ocean, at the same time as the levels of the universe and according to the same ninefold pattern. The ceremonial house had the shape of a beehive, but the upper structure was complemented below by another beehive, placed on its head and invisible, which it gave it the same egg-shaped form as that of the universe.”

GERARDO REICHEL-DOLMATOFF “THE LOOM OF LIFE”
(1978)

“According to ancient beliefs, honey falls on the plants (trees and flowers) as dew from heaven or out of the air and thus is considered to be a kind of food of the heavens.”

WILHELM HEINRICH ROSCHER *NEKTAR UND AMBROSIA* [NECTAR AND AMBROSIA]
(1883, 1)

An alchemical papyrus dated from late ancient times contains a puzzling recipe made with “mad honey”: “Preparation of emerald. 1 part burned copper, 2 parts verdigris, and a corresponding amount of Pontic honey, cook for one hour” (in Hengstl 1978, 272).

Like all later alchemical recipes, this recipe appears to contain secret instructions for a consciousness process associated with the transmutation of matter. The inclusion of psychoactive honey is particularly interesting.

In ancient times, honey was mixed with ground medicinal herbs (such as wormwood [cf. *Artemisia absinthium*]) and other pharmaceutical substances to produce what were known as “lick agents,” a kind of pharmaceutical “hard candy.” Some of these may have had psychoactive effects, for example: “A remedy to cool the uterus: hemp is pounded in honey and administered to the vagina. This is a contraction [of the uterus]” (*Papyrus Ebers* 821 [1550 B.C.E.]; in Manniche 1989, 82*).

The Mayans regard honey (*cab*) as a gift of the bee gods (*ah muzen cab*), a food from the heavens (Tozzer and Allen 1910, 298 ff.). An indigenous form of apiculture was practiced in the Yucatán in pre-Columbian times (Brunius 1995). In the Yucatán and Selva Lacandona regions (Chiapas), several species of native stingless bees (Family Meliponidae) make their honey from the nectar of specific flowers. The Lacandon know that at certain times of the year (the flowering periods), bees produce types of honey that have psychoactive or inebriating effects, even when consumed in small amounts. As little as one tablespoon is sufficient to produce noticeable effects. I once tried two tablespoons of such a honey dissolved in *atole* (a maize drink) and experienced rather strong feelings of inebriation and extreme good cheer.

The Yucatec Maya have domesticated *Melipona beecheii* and now keep these bees in special hives (hollowed-out tree trunks) to produce honey (Buchmann and Nabhan 1996). The significance of this honey is more religious and ritual than culinary. It is offered at various planting rites and also is fermented to make **balche’**, which is thus a type of **mead** (Brunius 1995). In the Yucatán, the honey made from certain vines (*Ipomoea* spp. and *Turbina corymbosa*) is called *xtabentum* or *xtabentun* (Souza Novelo et al. 1981, 32). Such honey has psychoactive effects and is preferred for making balche’. A liquor known by the same name is produced in the region of Valladolid. This honey is usually harvested in November and December (Brunius 1995, 20).

Certain active constituents in plants can pass into the nectar of the flowers, and the bees metabolize these either not at all or only a little when they produce honey. For example, the toxic grayanotoxins present in rhododendrons and the tropane alkaloids (especially **atropine**) found in belladonna flowers can both pass into the honey that is derived from their flowers.

Some species of rhododendron, for example azaleas, contain the toxic terpene andromedotoxin (= grayanotoxin, rhodotoxin).⁴²⁶

Humans have gathered and prized honey since the Stone Age. This Stone Age painting showing honey being gathered was discovered in the caves of Araña, near Valencia, Spain.

Incense

Other Names

Dhoop, dhup, fumigium, incensio, räucherwerk, sahumerio, saumerio, weihrauch

In every climate zone, humans have discovered plants that can be used as incenses for ritual, medicinal, and psychoactive purposes. The inhabitants of the oases in the extremely arid Atacama Desert (northern Chile) use the aromatic, resinous herbage of *Fabiana bryoides* as a shamanic incense. (Watercolor: Donna Torres)

The use of incenses for ritual, religious, magical, medicinal, hygienic, and other purposes is found throughout the world. Incense is a transcultural phenomenon. In most cultures, incense is regarded as a “food of the gods.” Some incenses are used for their unusually pleasant scents. Others are burned for their pharmacological effects. The latter typically have an unpleasant smell but induce psychoactive effects. Many parts of plants (such as laurel leaves; cf. ***Laurus nobilis***) are used as incense during esoteric rituals for their allegedly magical effects. From the form that the smoke takes on as it rises, the will of the gods or the malicious intent of demons can be read. Some incenses stimulate erotic feelings, while others are said to protect house and farm from diseases, spirits, and thieves. The use of incense gave rise to the practice of smoking (cf. **smoking blends**).

There are three main cultural centers for the use of incense: the ancient world (including the ancient Orient), the Indian subcontinent (including the Himalayan region), and Mesoamerica. The Native American incense culture developed separately and independently, while strong reciprocal influences existed between the ancient world, the Orient, and India. Extensive trade relationships between India and Egypt, resulting in the exchange of spices, medicinal plants, inebriants, and incenses, existed in ancient times. Egyptian graves dating to late antiquity have yielded containers filled with aromatic substances and inscribed with Indian and Chinese writing (Wollner 1995, 19).

The use of incense was very widespread during antiquity. Greek, Egyptian, and Roman gods all had their respective incenses (cf. Räscht 1995a, 312 ff.*). In the ancient literature, e.g., the writings of Dioscorides and Pliny, the laurel (***Laurus nobilis***) was known as *daphne* and was attributed with powerful mind-altering properties. So far, however, all attempts to use laurel for psychoactive purposes have failed (see Räscht 1996b), and no psychoactive constituents have been found to date (Hogg et al. 1974). This suggests that *daphne* was likely a name given to at least one or more other plants in antiquity. Perhaps one of these *daphne*, whose botanical identity is now unknown, was psychoactive.

The Uses of Incense

(from Räscht 1996b)

Incense is used to:

- make offerings to the gods and goddesses
- establish contact with deities, demons, and spirits
- make contact with the ancestors
- escort the dead into the afterlife

- banish or ward off negative spirits
- support meditation
- intensify prayers
- kindle love and the readiness for love
- increase one's own attractiveness
- honor guests
- conduct magical rituals
- improve conditions of hygiene
- disinfect rooms
- heal illnesses and dispel their causes
- induce specific spiritual experiences
- effect changes in consciousness
- effect changes in mood
- achieve specific medicinal or therapeutic effects
- disinfect or serve as an insecticide
- preserve food
- perfume clothes and hair
- spread joy and create amusement
- poison witches and offerings

“In Mexico, they know of a very unusual juniper bush, *Juniperus thurifera* (L.), and in Tibet we even find a species of juniper that grows at an altitude of 4,000 meters [and] that the Chinese call ‘hyiang ching’ (scented green). *Juniperus scopulorum* (Sarg.) and *Cupressus benthamii* (Endl.) are found in Mexico, while one encounters *Juniperus squamata* (Lamb.) and *recurva* in Nepal and Kashmir and *Juniperus sabina* (L.; sade tree) in Siberia. All of these juniper plants are different from one another and are also used by the indigenous medicine men for the most varied of treatments for diseases.”

ARNOLD KRUMM-HELLER *OSMOLOGISCHE HEILKUNDE* [THE OSMOLOGICAL ART OF HEALING] (1955, 28)

It is very likely that white henbane (*Hyoscyamus albus*), known as *apollinaris*, or the plant of Apollo, was the inebriant that the Pythia of Delphi, the famous oracular priestess of antiquity, used to enter a state of ecstasy (cf. also *Catha edulis*). The mysterious smoke of Delphi that the Pythia inhaled before sitting on the tripod and uttering her prophecies was most probably produced by burning henbane seeds.

During the Middle Ages, “sleep-bringing” incenses were used in medicine. These almost certainly had powerful psychoactive effects. A fourteenth-century Roman codex contains a recipe for such an incense; it consisted of equal parts of arsenic,⁴²⁷ mandrake root (*Mandragora officinarum*), and opium (see *Papaver somniferum*). Storax (the gum resin of *Liquidambar officinalis*) and olibanum (= frankincense; the resin from *Boswellia sacra*) were also added to this already potent blend, which was then strewn over glowing coals. This recipe was used as an alternative to **soporific sponges** and is also somewhat reminiscent of **witches’ ointments**.

During the Renaissance, the burning of incense was construed as an alchemical process (Krumm-Heller 1934, 1955). Matter is transformed through fire and then affects the mind, whether pharmacologically or psychologically. The element of fire creates smoke out of the element of earth, and the smoke joins with the element of air to “transform the mind.” That Agrippa’s recipe for incense (see below) has the ability to transform the mind is clear: he names many psychoactive plants (man-drake, henbane, hemp, poppy) whose smoke one should inhale. It was said that one could also conjure demons—in the ancient sense of the word—with incense:

For the purpose of prophecy, incenses for stimulating the imagination shall be preferred. These, in correspondence with certain higher spirits, make us skilled to receive the divine inspiration. . . . Thus, when a smoke is made from coriander and celery, or henbane along with hemlock, the demons should gather momentarily, and this is why these plants are called spirit herbs. (1.43) [1387]

In Asia and Arabia, the most valuable incense was considered to be the dark brown, resinous *lignum aloe* (*Aquilaria agallocha*), also known as aloe wood, agar wood, agar-agar, garugaru, and *lignum aspalathi*. It was used primarily for ritual purposes. There have been repeated reports of psychoactive effects resulting from burning *lignum aloe* or inhaling the very expensive **essential oil** extracted from it. *Lignum aloe* contains sesquiterpenes, chromone derivatives, a **coumarin** lignan derivative, and an alkaloid (Kletter 1992, 308).

Today, incenses continue to play a significant ceremonial and symbolic role during the commencement of entheogenic rituals around the world. *Breuzinho* (from *Protium heptaphyllum* and *Protium* spp.) is the main incense used by the Santo Daime cult (cf. **ayahuasca**). In Afro-American possession cults, various aromatic herbs and mints are burned (cf. **madzoka medicine**) to greet and attract the *orishas* (the Yoruba deities) (Voeks 1989, 123*). The wood of *Juniperus* species, known as cedar, is used as a fumigant in the North American peyote cult (the Native American Church; cf. ***Lophophora williamsii***). Copal (from *Protium copal*, *Bursera* spp.) or pine resin (*Pinus* spp.) is burned during the Mesoamerican *balche'* ritual (cf. **balche'**). During the Japanese tea ceremony, incense sticks made of *lignum aloe* or special tea ceremony blends made of several ingredients are burned (cf. ***Camellia sinensis***).

The burning of certain plants during healing ceremonies is a widespread phenomenon. In the Vaupés region of Colombia, the leaves of a Rubiaceae (*Retiniphyllum concolor* [Spruce ex Benth.] Muell. Arg.) are used for this purpose (Schultes 1978a, 196*). In Switzerland, juniper branches (*Juniperus communis* L.) are used.

Since ancient times, incenses have played a central role in shamanism. There is hardly any shamanic activity that does not incorporate the burning or fumigation of precisely defined plants or substances. Various species of juniper (cf. ***Juniperus recurva***) grow throughout the world, particularly in Europe, Asia (the Himalayan regions and Mongolia), and North America. They are used for ritual, magical, and medicinal purposes almost wherever they grow. In most cultures familiar with shamanism, juniper has a reputation for being a shamanic incense. Juniper is probably one of the oldest—it may even be the oldest—incense used by humans. This is certainly due to the fact that its leaves exude an exquisite and spicy aroma, even when burned fresh (Rätsch 1996a, 1996b).

Incense and Shamanism

Shamans in the Colombian Vaupés region inhale the aromatic balsam of *Styrax tessmannii* Perk., which is purported to be psychoactive (Schultes and Raffauf 1986, 277*).

In Peru and northern Chile (Atacama region), a number of incenses (from *Fabiana* spp., *Mentha* spp., *Senecio* spp.) are referred to by the names *koa*, *k'oa*, *khoa*, et cetera. They are used primarily during the ceremonies known as *señaladas*, when they are burned as an offering to the mother-goddess Pachamama (cf. ***Erythroxylum coca***).

During shamanic healings and rituals, the modern Nahuatl (Mexico) burn a blend of tobacco leaves (***Nicotiana tabacum***) and pine resin (from a *Pinus* species). Such an incense is said to keep away the malicious soul-eaters that live in Talocan (“the great flower of darkness”), the realm of dreams (Knab 1995, 29*). Mazatec shamans inhale large amounts of a blend of copal (resin from a *Pinus* species) and chili pods (***Capsicum* spp.**) before they begin their divinations. This incense blend is said to have psychoactive effects (Jonathan Ott, pers. comm.). The Cuna of the San Blas Islands (Panama) burn generous amounts of chili pods, often mixed with cocoa beans (***Theobroma cacao***), in order to dispel

malicious spirits (Duke 1975, 286*).

Among the North American Plains Indians, the most important ritual and shamanic incense is sage (***Artemisia* spp.**). The Flathead use an incense of *qepqep̄te* (*Artemisia ludoviciana* Nutt.) and *cqelshp* (*Pseudotsuga menziesii* [Mirbel.] Franco) in their sweat lodge ceremonies (Hart 1979, 278*).

The Indians of the Southwest prefer the piñon pine (*Pinus edulis*), which has played an important role in native culture as a food, medicine, and incense for at least six thousand years. The seeds are edible and high in nutritional value. The needles and resin are a component of many medicines. The Navajo believe that a squirrel planted the piñon pine (*cá’ol*) at the beginning of creation and that the first humans nourished themselves exclusively on pine nuts (*nictc’íi pináa’*). They use the resin as an incense in the night chant, their most important religious healing ceremony. The Tewa and Santa Clara Pueblo regard the pine as the first of all trees and its seeds as the first food (*tô*). The pine is the most important incense of the Pueblo Indians. The Zuni call the tree *he’sho tsi’tonne*, “gum branch.” The Hopi use primarily the needles of the pine as incense. Occasionally they also crumble the needles, mix them with wild tobacco (***Nicotiana* sp.**), and use the product as an incense powder. After a burial ceremony, pine resin is tossed into the fire at the house of the surviving relatives so that they can “smudge” and purify themselves. The resin is also used to protect against magic. For this purpose, the Hopi rub a drop of the resin onto their foreheads (Lanner 1981).

An Indian depiction of a shaman burning cocoa beans (Cuna-Mola Panama, ca. 1990)

Psychoactive Incenses

The psychoactivity of some of the incenses listed here is doubtful.
(from Fischer 1971; Krumm-Heller 1934; Krumm-Heller 1955; Ludwig 1982, 134 f.*; Rätsch 1995; Rätsch 1996a; Rätsch 1996b; Vinci 1980; supplemented)

Many manufacturers of incense sticks offer varieties that hint at psychoactive effects. However, these products do not contain any true psychoactive substances. (Incense stick packaging)

Botanical illustration of the Southeast Asian benzoin tree (*Styrax benzoin*), the source of the pleasant-smelling incense ingredient benzoin. (Engraving from Periera, *De Beginselen der Materia Medica en der Therapie*, 1849)

Shamans often use the leaves, branches, or bark of sacred trees as ritual and even psychoactive incenses. In the Himalayan region, shamans inhale copious amounts of juniper smoke (see ***Juniperus recurva***). The Chilean Mapuche shamans (*machi*), most of whom are female, use the cinnamon-scented bark of the sacred canelo tree (*Drimys winteri* Forst.⁴³⁴; Magnoliaceae), known locally as *voique*, *foique*, or *foye*, as an incense at all of their tribal and healing ceremonies (Mösbach 1992,

79*). Whether the incense actually does have psychoactive effects remains an open question; in any case, the Mapuche use an infusion of the leaves as an inebriating narcotic (Houghton and Manby 1985, 93*). The *machi* regard the tree as a panacea and use the bark as a tonic and stimulant (Mösbach 1992, 79*). The bark contains an essential oil, a pungent resin, and tannin. The leaves contain sesquiterpenes, such as drimendiol (Brown 1994; Wren 1988, 284*). Canelo is often combined with *Latua pubiflora*, *Fabiana imbricata*, and *Cestrum parqui* and burned as a psychedelic incense.

The Mapuche shamans of southern Chile use the sacred canelo tree (*Drimys winteri*) as a ritual incense. (Photographed in Valdivia, southern Chile)

The aromatic leaves of the Chilean boldo tree (*Peumus boldus*) are used as a ritual incense and also are purported to have psychoactive effects.

Poison ivy (*Toxicodendron radicans* [syn. *Rhus radicans*]) may have been used as a psychoactive incense in certain “witches’ cults.”

Malai sorcerers inhale the sweetish smoke of benzoin to help them change their shape. The essential oil distilled from benzoin has been reported to have inebriating or mood-enhancing effects.

Lignum aloe (*Aquilaria agallocha*), which becomes enriched with an aromatic resin as a result of fungal contamination, is a valuable incense. Arabian sheiks esteem the essential oil of lignum aloe, known as *ud*, as a highly effective aphrodisiac. In aromatherapy, the plant is considered to have potent effects upon the mind.

Another ritual incense attributed with psychoactive effects is composed of the leaves of the Chilean boldo tree (*Peumus boldus*), which contain alkaloids (1% boldine in the leaves; also norboldine) that have stimulating and possibly psychoactive effects (Mösbach 1992, 80*). Boldine is an aporphine alkaloid (cf. *Nymphaea ampla*) that increases the secretion of gastric juices and thus aids in digestion; it also promotes bile production and is antispasmodic. Overdoses and chronic use are said to have toxic effects. Psychotropic effects and even hallucinations have been mentioned (Pahlow 1993, 365*). The flowery-fruity-scented essential oil contains ascaridol, cineol, eucalyptol, and p-cymol and has anthelmintic effects.

Recipes for Psychoactive Incenses

Countless recipes for incense have been created, tested, discarded, or passed down through tradition. The following selection includes recipes that were developed over time and either were or are used for psychoactive purposes (Rätsch 1991b, 230–36*).

Incense of Hecate (late antiquity)

Equal parts of:

laurel leaf (*Laurus nobilis*)

myrrh (*Commiphora* spp.) olibanum (*Boswellia sacra*)

storax (*Styrax officinalis*)

Syrian rue seed (*Peganum harmala*)

Incense of Delphi (reconstruction of original recipe)

Equal parts of:

henbane seeds (*Hyoscyamus albus*)

laurel leaf (*Laurus nobilis*)

myrrh (*Commiphora* spp.)

Incense for Conjuring Lesser Devils (sixteenth century)

Equal parts of:

parsley root (*Petroselinum crispum*)

belladonna (*Atropa belladonna*)

coriander seed (*Coriandrum sativum*) hemlock root (*Conium maculatum*)

henbane (*Hyoscyamus niger*)

opium (*Papaver somniferum*) sandalwood (*Santalum album*)

Mix together and sprinkle onto glowing charcoals.

Spirit-Herb Incense (from Agrippa of Nettesheim)

Equal parts of:

celery (*Apium graveolens*)

coriander seed (*Coriandrum sativum*) hemlock root (*Conium maculatum*) henbane (*Hyoscyamus niger*)

Mix together and sprinkle onto glowing charcoals.

Incense for Leaving That Which Is Hidden Unknown (from Porphyrius)

Equal parts of:

coriander seed (*Coriandrum sativum*)

celery seed (*Apium graveolens*)

henbane (*Hyoscyamus niger*) opium/poppy capsule (*Papaver somniferum*) saffron (*Crocus sativus*)

Chop and mix all of the ingredients and bind with freshly pressed hemlock juice. Sprinkle the dried mixture onto glowing charcoals.

Roman Incense (from Pliny)

laurel leaf (*Laurus nobilis*)

juniper branch (*Juniperus* spp.; cf. *Juniperus recurva*) vervain (*Verbena officinalis* L. [?])

sage (*Salvia officinalis* L.)

thyme (*Thymus* sp.)

The four components of the psychoactive incense of the Mapuche shamans: *Fabiana* herbage, *Cestrum parqui* leaves, canelo bark, and a branch tip of *Latua pubiflora*.

A traditional European recipe for a psychoactive incense used to conjure spirits: The main ingredient is henbane, to which is added olibanum, fennel seeds, cassia cinnamon, and coriander.

Incense for Divining the Future (from Jeannine Rose)

Equal parts of:

olibanum (*Boswellia sacra*)

magic mushroom (*Psilocybe* [*Stropharia*] *cubensis* or *Psilocybe semilanceata*)

ska María pastora (*Salvia divinorum*)

Mix all of the ingredients with a pinch of parsley root (*Petroselinum crispum*) and sprinkle onto glowing charcoals.

Incense for Seeing Visions (from Jeannine Rose)

Equal parts of:

hemp flower, female (*Cannabis sativa*) sandalwood (*Santalum album*)

thorn apple seed (*Datura innoxia* or *Datura spp.*)

Add a pinch of violet root (*Viola odorata* L.) and perfume with sandalwood oil, benzoin, and tolu balsam. Sprinkle the finished blend onto glowing charcoals.

Incense for Conjuring Spirits

4 parts henbane (*Hyoscyamus niger*)

1 part cassia cinnamon bark (*Cinnamomum cassia*)

1 part coriander seed

1 part fennel root (or seed)

1 part olibanum (*Boswellia sacra*)

Ground the ingredients in a mortar to produce an incense powder: This incense should be taken into a ghostly, dark forest. Light a black candle on a tree stump and heat the incense censer. Burn the powder until the candle suddenly goes out. In the darkness, the spirits of the night will then appear from the smoke. To disperse them, burn a blend of equal parts of asafoetida and olibanum (Hyslop and Ratcliffe 1989, 15*).

Ritual Incense of the Tarahumara

copal (*Bursera* spp. or *Protium copal* resin) peyote (*Lophophora williamsii*)

Mongolian Shamanic Incense⁴³⁵

Equal parts of:

juniper branch (*Juniperus* sp.; cf. *Juniperus recurva*)

wild thyme herbage (*Thymus* spp.)

rabbit droppings (as desired)

Mongolian Shamanic Incense

Equal parts of (from Tschubinow 1914, 44*): juniper/sade tree (*Juniperus sabina* L.)

silver fir bark (*Abies alba* Mill. [syn. *Pinus picea* L.])

wild thyme (*Thymus serpyllum* L.)

Incense for Bodnath (Boudha)

Equal parts of:

balu (*Rhododendron lepidotum* Wall. ex Don) pama (pamo) (*Juniperus indica* Bertol.; Indian juniper)

shupa (*Juniperus recurva*)

Mix all ingredients and powder. Strew the powder (*sang*) onto glowing charcoals.

“Pressant”—Asthma Fumigant (1904)

40% fol. stramonii (*Datura stramonium*) 10% herba cannabis indic. (*Cannabis indica*)
2.5% herba hyoscyami (*Hyoscyamus niger*)
30% kalium nitricum (potassium nitrate)
2% anethol (from *Anethum graveolens* or others)
15.5% binding agent (e.g., gum arabic)

The smoke produced by burning this mixture is inhaled for asthma attacks.

“Hadra”—Asthma Incense Powder (ca. 1920)

This incense powder was once available in the pharmacies of central Europe. It was intended to be burned and inhaled to treat asthma attacks. It may also have been used for “other purposes.” Unfortunately, while the ingredients are known, the proportions of each are not.

herb. cannabis ind. (*Cannabis indica*), herbage fol. stramoni (*Datura stramonium*), leaf herb. hyoscyami (*Hyoscyamus niger*), herbage herb. lobelia (*Lobelia inflata*), herbage fol. eucalypti (*Eucalyptus* sp.), leaf kal. nitric (potassium nitrate)
menthol, **essential oil**

There are a number of other, similar preparations, all of which are no longer available. Many contemporary purveyors of incenses offer blends with psychoactive effects (based on their own self-experimentation). Pharmacognostic research has demonstrated that these often contain the branch tips of *Fabiana imbricata* and various resins (olibanum and others).

Some incenses are used to aromatize other psychoactive substances, such as betel nut (*Areca catechu*), ipadú (*Erythroxylum coca*), opium (*Papaver somniferum*), and tobacco (*Nicotiana tabacum*).

Activity and Pharmacology of Incenses

Today, there are a variety of scientific models for explaining the psychoactive effects of smoke and scent on human consciousness (cf. Laatsch 1991). There are essentially three mechanisms of action that can play a role, both alone and in combination with one another (from Rätsch 1996b):

“I was told that in earlier times the witches knew an herb called *kat*.^[436] Used with incense, it opened the inner eye, the unconscious. In combination with another herb, sumac,^[437] it produced hallucinations and was therefore not to be taken too frequently. When both herbs were used in the proper way, one could acquire the ability to leave one’s body. Unfortunately, the witches of today no longer know which herbs they were, although both are said to grow in England. It is also said that a woman will appear more beautiful if a man inhales incense mixed with *kat*. Magicians use something similar for the same purpose. Their mixture contains hemp [*Cannabis sativa*] and many other ingredients with tonic effects.”

GERALD B. GARDNER

URSPRUNG UND WIRKLICHKEIT DER HEXEN [ORIGIN AND REALITY OF THE WITCHES]

(1965, 109)

1. The smoke may contain pharmacologically active substances that, at appropriate dosages, can act like neurotransmitters or their antagonists in the nervous system.
2. The smoke may give off a characteristic scent with a demonstrably strong psychological activity.

Nearly all of the plants or raw extracts used as incenses contain **essential oils**, which are responsible for their scent. Experiments have demonstrated that certain odors induce powerful changes in the brain’s activity and thus unequivocal alterations in consciousness (Steele 1991*, 1992*,

1993*). It is assumed that these aromatic substances elicit primarily psychotogenic effects, i.e., although the substance does not act pharmacologically, the experience of the scent can alter a person's state of consciousness (scent as a catalyst for memory!). Some essential oils have been observed to have both pharmacological and psychological effects. When inhaled or taken internally, higher dosages of certain essential oils can result in powerful states of inebriation that from a neurophysiological perspective cannot yet be fully explained. The following incenses have been observed to produce the strongest psychoactive effects as a result of their essential oils: camphor, cedar (*Cedrus* spp.), cinnamon (*Cinnamomum verum*), cloves (*Syzygium aromaticum* (L.) Merr. et Perry [syn. *Eugenia caryophyllata* Thunberg]), copal, coriander, damiana, juniper (*Juniperus* spp.), laurel, lignum aloe, mugwort (***Artemisia* spp.**), rosemary (*Rosmarinus officinalis* L.), sade tree (*Juniperus sabina*), various sages (***Artemisia* spp.**, *Salvia* spp.), and wild rosemary (***Ledum palustre***). In addition, some of the constituents in **essential oils**, including thujone, eugenol, myristicin, safrole, and ledol, also have powerful psychoactive effects.

3. The smoke contains pheromones, which carry messages to the brain via the sensory organs.

Pheromones are rather simple chemical compounds that are related to hormones and function as sexual attractors in the plant and animal kingdoms (Jaenicke 1972). Although often odorless, they are as a result that much more effective. Animals and humans exude pheromones when it is time to mate. When a potential partner breathes in these molecules, they induce in him or her an irresistible urge to copulate. Male and female pheromones often differ in their chemical makeup. Certain aromatic substances that are produced in the fungal, plant, and animal kingdoms (e.g., the scent of the truffle, *Tuber* spp.) are chemically or structurally analogous or even identical to human pheromones. When these substances are inhaled in an incense, they can inflame a person's amorous desires. Vanillin, the main aromatic substance in vanilla (*Vanilla planiflora*; cf. **balche'**), which is also found in many balsams and resins, is very closely related to human pheromones and appears to exert a corresponding effect upon the nervous system. Almost all of the plants that contain vanillin are traditionally regarded as aphrodisiacs. The following incenses contain or create substances that are pheromone analogs: ambergris, benzoin, cloves, copal, ladanum (the exudate of *Cistus ladaniferus* L. [syn. *Cistus ladanifer* L.]), Peruvian balsam (*Myroxylon balsamum* [L.] Harms var. *pereirae* [Royle] Harms [syn. *Myroxylon pereira* (Royle) Baill.]), rockrose and gray-haired rockrose (*Cistus creticus* L. [syn. *Cistus incanus* L. ssp. *creticus*] = Cretian rockrose), storax (*Liquidambar* spp.), tolu balsam (*Myroxylon balsamum* [L.] Harms var. *balsamum*), and white sandalwood.

The effects of incenses on humans result from a complex series of psychological, pharmacological, and hormonal events. Unfortunately, there has been almost no research in this area. In addition, other factors that can play a role include hyperventilation, the "choking fits" that may occur as a result of deep inhalation, oxygen deprivation (which can also lead to hyperventilation), combination with other activities (such as drumming, rattling, body postures, songs), and cognitive structures. For example, some shamans inhale incense to the beat of a drum. In this manner, they are able to precisely control the rate at which they hyperventilate and the depth to which they inhale the incense. This enables them to purposefully induce and control different altered states of consciousness.

Kinnikinnick

Other Names

Atamaoya, heiliger tabak, holy tobacco, Indianertabak, Indian tobacco, killikinnick, kinikinnik, kinnecanick, kinnickinnick, k’nickk’neck, larb, native blend, ninnegahe, Uakan tobacco

Kinnikinnick is an Algonquian word that means “the mixed” or “something that is mixed.” It is used to refer to various ingredients and **smoking blends** that are ritually smoked by Native Americans, for example, in the proverbial peace pipe. The ingredients of such smoking blends are often called *larb*, a corruption of the French word *l’herbe* (Johnston 1970, 317*).

Smoking was and continues to be a part of all Native American ceremonies, including shamanic healings, powwows, meetings of the tribal councils, ratification of treaties, and vision quests. The Kiowa, for example, smoke sumac leaves (*Rhus glabra* L.) before they ingest peyote (*Lophophora williamsii*) to purify themselves for the ceremony (Kindscher 1992, 185*).

Early reports about the smoking habits of North American Indians often attributed kinnikinnick with a variety of psychoactive effects. One document described the effects as “narcotic,” while another claimed that it was “like opium” or that it made one drunk (Ott 1993*).

The main ingredient of the various mixtures is uva-ursi (*Arctostaphylos uva-ursi* [L.] Sprengel [syn. *Arbutus uva-ursi* L., *Arctostaphylos media* Greene, *A. officinalis* Wimm., *A. procumbens* Patzke, *Mairania uva-ursi* Desv., *Uva-ursi buxifolia* S.F. Gray, *Uva-ursi procumbens* Moench]), a member of the Ericaceae (Heath) Family. In North America, uva-ursi is also known by the names *kasin*, *ka-sixie*, *kaya’nl*, *kwicá*, *sklêwat*, *kinnikinnik*, or *smoking weed*. This prostrate-growing plant can easily be confused (and adulterated) with bog bilberry (*Vaccinium uliginosum* L.) and winter-green (*Gaultheria procumbens* L.) (Hoffmann-Bohm and Simon 1992, 331). Its leaves are added as an antiseptic ingredient to many diuretic teas (Paper et al. 1993). The Flathead Indians smoked uva-ursi in pipes and blew the smoke they inhaled into the ears of those suffering from earaches because of its numbing effects (Hart 1979, 281*). Prior to the introduction of tobacco, uva-ursi was smoked throughout the American Northwest. Later, the leaves were often mixed with tobacco (*Nicotiana tabacum*). The Chehali say that uva-ursi smoke causes a “drunken feeling” when inhaled. A S’Klallam man even warned against mixing yew needles (*Taxus brevifolia* Nutt.) and uva-ursi because the blend would have “too strong of an effect” (Gunther 1988, 44*).

Arbutin

Many Native American Indians know bearberry (*Arctostaphylos uva-ursi*) by the name *kinnikinnick* and use it as a basic ingredient in their ritual smoking mixtures. (Photographed in Colorado)

A kinnikinnick blend that is smoked in a peace pipe at ritual events. (Photograph: Karl-Christian Lyncker)

Dried uva-ursi leaves contain 5 to 12%, sometimes even as much as 15%, arbutin and occasionally

up to 2.5% methylarbutin (Hoffmann-Bohm and Simon 1992, 331). The leaves have antibacterial properties. High doses can induce labor (Hoffmann-Bohm and Simon 1992, 335). The leaves of the American plant contain the flavones myricetin and quercetin (cf. *Psidium guajava*, *Vaccinium uliginosum*) as well as arbutin, hydroquinone, and gallic acid (Veit et al. 1992). A closely related Mexican species, *Arctostaphylos arguta* (Zucc.) DC., is known in the local vernacular as *madroño borracho* (“drunken strawberry tree”), which may indicate a possible psychoactive activity (Martínez 1994, 205*).

One very popular admixture is the inner bark of *Cornus stolonifera* Michx., which is also often smoked by itself and is also known by the name *kinnikinnik* (Johnston 1970, 317*).

To aromatize the mixture, musk glands as well as various animal fats (such as buffalo fat) were sometimes used (Kindscher 1992, 226*).

Some kinnikinnick ingredients are clearly psychoactive, including the roots of *Veratrum viride*, the leaves and seeds of the thorn apple (*Datura stramonium*, *Datura innoxia*), the herbage of *Lobelia inflata*, the various tobacco species (*Nicotiana spp.*), sassafras bark (*Sassafras albidum*), and others (Hart 1979, 281*). Many of the ingredients in eastern kinnikinnick mixtures are commonly considered to be poisonous, and some are especially dangerous: *Datura stramonium*, *Euonymus* spp. (alkaloids; cf. Bishay et al. 1973), *Kalmia latifolia*, *Prunus serotina*, *Taxus* spp., *Veratrum viride* (de Wolf 1974). The different mixtures can have very different effects, which are likely due to a wide range of possible synergisms and pyro-chemical modifications.

Recipes

It is quite possible that the psychoactive effects of some kinnikinnick recipes are produced by a skillful combination of the various ingredients and the resulting synergistic effects, even though the individual ingredients might not themselves be psychoactive. On the other hand, there are also recipes that do contain powerful hallucinogenic ingredients (e.g., *Datura stramonium*). Unfortunately, information about the relative proportions of ingredients is not always provided.

The smoking blend called *sagackhomi* consists of equal parts of (Emboden 1986, 162*):

☐☐☐☐

Pre-Columbian pipe heads from North America, used for the ritual smoking of kinnikinnick. (From Hartwich, *Die menschlichen Genußmittel*, 1911)

☐☐☐

“A few years ago, an Indian from the Quileute tribe smoked *Arctostaphylos uva-ursi* leaves and became so inebriated that he danced barefoot in the fire until his soles were burned to a crisp and his feet were crippled forever. Several years before that, another old Indian became drunk from the inhaled narcotic after smoking the leaves of this plant. He was so drunk that he fell into the fire, burned his hands,

burned his nose completely off, and also parts of his lips. He lived like this for many more years.”

ALBERT REAGAN

“PLANTS USED BY THE HOH AND QUILEUTE INDIANS”
(1934, 76)

“With this wakan tobacco, we place You in the pipe, O winged Power of the west. We are about to send our voices to Wakan-Tanka, and we wish You to help us! This day is wakan because a soul is about to be released. All over the universe there will be happiness and rejoicing! O You sacred Power of the place where the sun goes down, it is a great thing we are doing in placing You in the pipe. Give to us for our rites one of the two sacred red and blue days which You control!”

PRAYER TO THE SACRED KINNIKINNICK

IN *THE SACRED PIPE* (BLACK ELK 1971, 19)

The Plains Indians smoke many species from the genus *Rhus*.

The American cranberry bush (*Viburnum trilobum*) is one of the plants traditionally smoked by the forest Indians.

The North American black cherry (*Prunus serotina*) is an ingredient in traditional smoking blends.

The leaves of the alpine bearberry (*Arctostaphylos alpina*) are smoked by Native Americans.

The silky dogwood (*Cornus amomum*) is known as kinnikinnick in the northeastern region of North America, where it is an important ingredient in smoking blends.

The bark of the dogwood variety *Cornus sericea* var. *sericea* is smoked by the forest Indians of North America.

The dried leaves of the North American wild strawberry (*Fragaria virginiana*) are an ingredient in kinnikinnick blends.

The leaves of the narrow-leafed laurel (*Kalmia angustifolia*), which are regarded as toxic, certainly belong among the pharmacologically active smoking herbs.

The mountain laurel (*Kalmia latifolia*) is a traditional ingredient in kinnikinnick.

Kykeon

Other Names

Ciceone, cyceon, einweihungstrank, initiation drink, kekyon, mischtrank, mixed drink

The word *kykeon* refers to a “mixed drink,” in particular the one that was used as the initiatory drink in the Eleusinian mysteries. According to the myth of Eleusis, the grieving Demeter, the Great Goddess and mother of grain, was wandering in search of her daughter Persephone (Kore, Prosperina), whom Hades had abducted and taken to the underworld. Because of her sorrow, the earth’s fertility had disappeared and its grain had withered. It was only when she encountered Metaneira that Demeter became happy once more:

Metaneira offered her a cup filled with wine, as sweet as honey, but she refused it, telling her the red wine would be a sacrilege.^[446] She asked instead for barley and water to drink mixed with tender leaves of *glechon*. Metaneira made the potion and gave it to the goddess as she had asked; and great Deo received the potion as the precedent for the Mystery. (*Homeric Hymn to Demeter*, line 207 ff.; in Wasson et al. 1998, 74)⁴⁴⁷

This drink, known as kykeon, the production of which was the well-guarded secret of two Eleusinian families, became the sacrament of initiation in the Telesterion.⁴⁴⁸ All of the mystics who wished to participate in the initiatory ceremonies had to drink it:

I fasted; I drank the mixed drink [*kykeon*]; I took it from the chest; after I had fulfilled my task, I placed it into the basket and from the basket into the chest. (Clemens of Alexandria, *Exhortation to the Heathen* 2.21, 2)

We can no longer reconstruct what really occurred inside the Telesterion.⁴⁴⁹ Yet the extremely sparse details that are known to us—for as in all mystery cults, there was an absolute rule of silence—indicate that initiates experienced collective psychedelic visions (Eyer 1993). One of the last lines in the *Hymn to Demeter* is “whoever among men who walk the earth has seen these Mysteries is blessed.” (*Homeric Hymn to Demeter*, line 479 ff.; in Wasson et al. 1998, 83)

Eleusis was founded around 2000 B.C.E., and the Telesterion was built around 600 B.C.E. In the beginning, the Eleusinian mysteries were probably more of a private cult, but they soon took on a local character and ultimately captivated the entire ancient world. The Lesser Mysteries took place during the month of Anthesteriōn (March), while the Greater Mysteries occurred in the month of Boëdromiōn (September). Because initiates were forbidden to speak about the secrets of the mysteries under penalty of death, scarcely anything about them is known (Travlos 1989).

But what was the kykeon made from? The Homeric hymns name the most important ingredients: water, barley (presumably malted), and a type of mint, probably water mint (*Mentha aquatica* L.) or polei mint (= pennyroyal; *Mentha pulegium* L.).⁴⁵⁰

The **essential oil** in water mint consists primarily of limonene, caryophyllene, and menthol, as well as some psychoactive α -thujone (Malingré and Maarse 1974). High dosages of limonene may produce psychoactive effects. But a drink that consisted solely of these ingredients would never have been capable of inducing profound entheogenic experiences, even if it was a kind of **beer**. It can be assumed that the barley drink fermented during the time between its preparation and its use and, thus,

had a low alcohol content. Karl Kerényi (1961) and Robert Graves (1957) appear to have been the first to speculate that the drink also contained an additional secret ingredient, namely a substance with visionary effects.

Robert de Ropp, in his classic book *Drugs and the Mind* (de Ropp 1961*), suggested that the mystery ingredient was opium, obtained from the poppy (***Papaver somniferum***), one of the plants sacred to Demeter. Could the many ancient depictions of Demeter holding barley and poppy capsules in her hands have been iconographic recipes for kykeon?

Robert Graves was the first to suggest that psychoactive mushrooms were the secret ingredient (Graves 1957). He subsequently provided a more precise formulation:

The water mint (*Mentha aquatica*), a shallow-water plant, may have been an ingredient in the initiatory drink used in the Eleusinian mysteries.

“It must have been very difficult for the initiated priests of Eleusis to procure the required doses for the approximately two thousand mystics with the necessary regularity.”

WOLFGANG SCHMIDBAUER

“HALLUZINOGENE IN ELEUSIS?” [“HALLUCINOGENS IN ELEUSIS?”]
(1969, 34)

Tantalus’s crime, the mythographers explain, was that, having been privileged to eat ambrosia, the food of the gods, with the Olympians, he later invited commoners to try it. *Ambrosia* was the name of Dionysus’s autumnal feast in which, I suggest, the intoxicant toadstool once inspired his votaries to a divine frenzy; and in my *What Food the Centaurs Ate*, I show that the ingredients given by Classical grammarians for ambrosia, nectar, and *kekyon* (Demeter’s drink at Eleusis) represent a food-oghan—their initial letters all spell out forms of a Greek word for “mushroom.” The story of Tantalus’s crime may have been told when wine displaced toadstools at the Maenad revels, and a toadstool—perhaps not *Amanita muscaria*, but the milder, more entrancing *Panaeolus papilionaceus* [cf. ***Panaeolus spp.***—was eaten by adepts at the Eleusinian, Samothracian, and Cretan Mysteries, who became as gods by virtue of the transcendental visions it supplied. (Graves 1966, 333 f.*)

The hypothesis advanced by Wasson et al. (1984), namely that the kykeon was mixed with ergot (***Claviceps paspali***, ***Claviceps purpurea***), has found support among some authors (Illmaier 1995; Ott 1978), while others have rejected the idea (McKenna 1996*; cf. the discussion in Valeňcič 1995).

The following psychoactive plants have been considered as possible additives to kykeon (McKenna 1996*; Ruck 1995, 142*; Schmidbauer 1969; Wohlberg 1990):

Amanita muscaria

Claviceps paspali

Claviceps purpurea

Convolvulus tricolor

Lolium temulentum

Panaeolus papilionaceus (cf. ***Panaeolus spp.***)

Papaver somniferum

Peganum harmala

Psilocybe cubensis

Psilocybe semilanceata
***Psilocybe* spp.**

One central problem in attempting to find a solution to this riddle has to do with the questions concerning the availability and reliable entheogenic activity of the psychoactive substance, for every year thousands of initiates would have drunk kykeon and had wonderful experiences because of it. Of all the possible ingredients, only the easy-to-grow mushrooms of the genus *Psilocybe* withstand such scrutiny. First, they are native to Greece and were known at the time (in contrast to ergot). Second, they can easily be grown, harvested, and dried throughout the year. Third, of all the candidates, they are the only substances that are free of side effects. Finally, there is no plant that is as dependable in its use as these mushrooms. Toxic reactions are unknown. In addition, none of the other candidates even comes close to inducing such magnificent visions. Because their effects very quickly manifest (in contrast to the fly agaric), especially when they are dissolved, the mystics could have entered those worlds that would make them “blissful” only a short time after having entered the Telesterion. It is also worth noting that Gordon Wasson (Wasson et al. 1998) became convinced that it was psychoactive mushrooms that had been used in Eleusis while he was having his own experiences with the Mexican magic mushrooms (*Psilocybe mexicana*).

Most Greek scholars, by the way, have called into question, ignored, or even dismissed this “mystery ingredient” hypothesis as a pipe dream (Burkert 1990; Foley 1994; Giebel 1990; Lauenstein 1987). Others have suggested that the kykeon of Eleusis was identical to the Persian **haoma** and the Indian **soma** (Wohlberg 1990).

In the early modern era, the plant known in the ancient world as *glechon* was interpreted as pennyroyal (*Mentha pulegium*), and a Cretan variety was distinguished from a German variety. Whether or not these two varieties are in fact the same species is difficult to determine. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Madzoka Medicine

Among many African tribes, spirit possession is both known and culturally encouraged as a sacred or magical act. There are numerous possession cults in which special mediums—often or even primarily women—enter into a state of trance or ecstasy and allow their bodies to be possessed by a spirit being. The spirit—whether a deity, demon, bush spirit, animal spirit, ancestor, spirit of a deceased person, or something else—speaks through the body of the enraptured person, who shouts out oracles and prophecies, can perform magical healings, and so on (Lewis 1978). The African possession cults have become established in the New World in the form of Santería, Umbanda, Candomblé, voodoo, et cetera. From an anthropological point of view, the African possession cults are related to shamanism but must be regarded as a separate phenomenon (Goodman 1991). Nevertheless, there are a number of parallels and overlaps, particularly with the cults of Southeast Asia (van Quekelberghe and Eigner 1996). “Also included in spirit possession are such spectacular practices as dervish dancing, walking on hot coals, sword swallowing, and transvestitism, not to mention such mysterious phenomena as ‘automatic writing’ ” (Lewis 1989, 42).

In the literature on possession, it is often claimed that the state of possession occurs “on its own” or, at best, in the context of magical rituals, sacrificial ceremonies, ecstatic drumming (“voodoo drumming”), and dancing. The literature on possession has a very similar tone to the early literature on shamanism in that it ignores the significance of pharmacological stimuli. However, the use of **incense**, for example, has been documented in most possession cults. And psychoactive plants are clearly used during the initiation ceremonies of the African voodoo cult in Benin (Verger 1995). Substantial amounts of the psychoactive pennyroyal (*Mentha pulegium*; cf. *Fabiana imbricata*, **kykeon**) are used in the Brazilian Candomblé cult (Voeks 1989, 123, 126*). In Haitian voodoo, hemp (*Cannabis sativa*) is said to play a specific role in triggering possession, and there are also reports of excessive rum drinking (see **alcohol**). *Justicia pectoralis* and *Cola acuminata* are used in the Afro-Cuban Santería cult (González-Wippler 1981, 95). It is quite possible that the use of certain psychoactive plants or products from Indian ethnoflora was adopted by the Afro-American possession cults. The following plants are used to prepare the initiation drink of the Candomblé cult: *Ipomoea pescaprae* Sweet [1402] (see *Ipomoea spp.*), *Mimosa pudica* L. and *Mimosa pudica* L. var. *acerba* Benth. (see *Mimosa spp.*), *Vernonia bahiensis* Tol., *Hibiscus* sp., *Hibiscus rosa-sinensis* L., *Mentha sativa* L., *Ocimum micranthum* Willd., *Camellia sinensis*, *Vismia guinensis* Pers., *Vismia cayennensis* Pers., *Urostigma doliarium* Miq., *Eugenia* sp., and *Eugenia jambosa* L. (Fichte 1985, 248).

“There are hardly any publications about the inebriants of the Afro-American religions. It is practically unknown that in Candomblé, when the conventional initiation drink is not sufficient to subdue the consciousness of the novice, a type of brainwashing is carried out . . . so that the conditioning of the initially wild-appearing trance can take place. If the orisha, the god, does not appear because the novice is consciously following the ritual, then the novice is given a drink of cold water in which a few leaves have been soaked. Witnesses attest that immediately and without exception, the novice falls into a deep stupor, the god possesses him in trance, and the initiation can be completed.”

HUBERT FICHTE

“PSYCHOLEPTICA DER ‘OBRIGAÇÃO DA CONSCIENCIA’ ”
(1985, 247)

Madzoka medicine consists of four plants:

It was once believed that no use of psychoactive or hallucinogenic plants occurred in Africa or in its cultures. Only in the past two decades has this area of ethnobotany come under greater scrutiny (de Smet 1996*). It can be expected that a great deal of interesting information will come to light.

The possession cult that serves for divination and healing in Malawi uses an herbal mixture, a madzoka medicine, to induce the trance that is required for spirit possession (*madzoka*). The fresh ingredients (presumably in equal parts) are crushed together, and the resulting paste is rubbed on the face, arms, and legs and sniffed into the nose. The trance is said to begin immediately. The mixture may be sniffed again during the trance (Hargreaves 1986, 27).

In South America, wormseed (*Chenopodium ambrosioides*), a plant introduced from North America, is used as an additive to coca (see *Erythroxylum coca*). *Securidaca longipedunculata* is drunk in Mozambique by those who are “possessed by evil spirits.” The powdered root acts as a potent sneezing powder when inhaled (cf. *Veratrum album*, snuffs). The Karanga people chew the root cortex to treat impotence. During their religious rites, the Balanta (Guinea-Bissau) use an aqueous extract from the root (which they call *tchúnfki*) because of its alleged psychoactive effects (Samorini 1996). The root, which contains 4% saponins, tannin, steroid glycosides, and gaultherine, numbs the mucous membranes. The root was recently found to contain three **ergot alkaloids**: elymoclavine, dehydroelymoclavine, and a new ergoline derivative, called compound A (Samorini 1996).

The bark of *Annona senegalensis* contains substantial amounts of tannin; mixed with palm oil, it is used as an antidote for poisoning (Assi and Guinko 1991, 30*). *Asparagus africanus*, the African asparagus, is used in Sotholand during circumcision rituals, when it is rubbed into artificially created wounds to give an initiate strength (Hargreaves 1986, 30 f.). It is possible that mixing the four components together may result in synergistic effects that are psychoactive.

The African annona is a component of the possession medicine that has psychoactive effects. To date, nothing is known about any possible psychoactive activity for this plant. (Copperplate engraving from Meister, *Der Orientalisch-Indianische Kunst- und Lust-Gärtner* [The Oriental-Indian Art and Pleasure Gardener], 1677)

Mexican wormseed (*Chenopodium ambrosioides*) is highly esteemed in folk medicine, especially for its anthelmintic and abortifacient properties. In Africa, it is one of the ingredients of an allegedly psychoactive preparation said to induce possession states. The plant has not been reported to have any psychoactive effects. It is possible that it reacts with the other ingredients or exerts a synergistic effect.

Mead

Other Names

Aqua mulla, **balche'**, cashirí, honey beer, honey kwass, honey mead, honey wine, honigbier, honigmeth, honigwasser, honigwein, hydromel, hydromeli, kaschiri (Arawak), madhu, melicraton, met, meth, metu, mid, mydromel, t'ädj

Mead is an alcoholic drink that is brewed from water, **honey**, other additives (“bitter herbs”), and wild or cultivated yeasts (*Saccharomyces cerevisiae*). Traditional mead has a very low alcoholic content (approximately 2 to 4%) and is not at all sweet, because the sugar in the honey is completely transformed into **alcohol**. The mead that is most popular today is a sweet, sticky drink with 14% alcohol that is brewed by fermenting a saturated solution of honey. In former times, honey was often fermented together with malt. As a result, the ancient literature often did not make a distinction between mead and **beer**. In recent years, an increasing number of drinks have come on the market that are reminiscent of mead (honey beer).

Mead, which probably was invented during the Stone Age, was found in many regions around the world. It was sacred in all ancient pagan cultures and was used ritually as a libation and for collective inebriation (Maurizio 1933). It was also considered sacred in ancient India and is sometimes associated with **soma**. The Indian gods were referred to as *madhava*, those who “sprang from the mead.” The beverage was also known to all Indo-European peoples. In ancient times, it was used primarily for medicinal purposes. The Celtic and Germanic tribes—both enthusiastic drinking peoples—considered mead sacred (Markale 1989, 203*) and were aware of the divine origins of the inebriating drink: “Among the Germanic peoples, mead itself was the symbol of the drink of the gods, which had fallen from the world tree like a heavenly dew” (Delorez 1963, 23*).

During Germanic libation ceremonies, the sacred mead (and/or **beer**) that was specially brewed for the festival was passed around the circle of participants in drinking horns decorated with mythical motifs. The priest or chief took the horn and drank to the gods, offered some to the earth, and sprinkled a few drops into the air. He thanked Wotan (Odin, Woden), the god of ecstasy and the lord of magical drinks. He called to the ancestors and to the heroes who had founded human culture, and he wished his tribe peace, well-being, and health. Then he passed the horn to the next participant, who once again drank to the gods, to friends, or to specific ancestors. The horn was passed on around the circle until it was empty.

Then another would immediately be brought to the circle, passed around, and emptied, until everyone in the circle was communally and simultaneously inebriated and the gods were present among the people (Gaessner 1941). As the effects of the alcohol became apparent, the door to the world of the gods and goddesses opened:

Mead was attributed with the power to enthuse humans and open to them the entrance to the supernatural world. It was thus to a certain extent the source of wisdom and artistic inspiration. (Fischer-Fabian 1975, 196)

It is likely that the Germanic peoples prepared their mead with inebriating berries (*Empetrum nigrum* and ***Vaccinium uliginosum***) and possibly also the root of white hellebore (***Veratrum album***).

The earliest sources on Germanic beer and mead brewing indicate that a variety of psychoactive plants were added to mead, including hen-bane (***Hyoscyamus niger***), wild rosemary (***Ledum***

palustre), bog myrtle (*Myrica gale*), and bearded darnel (***Lolium temulentum***) (cf. Maurizio 1933).

There have been some suggestions that mead or beer was brewed with the addition of mushrooms. But why would mushrooms be added to what was an only mildly alcoholic drink? The only sensible explanation is to improve the effects. Could the Germanic peoples have enriched their mead with such psychedelic mushrooms as liberty caps (***Psilocybe semilanceata***) or dark-rimmed mottlegills (***Panaeolus subbalteatus***)? After all, mead was a ritual drink that was consumed at communal gatherings so that the gods might come down and stay awhile among the inebriated people. A last memory of this practice was documented in the late Middle Ages, when Johannes Hartlieb wrote that a man died in Vienna because he had drunk a mead that contained mushrooms (chanterelles!) (cf. **witches’ ointments**). The fact that mead was being brewed with the addition of plant products can also be seen in the herbals written by the “fathers of botany.” For example, Tabernaemontanus wrote:

Odin garbed as an eagle—in this shape, the Germanic god of ecstasy stole the mead of knowledge and inspiration from the giants. (Stone carving from Stora Hammars III, ca. 700 C.E.; reproduction drawing by C. Räscher)

The Maya use the honey produced in the Selva Lacandona (Chiapas, Mexico) as a fermenting substance for making mead.

In recent years, fermented honey beverages have appeared on the market. Although these are usually regarded as honey beers, they are not allowed to be sold in Germany under this name because of the Bavarian Purity Law. The drinks are more similar to the mildly alcoholic (and not sweet) mead drinks.

“At the entrance to the enclosure is a tree
From whose branches there comes beautiful and harmonious music.
It is a tree of silver, which illumines;
It glistens like gold.

There are thrice fifty trees.
At times their leaves mingle, at times, not.
Each tree feeds three hundred people
With abundant food, without rind.

...

There is a cauldron of invigorating mead,
For the use of the inmates house. It never grows less; it is a custom That it should be full forever.”

“THE SICKBED OF CU CHULAINN”

(AN IRISH EPIC)

IN *ANCIENT IRISH TALES*

(CROSS AND SLOVER 1936, 189)

“In ancient times there was no mead. An old man had tried to make it out of honey. He mixed the honey with water and left the mixture to ferment overnight. The next day, he tried it and found it to be very good. The other people did not want to try the drink because they thought it would be poisonous. The old man said, ‘I will drink it. Because I am very old and it doesn’t matter if I die from it.’ The old man drank a lot of the mixture and fell down as if he were dead. He awoke that night and said that the brew was not poisonous. Then the men carved a large fermenting vat and drank all of the mead that they brewed. It was a bird who carved the first drum [= fermenting vat]. It drank all night long and in the morning, it transformed itself into a human.”

MYTH OF THE MATACO INDIANS

(WILBERT AND SIMONEAU 1982, 119*)

To a measure of good honey / take eight measures of water / mix together in a wide kettle / allow to simmer over a gentle fire without smoke / and continually remove the foam / until it becomes entirely clear: and the longer one wishes for the mead to keep / the longer it should simmer: afterward when it cools / pour it into a small cask / leaving three fingers / that he pours out.

If one wants it to be stronger and more powerful / then put ginger / cinnamon / cloves / galanga root / nutmeg [*Myristica fragrans*] and such herbs in it / one can also add a little saffron [*Crocus sativus*]; when it has been poured / one should store it for three months / and thereafter use it. (Tabernaemontanus 1731, 1526*)

In medieval England and Ireland, it was said that mead could increase a man's virility. For this reason, a newlywed couple were given a great amount of mead at their wedding in order to ensure the continuation of the clan. This practice is the source of the term *honeymoon*.

Mead also was and is still prized among some Native American tribes, who use it as a ritual drink (cf. **balche'**). The South American Mataco Indians brew their mead from honey, dried and ground *tusca* fruits (?), and water. They use the thick, hollowed-out stem of the bottle tree (*Chorisia insignis* H.B.K.; cf. **ayahuasca**) as a fermenting vat; as a result, the tree is known in Argentina as *palo borracho*, "drunken tree" (Wilbert and Simoneau 1982, 120 f.*). **Mead** was also known in North America. A note included with a North American herbarium specimen of the honey locust tree (*Gleditsia triacanthos* L.; Leguminosae) reads: "[T]he sweet pith of the pods is used as a remedy for catarrh, a mead is also simmered from it" (von Reis and Lipp 1982, 126*).

Africa, in addition to its ever-popular barley beer, also has mead and honey beers that are ascribed with magical protective powers. Because of this, people often sprinkle a few drops of the drink. In Ethiopia, the chopped branches of a buckthorn known as *gescho* (*Rhamnus prinoides*; Rhamnaceae) are added to brewing mead (Haberland 1981, 172). The honey collected from the mimosa (***Mimosa* spp.**) is preferred for brewing there. Mead brewed from a mixture of honey and water (1:5) is distilled to make a kind of schnapps (**alcohol**) (Haberland 1981, 173). Mead was also administered as an antidote for ***Strychnos nux-vomica*** poisoning.

In the summer of 1997, a "hemp mead" was introduced to the German market; the drink, however, contains no **THC**. Recipes for making mead with psychoactive mushrooms have recently been making their way around the underground (Kelly 1995).

Oriental Joy Pills

Other Names

Fröhlichkeitspillen, gandshakini (Sanskrit), gods-chaki, hab-i nishad (Arabic, “joy pills”), happy pills, joy pills, madgiun, madjnun, madshun, majoon, majun, ma’jun, mojun, nepenthe, orientalische fröhlichkeitspillen

The term *joy pills* refers to combination preparations consisting of four basic ingredients: opium (see *Papaver somniferum*), *Cannabis* products, *Datura* seeds, and spices. These combinations are efficacious psychoactive aphrodisiacs that activate the nervous system simultaneously in numerous places. The recipes are from the Orient and are thought to be very ancient.

In ancient India, the most important of the *vajikarana* (= aphrodisiacs) were those that exerted a psychoactive effect; these were made chiefly of opium, hashish, **wine**, et cetera (Bose 1981). According to the early Ayurvedic literature (e.g., the *Bavasita*) [1408], many recipes for aphrodisiacs contained opium, *Datura metel*, camphor, nutmeg, long pepper (*Piper longum*), ginger (*Zingiber officinale*), and bhang (Chaturvedi et al. 1981). During the Moghul period, inebriants composed of opium, hemp, *Datura*, and other substances (spices, **alcohol**) were common (Saleh 1981; Sangar 1980).

Joy pills were also known in Arabian lands, where they were used mainly by the dervishes:

They take opium dissolved in wine, milk, or water, and ingest it as “joy pills” (*hab-i nishad*), and since the 17th century they have also smoked it as a syruplike substance with various ingredients. . . . Opium leads the mystic within, transports him from the here and now, and inspires his contemplation of God. (Frembgen 1993, 202*)

In Europe, a variety of recipes for joy pills became known at the beginning of the nineteenth century. The *Encyclopädie der gesamten Volksmedizin* [Encyclopedia of All Folk Medicine] of 1843 states that “hemp is the main ingredient in the joy pills of the Orient” (Most 1943, 225*). The name given the pills in this reference is interesting, as it makes reference to the famous Homeric **nepenthe**:

In order to dispel bad moods and hypochondria, the Orientals, who are also known to take delight in opium smoking and opium eating, take their refuge in a mixture: *nepenthe* by name, which consists of the powder of the dried, uppermost leaves and flowers of hemp, in combination with opium, areca nut, spices, and sugar, which they swallow in pill form. (Most 1843, 194*)

A book about poisonous plants contains the following entry under *Datura metel*:

The seeds are also a component of the Oriental joy pills, which also contain poppy juice, hemp, and several spices; to the Orientals, for whom wine is forbidden, these represent a surrogate for the same and are said to incite an indescribable sense of well-being. They have recently also strayed into Europe, and in Marseilles they produced veritable symptoms of poisoning (Berge and Riecke 1845, 101).

Freiherr von Bibra was also aware of this agent of pleasure:

Mojun is a very strong preparation of hemp, poppy, thorn apple, crow's eyes, milk, and sugar, in other words, *gondschaki*, or *joy pills*, which were already mentioned by the ancient Sanskrit writers, appear to be entirely identical with one of the lighter Oriental preparations. (Bibra 1855, 271*)

We can certainly presume that joy pills were received with enthusiasm in certain European circles. They have always been renowned as powerful inebriants and extraordinarily effective aphrodisiacs. Reports of their effects often take on an effusive and poetic expression:

The joy pills are a flying carpet that bears one to the pearly strands of pleasurable sensuality. All of the senses are immeasurably heightened in the most exquisite manner. The inner happiness radiates throughout the body with the smile of bliss, just as the light of the sun allows the tears of heaven to appear as wonderful rainbows. The enjoyment of one's own body, of one's own being, and of existence, has a cultivated and subtle quality that sweetens life with the sense of divine eternity. The soul kisses the body, dances with it, and rides on the dragon of wisdom to the stars, which sparkle like the jeweled twinkling of the eyes of the immortals. Just as the blood flows through the body, the peace of the heart streams through the universe, which is illuminated in love by the breath of the gods. The Oriental joy pills are the ultimate, specific aphrodisiac.

"Bangu is also common in India, almost like amfion [= opium]; the seeds are like hemp seeds, the same is true for its leaves although they are a little smaller. The Indians eat these seeds and its leaves, but somewhat crushed, they say that it provides a good appetite for eating. Sometimes the leaves and seeds are mixed together, combined with areca or nutmeg leaves or massa, and sold on the corners in order to attract the good graces of the women. The wealthy enrich this bangu with cloves, camphor, ambergris, musk, and amfion, it dispels all of one's worries and makes them forget their misery, while at the same time it makes them happy and finally puts them to sleep, which some women make diligent use of when conducting the business of marital love, and themselves approach the male customers. It is also used by those burdened with much work and by slaves kept under hard conditions so that they might forget their burden from time to time. Even among those who are most sorrowful, or who are given to melancholy, it awakens an unnatural, happy mood and is thus a kind of remedy for melancholy, but only in the proper proportion, not too much and not too little, and as so long as one experiences its effects."

GEORGE MEISTER

DER ORIENTALISCH-INDIANISCHE KUNST- UND LUSTGÄRTNER [THE ORIENTAL-INDIAN ART AND PLEASURE GARDENER]

(1677, CH. 9, 30*)

"Ma'jun is an electuary that the Mussulmen [Muslims], especially the most debauched of them, take as a nerve stimulant, inebriant, and remedy for pain. An overdose will not infrequently lead to mental derangement. According to folk belief, it provides inebriation (*kaifa*) [and] courage (*quwwat*) and is used as an aphrodisiac. The main ingredients of this electuary are ganja, milk, butter, poppy seeds, datura or thorn apple flowers, *nuxvomica* powder, and sugar."

JA'FAR SHARIF (1921)

IN *DIE "ORIENTALISCHEN FRÖHLICHKEITSPILLEN" UND VERWANDTE PSYCHOAKTIVE APHRODISIACA* [THE "ORIENTAL JOY PILLS" AND RELATED PSYCHEDELIC APHRODISIACS] (RÄTSCH 1990, 15)

Even today, Oriental joy pills are a part of the Ayurvedic pharmacopoeia:

Majun or sweetness from hemp (*Cannabis*), consists of *ghee* and water as well as *bhang*, *ganja*, *caras*, *opium*, poppy seeds, *datura* (*Datura innoxia*) leaves and seeds, cloves, resin, anise, caraway, sugar, butter, flour, milk, cardamom, and *tabasir*. A dosage of one and a half to one *drachm* is sufficient for someone who takes this drug frequently. It tastes sweet and has a

decidedly pleasant scent. Occasionally, *Stramonium* seeds are also added, but never *Nux-vomica*. The effects are astonishing: ecstasy, a sense of elation, the feeling of flying, heightened appetite, and strong sexual desires. (Thakkur 1977, 317)

It is certainly no coincidence that this recipe is reminiscent of the composition of **witches' ointments**.

The following ingredients are required for each person: 0.3 g opium, ten datura seeds, 0.3 to 0.5 g hashish, and spices, resins, et cetera as desired. The ingredients are mixed together and added to clarified butter. The mixture should be poured out as soon as it has melted into a mass (cf. Rätsch 1990).

Green Chinese or Japanese tea (cf. *Camellia sinensis*) should be drunk as the pills are ingested to counteract the somniferous effects of the opium. The full effects usually manifest about four hours later and last for at least twelve hours.

Palm Wine

Other Names

Bourdon, cachiry, chica de caanguche, coroxo, maboca, mimbo, palmenwein, palmwein, salap, sura, suri, toddy, vino palmeo

In many parts of the world, winelike drinks are produced by fermenting palms (Palmae; formerly Areaceae); these preparations are generally referred to as palm wine (cf. **wine**). Either the juice pressed from the sweet fruits or the sap that flows through the trunk and the leaf ribs (bleeding sap) is used; both are fermented undiluted. Some palm fruits may also be mixed with water and used to make **beer** and **chicha**.

Usually it is the bleeding sap of various palms that is fermented to make wine. The young male inflorescences are often used; incisions are made into them after they are pressed or squeezed to stimulate the secretions. The sugary sap often starts fermenting as it flows from the stem (cf. *Cocos nucifera*). Sometimes a tapping hole may also be made in the upper trunk. Fermentation is usually initiated with yeast: *Saccharomyces* spp., *Candida* spp., or *Endomycopsis* sp. (Ofakor 1972).

Palm wine is a much-loved drink in Southeast Asia, where it is made from either the coconut palm (*Cocos nucifera*) or the sugar palm (*Arenga pinnata* [Wurmb.] Merr.):

Since the earliest times, it [the sugar palm, *Arenga pinnata*] has been tapped to obtain its sugar sap. To do this, the young, male inflorescences are cut off. From the site of the incision, 2 to 7 liters of sap flows daily over a period of two to five months. When the first incision site has been exhausted, an inflorescence below it will be tapped. One palm is said to provide up to 1,800 liters of sap, which is drained off into bamboo tubes. The sap contains approximately 15% sucrose and is either fermented into palm wine or boiled and made into a brown cane sugar that, pressed into disks, is then sold. (Bärtels 1993, 56*)

Pliny noted that the Egyptians used the date palm (*Phoenix dactylifera* L.) to produce wine. This Old World palm, which grows as tall as 30 meters, is found throughout Africa, the Near East, Arabia, and India. It has been cultivated for its fruits since antiquity (Stewart 1994, 151*). The sap tapped from the stems of older date palms begins to ferment immediately. This fermentation was known as palm wine (*vino palmeo*), and it was used as a ritual inebriant drink but was especially esteemed for its aphrodisiac qualities. It was often fortified with various other magical plants, presumably henbane (*Hyoscyamus niger*, *Hyoscyamus* spp.), mandrake (*Mandragora officinarum*, *Mandragora* spp.), or hemp (*Cannabis indica*). The inebriating effects of such a wine were described in a cuneiform text:

A man climbs a palm in order to tap its bleeding sap. (From Hartwich, *Die menschlichen Genußmittel* [The Human Agents of Pleasure], 1911)

“Every year the Shuar, who live in the rain forest in the eastern Andean foothills of Venezuela, celebrate a festival in which *B.[actris] gasipaës*, the chonta palm, plays a great role. When the strong winds of spring herald the approaching rain season and therewith the return of Uwi, the lord of fertility, the Shuar celebrate a sacred festival. Palm fruits are collected and the women chew the flesh of the fruit to prepare it for fermentation. Later, the beer is drunk by the men. Various sacred songs are also sung, all of which describe the life and uses of the palm.”

ANDREAS BÄRTELS

Since ancient times, the date palm and its fruits have been used to produce palm wine. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

“Yesterday’s drunkenness will not relieve today’s thirst.”

EGYPTIAN SAYING (LATE ANTIQUITY)

When a person has drunk the inebriating drink and his head has been seized by it, he forgets his words, they disappear as he speaks, his reason does not hold firm, the eyes of such a man are fixed, to help him recover, you should grate together liquorice juice . . . , beans, oleander . . . , he should drink it with oil and the inebriating drink before the descent of the *gula* [= “in the evening before the stars rise”], in the morning before the sun rises, and before anyone has kissed him, and so he will recover. (Sigerist 1963, 30)⁴⁵¹

The fruits of the date palm were also made into an inebriating drink, which the Egyptians called *srm.t*. This preparation may have been a beer to which date must was added (Cranach 1981*). This drink was often added to medicines. Palm wine was also used to wash corpses as part of the process of embalming mummies. Palm wine was also drunk as a remedy for hallucinations (Pliny 24.165 f.). In ancient times, saffron (***Crocus sativus***) and palm wine were mixed together with many magical plants.

There are seventeen species in the genus *Phoenix*, many of which are easily confused with the true date palm. Some species (e.g., *Phoenix reclinata* Jacq.) develop edible fruits that are also called dates. The sap of the Indian forest date palm (*Phoenix sylvestris* [L.] Roxb.) is also fermented into palm wine.

Palm wine is very popular in Africa, where it is used as a refreshing drink, a solvent for medicine, and an offering drink (libation). In West Africa, palm wine with cola nuts (***Cola* spp.**) is an important offering in the orisha rites. In the land of the Yoruba, Ogun is the shamanic god of iron and the smithy, of war, of the hunt, and of stones, and he is considered a mighty tamer of snakes. Because of his power, offerings made to him have great importance:

A woman wants to address Ogun; she comes and brings a calabash with cola nuts, for the sacrifice she has a dog and roasted yams in addition to palm oil and palm wine. The priest rises and turns to face the shrine. He begins with a libation of water or palm wine, then he takes a hammer made entirely from metal and touches the emblem of the god so that it makes a sound. As he does this, he says: “Hear us, O Ogun, Awo, controller of the world, chief of the gods, whose pupils man never sees, supporter of orphans, lord of the countless heavenly palaces!” . . . Then he pours the palm wine and the palm oil on or in front of the shrine and questions the cola nut. If the answer is favorable, then he places a piece of the nut on the shrine. Then the dog is sacrificed. (Bonin 1979, 251*)

In India, palm wine (called *salap*) is also used for shamanic purposes. The tribes who live in the jungles of Orissa, in particular the Sora or Saura, have for the most part retained their pre-Hindu, prehistoric religion, which consists primarily of establishing contact with the underworld and the spirits and ancestors who dwell in the realm beyond. It is said that the spirits and ancestors live in the underworld directly beneath the wine palms. Copious amounts of palm wine are consumed during the shamanic underworld ceremonies. The *kunan*, or shaman, consumes the inebriating drink from a special calabash. He uses the palm wine as a “fuel for traveling to the underworld” (Gerhard Heller, pers. comm.).

The saw palmetto (*Serenoa repens*), which grows throughout the southern regions of North America, was once used by Indians of the region to prepare inebriating drinks.

Saw palmetto fruits, which come from the saw palmetto (*Serenoa repens*), are fermented into a palm wine. In phytotherapy, the fruits are regarded as aphrodisiac.

The fruits of the cohune palm (*Orbignya cohune*) are used in the Central and South American tropics to make palm wine. (Photographed in the Maya Mountains, Belize)

In some places, palm wine may be distilled into *arrak* or palm schnapps (cf. **alcohol**).

Palm Wine Additives

As with all other alcoholic drinks, plants or other substances are sometimes added to palm wine to alter its effects (cf. ***Vitis vinifera***, **alcohol**, **balche’**, **beer**, **chicha**, **wine**).

In the Congo, roots of *Alchornea floribunda* are added to palm wine to make a beverage called *niando* (cf. ***Alchornea* spp.**). It has psychoactive and aphrodisiac effects (Scholz and Eigner 1983, 78*). Another palm wine from the Congo is made by adding iboga roots (see ***Tabernanthe iboga***). In Ghana, palm wine is mixed with the leaves of *Vernonia conferta*, known as *flakwa*, to produce aphrodisiac effects (Bremness 1995, 29*). In West Africa, the bark of *Mitragyna stipulosa* (DC.) O. Kuntze, which may contain alkaloids of the **yohimbine** type, is drunk with palm wine (cf. ***Mitragyna speciosa***). In central Africa, the root bark of *Strychnos icaia* L. (cf. ***Strychnos* spp.**) is added, and in West Africa the bark of *Corynanthe pachyceras* (cf. ***Corynanthe* spp.**).

In India, palm wine was once fortified with the seeds of ***Datura metel***. The Sora, a tribal people of Orissa, add an as yet undetermined root to their palm wine, known as *salap*, to give it a cannabis-like effect (Gerhard Heller, pers. comm.).

The goddess Hathor, shown here personified as a date palm, pours the inebriating palm wine. (Egyptian relief, eighteenth dynasty, sixteenth to fourth centuries B.C.E., from Luschan)

Pituri

Other Names

Bedgery, pedgery, pitchery, pitchuri, pitjuri, pituribissen, pituripriem, pituri quid

Pituri, in the broadest sense, is a word given to all plants and all products obtained from these plants (with additives) that the Australian Aborigines chewed or chew for hedonistic and magical purposes. The more recent literature uses *pituri* only to refer to the nightshade ***Duboisia hopwoodii*** (Horton 1994).

Usually pituri leaves are mixed with alkaline plant ashes and chewed as a quid. In this practice, the chewing of various wild tobacco species (*Nicotiana ingulba*, *N. gossei*, *N. stimulans*, *N. benthamiana*, *N. velutina*, *N. megalosiphon* [cf. ***Nicotiana* spp.**], and ***Goodenia lunata***) has more of a hedonistic character, whereas the chewing of ***Duboisia hopwoodii*** and *Datura* species⁴⁵² is more magical and religious in nature. The smoking of pituri may have developed as a result of exposure to the smoking habits of Europeans (Emboden 1979, 146*).

Pituri takes away hunger and thirst, has inebriating effects, and induces ardent dreams. This is presumably the reason why the Aborigines use(d) pituri as a magical agent. In Aboriginal magic, entering into what is known as the Dreaming, the transcendent and primordial state of being, is of primary significance. The Dreaming is an altered or different state of consciousness:

Everything in nature is a symbolic footprint of the metaphysical world, through whose actions our world was created. As with a seed, the inherent power of a place is also coupled with the memory of its origin. The Aborigines call this power the *Dreaming*, the dream of the place, and this dream is the foundation for the sacredness of the earth. Only in extraordinary levels of consciousness can one perceive the inner dream of the earth or attune oneself to it. (Lawlor 1993, 1)

It is in the Dreaming that all magical actions that affect the normal state (which is understood to be unreal) are determined and carried out. It appears that there were different types of pituri for different purposes and that the different types were associated with different songs, totems, and the corresponding dream paths or songlines. Several songlines were sung as “pituri paths.” There were even pituri clans (Watson et al. 1983, 308). Pituri was considered to be charged with the place of the land; it carries the dream of the place in which it grows and passes this on to humans.

The ritual and hedonistic use of pituri may be the longest continuous cultural use of a psycho-active substance in the history of all humankind. The culture of the Aborigines is the longest continuous culture in the world. It is possible that the Dreaming ancestors of the Aborigines were chewing pituri some forty thousand to sixty thousand years ago (Lawlor 1993).

Fermented pituri leaves (*Duboisia hopwoodii*) are the basis of pituri quids.

This painting by the Aboriginal artist Walangari Karntawarra Jakamarra (Collin McCormick) depicts the pituri plants as round, gray dots. (Detail, oil painting, ca. 1993)

“The natives also stick the chewed [pituri] in their ear, which causes their eyes to take on an unusual shine and their pupils to become very dilated.”

CARL HARTWICH

DIE MENSCHLICHEN GENUßMITTEL [THE HUMAN AGENTS OF PLEASURE]

(1911, 834 f.*)

The Gathering and Preparation of Pituri

Although *Duboisia hopwoodii* and *Nicotiana* spp. are both widespread in Australia, there are nevertheless certain areas that are preferred for gathering the plants. In the ethnographic and ethnobotanical literature, the authors repeatedly express their surprise that the Aborigines of the northern desert regions, where *Duboisia* bushes grow in abundance, nevertheless prefer leaves imported from the distant east. Unfortunately, no sources have been preserved that provide information as to why the Aborigines prefer the leaves from the eastern regions. There were presumably magical reasons, as the gathering of pituri always takes place according to certain songlines. The leaves are charged with the energy of the place or the land on which they grew. (It may be that the Aborigines were psychoactive gourmets who, like other gourmets, preferred cognac over all other brandies.) Before the Aborigines had contact with Europeans, there was an extensive network of trade in the central desert, and the so-called pituri roads on which the prized pituri was traded were a part of this (Emboden 1979, 145*).

The resins of various species of eucalyptus are added to pituri quids.

The very elaborate, complicated, and sophisticated processing methods used in the preparation of botanical raw products, e.g., to detoxify or enhance a plant's activity, are a typical feature of Australian ethnopharmacology (Beck 1992). Simple methods for preparing food and products play only a subordinate role. The Aborigines appear to have possessed a great skillfulness in the processing of medicinal and culinary products, and they spent a great deal of their time practicing these techniques (Isaacs 1987*).

Various ingredients are added to the dried or fermented pituri leaves to produce a quid. Some of these ingredients are plant ashes, while others are binding agents, such as animal hair (from wallabies, euros or wallaroos [a small kangaroo species], or rabbits), plant fibers (*Linum marginale*), yellow ocher, eucalyptus resin, and, in recent times, sugar (Peterson 1979, 179). *Duboisia* leaves can also be chewed by themselves, but the effects are not considered to be particularly powerful. *Nicotiana* species are always chewed in combination with plant ashes (O'Connell et al. 1983, 108).

All of the plants that are used as sources of ashes contain active constituents. The Aborigines have long used acacia wood, especially that from the mulga acacia, to make boomerangs, spear tips, digging sticks, and shields (Low 1992b, 181*). Acacias (*Acacia* spp.) have been found to contain alkaloids (tryptamines, e.g., *N,N*-DMT). Several acacias, such as *Acacia georginae*, contain the toxic substance fluoroacetate (Dowling and McKenna 1993, 146*). The ashes of both the oceanic acacia (*Acacia manguim*) and *Melaleuca* species contain salts and minerals and are rich in sodium (Ohtsuka et al. 1987). Some acacias, e.g., *Acacia aneura*, also produce a gum that can be added to pituri (O'Connell et al. 1983, 105). Unfortunately, we do not know how the plant ashes were produced. If acacia wood is simply burned, then it can be assumed that the DMT is destroyed by the fire. But if a special process is used to turn the wood into an ashlike substance, such as smoldering the wood at a

lower temperature or a similar process, then the DMT may have been preserved, and the concentration may actually have been increased⁴⁵⁴ (cf. *Erythoxylum coca*).

The gum-producing genus *Ventilago* has also been found to contain alkaloids (Collins et al. 1990, 61*).

Rock isotome (*Isotoma petraea* Muell.; Campanulaceae) was added to pituri to increase its potency (Low 1990, 192*). Members of the genus *Isotoma* are also used for psychoactive purposes in South America, primarily as additives to **ayahuasca** and **cimora**. Some additives were also used as substitutes for *Duboisia* and tobacco (see the table on page 781).

Actual reports of experiences with pituri are extremely rare. The effects of the various pituri species can differ considerably, and some can be quite powerful, as Gary Thomas has experienced (G. Thomas, pers. comm.). Some appear to have potently and others only weakly stimulating effects; the effects of some are euphoriant and of others visionary. According to the painter Collin McCormick, the effects of pituri leaves, whether from *Duboisia* or *Nicotiana*, are not very good when they are used alone. Only when combined with ashes are the desired effects brought out.⁴⁵⁵ He said that “the ash functions as an amplifier to the pituri.” Because pituri quids are often only briefly chewed and then are placed behind or even into the ear, it is possible that the DMT may be absorbed into the bloodstream from this location, which is known to be highly permeable to alkaloids (**scopolamine** patches can be placed behind the ear as a remedy for motion sickness). Perhaps the leaves also contain MAO inhibitors, so the DMT could be orally active (cf. **ayahuasca**). However, it is also likely that the DMT is able to enter the brain directly via the mucous membranes of the mouth, just as it can through those of the nose. In other words, pituri could be a highly effective psychoactive combination drug whose significance has not yet been fully recognized. Future research into pituri may provide some ethnopharmacological sensations.

Sake

Other Names

Chongha, chongjung, ju, kukhuaju, makoli, reishier, reishwein, rice beer, rice wine, saké, saki, taenju, tong dong ju, “wine”

Sake is brewed from water, rice (*Oryza sativa* L.), yeast (*Saccharomyces cerevisiae*), and the koji fungus (*Aspergillus oryzae*). A variety of methods may be used to prepare the hulled rice, after which it is mashed. Koji is then added, which transforms the rice’s starch into sugar. The rice is then mixed with water and fermented with the help of yeast. The alcohol content of the finished drink depends upon how much of the starch has been transformed into sugar. If 40% of the starch becomes sugar, the sake will contain 20% ethanol (= **alcohol**) (Kondo 1992, 42 f.). In former times, a *kuchikami no sake*, “sake chewed in the mouth,” was made using a very archaic method: Rice, chestnuts (*Castanea sativa* Mill.), and millet were chewed thoroughly and spat into a trough of water. After a few days, the mix would finish fermenting and be ready to drink. Sake is actually more like **beer** than **wine**. In Korea, sakelike drinks and their mashes have been distilled into high-proof rice schnapps for some five hundred years.

In ancient China, alcoholic drinks (*chiu*) made from rice were already known during the Neolithic period (over four thousand years ago). During the Chou era, rice wine was drunk as a gift of offering in the ancestor cult. This wine was brewed with the addition of wormwood (*Artemisia absinthium*) or dogwood (*Cornus* spp.) (Majlis 1981, 314). Sometimes saffron (*Crocus sativa*), ginger (*Zingiber officinale*), or the seeds of *Datura metel* were also used.

The art of sake brewing originated in China, rapidly spread to Korea, and was introduced into Japan around the seventh century. There, it has become a national drink and has retained its position in the world of inebriating drinks as a typically Japanese specialty.

In Japan, sake brewing falls under the protection of Matsuno’o, the god of sake (Kondo 1992, 26). The origins of the drink are traced back to the god Susanoonomikata, the brother of the sun goddess Amaterasu. He is said to have invented the inebriating drink in order to sedate the great snake of Lake Yamata so that he could kill it with his magical sword. Originally, sake was brewed as a “drink of the gods,” only for festivals and rituals of the Shinto cult. Great quantities were offered so that the gods would look with favor upon humans. When people drank it, they felt “like gods.” In contemporary Japan, sake is still also known as “nirvana wine,” because drinking it is supposed to lead one to nirvana. Over the course of history, certain sake-drinking rituals have evolved that bear a strong resemblance to the tea ceremony (cf. *Camellia sinensis*). But today, sake is enjoyed primarily as a part of profane life.

There are many varieties of sake, from dry to sweet, of which some are drunk ice cold and others lukewarm, warm, or hot. Dry, high-quality sake is always enjoyed cold or ice cold. Lower-quality sakes are heated so that the poor taste will not be apparent.

Sake was sometimes brewed with additives. A “black sake” was made with the addition of ashes from aromatic woods (presumably *lignum aloe*; cf. **incense**) and a *kikuzaké* (“chrysanthemum sake”) with the addition of chrysanthemum blossoms (*Chrysanthemum morifolium* Ramat.)⁴⁵⁷ (Kondo 1992, 17). Sake also may have once been brewed with *Phytolacca acinosa* (pokeweed). In tenth- and eleventh-century China, a “medicinal wine” was made from sake and *sû hé xiāng* (= storax, the resin of *Liquidambar orientalis* Mill.; cf. **incense**), to which the dried rhizome of *bai zhu* (*Atractylodes*

macrocephala Koidz.) was also added. One of the uses of this storax wine was to restore consciousness to a person who had passed out (Shen Kuo 1997, 68, 261*; cf. **han-shi**).

“The storax-scented wine . . . is very well suited for bringing the five organs [heart, liver, spleen, lungs, kidneys] into harmony with one another and for dispelling all diseases of the stomach. If one awakens in the morning with a cold, one should always drink a cup of this wine.”

SHEN KUO

PINSELUNTERHALTUNGEN AM TRAUMBACH [BRUSH DISCUSSIONS BY THE DREAM STREAM]
(1997, 68*)

Traditional sake vessels in Kamakura, Japan.

In Japan sake is often added to green tea (*Camellia sinensis*) during the cold months. In Korea, all sakelike drinks, and in particular the milky, mildly alcoholic *makoli*, play a significant role in the native shamanism, which continues to thrive in spite of thousands of years of suppression. *Taenju*, “wine,” is a central offering (libation) in all Korean shamanic ceremonies (Cho 1982, 107, 117). Because of the copious consumption of *makoli* and ecstatic dancing, powerful altered states of consciousness are often experienced during these offering ceremonies. A document from the thirteenth century notes:

During *Wei* (Korean *Ye*), people made offerings to the heavens at the October ceremony and drank, sang, and danced day and night. They called their ceremony *wutian* [Korean *much'on* = dance (in honor) of the heavens]. (Cho 1982, 12)

It is possible that in the past, a psychoactive mushroom (e.g., *Amanita pantherina*, *Panaeolus subbalteatus*, or *Psilocybe* spp.) may have been added to the *makoli*. After all, the “mushroom of immortality” is regarded as a gift of the *tengu*, the shamanic mountain deity.

A view of a Japanese sake brewery (woodcut from *Nihon Sankai Meisan Zu-e*, ca. 1800).

Smoking Blends

Other Names

Blends, rauchkräuter, rauchmischungen, smoking mixtures

Almost any plant can be smoked after it has been dried. Many psychoactive plants are smoked alone and unblended. Usually, however, one or more other herbs or extracts are combined with them. Herbs are very often mixed to produce specific psychoactive effects. Many smoking blends are important components of shamanic rituals or social situations.

In Amazonia, mixtures of resins from different *Virola* species (***Virola* spp.**) and tobacco (***Nicotiana tabacum***) are ritually smoked. Mataco shamans mix the seeds of ***Anadenanthera colubrina*** var. *cebil* with tobacco (***Nicotiana* spp.**) and an *Amaranthus* species so that they can diagnose and heal illnesses. In Mexico, Mayan shamans smoke blends of tobacco (***Nicotiana tabacum***) and thorn apple (***Datura innoxia***). The Huichol use a combination of wild tobacco (***Nicotiana rustica***) and marigold (***Tagetes lucida***). The Mam and Tzeltal Indians smoke wild tobacco together with fly agaric skins (***Amanita muscaria***) for divinatory purposes. Countless blends are used in North America (see **kinnikinnick**). The sadhus in India and Nepal are fond of blending hemp products (***Cannabis indica***) with ***Datura metel***, ***Aconitum ferox***, and cobra venom. In central Asia, henbane (***Hyoscyamus niger***, ***H. spp.***) is mixed with tobacco or hemp (***Cannabis sativa***, ***Cannabis ruderalis***). In Pakistan and North Africa, it is common to smoke hashish with tobacco (***Nicotiana tabacum***). In Southeast Asia, cloves (*Syzygium aromaticum*) are added to tobacco, and clove cigarettes are even manufactured in factories. In Australia, **pituri** is occasionally smoked. Sometimes hemp leaves are soaked in opium (***Papaver somniferum***) and a tincture of lobelia (***Lobelia inflata***) for smoking.

Recipes

In fact, of course, most herbs can be combined with one another for smoking. However, one should nevertheless proceed with caution when experimenting and begin with small dosages (cf. **kinnikinnick**).

Shiva/Shakti Blend

Equal parts of:

ganja (hemp leaves; ***Cannabis indica***)

dhatu (thorn apple leaves; ***Datura metel***)

“The smoke of dried coltsfoot with root, sucked in by means of a tube, is said to heal an old cough, but one must take a sip of raisin wine after each inhalation.”

PLINY

(26.36)

“Each of the different smoking blends allows one to strike a different key on the piano of consciousness states!”

A CONSUMER

IN *ISOLDENS LIEBESTRANK* [ISOLDE’S LOVE DRINK]

(MÜLLER-EBELING AND RÄTSCH 1986, 166*)

Indian Cigarettes (nineteenth century)

In the nineteenth century, pharmacies sold numerous pharmaceutical smoking blends that were prerolled into cigarettes. This recipe of the Parisian company Grimault et Cie. from 1870 is strongly reminiscent of **witches' ointments**. Per cigarette:

0.3 g belladonna leaves (*Atropa belladonna*)

0.15 g henbane leaves (*Hyoscyamus niger*)

0.15 g thorn apple leaves (*Datura stramonium*)

0.1 g Indian hemp leaves (*Cannabis indica*), soaked in opium extract and cherry laurel schnapps

Smoke one cigarette as needed.

Neumeier's Cigarillos (1913)

These pharmaceutical cigars were smoked as a remedy for asthma. Unfortunately, no amounts were given with the ingredients. They consisted of:

herba and radix brachycladi (*Trichocline argentea* Grisebach [syn. *Brachyclados stuckeri* Speg.]; cf. *Trichocline* spp.)

Cannabis indica

Grindelia robusta Nutt.

folia eucalypti (eucalyptus leaves)

folia stramoni (thorn apple leaves)

an outer leaf of *Nicotiana tabacum*

Smoke as needed.

Yuba Gold

In the international herb trade, one can even find finished herbal blends based upon hemp products. One popular product is Yuba Gold, which consists of (Miller 1985, 23*):

4 parts damiana leaf (*Turnera diffusa*)

4 parts skullcap herb (*Scutellaria lateriflora* L.)

¼ part lobelia herb (*Lobelia inflata*)

4 parts passionflower herb (*Passiflora incarnata*; cf. *Passiflora* spp.)

1 part spearmint leaf (*Mentha spicata*)

Legal Grass

This mixture is sold as a marijuana substitute (Brown and Malone 1978, 23*). It consists of:

Korean ginseng leaves (*Panax ginseng*) damiana (*Turnera diffusa*/*Turnera aphrodisiaca*) high-grade lobelia herb (*Lobelia inflata*) African yohimbe bark (*Pausinystalia yohimba*) hops (*Humulus lupulus*)

Creative Euphoria

Equal parts of:

marijuana (*Cannabis indica*, *Cannabis sativa*)

damiana (*Turnera diffusa*)

fly agaric mushroom (*Amanita muscaria*)

ska maría pastora (*Salvia divinorum*)

yohimbe bark (*Pausinystalia yohimba*)

“Legal High” Blend

Equal parts of:

leonotis herbage (*Leonotis leonurus*)

bog bilberry leaves (*Vaccinium uliginosum*)

aristolochia herbage (*Aristolochia triangularis*)

papaya leaves (*Carica papaya* L.)

marsh marigold herbage (*Caltha palustris* L.)

Hottentot Tobacco

Equal parts of:

kougoed (*Sceletium tortuosum*)

dagga (*Cannabis sativa*)

Aphrodisiac Smoking Blend I

Equal parts of:

hashish (*Cannabis indica*, *Cannabis sativa*)

fly agaric mushroom, dried (*Amanita muscaria*)

coca leaves, toasted (*Erythroxylum coca* var. *coca*)

Aphrodisiac Smoking Blend II

Equal parts of:

hashish (*Cannabis indica*, *Cannabis sativa*)

fly agaric mushroom, dried (*Amanita muscaria*)

thorn apple leaves (*Datura innoxia*, *D. stramonium*, *D. spp.*)

Mixture for Peyote Rituals

(cf. *Lophophora williamsii*, kinnikinnick)

Bull Durham tobacco (*Nicotiana tabacum*)

mokola leaves (*Rhus glabra* L.)

Hataj Mixture

5–8 hataj seeds (*Anadenanthera colubrina* var. *cebil*)

1 cigarette (*Nicotiana tabacum*)

1 pinch of aroma (*Amaranthus* sp.)
some aramo (*Mimosa* spp.)

“Mazatec Blend”

Equal parts of:

coleus (*Coleus blumei*)

ska maría pastora (*Salvia divinorum*)

Blending smoking herbs can clearly produce synergistic effects that may be desirable to a smoker (cf. Siegel 1976*). Some consumers have even begun to practice what may be termed “chemical engineering,” in which certain blends, combinations, and proportions of mixtures are designed to steer the specific effects of hemp in a particular direction. For example, combinations with tropane-rich nightshades (henbane, thorn apple, angel’s trumpet) are smoked for aphrodisiac purposes. To produce more profound psychedelic effects, hemp products may be combined with belladonna (*Atropa belladonna*) and fly agaric mushrooms (*Amanita muscaria*) (belladonna and fly agaric mushrooms have a positive synergy). Kitchen spices, coca leaves (*Erythroxylum coca*), and *Ephedra* herbage can be used for refreshing and invigorating effects. Some ingredients, e.g., *Psilocybe* mushrooms, are thought to have no pharmacological effect when smoked.⁴⁵⁸ Others, such as toad foam (cf. **bufotenine**, **5-MeO-DMT**), are extremely potent and can clearly obscure the effects of THC. The effects of many *Artemisia* spp. (*Artemisia* spp.) are antiasthmatic and muscle relaxing and are suitable for use in smoking blends, and it is possible that they may improve the absorption of the active constituents of the other ingredients in the blends. Continuing ethnopharmacological research into smoking herbs and mixtures will certainly provide many stimulating insights.

Coltsfoot leaves (*Tussilago farfara*) were once smoked as a tobacco substitute. Today, they are often mixed with hashish and used in medicinal and psychoactive smoking blends. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Snuffs

Other Names

Polvo alucinogeno, polvo psicoactivo, rapé, rapé dos Indios, rapé halucinogênico, schnupfdrogen, schnupfpulver, sternutators

A number of substances are traditionally ingested via the mucous membranes of the nasal passages by snuffing or inhaling for medicinal, ritual, shamanic, or hedonistic purposes. It is difficult to determine when humans first began the practice of snuffing. It probably originated around the time that milling stones or other milling techniques were being invented. Usually, very finely ground powders are used.

In the Old World, we know of only the occasional use of “sneezing powders”⁴⁵⁹ (sternutators) (cf. *Veratrum album*). In India, various plants, including hemp (see *Cannabis indica*), are used as medicinal snuffs. The same is true in Africa (see *Mesembryanthemum spp.*, *Sceletium tortuosum*).

In North America, a shamanic-ritual use has been demonstrated for only a few snuffs. In the Pacific Northwest, powders from polypores were snuffed during shamanic healing ceremonies (cf. “*Polyporus mysticus*”). In the forest regions of the Northeast, the ritual use of a snuff made of calamus roots was widespread (cf. *Acorus calamus*). We have no evidence indicating that tobacco was snuffed in North America. Although the practice of snuffing tobacco is now known throughout the world, it is actually seldom practiced.

South America is the center of the use of psychoactive snuffs, although such use has also been confirmed for many Caribbean islands (Hispaniola, Greater Antilles). Christopher Columbus was the first to describe the use of *cohoba* among the Taino Indians. Taino healers placed the powder on the heads of the *cenis*, the wooden figures of their deities. From there, they would use a tube to draw it into their noses, after which they would question the gods about the origins of diseases (Torres 1998; Torres n.d.). The first mention of the use of snuff powders in the Amazon came from the missionary Fray Pedro de Aguado in 1560 (Torres et al. 1991, 645).

Numerous objects that were used as snuff trays are known from the South America Andes region (Wassén 1985). Most of these are carved from wood, but some are made of such exotic materials as (fossilized or partially fossilized) whale bones. Most of these two-thousand-year-old snuff trays were found in San Pedro de Atacama (Chile), located at an altitude of 2,450 meters, and in neighboring areas. To date, the excavations of approximately five thousand graves have yielded 612 snuff kits. These usually consist of a woolen bag with a four-sided snuff tray, a snuffing tube of wood or bone,⁴⁶⁰ a small spoon, a small mortar with a pestle, and one or more leather bags containing snuff (Torres et al. 1991, 641; Cornejo B. 1994; Núñez A. 1969). In addition to the snuff, many of the leather bags contained a tiny bag of crushed malachite. The snuff has usually been preserved as an amorphous mass, although one bag yielded seeds that clearly belong to the *Anadenanthera* family. Chemical analyses of two samples of the amorphous masses verified the presence of the tryptamines *N,N*-DMT, 5-MeODMT, and bufotenine (Torres et al. 1991, 643). These findings suggest that the snuff was produced from *Anadenanthera colubrina* var. *cebil*.

“I felt how every single grain shot up through my nostrils and then exploded in my skull. Gradually, a wonderful weariness spread through my body. I turned my gaze to the river and nearly expected to see a mythical creature there rising from the depths.”

FLORINDA DONNER SHABONO

(1985)

This pre-Columbian snuff tray from San Pedro de Atacama is decorated with a jaguar, the most important shamanic animal, and fits nicely in the hand for snuffing. (Universidad del Norte Museum, San Pedro de Atacama)

Snuff tools, consisting of a tray and a snuff tube decorated with a “psychedelic” llama. (Universidad del Norte Museum, San Pedro de Atacama)

The Atacameños (Kunza) used the stems of the plant called *sorona*, *peril*, or *brea* (*Tessaria absinthioides* [H. et A.] DC.; Compositae) as snuff tubes. (Wild plant, photographed in the San Pedro de Atacama, northern Chile)

The ritual use of psychoactive snuffs appears to have spread north from South America, a fact attested to by both the age and the geographic concentration of the archaeological finds of snuff tools (Torres et al. 1991). The oldest known snuff device dates to 3000 B.C.E., while the oldest snuff tray found thus far has been dated to 1200 B.C.E. The iconography of this snuff paraphernalia incorporates all the elements of a shamanic worldview, including animal spirits, chimeras, erotic scenes, deities, winged beings, et cetera (Torres 1987a, 1987b, 1988). The iconography is strongly reminiscent of that of the later Tiahuanaco (= Tiwanaku) culture, where the use of snuffs is well documented (Berenguer 1987; Torres et al. 1991, 646; Wassén 1972). Snuff paraphernalia in the Tiahuanaco style appears in the region of the southern Andes and has been dated from 300 B.C.E. It can thus be assumed that the use of psychoactive snuffs was closely interwoven with the cultural development of this region (Torres 1993; cf. also Boetzkes et al. 1986, 62). The snuff trays from the late phase (Incan period) are nothing more than crude imitations of the tools from the archaic period. However, in the eighteenth century the art of the snuff tray flowered in Brazil once again (Wassén 1983).

The manner in which these snuff tools are used is clear. The powder is laid out in lines on the tray and snuffed into the nose through a tube. In general, the snuff powders are used to make contact with the higher reality and with beings that are ordinarily invisible. Sometimes hunters will take snuff in order to see where the game is hiding. The hunter will transform himself into an eagle, a condor, a jaguar; in this form, he will fly through the air or pace through the primordial forest and see the game.

The shamanic use of psychoactive snuffs is also widespread among the Indians of the Amazon and Orinoco regions. Here, snuff trays are not used; instead, many different kinds of tubes are used through which a person blows the powder into his own nose or into another's nose. There are also Y-shaped snuffing tubes made from hollow plant stalks that a person can use to snuff powder through both nostrils at the same time. Snuff tubes made from snails are a special invention. These are made from the shells of large land or freshwater snails (e.g., *Ampullaria* sp., *Strophocheilus* spp., *Poulimus gallina* Sultana, *Helix terrestris*) (Zerries 1980, 174, table 86; Wassén 1965, 62 ff.; Wassén 1967, 119). The apex (= tip, embryonic spire) of the snail shell is removed. The resulting opening is extended with a bone tube or hollow plant stalk. The powder is placed in the orifice of the snail shell, and the tube is then placed in a nostril and the snuff inhaled. Snail shells are also used to store snuff. Numerous snails from the genus *Strophocheilus* have been found in graves at San Pedro de Atacama (Llagostera et al. 1988, 93). Since these snails are from the tropical Chaco region, this may indicate that the shells were imported along with the seeds of *Anadenanthera colubrina*.

In ancient times, the black hellebore or Christmas rose (*Helleborus niger* L.; Ranunculaceae) was used to prepare a medicinal sneezing powder. However, these ancient *Helleborus* snuffs were likely not psychoactive. (Woodcut from Fuchs, *Kreüterbuch*, 1543)

“The ingestion of the hallucinogens had begun: gray-, green-, and khaki-colored powders waltz from one nostril to the next. Several people stand up, suddenly gripped by nausea, and vomit in the central plaza; emaciated dogs then come over and lick up this unexpected manna. Others have tears in their eyes, they spit out thick spittle that they can expel from their mouths only with great effort. Kremonoawe is dizzy. He sees fantastic landscapes dipped in orange, red, carmine, or scarlet. The round house, shaken by spasms, bends grotesquely. All at once a tornado of blood rises and floods everything, beings and things. Strange and horrifying people appear and dissolve again.”

JACQUES LIZOT

IM KREIS DER FEUER [IN THE CIRCLE OF FIRE]

(1982, 118)

The Desana, a Tukano-speaking tribe in Colombia, call their snuff powder *vihó*. It is usually produced from various species of ***Virola***. According to the mythology of the Desana, the sun created Vihó-mahse, “snuff-powder being,” at the beginning of time so that it could establish contact between humans and the creator (the sun god) through hallucinations. The actual snuff was the property of the sun god himself, who kept it hidden in his navel (from whom was his umbilical cord separated?), until his daughter scratched him there and discovered the powder. Vihó-mahse normally dwells in the Milky Way, the “blue zone” of hallucinations and visions, and is in a permanent trance. Using the earthly snuff, the shaman (*payé*) is able to reach this place and contact Vihó-mahse (Reichel-Dolmatoff 1971*).

The use of powerful psychedelic snuff powders is widespread among the Yanomamö (= Waika) of the Orinoco region and northern Brazil (Brewer-Carias and Steyermark 1976; Chagnon 1977; Chagnon 1994; Donner 1985; Lizot 1982). Most of the men—and not only the shamans—take *epena* or *ebene* daily. Even five- to six-year-old boys are allowed to snuff the powder, in accordance with the motto: Practice early if you wish to become a master. Women are not allowed to use snuff. The Yanomamö believe that spirit beings (*hekura* or *hekula*) dwell in their chests, as well as under cliffs and in mountains, and that the snuff aids them in contacting these beings (Brewer-Carias and Steyermark 1976, 63; Goetz 1970, 45; Henley 1995).

The shamans of the rain forest often take snuff before they treat a patient; this enables them to better see the origins of a disease. Sometimes (for example, among the Sanama), snuff is ingested collectively during funerals (Prance 1970, 62*).

An Amazonian snuff plays a central role in the novel *The Emerald Forest*, which was made into a motion picture by John Boorman. Both the novel and the film show the cultural significance of the visions or journeys to other realities facilitated by the psychoactive snuff (Holdstock 1986, 117 f., 152, 163 ff., 190 f.).

Peter T. Furst has proposed the theory that psychoactive snuffs were used in pre-Hispanic Mexico, but that the knowledge of their use had disappeared by the time of the Conquest (Furst 1974). The actual functions of the archaeological objects Furst draws upon to support his theory are disputed. The snuff expert Manuel Torres has called Furst’s theory into question on the grounds that, for example, the size of the objects in question made it impossible for them to fit them into a person’s nostril. But according to Torres (pers. comm.), an object from Guerrero that is now housed in the Museo Nacional de Antropología e Historia (Mexico City) may be a snuff tray. The discovery of a hollow ceramic figure from Colima first established proof that snuffing (of whatever substances) must have been known in Meso-america. In addition, certain Olmec pieces possibly were used as snuff trays (Furst 1996, 77, 78*). Furst regards the following plants as candidates for Mesoamerican snuffs: peyote (***Lophophora williamsii***), ololiuqui (***Turbina corymbosa***), *Piptadenia flava* (Spreng.) Benth., *Piptadenia constricta* (Mich. et Rose) Macbride, ***Mimosa* spp.**, ***Acacia* spp.**, ***Psychotria* spp.**,

and *Justicia pectoralis* (Furst 1974, 3 f.). It is also conceivable that *Virola guatemalensis* was used.

Today, the snuffing of more or less pure **cocaine** is a worldwide phenomenon. Other psychoactive substances are also snuffed, including the synthetic phenethylamine 2-CB,⁴⁶¹ MDMA (ecstasy or XTC), **DMT**, **scopolamine**, and crystallized ketamine (cf. Höhle et al. 1986, 65*; de Smet 1985, 102). As part of the “back to nature” movement, herb sellers have even begun blending psychoactive snuffs from legal ingredients. For instance, a mixture sold under the name Storm’s Breath consists of kava-kava (*Piper methysticum*), cola nut (*Cola spp.*), guaraná (*Paullinia cupana*), nutmeg (*Myristica fragrans*), and cinnamon (*Cinnamomum verum*); its effects are mildly stimulating and, surprisingly, not especially irritating.

Traditional Snuff Recipes

Amazonian Snuff Powder

Roasted seeds of *Anadenanthera peregrina* are ground very fine with tobacco and ash. Most people who try this powder experience extremely strong (allergic) reactions or pain. No one who has tried it has expressed a desire to try it again.

Shinã or Tsinã

This snuff powder is produced by the Jamamadis and Denís of the Brazilian Amazon. It consists of equal parts of roasted *Nicotiana tabacum* leaves and ashes from the bark of *Theobroma subincanum* Mart. and other *Theobroma* species (known as *cacau*). Both are ground fine and snuffed in the evening (Prance 1972b, 221*).

Baduhu-tsinã

The word means “deer snuff.” This snuff is made from a lichen (*Pyrenocarpus*) that grows on trees. The effects are more like those of a sneezing powder than those of a psychoactive shamanic drug (Prance 1972a, 16*; 1972b, 227*).

Yanomamö/Waika Snuff

Epena, Ebona, Ebene

The Yanomamö make a potent psychoactive snuff from the bark of *Virola theiodora* or *Virola elongata* and the leaves of *Justicia pectoralis*. The active constituent is the *Virola*; the *Justicia* leaves impart a more pleasant aroma to the powder and also appear to make it easier for the snuff to be absorbed through the nose (Prance 1972, 234 f.*). The ashes of the magnificent *Elizabetha princeps* tree are sometimes added to this blend (Brewer-Carias and Steyermark 1976, 60).

The Yanomamö (Waika) of northern Brazil use the bark of the *Virola theiodora* tree (also known as *epena*) to make a snuff and add ashes from the bark of *Elizabetha princeps*, which they call *amá*, *ama-asita*, or *chopó* (Brewer-Carias and Steyermark 1976, 63; Schultes and Raffauf 1990, 239*; cf. also Chagnon et al. 1970).

The Yanomamö do not consider *Elizabetha princeps* to be in and of itself hallucinogenic, but they

believe that it potentiates the effects of the active constituents (*Viola*, *Anadenanthera*) (Brewer-Carias and Steyermark 1976, 63).

They also make a snuff from the ground, roasted seeds of *Anadenanthera peregrina* (Prance 1972, 234 f.*).

Active Constituents

The main constituents of most South American snuffs used for shamanic purposes are the tryptamine derivatives **N,N-DMT**, **5-MeO-DMT**, and **bufotenine**. Some powders contain all three substances, while others contain only two or even just one (see the table on page 789). The sources of these tryptamines are species from the genera *Anadenanthera* and *Viola* (Holmstedt 1965). All other plants (e.g., *Elizabetha*, *Justicia*, *Manihot*, *Piper*, *Theobroma*) are only additives or substitutes and often have no psychoactive effects of their own. However, it is entirely possible that certain, as yet unknown synergistic activities may play an important role. Only the nightshade plants (*Brugmansia*, *Brunfelsia*, *Datura*, *Nicotiana*) contain potent psychoactive alkaloids. Chemical studies of some of the plants used as snuffs (*Maquira*, *Pagamea*), to the extent that they have been carried out at all, have not yet uncovered any definitive active constituents (Schultes 1980, 274). They may serve only as symbolic elements in the rituals (Schultes and Raffauf 1990, 389*). It would be interesting to conduct further research into the use of *Banisteriopsis* as a snuff (ingredient?).

These depictions of gods and mythical beings were found on pre-Columbian snuff trays from San Pedro de Atacama (Chile).
(Drawing: Donna Torres; reproduced with kind permission)

Soma

“Then the gods commanded us to gather all of the plants that could be dipped in the ocean and were suitable for obtaining the nectar of immortality; and in those days we were very strong.”

VALMIKI *RAMAYANA* (1983, 165)

“These are the plants, these highly gifted ones, that shall free the sick from their suffering! Truly, I confirm, you herbs, that your lord is Soma and that you were created by none other than [the seven-faced] Brishaspati [planetary god Jupiter]! The shadow that lies over us, that threatens us, shall be overcome.”

MAGICAL SAYING FROM THE ATHARVA VEDA
IN *MAGIE DES OSTENS* [MAGIC OF THE EAST]
(I. SHAH 1994, 159*)

Some authors believe that the original soma drink was pressed from rhubarb stems (*Rheum palmatum*) and fermented into a winelike drink.

Other Names

Ambrosia, amrita, bolud rtzi (Tibetan), haoma, homa, nectar, nektar, sauma, saumya, som

Soma is the earthly counterpart of *amrita*, the drink of immortality that is reserved for the gods in the heavens. The name *soma* was given to a deity, to a plant, and to the sacrificial drink prepared from the plant. The Aryans of the Indus Valley venerated and drank soma as part of a cult that existed some three thousand years ago (Aguilar I Matas 1991). Soma is the Indian counterpart of the Persian **haoma**. Today, the definitive botanical identity of soma is unknown.

In the Hindu tradition, the moon (originally called *soma*) is the ambrosia-filled drinking vessel of the gods. When the moon is full, the vessel is full; by the time the new moon appears, it has been emptied. It fills up again as the moon waxes. The moon is divided into sixteen sections. Every day, the gods drink up one of these sections. The moon is the lord of the plants, the deity who protects all plant life. For this reason, the soma plant must be gathered by moonlight and brought to the place of offering on a platform pulled by two goats. The sacrificial altar itself was made solely of *kusa* grass (Gupta 1991, 85*).

There were three soma preparations, called *asir*: the one made with milk was called *go*, the one with sour milk *dadhi*, and the one with barley *yava* (Gupta 1991, 85*). To prepare the drink, the stems of the soma plant were pressed between two stones. The “soma juice, which dissolves all sins” (Valmiki 1983, 21), was then mixed with water, milk, and other ingredients. It has sometimes been assumed that the soma prepared with barley was a kind of **beer** (*surâ*).

The priest at the fire altar offered soma (as a libation) to and consumed the drink in honor of Indra, the god of thunder, who is believed to be eternally inebriated on soma. The drink was also consumed by singers and poets because it inspired them to their art (Gonda 1978; Hauschild 1954).

The Vedas state that the urine of people inebriated on soma could be drunk, producing the same effects. Because the urine of people inebriated on fly agaric mushrooms is drunk in Siberia to induce further inebriation (Bourke 1996, 54 ff.**), Gordon Wasson put forth the hypothesis that the original soma plant must have been *Amanita muscaria*.⁴⁷⁰ However, Wasson’s hypothesis has been strongly

contested (McKenna 1996, 135 ff.*). The fact that there are no fly agaric mushrooms in the Himalayas is especially problematic. How were the Vedic religious communities supplied with the inebriant?

According to the Rig Veda, the soma plant grows only in the mountains; for this reason, all lowland plants, such as ***Peganum harmala***, can be eliminated as potential soma candidates (cf. Ott n.d.). It is also known that the Aryans acquired the plant by trading with the indigenous mountain tribes (Gupta 1991, 84*).

Some authors have speculated that soma was a **mead** made from **honey** (Hermanns 1954, 75), a kind of **wine** (rhubarb wine; Hummel 1959), or even a hopped **beer**. Others believe that soma was a fermented drink made from **honey** and the pressed juice of ephedra (***Ephedra spp.***) soaked in milk (Tyler 1966, 285*). However, the Rig Veda makes a clear distinction between soma and alcoholic drinks (*surā*) (Stutley 1980, 74).

Soma Plants

The original soma plant—hypothetical candidates

- Amanita muscaria* (L. ex Fr.) Pers. ex Hooker
- Argyreia nervosa* (Burm. f.) Boj.
- Bacopa monnieri* (L.) Pennell [syn. *Bacopa monniera* Wettst., *Monniera cuneifolia* Michx., *Herpestris monniera* (L.) H.B.K.]—sarasvati (Sanskrit)⁴⁷¹
- Calonyction muricatum* (L.) Don [syn. *Ipomoea turbinata* Lag., *Ipomoea muricata*] (cf. ***Ipomoea spp.***)
- Claviceps paspali* Stevens et Hall (parasitic on the koda grass *Paspalum scrobiculatum* L.)
- Claviceps purpurea*
- Ephedra spp.*:
 - Ephedra ciliata* F. et M. [syn. *Ephedra foliata* Boiss. ex C.A. Mey.]
 - Ephedra distachya* L.
 - Ephedra intermedia* Schrenk et C.A. Mey.
 - Ephedra pachyclada* Boiss.—hum (Hindi), huma (Hindi) (Gupta 1991, 84*)
 - Ephedra vulgaris* Rich. (= ***Ephedra gerardiana***)
- Equisetum* sp. (cf. ***Equisetum arvense***)
- Humulus lupulus* L.
- Mandragora turcomanica* Mizgireva (cf. ***Mandragora spp.***)
- Peganum harmala* L.
- Peganum harmala* in combination with *Psilocybe* sp. (“somahuasca”; cf. **ayahuasca analogs**)
- Polyporus* sp. (see “***Polyporus mysticus***”)
- Psilocybe (Stropharia) cubensis* (Earle) Singer
- Psilocybe semilanceata* (Fr.) Kummer
- Psilocybe (Stropharia) subcubensis* Guzmán
- Rheum* spp.⁴⁷²—wild rhubarb:
 - Rheum emodi* Wall.
 - Rheum officinale* Baill.
 - Rheum palmatum* L.
 - Rheum rhaponticum* L.
- Succulent(s) (cf. Ajaya 1980, 273 ff.)
- Vitis* sp., ***Vitis vinifera*** ssp. *sylvestris*—wild Afghani wine

Post-Vedic soma substitutes (O’Flaherty 1968)

- adara (not identified; cf. Gupta 1991, 84*)
- Andropogon* sp. (arjunnâni) [syn. *Cymbopogon* sp.] (cf. ***Cymbopogon densiflorus***)
- Basella cordifolia* Lam.—pûtkâ
- Cannabis indica* Lam.
- Ceropegia decaisneana*
- Ceropegia elegans*
- Ephedra gerardiana*** Wall. ex Stapf
- Ficus religiosa* L.
- Periploca aphylla* Dene.

putika (not identified with certainty, but perhaps *Basella cordifolia* or a fungus; cf. Kramrisch 1986 and Heim and Wasson 1970)
Sarcostemma brevistigma W. et A. [syn. *Asclepias acida*, *Cynanchium viminale*, *Sarcostemma acidum* Voigt, *Sarcostemma viminale* R. Br.⁴⁷³]
Setaria italica (L.) Beauv. (according to the *Satapatha Brahmana*)
Vitex negundo L.—indrasura (“Indra’s inebriating drink”)⁴⁷⁴

Plants that are referred to as soma in Sanskrit or another language

soma (Sanskrit):
 Eleusine coracana (L.) Gärt. [syn. *Cynosurus coracanus* L.]—African millet, finger millet
 Setaria glauca (L.) Beauv.
somlata (Nepali, “soma plant/moon plant”):
 Ephedra gerardiana
 somalata (Sanskrit):
 Caesalpinia bonduc (L.) Roxb.⁴⁷⁵
 Calotropis gigantea (L.) Dryander⁴⁷⁶
 Periploca aphylla Dene.
 Sarcostemma brevistigma W. et Arn. (also called soma)

somalutâ (Sanskrit):
 Ruta graveolens L.
somaraj (Hindi):
 Paederia scandens (Lour.) Merr. [syn. *Paederia foetida* L.] somarâñi:
 Vernonia anthelmintica (L.) Willd. [syn. *Serratula anthelmintica*, *Conyza anthelmintica*, *Centrathera anthelmintica*]

somatvak (Sanskrit):
 Acacia catechu (cf. ***Acacia spp.***)
somavalka (Sanskrit):
 Acacia polyantha (cf. ***Acacia spp.***)
somavalli (Sanskrit; Bengali: amrtavallî):
 Tinospora cordifolia (L.) Merr.⁴⁷⁷ [syn. *Menispermum glabrum*]—guduchi
 Cocculus cordifolius DC.
saumya/amsúmat (“rich in soma juice”):
 Desmodium gangeticum DC.⁴⁷⁸

Plants that are cultically or mythologically associated with soma

“brother of the great soma” (Shah 1994, 198*):
 Mucuna pruriens
 Limonia acidissima L. [syn. *Feronia limonia* (L.) Swingle, *Feronia elephantum* Corrêa]—elephant apple
palasha (flame of the forest, parrot tree):
 Butea monosperma (Lam.) Kuntze (Leguminosae) [syn. *Butea frondosa* Koen. ex Roxb.]

The palasa tree appears to have been a sacred tree even in the Vedic period. It is consecrated to the moon. Today, the tree is still associated in folklore with the divine soma drink (Gandhi and Singh 1991, 41*).

It has been suggested that an Asian species of horsetail (*Equisetum* sp.) may have been the soma plant. Horsetail, generally called *mu-ts’ê*, “wood thief,” was used in ancient China for polishing wood, rhinoceros horn, and ivory. (Illustration from Chi Han, *Nan-fang-ts’ao-mu chuang*, A.D. 304)

“One day Indra, the chief of the gods, felt a great thirst. The gods of his court asked the goddess Gayatri to go to the celestial mountain Mjavana where the Soma creeper grew and bring it back so that Indra would then have an uninterrupted supply of Soma forever after.

“Gayatri disguised herself as an eagle. She flew to the mountain and found it guarded by the sentries of the Moon. She swooped down and, in a trice, seized the creeper in her beak. Before the startled sentries could do anything she flew away, screeching triumphantly.

“One of the sentries, Krishanu, let fly an arrow at the bird. The arrow missed Gayatri but struck the vine. One of the leaves fell off and it fell to Earth and grew into the Palasa tree.”

AN EARLY INDO-ARYAN TALE

IN *BRAHMA’S HAIR*

(GANDHI AND SINGH 1989, 42*)

☐ In post-Vedic times, the sacred *peepal*, or bodhi tree (*Ficus religiosa*), was used as a soma substitute.

☐ Finger millet (*Eleusine coracana*) is still known by the name *soma* today; in Nepal, it is used to make beer and schnapps. (Millet field on the edge of the Kathmandu Valley, Nepal)

☐ The shrub *Calotropis gigantea* is called *somalata*, “soma plant,” in Sanskrit; whether it has psychoactive effects is unknown.

☐ Rue (*Ruta graveolens*) is called *somalutâ* in Sanskrit (and in several other languages) and is regarded as a possible ingredient in soma and perhaps haoma. Although the herb contains harmala alkaloids, no clear evidence of a psychoactive effect has been found.

“Inebriation is one of the inevitable effects of *mythos*. Cultures that no longer possess this are sober and burned out. The longing for a mythology is the drive for an inebriating drink, which excites the imbibor like soma, the divine inebriating drink of the Indian war and thunder god, who ingests it three times a day at the Brahmans’ sacrifices, and is consequently able to do his world-conquering deeds and is capable of presiding over the lightning bolt of the ancient god of heaven to open the path of victory for the campaigns of conquest of his chosen people, the Vedic Aryans.”

HEINRICH ZIMMER

ABENTEUER UND FAHRTEN DER SEELE [ADVENTURES AND TRAVELS OF THE SOUL]

(1987, 310)

Other authors, such as Terence McKenna (1996*), have speculated that the original soma plant was the magic mushroom ***Psilocybe cubensis*** (or another *Psilocybe* species), which grows abundantly on cow dung—and that this may be why cows are sacred in India. It has also been suggested that soma was made from a combination of ***Peganum harmala*** and ***Amanita muscaria*** or ***Psilocybe cubensis*** (cf. **ayahuasca analogs**). Of all of the candidates for soma that have been proposed, psilocybin mushrooms are the only psychoactive plants that produce effects like those in the fantastic descriptions of the Rig Veda:

Your juices, o purified Soma, all penetrating, as quick as thought, move of themselves like the descendents of quickly hurrying steeds; the heavenly, winged sweet-tasting juices, inciter of great cheer, radiant in the vessel. (Rig Veda 9)

Jonathan Ott has speculated that an Indian pharmacratic inquisition may have taken place during the post-Vedic period, with the result that the original visionary soma plant was replaced with a substitute that had only mildly stimulating or even placebo-like properties. We do know that in the post-Vedic period, the soma ritual was carried out with ***Cannabis indica*** and ***Ephedra gerardiana*** (O’Flaherty 1968). Other, nonactive plants were also used as substitutes (see table, page 793).

☐ The roots of the shrub *Desmodium gangeticum*, known in India by the name *salparni*, contain the psychoactive substances DMT and bufotenine. In Sanskrit, the plant is called *saumya*, “rich in soma juice.”

The sacred palasa tree, also known as “flame of the forest” (*Butea monosperma*), is closely connected to soma in mythology. (Wild plant, photographed in the Terai, Nepal)

A relatively recent theory suggests that ergot (*Claviceps spp.*) from an *Eleusine* species of grass was used as a substitute for soma (Greene 1993). Indeed, in western Bengal (India), a psychoactive use of *Paspalum* ergot (see *Claviceps paspali*) has continued into the present day.

In western India, the soma ritual in honor of Indra has been preserved in certain tribal rites (such as the *babo* ritual) into the present day (Jain n.d.). The Vedic fire ritual that was connected with the soma sacrifice has survived in India, eastern Asia, and even Japan (Staal 1983). The soma ritual is also thought to have served as the prototype for the kava ceremony of the South Pacific (see *Piper methysticum*).

Soma was likely nothing more than a catchall word, similar to the current words *drug*, *entheogen*, *psychedelic*, et cetera. Soma has become a symbol for the “perfect drug” (Huxley 1958).

The aura-soma therapy popular in esoteric circles has nothing to do with the Aryan soma but is a modern invention in which no psychoactive substances are used (Dalichow and Booth 1994).

The Asian medicinal plant *Bacopa monnieri* has been interpreted as soma. In Sanskrit, the plant is known as *sarasvati* (“that which flows”) and is named after the goddess of writers, artists, and poets. (Chinese illustration from the *Pen-t’sao-kang-Mu*, sixteenth century)

This Nepalese depiction of the somainebriated Indra, the god of thunder and of the heavens, shows him holding his thunderbolt (*vajra/dorje*) in his right hand. (Woodcut print from Shakya, *The Iconography of Nepalese Buddhism*, 1994, 63)

“Various drinks with somniferous and anodyne effects are mentioned in legends and reports from the past as well as from antiquity, and when one takes into account the ingredients used—in addition to mandrake, also opium, hemlock, Indian hemp, gall-nuts, as well as wine and other substances—one can believe that effects were indeed occasionally achieved with these. Indeed, we find confirmation for this assumption, for we hear of fatal incidents resulting from overdose when physicians used such mixtures.”

DETLEF RÜSTLER

ALTE CHIRURGIE [ANCIENT SURGERY] (1991, 77)

Soporific Sponge

Other Names

Spongia somnifera

In ancient times, herbalists and physicians searched for anesthetic agents that could be used during operations and in the treatment of wounds. Numerous psychoactive plants and their products were used in antiquity to anesthetize patients, including *Cannabis indica*, *Cannabis sativa*, *Conium maculatum*, *Hyoscyamus albus*, *Hyoscyamus muticus*, *Mandragora officinarum*, and *Papaver somniferum* (Grover 1965; Rüster 1991, 77 f.; Schmitz and Kuhlen 1989):

The use of narcotics during antiquity, for which henbane, Indian hemp, mandragora, opium, hemlock, and wine were the ones most often recommended, did not always revolve around the alleviation of pain but was also from time to time related to ritual customs and the attainment of states of inebriation. (Amberger-Lahrman 1988, 1)

As the early modern era began, the anesthetics used in medicine and surgery continued to be based primarily on opium (see *Papaver somniferum*) and henbane (*Hyoscyamus niger*) (Rüster 1991). *Atropa belladonna* was also used (Grover 1965). Henbane was apparently also used to sedate convicted criminals, for the oil that was pressed from it was known as “delinquent oil” (Arends 1935, 58*).

In the late Middle Ages and the early modern era, the most commonly used sedative that was also used as an anesthetic was the so-called soporific sponge. The recipes for soporific sponges tended to be relatively uniform (Brunn 1928; Kuhlen 1983) and were based upon the preparations of ninth- and tenth-century Islamic physicians (e.g., Rhazes). They were especially popular in the thirteenth, fourteenth, and fifteenth centuries. The primary ingredient was opium, to which mandrake roots (*Mandragora officinarum*) and henbane seeds (*Hyoscyamus niger*) were added. This mixture was kneaded in rose-hip juice (*Rosa canina* L.) and mixed with **wine** (cf. the fourteenth-century Roman Codex). The recipe for this narcotic is strongly reminiscent of that of the **witches’ ointments** of the early modern era as well as that of **theriac**. One recipe called for opium, juice pressed from mandrake leaves, hemlock, and henbane (Schmitz and Kuhlen 1989, 12). A twelfth-century recipe from Salerno used opium, henbane, poppy, mandrake, ivy (*Hedera helix*), mulberries, lettuce (*Lactuca virosa*), and hemlock (Brandt 1997, 41 ff.).

Soaked in wine, these mixtures were dripped onto a bath sponge (*Euspongia officinalis* L.), which was then inserted into the nostrils of the patient. The patient would then fall into a sleep filled with wild fantasies.

A number of authors have speculated that such soporific sponges were in use in ancient Jerusalem, and that the sponge dipped in vinegar that was offered to Jesus on the cross was actually one of these.

In the fifteenth and sixteenth centuries, there were still a number of *sedativa* and *anodyna specifica*, which are strongly reminiscent of the mixtures used to make soporific sponges. The physician and chemist Paracelsus (1493–1541) left such a recipe (cf. Schneider 1981):

2 drachmas opium thebaicum

1 half ounce cinnamon (*Cinnamomum verum* Presl)
1 pinch musk and ambergris
1 half ounce poppy seeds (*Papaver somniferum*)
1 half drachma mandrake roots (*Mandragora* sp.)
3 drachmas mastic resin (from *Pistacia lentiscus* L.)
1 drachma henbane juice (*Hyoscyamus niger*)

This mixture was later supplanted by laudanum, in particular *laudanum liquidum sydenhami*, which consisted of the following ingredients:

2 ounces opium
1 ounce saffron (*Crocus sativus*)
1 drachma cinnamon (*Cinnamomum verum*)
1 drachma cloves (*Syzygium aromaticum*)

These ingredients were digested in a pound of Malaga wine (Schmitz and Kuhlen 1989, 15). This agent was more of a psychoactive agent of pleasure than an anesthetic.

With this kind of medical treatment, it is easy to understand why powerful narcotics are needed. (Woodcut from Hans von Gersdorf, *Feldbuch der Wundartzney*, 1517)

The history of Western surgery is directly connected to the tradition of the narcotic sleeping sponge. (Woodcut, “The Wounded Man,” from Hans von Gersdorf, *Feldbuch der Wundartzney*, 1517)

Theriac

Because it was one of the main aromatic ingredients in theriac, angelica (*Angelica archangelica* L.) was once known as theriac spice or theriac herb. Angelica has no psychoactive activity. (Woodcut from the herbal of Matthiolus, 1627)

“I drink images: Theriac against death. How much longer?”

UWE DICK

THERIAK: 13 FÜGUNGEN [THERIAK: 13 STROKES OF FATE]

(1986, 47)

Vipers’ flesh was one of the basic ingredients in the ancient theriac mixtures. (Woodcut from Gesner, *Historia Animalium*, 1670)

Other Names

Deridek, electarium theriacale, electuarium theriaca, mithridatium, tary-_{ak}, tery-_ak (Iranian), theriaca, theriacum, theriak, theriakos, tiriaque, tyriacke

Toxicology, the science of poisons and the toxicity of substances, was established in ancient times. Because of the many murders by poisoning, at that time toxicology was focused primarily on the *antidoton*, “antidote.”

Antidotes are what physicians call those medicines that are not laid externally onto the body but are applied inside the body. Three general types of these can be distinguished: some are administered to counteract fatal poisons, others for so-called poisonous animals, the third is for ailments that occur as a result of a bad diet. Some, such as the so-called theriac, promise help in all three cases. (Galen, *De Antidotis* 1)

Theriac is the most renowned antidote of antiquity and was regarded as the “wonder drug of all wonder drugs” (Watson 1966). Theriac was developed by Andromachus, the personal physician of Emperor Nero (37–68 C.E.), and contained opium⁴⁷⁹ (***Papaver somniferum***) and vipers’ flesh along with various spices, roots, **honey**, and **wine**. At first, theriac was a further development of the so-called *mithridatium*, the antidote of the tyrannical king Mithridates of Pontos (132–63 B.C.E.). *Mithridatium* was formulated by the king himself, who, as a result of his public atrocities, was in constant fear of being poisoned.

According to Celsus (5.23, 3), *mithridatium* consisted of costus (*Costus* sp.), calamus (***Acorus calamus***), St. John’s wort, gum arabic, *Sapapenum*, acacia juice (***Acacia* spp.**), Illyric iris, cardamom, anise, Gallic spikenard, gentian root, dried rose leaves, poppy juice (= opium), parsley (***Petroselinum crispum***), cassia cinnamon (*Cinnamomum cassia*), sil, bearded darnel (***Lolium temulentum***), long pepper (see ***Piper* spp.**), storax, castoreum, turis, *Hypocistis* juice, myrrh, opopanax, malabathron leaves, flowers of the round rush, terebinth resin, galbanum, Cretan carrot seeds, spikenard, opobalsam, shepherd’s purse, rhubarb root (*Rheum* sp.), saffron (***Crocus sativus***), ginger (***Zingiber***

officinale), and cinnamon (*Cinnamomum verum*). In other words, it contained a number of psychoactive plants.

The recipes for theriac and *mithridatium* were later refined by Arabic physicians (Steinschneider 1971). But alongside the approximately sixty additional ingredients, the primary constituent was always opium. Among the other important ingredients were theriac spice (*Angelica archangelica* L. [syn. *Archangelica officinalis* Hoffm.]) and theriac root (***Valeriana officinalis***), as well as carrot seeds (***Daucus carota***).

Theriaks were increasingly employed (with quite differing degrees of success) to treat all manner of diseases, from the pervasive syphilis to the plague. The opium that was needed to prepare these panaceas was imported mainly from Egypt, whereby Venice acquired a central significance as the primary harbor of transshipment. As the demand for the drug grew, the price rose as well, so that opium was often “stretched” with foreign admixtures. Since the Venetian dealers generally received the drug in an as yet unsullied state, the theriaks of the Serenissima soon became the most preferred. In Germany, the city of Nuremberg gained a similar reputation, and it continued to be one of the European market leaders in the production of theriac into the eighteenth century. In order to demonstrate the good quality of the ingredients, theriaks were often mixed together in the marketplace during a folk festival. (Kupfer 1996a, 27*)

After the work of Andromachus, Galen, and the Arabic physicians of the Middle Ages, there were numerous recipes for preparing theriac. All of them listed **honey**, **wine**, bread (?), vipers’ flesh, opium, and spices as their most important ingredients. These mixtures even found their way into modern pharmacopoeias (*electuarium theriaca con opii*). Ultimately, theriac gave rise to the so-called elixir of long life and to Swedish bitters (Treben 1980, 60). At first, both of these products also contained opium. It was only during the time of the “drug wars” that opium was banished from these recipes. Cynical tongues have suggested that this step resulted in the removal of the only truly active constituent in these elixirs.

Wine

Other Names

Ju, khamr (Arabic, “inebriating”), oinos, *sdh*, vin, vinho, vino, wein

The term *wine* is generally used to refer to alcoholic products that through the action of yeast are fermented from undiluted fruit juices or, less frequently, bleeding sap (**palm wine**). The alcohol content is between 8 and 14% by volume and is thus significantly higher than in other fermented drinks (**balche’**, **beer**, **chicha**). The term *wine* is often construed as the product made from pressed grapes (*Vitis vinifera*), while the products fermented from garden or wild fruit juices are usually referred to by the name *fruit wines*. Wines can also be distilled, thereby yielding a corresponding variety of spirits (cf. **alcohol**). Winemaking was invented in many places around the world. All wines are well suited for use as solvents for other psychoactive ingredients.

It is possible that the Egyptians knew of a winelike drink containing mandrake that was called *sdh* (cf. *Mandragora officinarum*). Apparently, vintners produced it not from grapes (*Vitis vinifera*) but from pomegranate juice (*Punica granatum* L.). The texts describe the *sdh* drink as more inebriating than wine. It was praised in love songs as an aphrodisiac and was a popular libation (Cranach 1981, 266*). Many Egyptian drinking vessels were patterned after the lotus flower. In the pyramid texts, the lotus is mentioned together with the *sdh* drink. The two most important symbolic plants in Egyptian art and iconography are the lotus (*Nymphaea caerulea*, *Nymphaea lotus*) and the mandrake. In order to maintain the harmonic balance between the symbolic pair of lotus and mandrake, any drink that contained mandrake would theoretically need to be consumed from a lotus-shaped vessel.

In Scandinavia, bilberries (*Empetrum nigrum* L., *Vaccinium uliginosum*) were used to make inebriating wines. In northern Eurasia, birch sap (the bleeding sap that is produced when the bark is injured, usually from *Betula alba* L.) was fermented to produce alcoholic beverages (Hartwich 1911, 764 ff.*).

The stems of various rhubarb species can also be pressed to make wine. In fact, it has been speculated that **soma** was a kind of rhubarb wine.

Often, pressed fruit juices (e.g., from *Berberis vulgaris* L.) were mixed with **honey** to produce wines with a higher alcohol content. Honey was added to quince juice (*Cydonia vulgaris* L.; cf. *Erythroxylum coca*) in ancient times (Hartwich 1911, 760*).

In England, many people make fruit wine at home. Although wild fruits are preferred, almost any kind of fruit can be used for this purpose. A “counterculture” psychedelic wine is made from the fresh-pressed juice of forest berries (e.g., blackberries) and *Psilocybe semilanceata*.

In Chihuahua (Mexico), wines are made from the fruits of various yucca species (Havard 1896, 37*). Mexican Indians also ferment the juice of the fruits of *Opuntia tuna* Mill. and *Opuntia ficusindica* Haw. to produce a pink-colored wine known as *colonche*, the taste of which is similar to that of cider or apple wine (Havard 1986, 36 f.*). Because **mescaline** is present in *Opuntia*, it is possible that wines fermented from these fruits contain traces of the alkaloid. Pineapple juice (*Ananas comosus* [L.] Merr., *Ananas nanus* [L.B. Sm.] L.B. Sm.) can be made into a wine that is called *matzaoctli* in Nahuatl; it is produced and consumed primarily in Mazatlán, the “land of pineapples” (Bruman 1940, 148*).

In South America, a so-called *vino de cebil* (“cebil wine”) with presumably psychedelic activity was

or is brewed from the seeds/fruits of *Anadenanthera colubrina* var. *cebil*. Unfortunately, no recipes are known. In Chile, the Indians used maqui fruits (*Aristotelia maqui* l’Herit.) to prepare a “pleasant-tasting wine” called *tecu* (Hartwich 1911, 762*).

Wine is pressed from many different palm fruits, for example, from the fruits of the betel nut palm (*Areca catechu*) and the fruits of the saw palmetto (*Serenoa repens* [Bartr.] Small [syn. *Sabal serrulata* Michx., *Serenoa serrulata* (Michx.) Nichols.]; cf. **palm wine**). Saw palmetto wine has aphrodisiac effects in addition to the inebriating effects of alcohol. In phytotherapy and homeopathy, saw palmetto fruits are considered to be aphrodisiacs (cf. *Turnera diffusa*). They also have beneficial effects on benign prostate hyperplasia (Metzker et al. 1996).

The Australian Aborigines make fruit wines from *Pandanus spiralis* R. Br. (cf. *Pandanus spp.*), *Banksia* species, *Hakea* species, and a *Xanthorrhoea* species that are known respectively as pandanus wine, banksia wine, hakea wine, and grass tree wine (Bock 1994, 147*). The banksia wine is actually a kind of **beer** (Low 1990, 189*). The sap of *Eucalyptus gunnii* (cider gum), which collects in hollows of the trunk when the tree is injured, ferments more or less on its own, yielding a potently inebriating wine (Low 1990, 189*).

A wine can be made simply by allowing the fruits of the prickly pear (*Opuntia phaeacantha*) to ferment.

“This morning how grand is the space! Without bridle or spurs, in our haste Let us set out by horseback on wine, For the heavens—enchanted, divine!”

CHARLES BAUDELAIRE

“THE LOVERS’ WINE”

IN *LES FLEURS DU MAL* [THE FLOWERS OF EVIL] (1857)
(1993, 225*)

“Drunkenness, however, is that state of ecstasy in which one can leave reality and open oneself up to the supernatural.”

JEAN MARKALE *THE DRUIDS* (1999, 174*)

The stems of rhubarb (*Rheum officinale* Baill., *Rheum palmatum* L.), a plant originally from Tibet, not only are eaten as a gruel but also can be fermented into wine. The roots (rhei radix) have medicinal qualities and are used in laxative and diet teas. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Brazilian Indians esteem the fruits of the cashew tree (*Anacardium occidentale*), especially for their role in the production of inebriating winelike drinks. (Copperplate engraving from Meister, *Der Orientalisch-Indianische Kunst- und Lustgärtner*, [The Oriental-Indian Art and Pleasure Gardener] 1677)

For many connoisseurs, wine is a presentiment of paradisiacal joys. And sometimes even more: this Swiss label portrays the grape vine as the tree of knowledge.

Witches' Ointments

The famous witches' or flying brooms are said to have been made from birch brush. The witches' ointments were supposedly smeared onto the handle, which was then used as a dildo. The use of birch is interesting; in northern Eurasia, birch (*Betula* spp.) represents the shamanic world tree and is both culturally and biologically associated with the fly agaric mushroom. (Woodcut from Bock, *Kreutterbuch*, 1577)

One of the few depictions of a witch smearing herself with the flying ointment, after which she immediately flies out of the chimney. (Woodcut, early sixteenth century)

Other Names

Buhlsalbe, demon salve, flugsalbe, flying ointment, hexensalbe, hexenschmiere, oyntment, schlafsalbe, sleeping ointment, unguenta somnifera, unguenti sabbati, unguentum pharelis, unguentum populi

The famous “witches’ ointments,” that is, the substances alleged witches used to undertake their nocturnal “excursions,” were not an invention of the Inquisition, for they had already been mentioned in ancient texts (Luck 1962). The first mention of a “flying ointment” comes from Homer, the father of poetry: Hera smears herself with ambrosia in order to reach Zeus on Mount Ida by flying down from Mount Olympus and over Thrace’s snowcapped mountains, “over the highest peak, without ever touching the ground.” Zeus is profoundly amazed at how quickly she was able to make the journey without horse and wagon (*Iliad* 2.14.169 ff.). The most famous picaresque novel of late antiquity, the *Metamorphosis* (= *The Golden Ass*) of Apuleius (second century C.E.), includes a well-known reference to a witches’ ointment. The hero, Lucius, reports on the magical practices and witchcraft of the inhabitants of Thessalia, “the world-renowned home of magic” (Apuleius 2). According to his reports, the Thessalian witches knew how to bring mandrake manikins (cf. *Mandragora officinarum*) to life so that they could send them out and cause harm according to their wishes. They were also able to change their shapes and travel wherever they desired:

First Pamphile completely stripped herself; then she opened a chest and took out a number of small boxes. From one of these she removed the lid and scooped out some ointment, which she rubbed between her hands for a long time before smearing herself with it all over from head to foot. Then there was a long muttered address to the lamp during which she shook her arms with a fluttering motion. As they gently flapped up and down there appeared on them a soft fluff, then a growth of strong feathers; her nose hardened into a hooked beak, her feet contracted into talons—and Pamphile was an owl. (Apuleius 3.21)

Unfortunately, none of the ancient recipes has come down to us.

The medieval sources are silent on the topic. Only toward the end of the late Middle Ages was there speculation about witches’ ointments (Haage 1984), which were used variously to enable witches to fly or to transform them into animals (e.g., werewolves; cf. Leubscher 1950, Völker 1977). The

Renaissance not only rekindled an interest in the ancient world but also witnessed a revival in which all sorts of narcotic ointments with clear classical roots began to be used again in folk medicine and surgery (cf. **soporific sponge**; Piomelli and Pollio 1994).

Dr. Johannes Hartlieb (ca. 1400–1468) was the personal physician of the Wittelsbach dukes, writers, and diplomats. He not only left us one of the earliest German herbals (written around 1440; Werneck and Franz 1980) but also published the most important medieval source on the vestiges of the pagan world. Because he was a devoted Christian, he depicted the magical practices presented in his book *Das Buch aller verbotenen Künste* [The Book of All Forbidden Arts] (1456, originally titled *Das puoch aller verpoten kunst, ungelaubens und der zaubrey*) as reprehensible and dangerous.

Hartlieb was the first physician to write down a recipe for a witches' ointment, which can be found in chapter 32 of his book:

How the journey through the air occurs

In order to undertake such a journey, men and women, and in particular the fiends, use an ointment called *Unguentum pharelis*. It is made from seven herbs. Each of these herbs is picked exactly on the day to which it is assigned. Thus, they pick or dig up *solsequium* on Sunday, *lunaria* on Monday, *verbena* on Tuesday, *mercurialis* on Wednesday, *barba jovis* on Thursday, *capillus veneris* on Friday. From these they then prepare ointments by mixing in bird's blood and animal lard. But I will not describe this in detail, so that none will be corrupted by it. When they then wish, they smear this onto benches or chairs, rakes, or pitchforks, and fly away (on these). This is nothing other than nigromantie [= “black divination”⁴⁸⁰] and is strictly forbidden. (Hartlieb 1989a, 45)

It is not possible to make a definite botanical identification of the herbs that were associated with the days of the week (and the planetary gods). However, some of the names can be identified with plants that were called by the same name in the late Middle Ages.

It seems that this recipe from Johannes Hartlieb is more an agent of sympathetic magic than a psychoactive substance (cf. Biedermann 1974). That is, unless there are psychoactive ferns that have not yet been identified.

It appears that in the entire history of the witch hunts, only once was an ointment actually found that was successfully able to produce the effects attributed to it. When, in the year 1545, the duke of Lothringen lay in bed critically ill, a married couple was arrested and charged with having bewitched the duke. Both “confessed” to witchcraft while being stretched on the rack. During a subsequent search of their house, a container of ointment was found that was examined by Andrés de Laguna (1499–1560), the personal physician to the pope (cf. Rothman 1972). He recognized in the ointment *un cierto unguento verde como el del populeon* (“a certain green unguent like the poplar ointment”; cf. Vries 1991). Laguna speculated that the ointment contained *Cicuta* (hemlock), *Solanum* (?), *Hyoscyamus*, and *Mandragora* and tested it on the executioner's wife. She fell into a kind of coma or deep sleep that lasted for three days and complained irritably when she was pulled from her sleep, which had been filled with sweet dreams and erotic adventures.

For some Inquisitors, such as Pedro Ciruelo, it was clear that the alleged witches did not really fly to the sabbat but rather had hallucinatory experiences because of the ointment (Dinzelbacher 1995, 209).⁴⁸³

From the beginning, those who speculated about the nature of the witches' ointments—usually physicians of the early modern era (Vries 1991)—attributed the effects of the ointment to the presence

of plants from the Nightshade Family (Evans 1978; Fühner 1919; Harner 1973; cf. also Duerr 1978).

Johannes Wier (1515–1588), the personal physician of Duke Wilhelm von Jülich, discussed witches' ointments in his work (Weyer 1563) and cited a recipe for a witches' ointment from the book *De Subtilitate Rerum* by Hieronimus Cardanus (= Girolamo Cardano):

Ointments, which are said to have the power and the effect that one is able to see wondrous things because of them. These are prepared from children's fat, as they say, and celery juice, wolf's plant, tormentill, solano (night-shade), and soot. However, they are considered to be asleep because they see such things. But the things they see that widen their eyes are most often houses of pleasure, green gardens of delight, splendid meals, many and various decorations, pretty clothes, handsome youths, kings, lords, yes everything that they are anxious about and long for, they also mean nothing more than to enjoy such leisure and pleasure and to be made happy. But they also see the devil, ravens, dungeons, wastelands, and the hangman's or prosecutor's bag of tricks. . . . For this reason, the more strong is the conclusion that they are imagining that they travel through many far and strange lands, therein experiencing many different things, and also that the ointments described are not evil. (in Hauschild et al. 1979, 37)

In pagan times, the yew (*Taxus baccata*) was a sacred tree. Today, it is feared as poisonous. However, its red berries can be eaten without harm. According to folk tradition, one should not sleep beneath a yew tree, lest this lead to insanity and hallucinations.

Wier also described an “oil” that he invented himself that allegedly induces the exact same effects as those attributed to the witches' ointments. It consisted of:

This mixture was said to induce a long-lasting sleep with hallucinatory dreams. The English politician, philosopher, and author⁴⁸⁴ Francis Bacon (1561–1626) discussed the recipe of the Italian Cardano in his text *The Oyntment That Witches Use*. However, he misinterpreted the nature of the “soot,” replacing it with wheat flour. But soot almost certainly referred to grain smut (also known as grain soot) or even rye ergot (*Claviceps purpurea*). In addition, Bacon conjectured that the New World plants tobacco (cf. *Nicotiana tabacum* and *Hyoscyamus spp.*) and thorn apple (*Datura stramonium*) were suitable ingredients.

Paracelsus was also said to be knowledgeable about witches' ointments and other magical substances (cf. **soporific sponge**, *Papaver somniferum*). Johannes Praetorius (1630–1680) mentioned this in his book, which first appeared in 1668:

Paracelsus reported that the witches made their witches' ointments from the flesh of young, newborn children. They cooked them like a mush, together with herbs that cause sleep, such as poppy, nightshades, chicory, hemlock, and such. When the witches then smeared themselves with the ointment and uttered the following words: up and out, and off to nowhere, then in his opinion they believed that they could travel away through the fire walls, the windows, and through other small holes with the help of the devil. (Praetorius 1979, 40)

Hoffmann (1660–1742), a chemist from Halle (Germany), placed the yew (*Taxus baccata* L.),⁴⁸⁵ which is considered to be poisonous, alongside the nightshades and opium as ingredients in “sleeping ointments.” The Germanic peoples regarded the yew as a magical tree, and it was one of the rune

names (*eihwaz*). It is entirely possible that the yew does have psychoactive properties (cf. **kinnikinnick**). During a witchcraft trial in 1758, a witches’ ointment was said to contain the following ingredients: “mandrake root, henbane seeds, nightshade berries, opium juice” (Grünther 1992, 24). That this document lists other ingredients than the fat of a child is a complete exception to the standard recipes that were presented at witch trials.

Speculative recipes continued to appear in the literature of the nineteenth century. In one of his tales of witches, Ludwig Bechstein (1801–1860), the Romantic compiler of fairy tales, mentions the ointment of a weather witch that consisted of marsh violet (*Pinguicula vulgaris* L.), bewitching herb (possibly *Conyza* sp.), agrimony (*Agrimonia eupatoria* L.), black horehound (*Ballota nigra* L.), and devil’s bit scabious (*Scabiosa succisa* L. [syn. *Succisa pratensis* Moench]); the mixture was rubbed onto the arms (Bechstein 1985, 255).

The idea that the fly agaric mushroom (see ***Amanita muscaria***) might have been an ingredient in witches’ ointments is a twentieth-century notion. Another recent assumption is that the witches’ ointments were applied vaginally or rectally using a “witches’ broom,” a kind of dildo.

It was only toward the close of the nineteenth century that several brave individuals actually began to prepare and try the recipes that had been passed down. One of these was the esoteric scholar Carl Kiesewetter (1854–1895). After a number of seemingly successful experiments, he appears to have died as a result of a careless overdose. The spectacular and often cited report of Wilhelm Mrsich is probably more a literary product than an actual human pharmacological experiment, for he intentionally divulged no recipes (Mrsich 1978).

The only self-experiment that appears to have been authentic (using Portas’s recipe) seems to have been that of the German folklorist Will-Erich Peukert (1895–1969):

We had wild dreams. At first, horribly distorted faces danced before my eyes. Then I suddenly had the feeling [that] I was flying through the air for miles. The flight was repeatedly interrupted by deep dives. In the closing phase, there was an image of an orgiastic party with grotesque sensual excesses. (Peukert 1960)

The experiences of Siegbert Ferkel, cited in Marzell’s book (1964, 48*), also appear to be authentic. Hanscarl Leuner undertook a self-experiment but did not experience any effects (Leuner 1981, 67*). Most of the authors who have published works on witches’ ointments in recent years (e.g., Duerr, Grünther, Hansen, Harner, Kuhlen, vom Scheidt, Vries, Yilmaz) have been unable to report on any personal experiences. In contrast, the historian Walter Ulreich tried a homemade ointment of belladonna, poppy, hem-lock, “other herbs,” and pig fat; he too, however, did not meet with any success. The ride to the Blocksberg (a famous witches’ gathering place) did not occur (“On the Belladonna,” in *People in Motion*, Summer 1996, 66 f.).

Ingredients in the So-called Witches’ Ointments

☐

☐

☐

☐

The Romans called the white water lily (*Nymphaea alba*) Hercules' club. It was regarded as an aphrodisiac in late antiquity, while in the early modern era it was considered to be an ingredient in witches' ointments. Whether it has psychoactive effects like its Mexican and Egyptian relatives is unknown. It is conceivable that the plant could produce synergistic effects when combined with other substances.

The black hellebore or Christmas rose (*Helleborus niger*) has been associated with black magic and the preparation of witches' ointments since the Middle Ages.

Witches preparing an ointment to apply to a young novice (illustration from the magazine *Jugend* [Youth], 1926)

In the Middle Ages, vervain (*Verbena officinalis* L.) was a renowned magical plant that was used for magical protection and as an aphrodisiac. In the early modern era, it was thought to be one of the ingredients in witches' ointments. Vervain has no known psychoactive effects. The magical plant that classical texts refer to as *heira botane* ("sacred plant") has not yet been botanically identified. (Woodcut from Brunfels, *Contrafayt Kreuterbuch*, 1532)

"Tonight I rode far on my staff, and I now know things I did not know before."

FÓSTBROEDHARA SAGA (LATE THIRTEENTH CENTURY)

"She [the witch] knows no greater delight than mixing the body of God [= the host] into her filthy salves, to stuff it into her sexual organs and to season the rotten carrion of a defiled corpse with it."

STANISLAW PRZYBYSZEWKI *THE SYNAGOGUE OF SATAN* (2002, 30)

The pharmacognosy of witches' ointments is far from understood and represents a worthwhile area for human pharmacological research. Future researchers, however, must be willing to conduct self-experiments. Experimental research is also needed to determine whether the active constituents contained in the ingredients are actually able to be absorbed through the skin (cf. Grünther 1992, Waldvogel 1979).

The notion of hallucinogenic witches' ointments has produced a rich trove of prose literature. Here are just a few stories and novels of particular interest: Bechstein 1986; Delaney 1994; Görres 1948; Meyrink 1984, 179–186*; and Tieck 1988.

"In order to investigate the so-called witches' ointments, we must remind ourselves of the actual meaning of the natural sciences as an expansion of human consciousness, as a deepened insight into the nature of reality, into the unity of all living creatures, and the integration of humans in the bio-universe. When seen in this manner, the insights of the natural sciences into the microcosm and the macrocosm of objective reality, together with our subjective perceptions and our own mystical experience, could open the door to the spiritual world."

PATRICIA OCHSNER

ÜBER HEXENKULT, FLUGSALBEN AND HEXENKRÄUTER [ON THE WITCHES' CULT, FLYING OINTMENTS, AND WITCHES' HERBS]
(1997)

"Faces floated toward me from the darkness, first blurry and then taking on form. . . . I floated upward at great speed. It became light and through a pink veil I hazily recognized that I was floating over the city. The figures that had already oppressed me in my room accompanied me on this flight through the clouds. More and more of them joined me, and every minute lasted an eternity. The next

morning, as the first light came into my room, I thought I had awakened to a new life.”

SIEGBERT FERKEL, ON AN EXPERIENCE WITH A WITCHES’ OINTMENT
IN *ZAUBERPFLANZEN—HEXENTRÄNKE* [SPELL PLANTS— WITCHES’ DRINKS]
(MARZELL 1964, 48*)

Zombie Poison

“My first impression of the three ‘zombies,’ who apathetically continued with their work, was that there was something unnatural and strange about them. They appeared to do their work completely automatically, like robots, and held their heads so low that I would have had to bend down to see into their faces. . . . The worst thing was the eyes. No, it had nothing to do with my imagination. They were in truth the eyes of a corpse, not blind, but gazing rigidly into emptiness, without expression, lifeless, nonseeing. The entire face was like that, saying nothing, slack and empty. It appeared not just to be without expression, but to not even be capable of any expression at all. . . . These ‘zombies’ were nothing more than pitiable insane people, idiots, that were forced to perform heavy work in the fields.”

W. B. SEABROOK *GEHEIMNISVOLLE HAITI* [THE SECRET ISLAND]
(1931, 107, 108)

Other Names

Zombie powder, zombi poison

The voodoo cult (also called *vodou*, *vodun*, or *wodu*) is a syncretic system composed of elements of traditional Yoruba religion, early-modern-era Catholicism, and various influences from the magic of India, Native American concepts, and occult practices. The voodoo cult is practiced almost exclusively by the descendants of slaves brought to the New World from Africa and is centered in Haiti. Voodoo and other similar cults are also practiced on other Caribbean islands, in the southeastern United States, and in the northern areas of South America. Voodoo is a possession cult in which the participants individually or collectively enter into trance in order to have spiritual experiences, to heal, or to perform divinations (Planson 1975). Whether psychoactive substances play a significant part in this remains an open question (cf. **madzoka medicine**).

Although the zombie phenomenon is concentrated in Haiti, it is also known in Guadeloupe. Zombies, the “living dead,” were long regarded as the stuff of legend and dismissed as mere folklore (Metraux 1972). The fact that zombies have nothing to do with folklore but are a real phenomenon with a sociocultural background was first reported by Seabrook (1931), who even claimed to have encountered zombies.⁴⁸⁷ Zombies are not the resurrected dead but people who have been turned into the living dead (the process is known as zombification) by a poison known as zombie poison. Zombies are “in reality certainly individuals who have been artificially placed into a state of apparent death, buried, and then awakened and dug up, and are consequently as obedient as beasts of burden, as they must assume in good faith that they are dead” (Leiris 1978, 9). The earliest assumption was that the *bokors*,⁴⁹⁰ the voodoo sorcerers, used *Datura stramonium* to poison their victims. In Haiti and other Caribbean islands (e.g., Guadeloupe), *Datura* is called *concombre zombi*, “zombie cucumber.” In the Dominican Republic, the fruit of *Passiflora rubra* (cf. ***Passiflora* spp.**) is known as *pomme de liane zombie*, “the potato of the zombie liana” (von Reis and Lipp 1982, 197*). Other psychoactive substances have also been associated with zombification. One of the popular street names for PCP (= “angel dust”) is *zombie weed* (Linder et al. 1981, 10).

Ingredients in the Zombie Poison

(from Davis 1983b, 1988)

Guaiac wood (*Guaiacum officinale*) is regarded as an ingredient in the antidotes for zombie poison. Because of its resin content, the very hard and heavy wood is also used as an incense.

“If work was beautiful, then the rich would not have left it for the poor to do.”

HAITIAN SAYING

“The plantation and landowners had more or less smiled about it and claimed that zombies had simply been invented by the Danes, so that the fieldworkers would remain in their huts after the break of night and in this way would preserve the nocturnal peace and also minimize the damage from plundering the ripening harvest.”

HENRY S. WHITEHEAD

DER ZOMBIE [THE ZOMBIE] (1986, 8)

In the early 1980s, the American ethnobiologist Wade Davis was able to obtain in Haiti numerous samples of as well as the corresponding recipes for zombie poisons that were purportedly used for the zombification of humans (Davis 1983a, 1983b). The *bokors* prepare the poison and use it when a payment has been made. Surprisingly, the main ingredients of the recipes are plants and animals that produce psychoactive effects (see table, page 806). If possible, the zombie poison must be administered to the chosen victim through skin contact. Moreover, one “treatment” is usually not enough. Instead, the victim must come into repeated contact with the poison, often over a period of weeks, so that he will fall into a state of apparent death and can be buried and then dug up (Davis 1986). When the apparently “dead” victim is dug up, he is given an antidote that, so to speak, restores him to life. The antidote can also be used to protect a person from the poison (Davis 1983b).

The Effects of Zombie Poison

Davis has assumed that the primary active constituent in zombie poison is tetrodotoxin, a substance derived from the porcupine fish (*Diodon hystrix*). Although this substance can elicit states of apparent death, in higher concentrations it can induce actual death (Davis 1988). Tetrodotoxin ($C_{11}H_{17}N_3O_3$) is a neurotoxin and is one of the most poisonous, nonproteinaceous substances known, inducing complete neuromuscular paralysis. It is sixty times more potent than **strychnine** or D-tubocurarine (the active constituent in curare), and some five hundred to one thousand times more potent than hydrocyanic acid. For a man weighing 70 kilos, 0.5 mg of the pure substance can be fatal, and 20 g of the fish’s skin is lethal (Davis 1988, 145; Gage 1971). One piquant effect of tetrodotoxin is the occasional induction of apparent death with full consciousness, a condition that cannot be physiologically distinguished from true death, or only with extreme difficulty. As a result, many victims have been buried alive (Davis 1986, 1988).

However, Davis’s assumption that tetrodotoxin is the primary active constituent has been the subject of some contention (Anderson 1988). Though tetrodotoxin has been found to be present in the liver of the Caribbean porcupine fish, it was not detected in any of the samples of zombie poison that Davis was able to obtain (Yasumoto and Kao 1986).

Tetrodotoxin, a Potentially Psychoactive Substance

Japanese waters are home to a genus of pufferfish (*Fugu* spp.), known as fugu, that is prized in Japanese cuisine. Fugu, however, has one small drawback: it contains tetrodotoxin. Fugu was

mentioned in the oldest Chinese herbal, the *Pên's'ao Ching*. As early as the Han dynasty (202 B.C.E.–220 C.E.), the poison was known to be present in fugu liver. The poison is also present in the fish's skin, ovaries, and viscera. The poison immediately attacks the tongue and the viscera. Fugu poisoning was regarded as a disease for which there is no cure. Nevertheless, since at least 1596, these fish have been regarded as one of the most refined, expensive, and prized delicacies of Japanese cuisine. Fugu is “considered one of those rare delicacies that straddles the border between food and drug” (Davis 1986, 162). The following species are eaten in Japan:

Fugu rubripes rubripes Temminck et Schlegel

Fugu paradalis Temminck et Schlegel

Fugu vermicularis prophyreus Temminck et Schlegel

Fugu vermicularis vermicularis Temminck et Schlegel

The art of preparing fugu, which in Japan requires an examination and a license, does not entail removing the poison from the fish but, rather, leaving a trace of the poison in the food. Usually only well-to-do businessmen and the women they have hired for the night are present in fugu restaurants. There are approximately two thousand licensed chefs and a similar number of specialty restaurants. A fugu dinner is expensive and can cost as much as \$300 to \$600 per person. The erotic meal is also risky. For fugu patrons, playing with death has an almost erotic allure, and a meal of fugu is the ultimate aesthetic experience. Fugu is extremely delicious and produces an incredible effect!

Chiri is fugu meat that has been cooked in a soup containing the poisonous viscera. As a result, it is impregnated with the poison and has become an inebriating, euphoric, and aphrodisiac drug (Davis 1988, 152). The effects are phenomenal. At first, a pleasant tingling runs up one's back and head and hairs seem to vibrate where they meet the skin. One becomes mentally alert, awake, and libidinous. The effects of the alcohol in **beer** or **sake** are suppressed (in a manner similar to the effect of **cocaine**). Slowly, all of one's muscles become filled with an enormous tension and erotic prickling. Streams of energy swirl around the spinal column. One feels completely electrified. The effects on the sacral ganglia are very clear. In a male, this stimulation quickly becomes noticeable as a hard erection. Sexual desires are amazingly heightened. After my own experience, I understand all too well that it is best to have a fugu dinner with a romantic companion. I have personally found fugu to be a powerful psychoactive aphrodisiac.

And thus, in the repressive and otherwise “drug-hostile” society of Japan (where possession of 1 g of hashish can be punishable by five years of prison), fugu is the only legal psychotropic substance apart from tea (*Camellia sinensis*), coffee (*Coffea arabica*), **alcohol**, and **nicotine**. Although fugu is clearly an inebriating drug, it has been spared the negative connotations normally associated with drugs because it is regarded as a food (and a delicacy).

“Chemistry is applied theology.”

TIMOTHY LEARY *POLITICS OF ECSTASY* (1982, 271*)

“Life is the convergence of mind and matter.”

GALAN O. SEID (11/1996)

“It is in fact a miracle, a secret of the world in the full light of the day, to experience how the prosaic alcoholic matter in a glass of wine dispels sadness and worries, how ether fumes or chloroform can cause a person to temporarily lose consciousness, how morphine can dull even the most severe pain, and how Veronal, Luminal, and other preparations help a sleepless person to find slumber. No philosopher, no medical doctor, and no chemist has ever solved these riddles, and it is not likely that they will be solved in the future either. Today, and in the centuries to come, we will have to be satisfied with collecting the most comprehensive, certain, and reliable knowledge possible that stems from experience with these substances. And indeed, man will investigate ever more precisely how the countless natural and synthetic substances affect human beings, which concentrations and methods of administration are the most useful, which aftereffects appear, and how such factors as age, physical constitution, race, sex, occupation, and state of health have to be taken into consideration, etc. We should not look down upon such experience-based knowledge, for it leads to healing success or at least to the elimination of the anguishing symptoms of disease—and for a compassionate human being, this is certainly a matter of greater importance than the most wonderful theory about the physical and mental processes.”

HERMANN RÖMPP *CHEMISCHE ZAUBERTRÄNKE* [CHEMICAL POTIONS] (1950, 7*)

Over the past two centuries, pharmaceutical and pharmacological research has recognized that it is not the plants themselves that produce the particular effects but the principles or active constituents that reside within them. But what *is* an active constituent? Active constituents are chemically uniform substances (molecules) that can be extracted from plants with the help of solvents and which cause an effect when ingested. They either occur in the form of oily substances (bases) or can be crystallized out as salts.

Jonathan Ott, a chemist of natural substances, once discussed the effects of plants and plant spirits with a shaman in the Amazon. Ott used the metaphor that modern chemistry had discovered that the spirit of a plant exists in the form of a crystal. This picture made sense to the traditional shaman, for whom crystals are gateways to another reality, a kind of crystallized consciousness.

However, experiences with plants and their active constituents have made it evident that the effects of the molecule or the so-called main active constituent are not necessarily identical to the effects of the plant that contains the substance (cf. Storl 1996a*, 1996b*). The pharmacological explanation for this fact is that most plants contain a mixture of active constituents, and it is the synergy among these that is responsible for the characteristic effects of that plant. A plant usually induces a broader spectrum of effects than is produced by its isolated components. In other words, a pure constituent is more specific in its action.

There are people who believe that only natural substances are capable of producing good or tolerable effects, and that synthesizing those same molecules alters their pharmacological behavior so they will not work as well as the natural molecules. However, neither the chemical nor the pharmacological perspectives provide support for this notion.

Many people believe that “new” molecules that have been artificially produced by chemists, such as LSD, MDMA, and ketamine, are not as good as compounds found in the natural world. It would be wise to remember, however, that a chemist is not really able to create artificial molecules. All he or she can do is to make use of the properties of substances so that a specific molecule can form. Moreover, simply because a molecule that was first produced in a laboratory was at the time unknown in nature does not mean that the molecule does not occur in some plant that has not yet been discovered or studied. For example, *N,N*-DMT was first synthesized in a laboratory and described as an artificial molecule. Later, it was discovered that this same molecule occurs naturally in plants, animals, and even humans. Valium (= **diazepam**) is regarded as the artificial drug par excellence and

feared as an addictive poison. Yet this substance, which was initially synthesized in a laboratory, has since been found to occur naturally in potatoes and cereal grains. It is quite likely that LSD, MDMA, and ketamine will soon be detected in psychoactive plants as well. Chemists are merely transformers of matter; they are not gods. All they do is apply a “divine law.”

Active Plant Constituents and Neurotransmitters

Neurotransmitters, also known as transmitters or chemical messengers, are substances that are released at presynaptic nerve endings (or axon terminals), cross the synaptic cleft, and induce changes at the postsynaptic membrane, i.e., the next neuron (Black 1993*; Snyder 1989*; Spitzer 1996*). In other words, they are a chemical message that is sent out at the end of one neuron and read by the next. The first neurotransmitters to be discovered were the endorphins, substances that are produced in the body itself (= endogenous) and act within the nervous system in the same manner as **morphine** and other related opiates. We now know that the purposeful activation of particular neurotransmitters can induce psychoactive experiences or altered states of consciousness that resemble or even correspond to those induced by active plant constituents:

Man is his own drug producer; he simply needs to relearn how to stimulate his endogenous drugs as he needs and desires. . . . Until now, the deliberate and targeted stimulation of endogenous drugs has been an unexplored territory in the field of biomedicine. But ritual healing cults and archaic methods of healing (shamanism, the voodoo cult, healing dances, yoga, meditation) include numerous elements for stimulating the production of endogenous drugs, although the participants of course are typically unaware of the biochemical background. (Zehentbauer 1992*)

In other words, the perspective offered by neurochemistry tells us that an alteration in a person's state of consciousness is always triggered by some type of drug, whether this is a neuro-transmitter produced by one's own body or one that comes from outside in the form of an active plant constituent: "Endogenous drugs can produce effects similar to those produced by exogenous 'miracle drugs' " (Zehentbauer 1992, 113*).

Most shamans, however, prefer to use "plant spirits" to produce the states they desire, for the ingestion of a psychoactive substance is the most reliable method for achieving a desired altered state of consciousness. Mushrooms, for example, are always dependable. Shamans have no time for techniques that work only on occasion.

Research into migraines has shed some light onto the relationship between neurotransmitters and hallucinations or visions. Migraines are frequently accompanied by hallucinations (phosphenes, abstract patterns, strange shapes) whose form and content are often indistinguishable from the hallucinations or perceptual changes induced by the active constituents of plants. The only real difference is that migraines are very painful, whereas the states of consciousness produced by plant constituents are usually euphoric and pleasant in nature.

Analogies between Exogenous and Endogenous Neurotransmitters

(from Perrine 1996*; Snyder 1989*; Zehentbauer 1992*; supplemented)

“Molecules are alive!—I believe that chemical compounds can teach us just as well as plants.”

DR. ALEXANDER T. SHULGIN ASK DR. SHULGIN ONLINE, DRUG INFORMATION WEB SITE OF THE CENTER FOR COGNITIVE LIBERTY AND ETHICS

(1/1996)

There is evidence that *all* natural neuro-transmitters may show significant changes during an attack of migraine. . . . We see changes in adrenalin, nor-adrenalin, acetylcholine, histamine; and, often prominently, in 5-hydroxy-tryptamine (or serotonin). (Sacks 1985, 193*)

All of these neurotransmitters have their analogs in psychoactive plants: **cocaine**, **scopolamine/atropine**, **mescaline**, histamine, **muscimol/ ibotenic acid**, **morphine**, **psilocybin**, and **psilocin**. This means that the ability to produce hallucinations and visions is a normal property of our nervous system. It apparently makes no difference whether these states are caused by endogenous neurotransmitters or by exogenous neurotransmitters, i.e., active plant constituents.

Several neurotransmitters that are vitally important in the human nervous system also occur in plants. Acetylcholine can be found in the scarlet runner bean (*Phaseolus coccineus* L. [syn. *Phaseolus multiflorus* Lam.]), in various mimosas (***Mimosa* spp.**), in *Albizia julibrissin* Durazz., and in peas (*Pisum sativum* L.), all members of the Family Leguminosae. Serotonin occurs in numerous plants and fungi (***Panaeolus subbalteatus***). Bananas (***Musa x sapientum***) and the orange root (*Hydrastis canadensis* L.; Ranunculaceae) contain norepinephrine.

Why plants produce and contain human neurotransmitters is unknown to the scientific community (Applewhite 1973*). For the shaman, on the other hand, the answer is clear: The active constituent, the plant spirit, is a messenger in the neural network of nature. Every human, like every plant and animal, is one of infinitely many neurons in the nervous system of Gaia. The active constituents found in plants are the neurotransmitters, the communication system, of living nature.

Some psychoactive constituents can be found in humans as well as in other animals and plants. **Morphine**, for example, occurs in cow's milk, in the human brain, and in poppy juice. **Bufotenine** has been detected in human urine, in the secretions of certain toads, and in many plants and fungi. In those cases in which an active constituent of a plant is not identical to an endogenous substance, it is analogous. In other words, the active constituent behaves within the human nervous system in the same way as the endogenous neurotransmitter, occupying the same specific receptors at the neural terminals. This is the only reason that plant active constituents can do what they do. Substances that are not identical or analogous to neurotransmitters appear to be unable to induce any psychoactive effects (laughing gas is an exception⁴⁹¹). Alcohol appears to affect neuro-transmission in a variety of ways.

For the shaman, it is of no importance whether one of his plant spirits affects serotonin transmission, the adrenergic system, or some other aspect of the nervous system. He can achieve the same effects—trance, ecstasy, and journeying to another world—with pharmacologically quite different substances. Adolf Dittrich (1996*) came to a similar conclusion when he was developing a phenomenology of altered states of consciousness based upon his experimental and empirical research. He found that states with very different etiologies can have the same content.

Neurotransmission provides but one perspective for explaining the occurrence of altered states of consciousness. And all pharmacological explanations are ultimately nothing more than models for understanding the mysterious play of our consciousness.

The Active Plant Constituents from A to Z

The following section discusses the most important active constituents and types of substances found in psychoactive plants. Particular attention is given to those substances that have acquired a significance as a psychoactive drug in a cultural setting or have played a key role in the history of pharmacology. This section will also enable the reader to locate plants that contain a particular agent or substances of a particular type (see the various tables).

The names of the substances are spelled as they are most commonly found in the popular literature and consequently will not always conform to the spelling accepted in the chemical literature. Indeed, inconsistencies in both spelling and nomenclature are not uncommon in this field.

A primary focus of this section is on the cultural significance of the different active plant constituents. For other information, the reader is referred to the chemical, pharmacological, and neurochemical literature (e.g., Du Quesne and Reeves 1982*; Ebel and Roth 1987*; *Hagers Handbuch der pharmazeutischen Praxis* [Hagers Handbook of Pharmaceutical Practice]; Hunnius 1975*; Inaba and Cohen 1993*; Lenson 1995*; Lin and Glennon 1994*; Ott 1993*; Perrine 1996*; *Römpp Chemielexikon* [Roempp's Dictionary of Chemistry]; Roth et al. 1994*; Seymour and Smith 1987*; Shulgin 1992*; and Wagner 1985*).

The groups or types of substances discussed below include: β -carbolines, β -phenethylamines, coumarins, diterpenes, ergot alkaloids, essential oils, indole alkaloids, opium alkaloids, tropane alkaloids, and withanolides. The following individual substances are treated in their own sections: atropine, bufotenine, caffeine, cocaine, codeine, cytisine, diazepam, ephedrine, 5-MeO-DMT, harmaline and harmine, ibogaine, ibotenic acid, mescaline, morphine, muscimol, nicotine, *N,N*-DMT, papaverine, psilocybin/psilocin, salvinorin A, scopolamine, scopoletin, strychnine, THC, and yohimbine.

The flowers of the linden tree contain sedative substances that bind to benzodiazepine receptors. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

The milky sap that oozes from scored poppy capsules thickens into raw opium when exposed to air. In 1805, German pharmacist Friedrich Sertürner became the first person in the history of pharmacology to extract a pure chemical constituent from opium. He named the alkaloid morphia (= morphine) after Morpheus, the ancient god of sleep.

Atropine

Other Names

Atropin, atropina, atropinum, atropium, DL-hyoscyamine, d,l-hyoscyaminum, DL-tropyltropate, (±)-hyoscyamine, 3α(1α*H*,5α*H*)-tropanyl-(*RS*)-tropate, tropintropate

Empirical formula: C₁₇H₂₃NO₃

Substance type: **tropane alkaloid**

Atropine was first isolated from the deadly night-shade (*Atropa belladonna*) in 1820 by Rudolph Brandes, who named the compound after the genus. Atropine is found in many plants of the Nightshade Family (including the genera *Atropa*, *Brugmansia*, *Datura*, *Hyoscyamus*, *Latua*, *Mandragora*). Atropine is chemically related to **cocaine** (Willstaedter 1889). It also is closely related to **scopolamine** and hyoscyamine. Hyoscyamine, which is present in many living plants, quickly racemizes into atropine when the raw drugs are dried or stored.

A therapeutic dosage is usually considered to be 1 mg. It is possible that 10 mg is lethal for children and babies, but not for adults:

Relatively high doses (10 mg atropine sulfate and above) have a stimulating effect on the central nervous system, affecting especially the cerebrum, diencephalon, and medulla oblongata. The arousal is followed by an anesthesia-like paralysis that can lead to coma and a fatal respiratory paralysis. (Roth et al. 1994, 945*)

The lethal oral dosage for an adult is approximately 100 mg (Roth et al. 1994, 765*).

The range of atropine's effects includes psychomotor agitation, excitation, constant repetition of a particular activity pattern, a need to talk, euphoria, crying spells, confused speech, hallucinations, spasms, delirium, flushing of the skin, drying of the mucous membranes, coma, unconsciousness, and heart arrhythmia (Roth et al. 1994, 945*). One particularly characteristic effect is a long-lasting dilation of the pupils (mydriasis). It is because of this effect that atropine has long been used in ophthalmology (Jürgens 1930). Atropine is also utilized as a component in certain anesthetics (in combination with **morphine**). Injections of atropine are often administered prior to surgery so that the mucous membranes will remain dry during the procedure and the patient will not choke on his or her own saliva. Atropine has also been used to treat asthma (Terray 1909).

When it is given orally, the typical effects of atropine (dry mouth, pupillary dilation, increased pulse rate) manifest about twice as strong as compared to intramuscular injection (Mirakhur 1978). Some of the atropine is excreted in the urine unchanged (Roth et al. 1994, 945*).

Atropine is an important antidote in cases of poisoning (overdoses) caused by the fungal toxin muscarine (cf. *Inocybe* spp.), *Digitalis purpurea*, hydrogen cyanide, opium (cf. *Papaver somniferum*), and **morphine** (Römpp 1995, 298*). Overdoses of atropine can be successfully treated with morphine.

Because of its unpleasant side effects (dryness of the mouth, difficulties in swallowing, disturbances in vision, confusion), atropine as a pure alkaloid has never acquired any cultural significance as a psychoactive substance. However, the medical literature does contain a few reports of "atropine addiction" (Flincker 1932).

Commercial Forms and Regulations

Atropine is available both as a pure substance and as atropine sulfate. Although regulated as a dangerous substance, it can be obtained with a prescription and is not included on any list of “narcotic drugs” (Koerner 1994, 1573*).

β-Carbolines

Other Names

Beta-carbolines, β-carbolines, βCs

β-carbolines are derived from the actual β-carbo-line (norharmane). They belong to the group of **indole alkaloids** and are closely related to tryptamines. They consist of an indole skeleton and various side chains.

The psychoactive effects of β-carbolines are due primarily to the harmala alkaloids **harmaline**, **harmine**, harmalol, harmane (1-methyl-β-carbo-line), and norharmane (β-carboline) (Naranjo 1967). The simpler (-carboline) alkaloids occur in numerous plants (Allen and Holmstedt 1980).

Many plants that produce psychoactive effects or are utilized for psychoactive purposes contain β-carbolines (including *Acacia* spp., *Arundo donax*, *Banisteriopsis caapi*, *Banisteriopsis* spp., *Mucuna pruriens*, *Papaver* spp., *Passiflora* spp., *Peganum harmala*, *Phalaris arundinacea*, *Phalaris* spp., *Psychotria* spp., *Strychnos* spp., *Viola* spp., *Tribulus terrestris*, and *Amanita muscaria*). These compounds are also present in tobacco smoke (cf. *Nicotiana tabacum*) and in many plants that are used traditionally to make **ayahuasca** or are now used as **ayahuasca analogs** (Schultes 1982).

Many β-carbolines occur as endogenous substances in animals and in humans, where they serve important functions in the nervous system (Bringmann et al. 1991). They appear to influence both moods and dreaming. It is likely that norharmane (β-carboline) occupies a specific β-carboline receptor. Harmane is the endogenous MAO (monoamine oxidase) inhibitor, suppressing MAO-A (Rommelspacher et al. 1991). This allows the endogenous **N,N-DMT** to persist for a longer duration and trigger visionary perceptions that manifest either as spontaneous visions during the waking state or as dreams while sleeping (Callaway et al. 1995).

The harmala alkaloids harmaline, harmine, harmane, and tetrahydroharmane are all MAO inhibitors that inhibit primarily MAO-A (Buckholtz and Bogan 1977; McIsaac and Estévez 1966).

In the presence of certain foods, MAO inhibitors are considered to be dangerous or even very dangerous. Tyramine, which is found in such foods as aged cheese, is especially hazardous. If it is not broken down by MAO, it can cause severe toxic effects to an organism. More-recent studies, however, have shown that the dangers have been greatly exaggerated in both the literature and “on the street.” Moreover, the amount of tyramine contained in most “dangerous” foods tends to be rather low (Berlin and Lecrubier 1996).

β-Phenethylamines

Other Names

β-phenethylamines, PEAs, 2-phenethylamines

β-phenethylamines are derivatives of phenethylamine (Shulgin 1979). The biogenic 2-phenethylamine (PEA) dilates the blood vessels in the brain and consequently can, under certain circumstances, cause headaches or migraines (cf. *Theobroma cacao*). The most well-known psychoactive β-phenethylamine is **mescaline**, a component of numerous cacti.

Many cacti (including *Gymnocactus* spp.⁴⁹² and *Opuntia* spp.) contain phenethylamines that are structurally very similar to mescaline but whose effects are practically unknown (West et al. 1974). It is quite possible that such substances as candicine (*Trichocereus* spp.), hordenine (*Ariocarpus* spp., *Opuntia clavata* Eng.; cf. Meyer et al. 1980 and Vanderveen et al. 1974), and macromerine (*Coryphantha* spp.) produce psychoactive effects when used at the appropriate dosages. This area still offers many opportunities for experimental human pharmacology (Heffter technique). Such experimentation could, for example, lead to a psychoactive use of the South American *Noto-cactus ottonis* (Lehm.) Berg. [syn. *Parodia ottonis*] (cf. Hecht 1995, 82), a cactus that is often found at places where cacti are sold, is very easy to grow, and contains hordenine (Shulgin 1995, 16*). The genus *Lobivia* also contains hordenine (Follas et al. 1977).

Hordenine and related substances (occasionally in high concentrations) are also found in other plants, such as the Himalayan Leguminosae *Desmodium tiliaefolium* G. Don (Ghosal and Srivastava 1973).

Numerous phenethylamines that have psychoactive effects (both empathogenic and/or psychedelic) have been synthesized (e.g., MDMA, MDA, MMDA, MDE, 2-CB, et cetera; cf. Shulgin and Shulgin 1991*).

PEA

Hordenine

MDMA

Notocactus ottonis, a cactus originally from eastern South America, contains the β-phenethylamine hordenine.

Numerous cacti, including this *Melocactus* species, contain phenethylamines, some of which have psychoactive properties. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Bufotenine

Other Names

Bufotenin, 5-hydroxy-*N,N*-dimethyltryptamine, 5-OH-DMT, mappin, *N,N*-dimethylserotonin, 3-[2-(dimethylamino)ethyl]-1H-indol-5-ol

Empirical formula: C₁₂H₁₆ON₂

Substance type: tryptamine (**indole alkaloid**)

Bufotenine was first isolated in 1893 from secretions of the common toad (*Bufo vulgaris* L.) (Shulgin 1981). In 1954, it was found in *Anadenanthera peregrina*. Bufotenine also occurs in the false death cap (*Amanita citrina* [Schaeff.] S.F. Gray) (Keup 1995, 11; Wieland and Motzel 1953) and in other members of the genus (cf. *Amanita pantherina*). Indeed, the symbolic relationship between toads and mushrooms is very interesting in this context (see *Amanita muscaria*). Bufotenine has also been found in *Anadenanthera colubrina* (*Piptadenia* spp.), *Arundo donax*, *Banisteriopsis* spp., *Mucuna pruriens*, and *Phragmites australis*. Bufotenine is a tryptamine derivative and is closely related to *N,N*-DMT, 5-MeO-DMT, and **psilocybin** and psilocin. Chemically, it is almost identical to melatonin (for more on melatonin, see Reiter and Robinson 1996).

Bufotenine has been detected in human urine on numerous occasions (Räisänen 1985) and thus we know that it is a natural substance that is metabolized in the human body. The molecule is very stable. Approximately 16 mg is considered to be an effective dosage. The pharmacology of the substance has been little studied.

The first report of the hallucinogenic effects of bufotenine was published by Fabling and Hawkins (1956), who tested the substance on prison inmates (probably against their will). This was followed by additional research with humans, including some studies in which the substance was tested under highly unethical conditions by being injected into patients in a closed psychiatric institution without their permission, or even against their will. The patients were administered overly high doses and also subjected to electroshocks and other procedures. In this setting, no visions were reported. It was concluded that bufotenine does not produce visions but has only toxic effects (Turner and Merlin 1959). Subsequent studies strengthened the theory that bufotenine should not be classified as a hallucinogen (Mandell and Morgan 1971). A more recent study using only one subject found no hallucinogenic effects, although changes in the emotional domain were observed (McLeod and Sitram 1985). Almost all of the reports have noted that the faces of the test subjects turned red or even purple (Fabling and Hawkins 1956). The belief that bufotenine is not a true psychedelic drug has persisted into the present day (e.g., Lyttle et al. 1996; this study, however, is not based on any personal experiments). In its pure form, bufotenine has never acquired any cultural significance as a psychoactive substance.

Bufotenine and *Bufo marinus*

Since ancient times, there have been numerous reports of toads being used to prepare love drinks and other witches' brews, and even **witches' ointments** (Degraaff 1991; Hirschberg 1988). Researchers (prematurely) dismissed such reports as fantasy. In China and Mesoamerica, there is good evidence

for the use of toads in magical brews. Chinese toad secretions (*ch'an su*) contain large amounts of bufotenine (Chen and Jensen 1929). In China and Japan, preparations containing bufotenine are sold as aphrodisiacs (Lewis 1989, 70).⁴⁹³

In Mesoamerica, the toad was regarded as a manifestation of the Earth Mother, for example, in the form of the Aztec earth goddess Tlatecuhtli (Furst 1972; 1974, 88*). In the region, toads (and frogs) are associated with the rain gods (*chac*) and rainmaking. The Tarahumara refer to toads as “powerful rainmakers.” The Olmecs—whose culture is thought to have been the first Meso-american civilization—depicted toads in their sacred art and probably used them as hallucinogens. An Olmec object made of green jade and shaped like a toad has been interpreted as a tray for **snuff powder** (Peterson 1990, 46*). In general, the toad was probably the most important Olmec deity (Furst 1981; Furst 1996*; Kennedy 1982; Taylor n.d.).

A cylindrical ceramic container (late Classic period) containing a *Bufo marinus* (cane toad) skeleton was found in Seibal, a Mayan ceremonial center. It may have been used as a vessel for drinking **balche'**. Hundreds of ritually interred cane toad skeletons were discovered in post-Classic Mayan ritual depots on the Caribbean island of Cozumel (Hamblin 1981; 1984, 53 ff.). A report from the colonial period indicates that toads were an ingredient in **balche'** or **chicha**. *Bufo marinus* is also an ingredient in **zombie poison**.

The secretions of *Bufo melanostictus* contain bufotenine. In traditional Chinese medicine, the crystallized raw drug obtained from these secretions is regarded as an excellent aphrodisiac.

Bufotenine

In Mesoamerica, *Bufo marinus* is known variously as *henhen* (Tzeltal; cf. Hunn 1977, 247), *bab* (Mayan), *äh báb* (Lacandon), and *tamazolin* (Aztec). Numerous stone sculptures of toads as well as some toad bones were discovered in the main temple (Templo Mayor) of the Aztecs (Ofrenda 23; Alvarez and Ocaña 1991, 117, 128). All of the finds suggest that *Bufo marinus* was used in rituals or had a cosmological significance. Today, some Mexican Indians still eat skinned toads, while their secretions are sold at Mexican *brujería* markets as a love powder. The toad itself is invoked as a love magic in magical prayers (*oración del sapo*). The toad’s mucus is rolled into little balls that are then rubbed behind the ear as an aphrodisiac. Many people in Mexico still wear toad-shaped amulets today; they may, for example, be made from amber or obsidian from Chiapas.

In the southern part of Veracruz, *curanderos* (“healers”) or *brujos* (“sorcerers”) still use a preparation of *Bufo marinus*. To prepare it, they capture and kill ten toads. The glands are removed and crushed to produce a paste, to which lime (probably slaked lime) and ashes from a botanically unidentified plant called *tamtwili* are added. The combination is then mixed in water and boiled until there is no more “bad smell” (usually all night long). The solution is then mixed with **chicha** (maize beer) and filtered. The remaining fluid is kneaded into maize dough, lime brine, and five kernels of sprouted maize, and the mixture is laid out in the sun for a few days so that it can ferment, after which it is dried over a fire. This product (*piedrecita*, “little rocks”) is then stored far away from any human dwellings. In earlier times, special huts were used to store this magical substance. For consumption, a few pieces are cut off, ground, and soaked in water. After the insoluble ingredients have settled, the solution is poured off and boiled for a considerable time until it gives off a certain odor. Today, the drink is no longer ingested collectively but is used by only one person at a time under the supervision of a *curandero*. The effects begin after approximately thirty minutes and are first manifested as an

increase in the pulse rate and a shaking of the muscles and limbs, followed by headaches and delirium. This state lasts three to five hours. In former times, the drinking of this brew was an important part of the initiation of boys into adulthood. Sacred songs were sung to the initiate while he was delirious. The initiate was told to allow the visions he was going to experience to impress themselves well upon him (Knab n.d.).

It appears that the hallucinogenic effects of *Bufo marinus* were also known in Argentina, for it is considered there to be one of the “temptations” of Saint Anthony (see *Claviceps purpurea*) (Rosemberg 1951).

Originally from the Americas, *Bufo marinus* was introduced to Australia, where it is now known as the cane toad and its secretions are allegedly used as a psychoactive drug. Under Queensland’s Drug Misuse Act, bufotenine is an illegal substance in Australia (Ingram 1988, 66). In recent years, the press has been reporting increasing cases of toad lickin’ (Lyttle 1993), a practice in which the secretions of *Bufo marinus* are licked off the toad:

When licking the expressed secretions (abusers reported that it is possible to “milk” twice a day), a furry sensation on the lips and tongue quickly becomes manifest. Five to ten (up to 30) minutes later, nausea is common, and only 20 to 30 minutes after ingestion, sometimes earlier, hallucinations of various kinds set in, beginning more rapidly and not lasting as long as with LSD. (Keup 1995, 12)

The thickened juice of boiled animals is also ingested in Australia (Keup 1995, 14). A decoction of the dried skin (known as cane skin tea) is also used (*Der Spiegel* 32 [1994]: 92).

The secretions from *Bufo marinus* contain catecholamines (dopamine, *N*-methyldopamine, adrenaline, noradrenaline) and tryptamines (serotonin, *N*-methyl-serotonin, bufotenine, bufotenidine, dehydrobufotenine), as well as glycoside-like toad toxins (Deulofeu and Rúveda 1971; Lyttle 1993, 523 f.). The skin has been found to contain **morphine**. The toad toxins (bufotoxine, bufogenine, and bufadienolides) are cardiotoxic and are similar to digitalis in their effects: nausea, vomiting, increase in blood pressure, confusion, and psychotic states (Keup 1995, 12). Smoking is probably the safest method to ingest *Bufo marinus* secretions, as the burning process apparently destroys the toxic components while leaving the bufotenine intact (Alexander Shulgin, pers. comm.). The ethnobotanist Brett Blosser smoked dried *Bufo marinus* secretions (approximately 1 mg every few minutes) and reported experiencing tryptamine-like hallucinations similar to those induced by the secretions of *Bufo alvarius* (cf. **5-MeO-DMT**) (B. Blosser, pers. comm.).

The few reports of the effects of smoked toad skin indicate that they are hallucinogenic. One Australian user stated, “I am seeing the world through the consciousness of a toad” (Lewis 1989, 71).

In traditional Chinese medicine, the secretions of various toads (*Bufo bufo gargarizans* Cantor, *Bufo melanostictus* Schneider) have long been used as remedies, tonics, and aphrodisiacs. Many of these secretions (*secretio bufonis*) contain the hallucinogenic constituent bufotenine. (Illustration from the *Ch’ung-hsiu cheng-ho pen-ts’ao*.)

The common toad (*Bufo bufo*) was sacred to the Germanic and Baltic peoples. Only with the introduction of Christianity was the toad demonized and declared to be an animal of the devil. The hallucinogenic substance bufotenine was isolated from its secretions. (Woodcut from Gessner, *Historia Animalium*, sixteenth century.)

“SMOKE IT! At the Police Department of Drugs in Brisbane [Australia] is a Heinz baby food can labeled ‘Venom cane toad,

hallucinogenic, bufotenine.’ Inside the can is a dry, flaky, crystalline, brown substance with an unpleasant odor. This substance comes from dried toad skin, which contains natural bufotenine. It can be broken into small pieces and smoked in a water pipe or a simple pipe. It is said to cause an intense hallucinogenic effect which lasts for several hours.”

STEPHANIE LEWIS *CANE TOADS: AN UNNATURAL HISTORY*
(1989, 70)

The active constituent bufotenine was first isolated from secretions of the common toad. The heathen tribes of the Baltic region venerated the toad as a goddess. It is possible that they were aware of the psychoactive effect of the toad’s secretions. (Illustration from 1912)

The title and cover art for the Australian rock music sampler *Toad Lickin’* alludes to a practice known in northeastern Australia in which hallucinogenic secretions are licked from toads. (CD cover, 1990)

The following species of toads contain significant amounts of bufotenine: *Bufo alvarius* (cf. **5-MeO-DMT**), *B. americanus*, *B. arenarum*, *B. bufo bufo*, *B. calamita*, *B. chilensis*, *B. crucifer*, *B. formosus*, *B. fowleri*, *B. paracnemis*, *B. viridis* (Deulofeu and Rúveda 1971, 483).

Commercial Forms and Regulations

Bufotenine is marketed as bufotenine hydrogen oxalate. In the United States, bufotenine is classified as a Schedule I drug (Shulgin 1981). In contrast, in Germany it is not considered a narcotic and is not illegal (Körner 1994, 1572*).

Caffeine

Other Names

Cafeina, caféina, caffeina, coffein, coffeinum, guaranin, koffein, methyltheobromin, methyltheobromine, 1,3,7-trimethyl-2,6(1*H*,3*H*)-purindion, 1,3,7-trimethylxanthine, thein, theine

Empirical formula: $C_8H_{10}N_4O_2$

Substance type: purine

Caffeine was first isolated from coffee beans (*Coffea arabica*) and named after the genus. However, this stimulating substance actually occurs in many plants (see the table on page 821). Caffeine has stimulating effects upon the central nervous system because it inhibits the enzyme phosphodiesterase, which inhibits the conversion of endogenous substances (cAMP into AMP). This stimulation is usually accompanied by an increase in heart activity, increased urgency of micturition, sensations of heat, and a rise in body temperature. Vasodilation in the brain dispels tiredness and perception becomes more acute. A normal effective dosage is about 100 mg (equal to approximately one cup of strongly brewed coffee). Undesirable side effects begin to appear at 300 mg unless one is used to this level of consumption. There have been repeated reports of “caffeine addiction” in the United States (Weil 1974). Overdoses of caffeine tend to be unpleasant in nature (cf. *Ilex guayusa*):

Acute caffeine poisoning causes inebriation-like states of excitation accompanied by ringing in the ears, headaches, dizziness, racing heart, muscle tension, insomnia, restlessness, confusion, deliria, cramps, urge to vomit, diarrhea, urgency of micturition. (Roth et al. 1994, 786*)

It has occasionally been suggested that *Catha edulis* contains caffeine, but this assumption has never been confirmed and can now actually be ruled out.

Caffeine is used medicinally to treat heart weakness, neuralgia, headaches, asthma, and hay fever and is also administered in homeopathic preparations. It is used as an antidote for poisonings and overdoses of **alcohol**, **nicotine**, **morphine**, and **THC**.

Commercial Forms and Regulations

Caffeine is available as a pure substance and as caffeine monohydrate. It is a legal substance.

Benzoyllecgoninmethylester, cocain, cocaïn, cocaina, d-cocain, erythroxylin, kokain, methylbenzoyllecgonine, methylbenzylekgonin, (±)-methyl-[3β-benzoyloxy-2α(1α*H*,5α*H*)-tropancarboxylate], O-benzoyl-[(−)-ekgonin]-methylester, 3-benzoyloxy-8-methyl-8-azabicyclo[3.2.1]octan-2-carboxylicacidmethylester, 3β-benzoyloxy-2β-tropancarboxylicacidmethylester

Street Names

Autobahn, blow, C, candy, charlie, coca, coca pura (Spanish, “pure coca”), coco, coke, cousin, donuts, doppelter espresso, flake, koks, la blanca, lady snow, la rubiecita, line, linie, mama coca, nasenpuder, nose candy, peach, perica, puro (Spanish, “pure”), schnee, schneewittchen, schniefe, schnupfschnee, sniff, snow, snowwhite, strasse, strässchen, Ziggy’s stardust

In the history of human culture, no other psychoactive plant constituent has had such an impact as cocaine. Because of its enormous cost, however, cocaine is consumed primarily in wealthier circles.

Empirical formula: $C_{17}H_{21}NO_4$

Substance type: coca alkaloid

The cocaine molecule is structurally related to tropine and other **tropane alkaloids** (Roth and Fenner 1988, 311*). Today, cocaine is the most consumed psychoactive plant constituent in the world. Pure cocaine (as a base) is not water soluble but can be dissolved in **alcohol**, chloroform, turpentine oil, olive oil, or acetone. Cocaine salts are water soluble.

History

In 1860, the German chemist Albert Niemann first isolated cocaine from the leaves of the Peruvian coca bush (***Erythroxylum coca***). The German pharmacist Friedrich Gaedeke (1855) may have represented the alkaloid before this. By around 1870, cocaine was being used as an agent of pleasure, and it was employed at this time to treat alcohol and morphine withdrawal as well as melancholy. The ophthalmologist Karl Koller, a friend of Sigmund Freud, introduced cocaine as a local anesthetic for eye surgery in 1884. Hermann Göring’s use of cocaine was famous, and Adolf Hitler, who also used other stimulants (cf. **strychnine**), is thought to have consumed cocaine as well (Phillips and Wynne 1980, 112).

Later, other substances derived from cocaine, including eucaine, procaine (= Novocaine), tetracaine (= Pantocaine) (1930), lidocaine (= Xylo-caine) (1944), mepivacaine (= Scandicaine) (1957), prilocain (= Xylonest) (1960), bupivacaine (1963), and etidocain (= Duranest) (1972), were also used as local anesthetics (Büsch and Rummel 1990; Schneider 1993, 19*). Holocaine was also regarded as a substitute.

The goal of chemists and pharmacologists to carve out the effective core of the cocaine

molecule and retain the desirable and remove the undesirable effects was achieved in an exemplary manner with the synthesis of procaine (1905). (Büsch and Rummel 1990, 490)

In 1923, Willstätter and his coworkers worked out the complete synthesis of cocaine. The precursors are succindialdehyde, methylamine, and mono-methyl- β -keto-glutarate. However, this synthesis has never achieved pharmaceutical importance. Practically speaking, all of the cocaine used in the pharmaceutical industry is derived from the coca plant. In 1976, 410 kg of cocaine were legally extracted for this purpose (Täschner and Richtberg 1982, 64).

Production and Use

An analysis of thirteen South American *Erythroxylum* species found that cocaine is present only in *Erythroxylum coca* and *Erythroxylum novogranatense* (Holmstedt et al. 1977). Hair analysis of Egyptian mummies has revealed the presence of ecgonin, the first metabolite of cocaine, which indicates that the ancient Egyptians either consumed cocaine or an unknown African plant that metabolizes to ecgonin (Balabanova et al. 1992*).

The coca plantations that are the source of cocaine are known as *cocales*. Bolivian *huanaco* leaves (*Erythroxylum coca* var. *coca*) are preferred for cocaine production because they are the highest yielding. With good chemicals and chemists, it is possible to produce 1 kg of pure cocaine from 100 kg of coca leaves. In the early 1980s, some 100 tons of pure cocaine were exported from Colombia alone.

The entire process of cocaine production, as well as the smuggling routes, the cartels, and everything from the connections between politicians and the cartels to the consumption of cocaine even by politicians in the White House, has been documented in countless reports on the radio and television and in magazines and well-researched books (Morales 1989). It is difficult to escape the impression that the cocaine saga is one of the best-known stories of our times but one that is officially ignored. Our leaders still act as though the Mafia is using the white powder to corrupt and dominate the world. In reality, the chief benefactors of the billion-dollar business are the banks and the countless politicians and law-enforcement personnel involved in the trade (Sauloy and Le Bonniec 1994).

Cocaine

“Cocaine-using policemen chase cocaine-using pimps away from cocaine-using whores visited by cocaine-using johns, while cocaine-using journalists report about it for their cocaine-using target audiences. I despise all of this: every time I find myself bending over a plate or a mirror with a bill in my nose, I quietly despise myself. When the line is in the brain, this contempt is washed away. When the line is in the brain, the mind becomes deaf and mute. When the line is in the brain, the character turns around.”

HELGE TIMMERBERG “KALTMACHER KOKAIN” [KILLER COCAINE]
(1996, 36)

The snuffing of crystallized cocaine appears to have been discovered in North America at the beginning of the twentieth century and spread from there. Shortly after 1900, pure cocaine was being ingested together with **betel** and lime in India, Ceylon (Sri Lanka), and Java. The use of cocaine as an athletic doping agent began in the 1940s (Fühner 1943, 195*). Little has changed since that time. Cocaine dealers still find some of their best customers in the soccer stars of the German first league and sports heroes in the United States.

Basuko is dried cocaine base (an intermediate step in the production of the pure alkaloid). *Sucito*,

or joints made of *basuko*, have been smoked in Colombia since about 1930 (Siegel 1982b, 274). Cocaine is usually produced as a hydrochloride but sometimes also as an oxalate or hypochloride (HCL). Street cocaine is almost exclusively cocaine HCL. Most of the illicit cocaine available in Europe is only about 30% pure, as the expensive pure drug is usually “cut.” The substances that are most commonly used to “cut” cocaine are:

- Inactive additives: milk sugar (lactose), grape sugar (glucose), baking powder, talc (talcum), borax, cornstarch, inositol, mannitol
- Active additives: speed (amphetamine, fenetyllin, ritalin) and “freeze” (novocaine, benzo-caine), PCP (“angel dust”), methedrine, pemoline, **yohimbine**, lidocaine, procaine, tetracaine, **caffeine**, quinine, heroin (Täschner and Richtberg 1982, 65; Voigt 1982, 84)

Dosage

A “line” of cocaine typically contains between 20 and 100 mg of cocaine, depending on the purity of the substance and the consumer’s preference. Many users consume between 2 and 3 g in a day or night. It is said that “the first line of the day is the best.”

Ritual Use

Cocaine has been called the champagne of drugs, the drug of high society, the drug of the rich, et cetera, and it is certainly most often associated with the wealthier classes. As a result, consumption of the drug has taken on a strong social character. Cocaine is rarely used by one person alone. When it is taken with others, the consumption follows a rather well-defined ritual. The person providing the costly substance lays out several lines (preferably on a mirror), then takes a currency note (often of high value) and rolls it up. One end of the rolled bill is placed in a nostril and held with one hand, while the other hand is used to press the other nostril closed. Half of one line, or a small line, is then snuffed into the nostril. The person then switches nostrils and snuffs the remaining powder, after which the mirror is passed to the next person. This circle may be repeated several time, and it is customary for each of several participants to prepare lines from their own supply.

Artifacts

The cultural significance of cocaine in the modern world cannot be overlooked. Artists, musicians, and writers use it as a stimulant, while highly paid computer experts, software engineers, and programmers would hardly be able to keep up with the demands of their jobs without their “coke.” Stockbrokers, financial gurus, and election staffers may use cocaine until they are ready to collapse. Even some of the soccer stars who jog into the stadium sporting T-shirts with such incongruous imprints as “Keine Macht den Drogen” (“No Power to Drugs”) are high as a kite on cocaine. According to several estimates, the highest per capita consumption of cocaine is found in Silicon Valley and on Wall Street.

The first literary treatment of cocaine is found in the Sherlock Holmes novel *A Scandal in Bohemia*, by Sir Arthur Conan Doyle, published only two years after Koller’s discovery (Phillips and Wynne 1980, 45). In this book, the astonishing abilities of this brilliant detective are attributed in part to his use of cocaine. By the time of the following novel, *The Sign of the Four*, Sherlock Holmes is injecting the pure alkaloid intravenously (Voigt 1982, 38).

The most famous novel of the British writer Robert Louis Stevenson, *Dr. Jekyll and Mr. Hyde*, was written in only four or six days and nights—with the assistance of the magic powder, of course (Springer 1989, 8; Voigt 1982, 38).

The novellas of the expressionist poet Walter Rheiner (1895–1925), in which he referred to the drug as “the eternal poison” and “the loved and hated poison,” played a great role in shaping the image of demonic seduction by pharmaceutical cocaine (Rheiner 1979).

At the beginning of the twentieth century, the physician Gottfried Benn (1886–1956) wrote and published numerous poems about cocaine (of which he was very fond) that at the time were deemed rather shocking (Benn 1982; vom Scheidt 1981, 401). Many other authors have also been inspired by cocaine, including Georg Trakl, Thomas Zweifel, Josef Maria Frank Fritz von Ostini, Klaus Mann, and Jean Cocteau (Springer 1989).

Cocaine is also the subject of many novels. The classic cocaine novel, *Cocaine*, was written by Pitigrilli (= Dino Sergè, 1927). The drug has often been treated within its current criminal context (Bädekerl 1983; Fauser 1983), while other novels have been written from a futuristic perspective (Boye 1986). The “coke scene” has also provided a rich source of literary inspiration (McInerney 1984; Ellis 1986).

The famous novel *Cocaine*, penned by the Italian author Pitigrilli (a pseudonym), is a literary cocaine hallucination that continues to influence the literature inspired by cocaine in the present day. (Cover of an American edition)

“Now look! The shivering stars stand still again, just for a moment.—Sacred poison! Sacred poison!—Tobias sensed and saw the demon standing far above the night sky, as familiar as it was terrifying. He knew and whispered up to the sky: *You are death, mercy and life. You have no god beside you.*”

WALTER RHEINER *KOKAIN* [COCAINE] (1918)

“Cocaine”

“The decomposition of the Self,—how sweet, how deeply desired.

You grant it to me: already my throat is raw,
already the foreign sound has reached
unspoken structures at the foundation of my Self.

“No longer bearing the sword that was born from the mother’s womb.
to fulfill a task here and there
To hit with steely might—: sunken into the heath,
where hills give rest to barely hidden forms!

“A tranquil smoothness, a little something.
There—
And now for the space of a breath
the primordial rises, condensed.
Not-his quake brain showers of mellow impermanence.

“Blasted Self—oh quenched ulcer—
dispersed fevers—sweetly destroyed defense:—
Flow out, flow out!—give birth
with bloodied womb
to the deformed.”

GOTTFRIED BENN *DER PSYCHIATER* [THE PSYCHIATRIST]
(1917)

The composer Richard Strauss (1864–1949) wrote his opera *Arabella* while under the influence of cocaine (Springer 1989, 8; Timmerberg 1996).⁴⁹⁶ Countless compositions have had cocaine as their subject, including *Cocaine Lil*, for a mezzo-soprano and four female jazz singers, by the contemporary composer Nancy van de Vate (CD Ensemble Belcanto, Koch, 1994). From the 1920s to the 1940s, the white powder fueled the work of especially jazz and blues musicians, and Chick Webb,

Luke Jordan, and Dick Justice even gave it a musical treatment (“Cocaine Blues”).

Veritable blizzards of cocaine have passed through the brains of many of rock music’s greats, who then set their experiences with the “fuel” to music. A few examples are Country Joe McDonald (“Cocaine”), Black Sabbath (“Snowblind”), Little Feat (“Sailin’ Shoes”), the Rolling Stones (“Let It Bleed”), Jackson Browne (“Cocaine”), and David Bowie (“Ziggy Stardust”).

The “hippie” band known as the Grateful Dead sang about the white powder in their song “Truckin’,” one of their few hits to make it onto the charts. Eric Clapton’s interpretation of J. J. Cale’s song “Cocaine” became a worldwide success and has been played millions of times over. The reggae artist Dillinger released an album named *Cocaine*. The drug also left its mark on the German music scene, influencing or even appearing in the music of Hannes Wader, Konstantin Wecker, Abi Ofarim, and T’MA a.k.a. Falco (“Mutter, der Mann mit dem Koks ist da” [“Mother, the Man with the Coke Is Here”]; BMG Records 1995).

Cocaine has been the subject of at least one theater work: The American playwright Pendleton King wrote a piece entitled *Cocaine* that was produced for the stage in 1917 (Phillips and Wynne 1980, 93 ff.).

Medicinal Use

The medicinal applications of cocaine were discovered only a short time after the isolation of the molecule itself. Cocaine was initially used for local anesthesia⁴⁹⁷ in ophthalmology and dentistry, and infiltration anesthesia was developed just a few years later (Custer 1898). Because analogs (e.g., procaine) were developed that produce specific effects with no psychoactive side effects, cocaine is rarely used as an anesthetic today.

Pharmacology and Effects

Cocaine stimulates the central nervous system, especially the autonomic (sympathetic) system, where it inhibits the reuptake of the neurotransmitters noradrenaline, dopamine, and serotonin and increases the time in which they remain in the synaptic cleft. Cocaine has a powerful effect upon the peripheral nervous system, which explains its efficaciousness as a local anesthetic. It has strong stimulant and vasoconstricting properties. Very high dosages of cocaine are said to be able to induce hallucinations, an effect that is frequently noted in the neurological literature (Pulvirenti and Koob 1996, 49) as well as in prose and poetry (Rheiner 1979, 27). Hallucinations (of nonexistent people, images, flickering lights) often occur during nights in which dosages of 2 to 3 g have been taken. For many people, cocaine also dispels fear. It stimulates a need for alcoholic beverages at the same time that it strongly suppresses the effects of **alcohol**. A similar dynamic applies to **nicotine**.

In a certain sense, there is something unsatisfying about the effects of cocaine. A person may sense that satisfaction could be achieved if the effects could possibly be increased. However, using more cocaine does not produce an enhancement of its effects.

Just as coca was and is employed in South America as an aphrodisiac, cocaine has a similar use in the West. Cocaine’s reputation as an aphrodisiac can be traced back to Sigmund Freud (1884) and has been repeatedly confirmed in the pharmacological literature:

At a high level of intoxication, central excitation sets in with characteristic shivering, an initial state of euphoria that turns into delirium and hallucinations. For women, the stimulation . . . not infrequently has an erotic character and has resulted in later accusations of sexual misconduct against the operating physician. (Fühner 1943, 196*)

Some psychiatrists believe that cocaine stimulates the “sexual center” of the brain (Siegel 1982a).

For many users, cocaine is inevitably associated with sexuality (MacDonald et al. 1988; Phillips and Wynne 1980, 221).

Cocaine relaxes and opens the sphincter muscles, which makes anal penetration easier as well as substantially more pleasurable. However, cocaine (much like **ephedrine**) often has an adverse effect on erectile function and consequently leads to temporary impotence (cf. Siegel 1982a).

The addictive potential of cocaine has been the subject of much debate. This issue does not appear to be oriented toward the user as much as it reflects the current legal situation. In recent years, there have been efforts to develop a vaccination against “cocaine addiction.” Of course, the research in this area is conducted on rats (Hellwig 1996). The effect of cocaine on the brain is also an object of much research, since studies that confirm the adverse effects of cocaine are likely to receive financial support from the government. Studies that do not have a political agenda are the exception rather than the rule (Volkow and Swann 1990).

“Look at this shining heap of crystals! They are Hydrochloride of Cocaine. . . . [T]here was never any elixir so instant magic as cocaine. Give it to no matter whom. Choose me the last loser on the earth; take hope, take faith, take love away from him. Then look, see the back of that worn hand, its skin discolored and wrinkled. . . . He places on it that shimmering snow, a few grains only, a little pile of starry dust. The wasted arm is slowly raised to the head that is little more than a skull; the feeble breath draws in that radiant powder. . . . Then happens the miracle of miracles, as sure as death, and yet as masterful as life . . . at least faith, hope and love throng very eagerly to the dance; all that was lost is found.”

ALEISTER CROWLEY *COCAINE*
(1918)

The reggae album *Cocaine*, by the Jamaican artist Dillinger, glorifies not only the white powder but also hemp smoke. (CD cover 1986, Charly Records)

“Mother, the Man with the Coke Is Here,” a German cocaine hit of the Golden Twenties, was recently reissued in a new version with updated lyrics by Falco, a veteran of the Neue Deutsche Welle (“German New Wave”). (CD cover 1995, Sing Sing)

People who use cocaine frequently suffer from a runny nose (“coke sniffles”) the following day. Users may counteract this undesirable and unpleasant aftereffect by rinsing their nose with a saline solution (e.g., with medicinal salts). Many users rub vitamin E oil in their nose, a practice said to regenerate the highly irritated mucous membranes in the nose (Voigt 1982, 72). Although cocaine can be very helpful in dealing with an acute attack of hay fever, chronic use can actually contribute to the condition.

Crack or Free-Base Cocaine

In the German press, crack has been portrayed as “death for a few dollars,” “the devil’s drug from the U.S.A.,” et cetera. The general idea seems to be that “cocaine was a miracle, but crack, crack was better than sex” or “cocaine was purgatory—but crack is hell” (in *Wiener* 6 [1986]: 65, 66).

Crack, which is also known as base, free base, baseball, rocks, Roxanne, and supercoke, is nothing more than smokeable free-base cocaine (Siegel 1982b). In other words, crack is cocaine in the form of a free base (Pulvirenti and Koob 1996, 48). It can be obtained from an aqueous solution of cocaine hydrochloride to which an alkaline substance (such as sodium carbonate) is added. The cocaine salt is transformed into the pure base, or, in other words, the pure substance. It can then be purified with ether, causing the cocaine to crystallize out. Crack is usually “smoked” (i.e., vaporized and inhaled) in glass pipes. A typical dosage ranges from 0.05 to 0.1 g. The effect is very similar to that of snuffed

cocaine but is much more intense:

Although crack is a derivative of cocaine, there is little comparison between the mild and mostly stimulating cocaine inebriation and the effects of the short-term crack high, which can literally bowl one over. Whereas cocaine produces a euphoric sensation of great concentration and razor-sharp intelligence for about 20 to 60 minutes, crack lasts for only three to five minutes while giving the consumer an incredibly strong kick with regard to physical sensations as well as the euphoria of absolute omnipotence. Of course, this has resulted in many myths, including one that crack is particularly pure. (Sahihi 1995, 37*)

Ethnologists have begun using the field methods typical of the discipline to study the “crack phenomenon,” which appears to be a typically American product (Holden 1989). “Crack life” is a reflection of the problems in American society and reveals deep social fissures and cultural anomalies. For users, the “crack way” is an important form of identity formation. Crack is frequently found together with prostitution, as “addicts” may accept it as a form of payment for sexual services (Carlson and Siegal 1991).

On the street, the following substances may be used as substitutes for cocaine or crack in times of shortage: procaine, **caffeine**, benzocaine, phenylpropanolamine, lidocaine, and **ephedrine** (Siegel 1980).

Commercial Forms and Regulations

Cocaine hydrochloride is available through the pharmacy trade. The German Drug Law lists cocaine as a “narcotic drug in which trafficking is allowed but which may not be prescribed” (Körner 1994, 42). In the United States, the Controlled Substances Act classifies cocaine as a Schedule II substance.

Cocaine was used widely in Germany and Italy during the Golden Twenties. Many cartoonists poked fun at the subject. (Cartoon, Germany, circa 1920)

Codeine

Other Names

Codein, codeina, codéine, codeinum, 4,5α-epoxy-3-methoxy-17-methyl-7-morphinen-6α-ol, kodein

Empirical formula: $C_{18}H_{21}NO_3H_2O$

Substance type: **opium alkaloid**

In 1832, codeine was isolated from opium, which has a codeine content of 2 to 3% (see ***Papaver somniferum***). Codeine is also biosynthesized in the roots of *Papaver somniferum* L. cv. Marianne (Tam et al. 1980). It is possible that trace amounts of codeine can also be found in other *Papaver* species (*Papaver bracteatum*, *Papaver decaisnei*; cf. ***Papaver spp.***) (Theuns et al. 1986). Codeine is also an endogenous neurotransmitter in humans (cf. **morphine**).

A dosage of 20 to 50 mg produces “general mental stimulation, warmth in the head, and an increase in the pulse rate, as also appear after the consumption of alcohol” (Römpp 1950*). Codeine does not appear to be metabolized in the body and is excreted unchanged.

Because codeine suppresses the urge to cough, its most important pharmaceutical use is in cough syrups. The dosage when codeine is used as a cough suppressant is 50 mg three times a day. A dosage of 100 to 200 mg results in sleep and sedation. Higher dosages elicit effects comparable to those of morphine. The medical literature contains repeated mentions of “codeine addiction.” Codeine “addicts” are said to ingest up to 2 g of codeine daily (Römpp 1950, 115*). Today, codeine is gaining increasing medicinal importance as a substitution therapy for heroin addicts (Gerlach and Schneider 1994). The pharmaceutical industry synthesizes codeine primarily from thebaine, the main active constituent in *Papaver bracteatum* Lindl. (cf. ***Papaver spp.***) (Morton 1977, 125*; Theuns et al. 1986).

Codeine has acquired a certain significance in the music scene (jazz, rock, psychedelia), primarily as a substitute for heroin or **morphine**. Buffy Saint-Marie sang about the anguish of her codeine dependence in the song “Cod’ine” (LP *It’s My Way!* Vanguard Records 1964). Quicksilver Messenger Service later covered the song and made it famous. In the 1990s, the wave band Codeine had several albums out through Sub Pop. Cough syrups⁴⁹⁸ with a high codeine content were often consumed as inebriants at concerts, festivals, et cetera (usually in combination with **alcohol** and **cannabis**) (Bangs 1978, 158).

Commercial Forms and Regulations

Codeine is available as a pure substance and as codeine hydrochloride, codeine phosphate, and codeine phosphate hemihydrate. Codeine is on Schedule III in the United States. Preparations containing codeine (tinctures, cough syrups, et cetera) require a special prescription (i.e., with no refills allowed and/or on special prescription forms). But in other countries, including France, Spain, Nepal, and India, a prescription is still unnecessary and the medicine can be obtained over the counter from any pharmacy.

“And you live off your days on cod’ine And it’s real, real one more time.”

BUFFY SAINT-MARIE “COD’INE”

(LP *IT'S MY WAY!* 1964)

Codeine

The album *Barely Real*, by the American underground band Codeine, provides a clear demonstration of the effects of the opium alkaloid codeine on the artists. The drawn-out melodies, slow rhythms, and restrained monotony make it difficult for the listener to remain awake. (CD cover 1992, Sub Pop)

Coumarins

Other Names

Benzo-pyrones, coumarines, cumarines, kumarine

Empirical formula: $C_9H_6O_2$ (= 1,2-benzopyrone)

Substance type: benzopyrone

Coumarin (= chromen-2-on, kumarin, 2H-1-benzopyran-2-on, o-cumar[in]acid lactone), which has a scent like that of vanilla, crystallizes into colorless prisms and is easily soluble in **alcohol**, ether, and **essential oils**. Pure coumarin is exuded from what are known as tonka beans, and for this reason it is also called tonka bean camphor. Coumarin is biosynthesized by the hydroxylation of cinnamic acid or coumarin glycoside. Even plants that do not actually contain any coumarin often produce it when they wilt (giving off the smell of hay) or dry (e.g., *Anthoxanthum odoratum*, *Galium odoratum*, ***Sida acuta***).

The black seeds (tonka beans) of the South American tonka tree (*Dipteryx odorata*) exude crystalline, almost pure white coumarin. In Venezuela, the coumarin that is rubbed from the seeds is utilized to aromatize tobacco and snuffs.

Coumarin

Extracts from ripe and wonderfully fragrant vanilla beans are rich in coumarins. Vanilla has a pheromone-like effect on humans, inducing courtship behavior. (Illustration from Hernández, *Rerum medicarum Novae Hispaniae*, Rome, 1651)

Coumarins in Psychoactive Plants

(from Gray and Waterman 1978; Römpf 1995*; Shoeb et al. 1973; supplemented) Coumarins (e.g., benzofuran) have been found in the following plants with demonstrated or purported psychoactivity:

For plants containing the coumarin derivative scopoletin, see **scopoletin**.

Umbelliferone, aesculine, and furocoumarin are all coumarin derivatives. More than six hundred natural coumarins are now known. About two hundred coumarins occur in the Family Rutaceae (including the genera *Zanthoxylum*, *Evodia*, *Ruta*, *Thamnosma*, *Dictamnus*, *Eriostemon*, *Citrus*, and *Aegle*), where they appear to have great chemotaxonomic importance (Gray and Waterman 1978; Tatum and Berry 1979).

Coumarins occur in some plants that are used for psychoactive purposes (see **scopoletin**). Coumarin is the substance responsible for the specific taste of woodruff punch, and it is also present

in fahan tea (*Angraecum fragrans* Du Petit-Thouars), which Bibra (1855*) described as psychoactive. Fahan was once used as a substitute for green tea (*Camellia sinensis*) and was mixed with tobacco (*Nicotiana tabacum*) and rolled into cigars (Frerichs et al. 1938, 1234*).

High dosages of pure coumarin can cause headaches, dizziness, lethargy, stupor, and even respiratory paralysis (Roth et al. 1994, 796*). Coumarin is said to be toxic to the liver and for this reason was banned as a component or ingredient in food. However, the toxicity is very doubtful, and the alleged carcinogenic effects are also questionable (Marles et al. 1987).

Commercial Forms and Regulations

In the United States, coumarin has been banned as a food additive since 1954. It has been placed in Class 3 of the Swiss Poison List. In Germany, drinking brandies (38% **alcohol**) are allowed to contain a maximum of 10 mg of coumarin per liter (Roth et al. 1994, 402*).

“Coumarins, which Vogel recently discovered in tonka beans (*Diperix* [sic] *odorata*) and Fontana then found in sweet clover (*Melilotus officinalis*), also occur in woodruff (*Asperula odorata*). Everyone knows that woodruff is added to wine in many places in Germany and in France because, as it is said, this improves the taste, but in reality this is probably done to make it more stimulating. . . . Nevertheless, it is doubtlessly worthy of notice that both in Africa [the fahan tea] and in Europe, two plants are used as stimulating or exhilarating agents that contain the very same substance that they very likely thank for precisely this stimulating effect.”

Cytisine

Other Names

Baptitoxin, cytiton, laburnin, 1,2,3,4,5,6-hexahydro-8*H*-1,5-methano-pyrido[1,2α] [1,5]diazocin-8-ol, sophorin, ulexin

Empirical formula: C₁₁H₁₄N₂O

Substance type: quinolizidine alkaloid, lupine alkaloid

Cytisine is found in numerous legumes (Leguminosae) (Plugge 1895), such as the rain shower tree (*Laburnum anagyroides* Medikus [syn. *Cytisus laburnum* L.]).⁴⁹⁹

Since cytisine acts to stimulate the central nervous system, states of excitation and confusion (with hallucinations, delirium), muscle spasms, as well as general clonic-tonic spasms in the extremities not infrequently occur. (Roth et al. 1994, 443*)

Cytisine docks to the acetylcholine (ACh) receptors of the central nervous system, the ganglia, and the neuromuscular endplate. The ganglia-blocking effects of cytisine are similar to those of **nicotine** and can induce **strychnine**like spasms, especially hallucinations, and even unconsciousness and ultimately death. However, the lethal dosage for humans is unknown (Roth et al. 1994, 801 f.*). The nicotine-like effects also explain the ethnopharmacological use of plants containing cytisine as tobacco substitutes.

Other lupine alkaloids and cytisine derivatives have been found in many plants from the Family Leguminosae, including ***Lupinus spp.*** and *Echinosophora koreensis* Nakai (a close relative of the genus *Sophora*) (Murakoshi et al. 1977).

Commercial Forms and Regulations

Cytisine is sold in its pure form and is not subject to any regulations (Roth et al. 1994, 802).

Cytisine

The ripe seeds of the golden chain tree (*Laburnum anagyroides* = *Cytisus laburnum*) contain up to 3% cytisine. In Germany, the dried leaves of the tree were smoked during the years following World War II as a stimulating substitute for tobacco.

The magnificent flowers of the Philippine jade vine or emerald creeper (*Strongylodon macrobotrys* A. Gray) contain cytisine and other alkaloids.

“During the World War, the leaves of plants containing cytisine were a popular substitute for tobacco in many countries in which tobacco was not readily available. The toxicity of these plants can be seen in the fact that a cytisus cigarette causes the same nausea to

nonsmokers as a real tobacco cigarette does, while those who are used to tobacco do not notice any discomfort.”

Plants Containing Cytisine

(from Bock 1994, 75 ff.*; Römpp 1995*; Roth et al. 1994*; supplemented)

Diazepam

Other Names

7-chlor-1,3-dihydro-1-methyl-5-phenyl-2*H*-1,4-benzodiazepin-2-on, sleeping pill, tranquilizer, Valium

Empirical formula: C₁₆H₁₃ClN₂O

Substance type: benzodiazepine

Diazepam, better known as Valium, was originally synthesized in the laboratory and introduced as a therapeutic drug (psychopharmaca, tranquilizer) in the 1960s. The substance produces sedative, euphoric, and especially anxiolytic (anxiety-reducing) effects (Henningfield 1988, 17, 35*).

During the investigation of diazepam's pharmacology, it was discovered that the human nervous system has a special receptor for this molecule, known as the benzodiazepine receptor or the [³H]-diazepam receptor. Luk et al. (1983) found three isoflans in the urine of cattle that may possibly dock (as neurotransmitters) in the benzodiazepine receptor. It is known that the kavapyrones (cf. *Piper methysticum*) bind to the [3H]-diazepam receptor. Recently, flavonoids in the buds of the South American linden tree (*Tilia tomentosa* Moench; Tiliaceae; cf. **tila**) were found to bind to the benzodiazepine receptor. A substance found in *Passiflora caerulea* L. (cf. *Passiflora* spp.), 5,7-dihydroxyflavone, also docks to the same location (Viola et al. 1994).

The benzodiazepine receptor has been shown to be present in all vertebrates, suggesting that it appeared at a very early date in the evolution of the nervous system and has been preserved into the present. This indicates that it plays an important function in the nervous system and that there are endogenous substances that bind to it in order to transmit certain messages (Müller 1988).

But what do these substances look like? At first they were thought to be polypeptides, but then traces of diazepam and desmethyldiazepam were discovered in the brains of humans and other animals. Because diazepam and its initial metabolite appear in breast milk and the placenta after the ingestion of Valium (Wessen et al. 1985), it was first believed that the diazepam must have been introduced into the body from outside. But when diazepam was subsequently also found to be present in brains that dated to a time before the discovery of Valium synthesis, it was concluded that diazepam was not a synthetic chemical at all but a naturally occurring neurotransmitter in the nervous system (Müller 1988). Thus it was demonstrated that “Valium, the very symbol of chemical psychopharmaca” (Zehentauer 1992, 121*), is actually a natural substance.

Pharmacologists were surprised when subsequent research demonstrated the presence of diazepam and desmethyldiazepam in potatoes (*Solanum tuberosum* L.; cf. *Solanum* spp.) and in such diverse grains as wheat (*Triticum aestivum* L.; cf. **beer**), corn/maize (*Zea mays*), and rice (*Oryza sativa* L.; cf. **sake**) (Müller 1988). Valium, in other words, is a natural active constituent in plants. However, the concentration in these plants is so low that a person would likely not notice any Valium effects even after consuming a whole sack of potatoes.

Valium is one of the most widely used sedative drugs in modern society and is normally prescribed for the treatment of anxiety and sleeping disorders.⁵⁰⁰ Not surprisingly, Valium also finds use as a recreational drug in some circles, particularly in combination with other substances. Its euphoric

properties can be greatly affected by **alcohol**, which can at times counteract the sedative properties, resulting in powerful stimulating effects.

Valium is one of the more commonly used psychopharmaca in the music scene. Several rock bands, including the classic “space rock” band Hawkwind (“Valium 10,” 1978), have dedicated titles to the substance.

Commercial Forms and Regulations

Valium is available by prescription only. In the United States, it is listed as a Schedule IV drug under the Controlled Substances Act.

Diazepam

“The fact that Valium is ultimately 100% natural is not without a certain irony. For many ideologically tinged critics of psychopharmaca, benzodiazepines have become the very symbol of the evils of chemistry for the mind.”

WALTER MÜLLER

“SIND BENZODIAZIPINE 100% NATUR?” [ARE BENZODIAZEPINES 100% NATURAL?]
(1988, 674)

The potato (*Solanum tuberosum* L.), a member of the Nightshade Family, contains highly toxic solanum alkaloids, primarily αsolanine, in all parts of the plant, including the green potatoes and the young sprouts. The tubers have been discovered to contain traces of naturally occurring diazepam. (Woodcut from Tabernaemontanus, *Neu Vollkommen Kräuter-Buch*, 1731)

Diterpenes

Other Names

Diterpene, diterpènes, diterpenoids, diterpenos

Diterpenes are not alkaloids but non-nitrogenous natural substances composed of four isoprene groups. They are related to the monoterpenes and sesquiterpenes and belong to the terpene group. Diterpenes occur in numerous plants and several **essential oils**.

Some diterpenes regulate plant growth. Termites, sponges (*Spongia spongens* L.), and coelenterates contain bioactive diterpenes that have inhibiting effects upon certain bacteria (Buchbauer et al. 1990, 28). There are even sweet-tasting diterpenes, such as the natural sweetening agents in *Stevia rebaudiana* (Bert.) Hemsl., the leaves of which are used to sweeten maté (cf. *Ilex paraguariensis*).

The first psychoactive diterpene to be discovered was **salvinorin A**. It is very likely that there are other psychoactive diterpenes that have not yet been isolated, pharmacologically tested, or chemically described. Some psychoactive alkaloids are diterpene derivatives. Aconitine, the primary active constituent in monkshood (cf. *Aconitum ferox*, *Aconitum napellus*), is a diterpene alkaloid. Diterpene alkaloids also occur in *Delphinium* and *Spiraea*.

Diterpenes in Psychoactive Plants

(from Buchbauer et al. 1990; Rein 1979; supplemented)

Ephedrine

Other Names

Aphetonin, efedrina, ephedrin, ephédrine, ephedrinum, ephetonin, erythro-2-methylamino-1-hydroxyl-1-phenylpropane, (1*R*,2*S*)-2-methylamino-1-phenyl-1-propanol

Empirical formula: C₁₀H₁₅NO

Substance type: ephedra alkaloid

Ephedrine was first isolated in 1887 by Nagai from *Ephedra distachya* (cf. ***Ephedra* spp.**) and was first introduced into ophthalmology as Mydriaticum (cf. **atropine**). Since around 1925, the alkaloid also been an important asthma medication (Schneider 1974, 2:54*).

Ephedrine occurs in almost all species of ephedra (cf. ***Ephedra gerardiana***, ***Ephedra sinensis***, ***Ephedra* spp.**). Two Malvaceae, *Sida acuta* Burm. and *Sida rhombifolia* L. (***Sida* spp.**), which are smoked along the Mexican Gulf Coast as a marijuana substitute (cf. ***Cannabis indica***), also contain ephedrine (Schultes and Hoffmann 1992, 56*). Ephedrine is probably present in other species of *Sida* as well. Ephedrine has also been found in ***Aconitum* spp.**, yew (*Taxus bacata* L.; cf. **witches' ointments**), and khat (***Catha edulis***) (Römpp 1995, 1191*; Roth et al. 1994, 695*).

Ephedrine has sympathomimetic effects and causes an increased excretion of the endogenous neurotransmitter noradrenaline, which is responsible for the stimulant effects (Kalix 1991). Ephedrine hydrochloride has potent stimulant effects; it improves the general mood and may even induce euphoria. These effects can last up to eight hours. It is known that “therapeutic overdoses of ephedrine (Aphetonin) can also cause pronounced states of excitation combined with sexual arousal” (Fühner 1943, 199*). In men, however, ephedrine induces a temporary state of impotence. Ephedrine is a popular doping agent for athletes but is prohibited for this purpose (Körner 1994, 1483*). There have been reports of “ephedrine addiction” (Prokop 1968).

Because ephedrine helps reduce swelling of the mucous membranes, it is a component of many cough syrups (see **codeine**). Ephedrine suppresses the effects of **alcohol** and is administered subcutaneously to prevent hypotension during anesthesia (Morton 1977, 35*). Between 55 and 75% of ephedrine is excreted in the urine unchanged (Roth et al. 1994, 812*). The effective oral dosage is 5 to 10 mg.

The closely related ephedra alkaloids have similar effects but vary in their potency (Reti 1953). Pseudoephedrine is significantly weaker, while the related ephedroxanes tend to have depressant effects (Hikino et al. 1985). Pseudoephedrine can be used to produce methcathinone, which in the United States is smoked as “speed” or snuffed like cocaine (it is also used as a substitute for cocaine) (Glennon et al. 1987).

Although ***Catha edulis*** does contain *d*-norisoephedrine, it is not the plant’s primary active constituent, as was previously assumed (Wolfes 1930). However, cathinone, the psychoactive constituent in khat leaves, is metabolized into ephedrinene (Brenneisen et al. 1986; Kalix 1991). Norephedrine, the *nor*-form (a *threo*-isomer) of ephedrine, lacks a methyl group on the side chain. Up to 90% of norephedrine is excreted unchanged (Cho and Segal 1994, 58).

Removing the hydroxyl group from the ephedrine molecule by either reduction or β-hydroxylation

yields amphetamine (Cho and Segal 1994, 57). Amphetamine is one of the most highly effective stimulants known. Numerous derivatives have been developed from amphetamine (e.g., Ritalin, methamphetamine, MDMA; cf. **herbal ecstasy**). In addition to their stimulating effects, several of these substances also induce empathogenic and even hallucinogenic effects (Cho and Segal 1994). Amphetamine has not yet been found to occur in nature.

Commercial Forms and Regulations

Ephedrine is available as anhydrous ephedrine (ephedrinum anhydricum), ephedrine hemihydrate, or (most often) ephedrine hydrochloride ([+]-ephedrine-HCL). Ephedrine and ephedrine preparations (medicinal drugs) require a prescription. Because ephedrine is now regarded as a precursor substance for the illegal synthesis of MDMA, it is only rarely prescribed and is strictly controlled. In Germany, only combination preparations (cough medicines) in which a single dosage may not exceed 10 mg of ephedrine can be purchased in a pharmacy without prescription (Roth et al. 1994, 812*). A number of high-profile cases, including one in which a young professional athlete died after ingesting ephedrine before training, resulted in the banning of most ephedrine preparations in the United States in 2004.

Ephedrine

Swiss ephedra (*Ephedra helvetica*) contains ephedrine.

Ergot Alkaloids

Other Names

Ergoline, ergoline alkaloids, ergot alkaloids, ergotalkaloide, mutterkornalkaloide

Ergot alkaloids are derivatives of lysergic acid or clavine derivatives and belong to the group of **indole alkaloids**. They are found in many climbing plants (Convolvulaceae) and fungi (***Claviceps purpurea*, *Claviceps paspali*, *Claviceps spp.***). The ergot alkaloids can be divided into two groups that exhibit stark pharmacological differences. One group is composed of alkaloids that are highly toxic and cause gangrenous ergotism, while the other group consists of psychoactive alkaloids with hallucinogenic effects. Both types may be present in the same plant (Hofmann 1964).

The following ergot alkaloids have been found in the Convolvulaceae: agroclavine, ergine, ergonovine, isoergine (= isolysergic acid amide), chanoclavine I and II, racemic chanoclavine II, elymoclavine, festuclavine, lysergene, lysergol, isolysergol, molliclavine, penniclavine, cycloclavine, stetoclavine, isostetoclavine, ergometrine, lysergic acid- α -hydroxyethylamide (= lysergic acid methylcarbinolamide), isolysergic acid- α -hydroxyethyl-amide (= isolysergic acid methylcarbinolamide), ergosine, and ergosinine (cf. ***Argyrea nervosa*, *Convolvulus tricolor*, *Ipomoea violacea*, *Ipomoea spp.*, *Turbina corymbosa***).

One hallucinogenic ergot alkaloid is ergonovine (ergometrine, D-lysergic acid-L-2-propanolamide, ergobasin, ergotocine, ergostetrine, ergotrate, syntometrine, N-[α -(hydroxymethyl)ethyl]-D-lysergic amide). Ergonovine maleate is psychoactive at dosages between 3 and 10 mg (Bigwood et al. 1979). The semi-synthetic methylergonovine has also been reported to induce psychoactive effects (Ott and Neely 1980).

Ergine (= lysergic acid amide, LSA, lysergic amide, 9,10-didehydro-6-methylergoline-8 β -carboxamide) induces psychoactive effects reminiscent of those produced by LSD (lysergic acid diethylamide). LSD is a slight chemical variant of lysergic acid amide that can be produced from ergot (***Claviceps purpurea***). LSD is a psychopharmaca, a “remedy for the soul” (Albert Hofmann) whose entheogenic effects are very well known (Hofmann 1979*).

The ergot alkaloids dihydroergotaminemesilate, dihydroergotamintartrate, ergometrine hydrogen-maleate, and ergotamine tartrate have a variety of uses in medicine, including as treatments for labor contractions and migraines.

Commercial Forms and Regulations

Ergonovine requires a prescription. In the United States, ergine is a controlled substance (Ott 1993, 437*). LSD is illegal throughout the world.

Lysergol

Lysergic acid amide (LSA)

Lysergic acid diethylamide (LSD)

Saint Anthony is the patron saint of people afflicted with Saint Anthony's fire, a severe condition caused by the ingestion of ergot alkaloids. (Statue in Cloister Unterlinden, Colmar, Elsass)

Essential Oils

Other Names

Aroma, ätherische öle, ätherischöl, essence, essenz, etherisches öl, volatile oil

Essential oils are complex mixtures of carbohydrates, alcohols, ketones, acids and esters, ethers, aldehydes, and sulfur compounds that are volatile and evaporate at low temperatures. Essential oils can exhibit tremendous variation in their composition. Each specific mixture produces its own characteristic scent. For the most part, essential oils are distilled from raw drugs or stock plants through a variety of techniques. Essential oils are used medicinally in what has become known as aromatherapy. This healing system was founded by René-Maurice Gattefossé (1881–1950) and is gaining increasing recognition throughout the world (Carle 1993; Henglein 1985; Kraus 1990; Strassmann 1991).

Many psychoactive plants contain essential oils. They are sometimes the only active constituents, while sometimes they occur only in trace amounts. Several components are present in the essential oils of most plants that have unequivocal psychoactive effects.

Eugenol

Eugenol is known to be stimulating, anesthetic, and psychoactive (Sensch et al. 1993; Toda et al. 1994). High concentrations of eugenol occur in the essential oil of clove (*Syzygium aromaticum*).

Myristicin

Myristicin is regarded as the hallucinogenic component of many essential oils (Wulf et al. 1978, 271). Myristicin is present in dill (*Anethum*), lovage (*Levisticum officinale*), parsnips (*Pastinaca* sp.), and parsley (***Petroselinum crispum***). The essential oil of the Australian *Zieria* species (Rutaceae) contains up to 23.4% myristicin. It is thought that myristicin is metabolized into an amphetamine derivative (MDA) (cf. ***Myristica fragrans***).

Safrole

Safrole is found in cloves (*Syzygium aromaticum*) and in the sassafras tree (*Sassafras albidum*). Safrole is one of the most important precursors for the synthesis of MDMA and other similar substances (MMDA, MDE, MDA). The halogen derivatives of safrole, the closely related piperonal and isosafrole, are also suitable for this purpose (Yourspigs 1995). In the body, safrole is thought to be metabolized into amphetamine derivatives.

Thujone

In nature, thujone exists in two forms: α -thujone and β -thujone. The common tansy (*Tanacetum vulgare*), whose name is derived from the Greek word *athanaton* (“immortal”), is very rich in thujone (= tanacetone; cf. Semmler 1900). According to myth, Ganymede became immortal because he had eaten tansy (Albert-Puleo 1978, 65).

☐

Myristicin

☐

Safrole

☐

Thujone

☐

The Romans held rosemary (*Rosmarinus officinalis*) in high esteem as an incense; it contains an essential oil with psychoactive constituents.

☐

Cloves are the flower buds of a tropical tree (*Syzygium aromaticum* [L.] Merr. et L.M. Perry). They contain a great quantity of an essential oil with anesthetic and stimulating properties; the oil consists primarily of eugenol.

☐

The Western or giant red cedar (*Thuja plicata*), also known as the giant arborvitae, contains an essential oil that is rich in thujone and can be potently inebriating.

☐

The Moroccan cedar (*Cedrus atlantica*) has been found to contain thujone.

Clary sage (muscatel sage) (*Salvia sclarea* L.) has a high thujone content. During the nineteenth century, this plant was used in England instead of hops (***Humulus lupulus***) to produce a more potent type of **beer**. Other plants that contain thujone (***Artemisia absinthium***, *Artemisia vulgaris*) were used for the same purpose (Albert-Puleo 1978, 69).

Thujone kills the common roundworm *Ascaris lumbricoides* (Albert-Puleo 1978, 65). The pharmacological effects of thujone are very similar to those of **THC** (cf. ***Artemisia absinthium***).

Ud Oil

It has often been reported that *ud* oil, the essential oil in lignum aloe or aloe wood (*Aquillaria agallocha* Roxb. [syn. *Aquillaria malaccensis* Lam.]; Thymeleaceae), can induce psychoactive effects:

As an incense or aromatic oil, it is used to treat mental and psychological disturbances as well as emotional instability, particularly in cases when this has been produced by negative mental energies. Our experience indicates that aloe wood has unusually relaxing and mood-enhancing properties. It produces a state of trance and introspection and lifts the mind to higher plains of perception. It facilitates the attainment of high levels in meditation. For this reason, it should not necessarily be used prior to a work-filled day in which concentration and quick reactions are required. (Ashisha and Mahahradanatha 1994, 10)

Sufis utilize the precious lignum aloe or distilled *ud* oil (essence) for advanced stages of Islamic mysticism:

One could say that only those individuals whose minds are more highly developed experience the benefits of *ud*. In fact, it is only used to treat imbalances during the last three states of mental development. (Moinuddin Chishti 1991, 118*)

Plants Containing Psychoactive Essential Oils

(from Albert-Puleo 1978; Bock 1994*; supplemented)

The Southeast Asian ylang-ylang tree (*Cananga odorata*) is the source of an essential oil with a sweet, pungent aroma that is used in tantric rituals as an aphrodisiac and has also been shown to have psychoactive effects.

Early European illustration of the American tuberose (*Polianthes tuberosa*), which produces a valuable essential oil with an enchanting scent. (Woodcut from Gerard, *The Herball or General History of Plants*, 1633)

The essential oil of sage (*Salvia officinalis*) contains constituents with inebriating properties.

“Coriander was one of the first spices used by man. Its seeds have been found in Bronze Age ruins on Thera (Santorini) and Therasia as well as in the graves of pharaohs, and we know that it was cultivated in Assyria and Babylon. The Egyptians added it to wine to potentiate its inebriating effects. It used in India during religious and magical ceremonies. The Hebrews called it *gad* and were very fond of it. In Mycenae, one of the oldest cities in Greece, it was used as a spice to improve bland meals. The Romans believed that the coriander from Egypt was the best and they used it to spice their bread and stews and knew it as an ingredient in their Roman bouquet garni.”

WAVERLY ROOT

WACHTEL, TRÜFFEL, SCHOKOLADE [GAME HENS, TRUFFLES, CHOCOLATE] (1996, 195 f.*)

“Let my soul inhabit various flowers,
let it become inebriated on their scent,
only too soon will I have to depart crying,
to stand before the face our mother in the kingdom of the dead.”

AZTEC SONG IN *ANCIENT NAHUATL POETRY* (BRINTON 1887, 79*)

Aromatic lignum aloe (lignum aquillariae resinatum) contains p-methoxycinnamic acid, agarotetrol, and the sesquiterpenoids agarol, agarospirole, α - and β -agarofurane, dihydroagarofurane, 4-hydro-dioxydihydroagarofurane, and oxo-nor-agarofuran, among other

constituents.

Essential Oils as Aphrodisiacs

Some essential oils are attributed with aphrodisiac effects. Perfume manufacturers consider the aroma of the Mexican tuberose (*Polianthes tuberosa* L.; Agavaceae) (cf.Dressler 1953,144*) to be aphrodisiac.

The evergreen ylang-ylang tree (*Cananga odorata* [Lam.] Hook. f. et Thoms. [f. *genuina*] [syn. *Canangium oderatum* Baill.]), which thrives only in tropical regions, is the source of the oil of the same name. In India, ylang-ylang oil is regarded as the favorite oil for tantric rituals because it is believed to have potent aphrodisiac effects and to stimulate and refine erotic sensations. Today, individuals throughout the world use ylang-ylang oil to ritualize their own eroticism (Huron 1994; Kraus 1990; Strassmann 1991). The flowers contain 1.5 to 2.5% of an essential oil composed of linalool, safrole, eugenol, geraniol, pinene, cadinene, and sesquiterpenes. There have been frequent reports of ylang-ylang having mind-altering powers. Pharmacologically, this effect is probably due to the safrole component of the essential oil (Rätsch 1996). Above a certain concentration, safrole appears to produce psychoactive effects that are quite similar to those of MDMA (see **herbal ecstasy**).

“It has been said that a Sufi *attar*, a maker of aromatic essences, one day reached the *Fardaws* region, the highest of the heavens, while performing his mystic exercises. When he arrived there, he smelled a certain scent. After returning to his normal state of mind, he concocted a similar aroma, and this is the origin of the name: ‘gate to the highest heavens’ [*jannat al-Fardaws*].”

SHAYKH HAKIM MOINUDDIN CHISHTI *THE BOOK OF SUFI HEALING*
(1991, 118*)

“And on that meadow is a tree
which is of such beauty to behold.
Its roots are galanga and ginger,
its branches are pure white turmeric,
and its flowers are of delicate nutmeg,
the bark is sweet aromatic cinnamon,
the fruits are wonderfully scented cloves.
You also find plenty of cubeb.”

“THE BALLAD OF THE LAND OF PLENTY” (IRELAND, FOURTEENTH CENTURY)
IN *SCHLARAFFENLAND* [LAND OF MILK AND HONEY]
(RICHTER 1984, 137)

Asarabacca (*Asarum europaeum* L.; Aristolochiaceae) is rich in the psychoactive asarone. (Woodcut from Fuchs, *Läebliche abbildung und contrafaytung aller kreüter*, 1545)

5-MeO-DMT

Other Names

Dimethyl-5-methoxytryptamine, 5-methoxy-DMT, 5-methoxy-*N,N*-dimethyl-tryptamine, *O*-methylbufotenine, 3-[2-(dimethylamino)ethyl]-5-methoxy-indole, toad foam

Empirical formula: $C_{13}H_{18}N_2O$

Substance type: tryptamine (**indole alkaloid**)

5-MeO-DMT was first discovered in *Dictyoloma incanescens* DC. and later was isolated from *Anadenanthera peregrina* as well. It occurs in a very large number of plants, often in association with *N,N*-DMT (see the table on pages 853–854). Its effects are somewhat more potent than those of *N,N*-DMT. When the two are administered simultaneously, 5-MeO-DMT more quickly occupies the specific receptors. 5-MeO-DMT is a natural neurotransmitter in the human nervous system. When 5-MeO-DMT (10 to 20 mg) is smoked or vaporized and inhaled, the effects are almost immediately apparent, are incredibly extreme, and last about ten minutes. Many people report having shamanic experiences with this substance as well as experiencing states of enlightenment and the clear light of nirvana (Metzner 1988).

The Colorado River toad (*Bufo alvarius*) is native to the area around Tucson, Arizona. These toads spend nine months of the year underground, buried in the mud that keeps them protected from the burning desert sun. The toads emerge from their hiding places with the first rains and begin their courtship (Smith 1982, 97–100). They remain visible for only three months. Like all toads, *Bufo alvarius* develops mucous secretions in two glands that are located on the neck. The secretions of the Colorado River toad, however, do not contain bufotoxine, the toxic substance that is found in the secretions of most other toads. Instead, the dried mass contains 15% 5-MeO-DMT (Erspamer et al. 1965, 1967).

The native tribes that lived in the North American Southwest made fetishes of this *Bufo alvarius*. However, it was only in recent times that the toad's cultural importance and its psychedelic use were discovered, or more likely rediscovered (cf. Davis and Weil 1992). The toad is “milked” by being held firmly without being crushed. Both glands are then massaged gently until a fat stream of the secretion squirts out. The secretion is caught on a piece of glass, where it is allowed to dry and crystallize. The yellowish crystalline mass then can be scraped off, mixed with different herbs (such as damiana [*Turnera diffusa*]), and smoked. The toad, which is released unharmed, is quickly able to replenish the loss in its secretions.

When taken orally, *Bufo alvarius* secretions are apparently toxic, whereas they are not poisonous when smoked (Weil and Davis 1994). Davis and Weil have suggested that the dried secretions of *Bufo alvarius* were traded to Mexico in pre-Columbian times and that the priests and shamans there smoked or used it in some other manner (Davis and Weil 1992; cf. **balche'**, **bufotenine**).

In Arizona, there is now a Church of the Toad of Light, which uses the secretions of *Bufo alvarius* as a sacrament (Most 1984; Ott 1993, 396*).

Commercial Forms and Regulations

Pure 5-MeO-DMT is available from chemical suppliers. While the substance is not explicitly mentioned in the narcotics laws, the fact that it could be interpreted as a DMT analog may result in problems with the law.

5-MeO-DMT

“We sat in a circle with some friends and smoked a joint of toad secretions. I inhaled deeply and passed the joint on. Immediately, a mandala unfolded before me. A dragon was sitting in each corner, and in the circle in the center was a cyclone. No sooner had I recognized the cyclone than I was pulled into it. The cyclone was turning in a clockwise direction—and yet time was going backward. Dragons, amphibians, and dinosaurs appeared in the cyclone, and they too were pulled into eternity. At first, I was surprised that Tibetan dragons and dinosaurs were appearing together in the waves, but then I realized that they represented two metaphors for the same principle. I was drawn further and further along by the deluge of images until I finally arrived at the journey’s end. I sat like a toad or a newt in a Permian bog. The water around me was black, and in the murky fog I saw gigantic ferns and horsetails. Somehow, I communicated with the strange amphibians and realized that I was able to communicate not only with beings of another kind but also across the barriers of time, across millions of years.”

AN EXPERIENCE WITH *BUFO ALVARIUS SECRETIONS* [1495]

The Colorado River toad (*Bufo alvarius*) lives only in Arizona. Its secretions contain high concentrations (up to 15% of dry weight) of 5-MeO-DMT.

This drawing depicts the experience of a volunteer subject after smoking 5-MeO-DMT.

Harmaline and Harmine

Other Names

Harmaline: 4,9-dihydro-7-methoxy-1-methyl-3*H*-pyrrol [3,4-*b*] indole, harmalin, harmalolmethylester, harmidin, harmidin, 3,4-dihydroharmin

Harmin: banisterin, banisterine, harmin, 7-methoxy-1-methyl- β -carboline, telepathin, telepathine, yageine

Empirical formula: C₁₃H₁₄N₂O (harmaline), C₁₃H₁₂N₂O (harmin)

Substance type: β -**carbolines**, harmala alkaloids (**indole alkaloids**)

Harmaline and harmin are found in *Banisteriopsis caapi* and *Peganum harmala* (Beringer 1928; Beringer 1929; Chen and Chen 1939). Harmin also occurs in numerous other plants (see **ayahuasca analogs**). Harmaline and harmin not only are strong MAO inhibitors (Pletscher et al. 1959; cf. β -**carbolines**) but also have antibacterial properties (Ahmad et al. 1992). Harmin was an early treatment for Parkinson's disease (Halpern 1930b):

Harmin lessens the exaggerated excitability of the parasympathetic system in Parkinson's patients, increases the low excitability of the sympathetic system, also promotes the excitability of the vestibular apparatus, and puts the patient in a state of euphoria, helping them to better accept their affliction. (Roth et al. 1994, 548*)

In the 1960s, the Chilean psychiatrist Claudio Naranjo (1969*) introduced harmaline and harmin to psychotherapy as "fantasy-increasing drugs" (cf. **ibogaine**). The extent to which these substances are psychoactive is questionable. To investigate the supposed "psychedelic" effect of harmin,

Maurer (together with Lamparter and Dittrich) tested the hypothesis that harmin is a hallucinogen in 11 self-experiments with a sublingual dosage between 25 and 750 mg. Contrary to expectations, however, harmin did not prove to be a substance that exhibited many similarities to classic hallucinogens such as mescaline or psilocybin. Maurer characterized the state that harmin induced as more of a retreat from one's surroundings and as a pleasant relaxation with a mildly reduced ability to concentrate. Short-term and elementary optic hallucinatory phenomena were observed only to the degree that they would otherwise also appear naturally during reduced contact with one's surroundings. With dosages above 300 mg, such undesirable vegetative and neurological symptoms as dizziness, nausea, and ataxia became more apparent, precluding any increase in dosage above 750 mg. (Leuner and Schlichting 1986, 170*)

Crystallized harmaline has a characteristic light yellow color. (Photo: Karl-Christian Lyncker)

Harmaline

Harmine

Most experimenters have called into question the reports that Naranjo (1979*) published from his psychotherapeutic practice. It may be that he administered **ayahuasca**, and not any pure substances, to his patients.

Today, harmaline and harmine are primarily used in the production of pharmahuasca (**ayahuasca analogs**).

Commercial Forms and Regulations

Both substances are available through chemical suppliers. They may be purchased without restriction and are not subject to any legal regulations (Ott 1993, 438*).

Ibogaine

Other Names

Endabuse, ibogain, ibogaina, ibogaïne, NIH 10567, 12-methoxy-ibogamin, 12-methoxy-ibogamine

Empirical formula: $C_{20}H_{26}N_2O$

Substance type: **indole alkaloid**, indole alkylamine, ibogane type

Chemically, ibogaine is closely related to the **β -carboline**s, and particularly to **harmaline** and **harmine**. It belongs to the group of cyclic tryptamine derivatives.

Ibogaine was first isolated from the root cortex of ***Tabernanthe iboga*** in France in 1901 (Dybowsky and Landgren 1901). Ibogaine and analogous alkaloids (ibogane type) also occur in *Pandaca retusa* (Lam.) Mgf. [syn. *Tabernaemontana retusa* (Lam.) Pichon] (cf. ***Tabernaemontana spp.***), a dogbane species native to Madagascar (Le Men-Olivier et al. 1974). Many genera in the Family Apocynaceae, including *Tabernaemontana*, ***Voacanga spp.***, *Stemmadenia*, *Ervatamia*, and *Gabunea*, contain ibogaine-type **indole alkaloids** (ibogamine, tabernanthine, voacangine, ibogaline) (Prins 1988, 5).

Between 1940 and 1950, most research into ibogaine was conducted in France. Because it exhibited potent stimulating properties, the initial pharmacological research focused on ibogaine's neuropharmacological effects. Only later were the hallucinogenic effects more precisely studied (Sanchez-Ramos and Mash 1996, 357).

In the 1960s, the Chilean psychiatrist Claudio Naranjo introduced ibogaine into psychotherapy as a “fantasy-enhancing drug” (Naranjo 1969*). One subject provided the following account of a shamanic experience during a psychotherapeutic session with the “stomach drug” ibogaine:

Ibogaine

I am a panther! A black panther! I defend myself, I stand up. I snort powerfully, with the breath of a panther, predator breath! I move like a panther, my eyes are those of a panther, I see my whiskers. I roar, and I bite. I react like a panther, offense is the best defense.

Now I hear drums. I dance. My joints are gears, hinges, hubs. I can be a knee, a bolt, could do something, indeed almost anything. And I can loose [sic] myself again in this chaos of nonexistence and the perception of vague, abstract ideas of changing forms, where there exists a sense of the truth of all things and an order that one should set out to discover. (Naranjo 1979, 188*)

In Europe, the Swiss psychiatrist Peter Baumann provided the main impetus for the use of ibogaine in psychotherapy:

Baumann reported about experiments with completely synthetic ibogaine, which he used on only a few patients with whom a long and positive therapeutic relationship existed. The dosage was usually 5 mg/kg of body weight. At this dosage level, the effects lasted for approximately 5 to 8

hours and diminished only very slowly. In his experiments with ibogaine, the author found that it was not the substance as such that triggered a specific effect but that it induced an unspecific psychological and physical stimulus that was then responded to in the language that patient was accustomed to using with this therapist. (Leuner and Schlichting 1986, 162)

Unfortunately, an accident led to this initially promising research being halted. Marina Prins (1988) subsequently compared Baumann's results with those reported by Naranjo.

Today, ibogaine is in the spotlight of neuropharmacological research because it has been shown that this alkaloid can be used to reduce and cure the addictive behavior of people dependent on other drugs (heroin, cocaine) (Sanchez-Ramos and Mash 1996; cf. *Maps* 6 [2; 1996]: 4–6). For example, ibogaine has been found to suppress the motor activity that occurs during opiate withdrawal. It has been proposed that ibogaine, when

ingested by opiate addicts in a single high dosage, dramatically reduces withdrawal symptoms while simultaneously causing a trip that provides the patient with such deep insights into the personal causes of the addiction that a majority of the individuals who receive such therapy can live for months without relapse. However, it should be noted that several additional sessions may be necessary before a persistent stabilization occurs. (Naeher 1996, 12)

Experiments with primates have shown that ibogaine reduces opiate addiction and partially blocks withdrawal symptoms. Although the neuropharmacological mechanism behind these effects has not yet been discovered, Deborah Mash and her team in Miami (Mash 1993; Mash et al. 1995) are researching this question. Ibogaine has been demonstrated to interact with numerous different receptors, and it has been concluded that this breadth of interaction is the reason for ibogaine's effectiveness in addiction therapy (Sweetman et al. 1995).

In the United States, the use of ibogaine to treat addiction has been patented as the clinical Lotsof procedure (Lotsof 1995). Whether this procedure will receive endorsement from the medical community remains to be seen (Touchette 1995). A novel about this facet of ibogaine (which incorporates such actual people as Howard Lotsof) was published in Slovenia (Knut 1994).

Ibogaine enjoys a reputation for being an exceptionally potent and stimulating aphrodisiac (Naranjo 1969*).⁵⁰² The research to date has entirely neglected this aspect.

Another substance of pharmacological and therapeutic interest is noribogaine, which is chemically and pharmacologically very similar to Prozac (fluoxetine). In the United States, Prozac is one of the most frequently prescribed psycho-pharmaca for depression, and it is celebrated as the "happy drug" in the popular press (Kramer 1995; Rufer 1995*).

Dosage and Application

Two to four tablets containing up to 8 mg ibogaine per tablet may be given daily as a stimulant for states of exhaustion, debility, et cetera. Nausea, vomiting, and ataxia are possible side effects. When used for psychotherapeutic purposes (Baumann), dosages of 3 to 6 mg of ibogaine hydrochloride per kg of body weight were administered. For psychoactive purposes, dosages of around 200 mg are recommended (Prins 1988, 47).

Commercial Forms and Regulations

Ibogaine was formerly available as a medicine under the trade name Bogadin (Schneider and McArthur 1956). In the United States, ibogaine is considered a Schedule I drug and has been prohibited since 1970. However, ibogaine hydrochloride is marketed under the trade name Endabuse

and can be used with the appropriate special permit. In Germany, ibogaine is not considered a narcotic under the guidelines of the narcotic laws and is therefore legal (Körner 1994, 1573*).

“We are assuming that ibogaine triggers a fractal time structure that resembles the architecture of the REM dream phase during sleep by activating certain amygdaloid–cortico-thalamic circuits in the brain stem.”

JULIE STALEY

LECTURE AT THE ENTHEOBOTANY CONFERENCE (SAN FRANCISCO, 1996)

The Slovenian novel *Iboga*, by Amon Knut Jr., has as its subject the therapeutic effects of ibogaine for alcoholism, cocaine abuse, heroin addiction, and nicotine dependency. (Book cover; Maribor: Skupina Zrcalo Publishers, 1994)

Ibotenic Acid

Other Names

α -amino (3-hydroxy-5-isoxazolyl)acetic acid, $\tilde{\alpha}$ amino-2,3-dihydro-3-oxo-5-isoxazole-acetic acid, ibotenic acid, “pilzatropin,” prämuscimol

Empirical formula: C₅H₆O₄N₂

Substance type: amino acid

Ibotenic acid was first isolated in 1964 from the Japanese mushroom *Amanita strobiliformis* (Paul) Quél. The Japanese name for this mushroom is *ibotengu-take* (“warty *tengu* mushroom”), and ibotenic acid was named after it (Ott 1993, 341*; Takemoto et al. 1964). Ibotenic acid is also found in *Amanita muscaria* and *Amanita pantherina* (Eugster et al. 1965). It may also be present in members of the genus *Botelus* (porcini mushrooms).

Ibotenic acid is structurally related to the neurotransmitter glutamate and may behave similarly in the nervous system. A psychoactive dose is regarded as 50 to 100 mg. Ibotenic acid is converted into **muscimol** when stored (Good et al. 1965).

Ibotenic acid

A traditional mask of *tengu*, the Japanese fly agaric mushroom spirits. Ibotenic acid was named after these spirits and their mushroom.

Commercial Forms and Regulations

Ibotenic acid is available from chemical suppliers and is a legal substance (Ott 1993, 440*).

Indole Alkaloids

Other Names

Indolalkaloide, indolamine alkaloids, indole, indoles

Indole alkaloids are derived from the indole ring system and appear almost exclusively in the families Apocynaceae⁵⁰³ (*Alchornea* spp., *Alstonia scholaris*, *Aspidosperma quebracho-blanco*, *Catharanthus roseus*, *Rauvolfia* spp., *Tabernaemontana* spp., *Tabernanthe iboga*, *Vinca* spp., *Voacanga* spp.), Loganiaceae (*Gelsemium sempervirens*, *Strychnos nux-vomica*, *Strychnos* spp.), and Rubiaceae (*Corynanthe* spp., *Mitragyna speciosa*, *Pausinystalia yohimba*). Indole alkaloids also occur in certain ascomycetes (*Balansia cyperii*, *Claviceps paspali*, *Claviceps purpurea*, *Claviceps* spp.), other fungi (Tyler 1961), and several climbing vines (*Ipomoea violacea*, *Turbina corymbosa*) (Hofmann 1966; cf. **ergot alkaloids**).

Included among the large group of indole alkaloids (Trojánek and Blaha 1966) are the **β-carbolines** with **harmaline** and **harmine**; the tryptamine derivatives **bufotenine**, *N,N*-DMT, **5-MeO-DMT**, **psilocybin**, and psilocin; the ergot alkaloids; and the alkaloids of the ibogane type (ibogaine, voacangine), yohimbane type (**yohimbine**), and strychnane type (**strychnine**). Indoles are also found in the genus *Uncaria*, several species of which are used as **ayahuasca** additives (Phillipson and Hemingway 1973).

Many indole alkaloids are psychoactive or occur in plants that are utilized for traditional psychoactive purposes (Lindgren 1995; Rivier and Pilet 1971; Schultes 1976).

Mescaline

Other Names

Mescaline, meskalin, mezcalin, mezkalin, 3,4,5-trimethoxy-benzolmethanamine, 3,4,5-trimethoxy- β -phenethylamine, 3,4,5-trimethoxyethyl-phenylamine, TMPFA, 2-(3,4,5-trimethoxy-phenyl)-ethylamine

Empirical formula: $C_{11}H_{17}NO_3$

Substance type: lophophora alkaloid, β -phenethylamine

Mescaline was first isolated in 1886 from “mescal buttons,” the aboveground parts of the peyote cactus (***Lophophora williamsii***), and was named after them. Mescaline is the most thoroughly studied of all psychoactive plant constituents. In the period between 1886 and 1950, more than one hundred mescaline research studies were published in the German language alone (Passie 1994). This alkaloid was found to be a component of numerous cacti (see the table on page 847). And it is possible that mescaline is produced from dopamine in vitro (Paul et al. 1969; Rosenberg et al. 1969).

Arthur Heffter was the first person to initially test an isolated plant constituent on himself (Heffter 1894). The classic Heffter dosage consisted of 150 mg mescaline hydrochloride (HCL). A psychedelic dosage is now considered to be 178 to 256 mg of mescaline HCL or 200 to 400 mg of mescaline sulfate. The highest measured dosage reported in the literature was 1,500 mg. Taken orally, 5 mg/kg of pure mescaline is regarded as a hallucinogenic dosage. In the toxicological literature, there is no known lethal dosage of mescaline when it is ingested orally (Brown and Malone 1978, 14).

Western psychiatry has been aware of consciousness-altering drugs since the nineteenth century. Mescaline was the first substance to be tested and applied in psychiatry. At the time, researchers regarded the effects of mescaline on a healthy subject as inducing a state that was otherwise known only in psychopathic patients. This led to the idea of pharmacologically induced “model psychoses” (Leuner 1962*). The effects of mescaline (and also of **psilocybin**) were described as “intoxication, toxic ecstasy, clouding of consciousness, hallucinosis, model psychosis, drug intoxication, emphasis, daydream,” et cetera (Passie 1994). Only in recent years has there been a shift in thinking away from the model psychosis concept and a recognition that psychedelic states and psychoses do not have a common origin (Hermle et al. 1988*, 1992*, 1993*).

The predominant effects of mescaline are a “reveling of the individual senses and primarily visual orgies” (Ellis 1971, 21). The mescaline inebriation was first systematically described by Kurt Beringer in 1927. To date, there have been many encounters with the substance, and the most commonly reported experiences are ecstatic and visionary in nature:

My awareness of subject and object disappeared, and I felt dissolved, rising in an orchestra of sounds. This ecstatic state was accompanied by an indescribable sensation of happiness. (Ammon and Götte 1971, 32)

It has often been suggested that pure mescaline can be taken in place of ***Lophophora williamsii***. “However, most peyote users are of the opinion that synthetic mescaline cannot be compared with the

effects of peyote” (Harp 1996, 16).

On the Cultural History of Mescaline

Aldous Huxley (1894–1963) made the psychedelic effects of mescaline famous in his two essays “The Doors of Perception” and “Heaven and Hell.”

Usually the person taking mescaline will discover an inner world that is so obviously something given, so enlighteningly eternal and sacred, as the transformed outer world that I had perceived with my eyes open. (Huxley 1970, 32*)

It is very likely that Hermann Hesse also had contact with mescaline, and that it may have inspired his novel *Steppenwolf*, one of the cult books of the hippie generation. The psychedelic rock band Steppenwolf took its name from the book, and the novel also became a motion picture starring Max von Sydow (USA 1974).

Nationalgalerie, a German New Wave band, sings on its album *Mescaline*, “To be transformed by a trickster fairy. My lawyer advised me to take some mescaline” (Sony Records, 1995).

Mescaline

“Peyote is always on mescaline.
Humans are sometimes on mescaline.
But no peyote could stand to always be on human.
We are but a side-effect of god.”
GALAN O. SEID UNPUBLISHED POEM (CA. 1985)

“Mescaline is the final, ultimate cult that does away with every cult.”
GÜNTER WALLRAFF *MESKALIN*
(1968, 13)

The cover of a very rare publication by the author Günter Wallraff regarding his experiences with mescaline.

Opuntia cylindrica is found in the Atacama Desert (northern Chile). It is easily identifiable by its very long, reddish thorns. The cactus contains mescaline, and the former inhabitants of oases in the region may have once used it for psychoactive purposes.

Cacti Containing Mescaline

(from Doetsch et al. 1980; La Barre 1979; Mata and McLaughlin 1982*; Shulgin 1995*; Lundström 1971; Pardanini et al. 1978; Ott 1993*; Turner and Heyman 1960)

Some species from the genus *Gymnocalycium* have been found to contain mescaline.

□

Although mescaline has been detected in some members of the genus *Opuntia*, no traditional use of these plants as psychoactive substances is known.

The French novelist and artist Henri Michaux (1899–1984) studied mescaline during the 1960s and ingested it to see what effects it might have upon his creativity. Like many other Frenchmen, however, he summarized his experience as an “accursed miracle” and scribbled his experiences of inner turmoil on paper (Michaux 1986). Today, these “drawings” are still reproduced in publications as an example of the “psychosis-like” effects of mescaline.

Commercial Forms and Regulations

Mescaline is available primarily as a hydrochloride or sulfate. In Germany, it is considered a “narcotic in which trafficking is prohibited.” In the United States, the Controlled Substances Act lists mescaline as a Schedule I substance (Körner 1994, 38*).

□

Many species of the Mexican prickly pear (*Opuntia* spp.) contain mescaline and other phenethylamines. To date, we know of no *Opuntia* that was used traditionally as an entheogen. (Woodcut from Tabernaemontanus, *Neu Völlkommen Kräuter-Buch*, 1731)

Morphine

Other Names

4,5α-epoxy-17-methyl-7-morphinen-3,6α-diol, morfina, morphin, morphinium, morphium

Empirical formula: $C_{17}H_{19}NO_3$

Substance type: **opium alkaloid**

Sometime around 1803 and 1804, Friedrich Wilhelm Adam Sertürner (1783–1841), a pharmacist's assistant, first isolated morphine as the “sleep-inducing principle” in opium (cf. ***Papaver somniferum***, **opium alkaloids**). This achievement was the most important “quantum leap” in the history of pharmacology and represents the beginning of the true chemical investigation of plants. Today, the Sertürner Medal is still awarded for exceptional work in pharmaceuticals.

Morphine may also be present in *Papaver decaisnei* Hochst., *Papaver dubium* L. [syn. *Papaver modestum* Jordan, *Papaver obtusifolium* Desf.], and *Papaver hybridum* L. (Slavík and Slavíková 1980). Whether morphine occurs in ***Argemone mexicana*** and other *Papaver* species (***Papaver spp.***) is doubtful, while the idea that hops (***Humulus lupulus***) contains morphine is a figment of someone's imagination. Tiny traces of the substance have been found in hay and lettuce (cf. ***Lactuca virosa***) (Amann and Zenk 1996, 19). Morphine has also been detected in the skin of *Bufo marinus* toads (cf. **bufotenine**) (Amann and Zenk 1996, 18).

Morphine

“Morphine is to opium as alcohol is to wine.”

JEAN-MARIE PELT *PFLANZENMEDIZIN* [PLANT MEDICINE]
(1983, 70*)

Since the time when morphine was first detected in breast milk, cow's milk, and human cerebrospinal fluid, it has been known that it is a natural endogenous neurotransmitter in higher vertebrates, including humans (Amann and Zenk 1996; Cardinale et al. 1987; Hazum et al. 1981). Morphine does not bind well to the enkephalin receptors (to which the endorphins dock) but docks at the specific morphine (m) receptors (Hazum et al. 1981). It is most likely biosynthesized in the body from dopamine (Brossi 1991). Another closely related substance, **codeine**, is also endogenous in humans (Cardinale et al. 1987).

Morphine is the best and strongest natural painkiller known. Its efficaciousness is surpassed only by that of the synthetic morphine analogs (heroin, fentanyl). Morphine is particularly well suited for treating chronic pain, such as in cancer therapy (Amann and Zenk 1996; Melzack 1991). Endogenous morphine constitutes the body's own pain medication:

Studies on rats have shown that among animals who were suffering from arthritis, morphine concentrations in the spinal cord and urine were significantly elevated. Because of this, it is

assumed today that the organism produces increased amounts of morphine in certain disease states. Consequently, endogenous morphine may serve to regulate pain in the organism. Morphine exists in animal and human tissue and is excreted in significant amounts in the urine. (Amann and Zenk 1996, 24)

About 30 mg orally represents an effective dosage. Habitual morphine users may use as much as 1 g per day (Hirschfeld and Linsert 1930, 255*):

It is known that opium eaters experience a significant increase in sexual functions during the initial period of opium consumption. During opium inebriation, erotic images appear and may even include extraordinary sexual fantasies. . . . The effects of morphine are similar, where an increase in sexual excitability was observed following several weeks of taking 0.03 to 0.06 g per day. (Max Marcuse, 1923, *Handwörterbuch der Sexual-wissenschaft* [Handbook of Sexual Sciences])

When used for sedation, in anesthesia, and for calming and antispasmodic purposes, pharmaceutical preparations of morphine hydrochloride and **atropine** sulfate or morphine hydrochloride and **scopolamine** hydrobromide are used—the final reminders of the recipes for the former **soporific sponges**.

During the Golden Twenties, the use of morphine in Berlin society circles was depicted in numerous pictures and illustrations (e.g., by Paul Kamm) that appeared in magazines. These illustrations played a great role in creating the stereotype of the “Morphinist”(cf. *Papaver somniferum*), who also became the object of literary treatments (Bulgaka 1971; Mac From 1931). Even the life story of the man who first discovered the substance, Friedrich Wilhelm Sertürner, became the subject of a novel (Schumann-Ingolstadt n.d.). Heroin, a derivative of morphine, has also inspired a rich body of literature. One of the first of this was the novel *Heroin*, by Rudolf Brunngraber (1952*), which dealt with the role of heroin in Egypt during the Golden Twenties.

Morphine was and still is a popular inebriant in the music scene (particularly that of jazz and rock). “Sister Morphine,” a song by the Rolling Stones (*Sticky Fingers*, Virgin Records, 1971), is arguably the most famous hymn to the drug. Morphine, a crossover band that mixes elements of cool jazz and modern rock, took its name from the alkaloid, and one of its albums is titled *Cure for Pain* (Rykodisc, 1993).

Commercial Forms and Regulations

Morphine is available from pharmacies in the form of morphine hydrochloride. Although morphine is covered by narcotics laws, it can be obtained with a special prescription. In the United States, morphine is a Schedule II substance.

“Illusionary ecstasies travel down confused nerves,
nervous trembling moves through pale hands,
the lips, red as a poppy, narrow as a knife, foam,
As if sensing blood in cups of gold,
A fragrance of orchids in the room,
pale yellow, heavy azaleas,
An arm bends in crazed desire,
A mouth grimaces quietly,
A gasp presses from the narrow chest: Morphi-um!”

ED. GOLLAND BRESLAU

IN *DER JUNGGESELLE* [THE BACHELOR]

(1921)

In the early twentieth century, morphine (also known as morphium) was used as a cure for alcoholism. (Advertisements from German magazines 1907/1908)

The discovery of morphine or morphium led to some of the most significant innovations in the history of pharmacology and neurophysiology. The discovery has been described many times, even in novels. (Book cover, no date; novelized version of the life of German researcher F. W. Sertürner)

The American jazz-rock fusion trio Morphine has the best “cure for pain”: one of their songs is called “Let’s Take a Trip Together.” (CD cover 1993, Rykodisc)

“Please, Sister Morphine, turn my nightmares into dreams.
Oh, can’t you see I’m fading fast
and that this shot will be my last . . .”

Muscimol

Other Names

Agarin, 5-(aminomethyl)-3-[2*H*]-isoxazolone, pyroibotenic acid, 3-hydroxy-5-aminomethyl-isoxazole

Empirical formula: C₄H₆O₂N

Substance type: amino acid, isoxazole derivative

Muscimol was first described in 1964 as a constituent of ***Amanita pantherina***. Muscimol is the decarboxylated product of **ibotenic acid** and is considered to be more psychoactive than it. Some 15 to 20 mg is regarded as a psychoactive dosage (Müller and Eugster 1965; Ott 1993, 446*; Scotti et al. 1969).

Muscimol is an analog of the neurotransmitter GABA (gamma amino butyric acid) and docks to its receptor (Johnston 1971). Kavapyrones (cf. ***Piper methysticum***) also bind to the same receptor.

Ibotenic acid as well as muscimol were detected in the urine of people who had eaten fly agaric mushrooms (***Amanita muscaria***) about an hour earlier. An experiment with mice conducted by the same team of researchers found that the amount of active constituents in the urine passed by one inebriated animal was not sufficient to inebriate another animal (Ott et al. 1975).

Commercial Forms and Regulations

Muscimol can be purchased from chemical suppliers. The substance is legal and is not subject to any specific regulations.

Muscimol

The panther cap (*Amanita pantherina*) is found throughout Eurasia and North America. Its effects are similar to, but more pronounced than, those of the fly agaric. (Photograph: Paul Stamets)

Nicotine

Other Names

Nicotin, nikotin, (–)-nikotin , 1-methyl-2(3-pyridyl)-pyrrolidine, 3-(1-methyl-2-pyrrolidinyl)pyridine

Empirical formula: C₁₀H₁₄N₂

Substance type: pyrrolidine alkaloid, pyridine alkaloid, tobacco alkaloid

Nicotine was first discovered in tobacco (*Nicotiana tabacum*) and was named for the genus. It occurs in numerous species of *Nicotiana* as well as other members of the Nightshade Family. It has also been found in club moss (*Lycopodium clavatum*).

Nicotine is very easily absorbed through the mucous membranes and even through the skin. Consequently, plants that contain nicotine can be smoked or administered as **enemas**. Nicotine is broken down through oxidation, and about 10% is excreted unchanged. It has stimulating effects upon the central nervous system and has paralyzing effects at very high dosages (cf. **cytisine**). In the peripheral nervous system, nicotine behaves in a similar manner as the neurotransmitter acetylcholine. High dosages can result in sudden death due to respiratory paralysis or cardiac arrest within five minutes of ingestion (Roth et al. 1994, 864*). From 40 to 60 mg represents a lethal dosage for humans (Frerichs, Arends, Zörnig, *Hagers Handbuch*). **Diazepam** can be effective as an antidote for nicotine poisoning (Roth et al. 1994, 865*). Nicotine is now generally regarded as highly “addictive” (Schiffman 1981). Although it is commonly assumed that nicotine causes cancer, uncertainty has been expressed about this theory (Schievelbein 1972).

Nicotine has been detected in Egyptian mummies (New Kingdom) (Balabanova et al. 1992*). However, this discovery should not be taken as evidence that the Egyptians knew of wild tobacco (*Nicotiana rustica*), as the Balabanova team in Munich has suggested, for some Old World plants also contain nicotine (see the table at right).

Commercial Forms and Regulations

Nicotine can be obtained in its pure form from chemical suppliers. It is subject to the laws covering the transport of dangerous substances and is classified as a Category 1 substance on the Swiss Poison List. In the United States, pure nicotine is available only with a prescription (Ott 1993, 447*). In Germany, it is subject to the laws regarding dangerous substances but is not regarded as a “narcotic.”

Plants Containing Nicotine

(from Bock 1994, 93*; Römpf 1995, 2995*; Schultes and Raffauf 1991, 37*; supplemented)

Nicotine

A smoking Indian inspects his tobacco plants. Native Americans cultivate tobacco strains with especially high nicotine contents.

N,N-DMT

Other Names

Dimethyltryptamin, dimethyltryptamine, DMT, nigerin, nigerina, nigerine (1946), *N,N*-dimethyltryptamine, 3-[2-(dimethyl-amino)ethyl]-indole

Empirical formula: C₁₂H₁₆N₂

Substance type: tryptamine (**indole alkaloid**)

R. H. F. Manske first created DMT as a synthetic substance in the laboratory in 1931. It was not until 1955 that it was isolated as a natural compound in the seeds of *Anadenanthera peregrina*. It is found in a great number of plants and also occurs naturally in humans and other mammals (see table, pages 853–854). *N,N*-DMT is closely related to **5-MeO-DMT** and **psilocybin**/psilocin.

N,N-DMT and 5-MeO-DMT are among the psychedelics whose effects are short in duration. They are not orally effective in an isolated form (as a salt or a base) because the MAO enzyme breaks them down before they can pass through the blood–brain barrier (cf. **ayahuasca**, **β-carbolines**). They reveal their awesome effects only when injected by syringe (Strassman et al. 1994), snuffed, or smoked. When *N,N*-DMT or 5-MeODMT is injected intravenously, the effects last some forty-five minutes; when the substance is smoked or snuffed, the effects last only ten minutes. Subjectively, however, those few minutes may seem to have spanned centuries. People who have had experiences with DMT unanimously agree that it is easily the most powerful psychedelic known (cf. McKenna 1992; Meyer 1992). Some people have described DMT as “crystallized consciousness.” When DMT is smoked, it is said that the “scent of enlightenment” fills the air. Only “a few seconds after taking it, DMT acts like the trumpets of Jericho upon the gates of perception” (Kraemer 1995, 98). DMT experiences can be so extraordinarily alien that most subjects find it extremely difficult or even impossible to describe them in words. Many people speak of contact with strange beings (aliens, fairies, machine elves, et cetera) (Bigwood and Ott 1977; Leary 1966; McKenna 1992; Meyer 1992).

When pure DMT is smoked or vaporized and inhaled, the effective dosage lies around 20 mg (although amounts as high as 100 mg are sometimes smoked). The dosage for **ayahuasca** and **ayahuasca analogs** ranges from 50 to 100 mg. When DMT is injected, the typical dose is 1 mg/kg of body weight (Ott 1993, 433*).

DMT is also produced in the human nervous system, where it appears to serve an important function as a neurotransmitter (Barker et al. 1981; Callaway 1996; Siegel 1995b). Neurobiologists are as yet uncertain about the role DMT might play in the nervous system. Hyperventilating causes the concentration of DMT in the lungs to increase (Callaway 1996). One physician has reported that the release of endogenous DMT is highest at the moment of death. It is my opinion that this chemical messenger is responsible for the ultimate shamanistic ecstasy, for enlightenment, and for the merging into the “clear light of death.” An experiment in which DMT was given to practicing Buddhists found that the subjects had experiences and visions that corresponded to the Buddhist teachings (Strassman 1996).

DMT has clearly inspired numerous novels in the fantasy and science-fiction genres. The novel *Kalimantan* deals with the search for a fictitious hallucinogenic drug called *seribu aso*. The

descriptions of the effects of this drug agree perfectly with the descriptions of DMT trips (Shepard 1993). Several novels, including the *Valis* trilogy of the science-fiction master Philip K. Dick (1928–1982), also appear to represent a literary attempt to understand the hyperdimensionality of DMT experiences (Dick 1981a, 1981b, 1982).

Commercial Forms and Regulations

DMT occurs as a free base, an HCL, and a fumarate. Although the fumarate crystallizes out easily, it contains only 60% of the pure substance. DMT is classified as a Schedule I drug in the United States and is a “narcotic drug in which trafficking is not allowed” in Germany as well as in Switzerland (Körner 1994, 38*).

N,N-DMT

“DMT is everywhere!”

DR. ALEXANDER T. SHULGIN

ASK DR. SHULGIN ONLINE DRUG INFORMATION WEB SITE OF THE CENTER FOR COGNITIVE LIBERTY AND ETHICS

“DMT is the *Tyrannosaurus rex* of psychedelics.”

T-SHIRT

“DMT trips are some of the most intense drug experiences in the world and only the fact that they last a short time makes them tolerable. . . . Every human brain also normally contains DMT. Why? What is such a strong drug doing there? Why does stress increase the amount of DMT, which is then released into the cerebrospinal fluid—the fluid that surrounds the spinal cord?”

RONALD SIEGEL *HALLUZINATIONEN* [HALLUCINATIONS] (1995B, 401*)

The seeds of the Leguminosae *Desmodium tiliaefolium* contain detectable amounts of *N,N*-DMT and bufotenine.

Plants Containing DMT

(from Block 1994*; Smith 1977; Montgomery, pers. comm.; Ott 1993*; Schultes and Hofman 1980, 155*; supplemented)

DMT has been detected in several species of *Desmodium*. (From Hernández, 1942/46 [Orig. pub. 1615]*)

“The first puff immediately took me into a completely different reality, a reality immanent to the normal one but surpassing it by leaps and bounds. Dripping and pearling off my companions were blue and violet dabs of color that extended and flowed together through the room. The small drops were overlapping and pushing into each other, arranging themselves into the most magnificent patterns and forming a circle.

“When the room had become a cathedral of dancing patterns, rays of light shot through the room, jumping from one person to the next. A glowing ring of bodiless consciousness and high-caliber energy shot through the circle. The chakras were blooming. I was able to see and feel them clearly. The kundalini energy shot to the top and sprayed from the heads, to join together with the eternity of that which can be experienced. I sensed the power of the ring and was initiated into an ancient cult. The person across from me looked like a priest from an earlier culture.

“The bustling activity of the patterns of magnificent color and thousandfold patterns became wilder and ever more intense. I was able to perceive absolutely the same things whether I kept my eyes open or closed. The flying lights and swinging colors became pure light that condensed into cosmic laughter. A tryptamine initiation.”

Opium Alkaloids

Other Names

Opiate, opiates, opium compounds

The study of opium and the isolation of its constituents ranks among the most important achievements in the history of pharmacology (cf. *Papaver somniferum*). In ancient times, opium was already known as the best of all analgesics (cf. **soporific sponge**). The isolation of **morphine** from opium revolutionized pain therapy in Europe. No other component of opium has a comparably powerful effect. The potency of morphine would not be exceeded until heroin (diacetylmorphine) was synthesized (Snyder 1989). Subsequent pharmacological research has led to the creation of numerous morphine analogs (fentanyl), some of which are as much as 7,500 times more potent than morphine (Sahihi 1995, 31ff.*).

The opium alkaloids **codeine** and **morphine** have become culturally significant as psychoactive substances. **Papaverine** is used in medicine as a treatment for impotence.

Some opium alkaloids are also found in other *Papaver* species (***Papaver spp.***), although these species usually contain only traces of these substances (Khanna and Sharma 1977; Küppers et al. 1976; Phillipson et al. 1973; Phillipson et al. 1976).

Aporphines, whose structures are analogous to those of the opium alkaloids, occur in *Papaver fugax* Poir. [syn. *Papaver caucasicum* M.-B., *Papaver floribundum* Desf.] and ***Nymphaea ampla***. Other substances related to the opium alkaloids are present in ***Argemone mexicana***, ***Eschscholzia californica***, ***Nuphar lutea***, and ***Papaver spp.***

“The hall of wonder drugs [at the German Museum in Munich] is huge, a curious demonstration of German pharmacology. Morphine, methamphetamine, adolphine (a synthetic heroin named after Hitler), etc. Every drug on display comes with a complete little biography of its own. The little sign next to methamphetamine says that it was given to Stuka pilots in World War II and that soldiers at the eastern front took it in order to stay awake. And that it was Hitler’s favorite drug. We learn about the various nicknames: ‘coffee substitute,’ ‘lightning powder,’ etc.”

ROCK SCULLY

AN AMERICAN ODYSSEY (1996, 15 f.)

The most powerful tool of the American heavy metal band Tool is a strong *Opiate* (CD cover 1992, BMG Music)

The Constituents of Opium

The composition of the alkaloid mixture can vary greatly, depending upon the strain of poppy, the location of cultivation, and the processing technique (Krikorian and Ledbetter 1975).

Papaverine

Other Names

1-(3,4-dimethoxybenzyl)-6,7-dimethoxyisochino-line, papaverin, papaverina, papavérine

Empirical formula: $C_{20}H_{21}NO_4$

Substance type: **opium alkaloid**

Papaverine is a component of opium (0.3 to 0.8%) and was named after the genus *Papaver* (cf. *Papaver somniferum*). Papaverine has very weak psychoactive properties but is a powerful vasodilator. Effective dosages start at 200 mg. An extract of *Nuphar lutea* has similar effects.

In recent years, papaverine has been used to treat impotence, often with good success (Mellinger et al. 1987). When used for this purpose, the substance is injected directly into the corpus cavernosum when the penis is flaccid (so-called SKAT therapy; cf. Ernst et al. 1993). Among the problems that this method may cause are painful priapism (persistent erections for up to thirty-six hours without sexual arousal!) and inflammation of the penis (Sanders 1985).

Commercial Forms and Regulations

The substance, available as papaverine hydrochloride, is sold in suppository form and in solution for injection. Papaverine is available only with a prescription.

Papaverine

Papaverine, an active constituent isolated from opium, is prescribed for impotence and is injected into the penis.

Psilocybin/Psilocin

Other Names

Psilocybin: CY-39, indocybin, O-phosphoryl-4-hydroxy-*N,N*-dimethyltryptamine, 3(2-dimethyl-amino)ethylindol-4-ol dihydrogenphosphatester

Psilocin: 4-hydroxy-*N,N*-dimethyltryptamine, psilocine, psilocyn (misspelling in the legal literature), 3-[2-(dimethylamino)ethyl]-1*H*—indole-4-ol

Empirical formula: C₁₂H₁₇N₂O₄P (psilocybin), C₁₂H₁₆N₂O (psilocin)

Substance type: tryptamines, indole amines (**indole alkaloids**)

Psilocybin was first isolated from ***Psilocybe mexicana*** and identified by Albert Hofmann in 1955 (Hofmann et al. 1958, 1959). The phosphorylated indole amine psilocybin is transformed into psilocin by splitting off the phosphoric acid group (Hofmann and Troxler 1959). Because the protection the phosphoric acid would provide is lacking, psilocin easily oxidizes with the phenolic hydroxyl group, resulting in blue quinonoid products. This explains why psilocybin mushrooms turn blue after they have been squeezed and harvested (cf. ***Panaeolus cyanescens***, ***Psilocybe cyanescens***). In the body, psilocybin is immediately metabolized into psilocin, which is the actual psychoactive constituent.

Psilocybin and psilocin are closely related to baeocystin (= O-phosphoryl-4-hydroxy-*N*-methyltryptamine, norpsilocybin), which probably represents the biogenic precursor of psilocybin (Repke et al. 1977; cf. also Brack et al. 1961 and Chilton et al. 1979). Baeocystin may be a derivative of tryptophan (Brack et al. 1961).

The usual psychedelic dosage of psilocybin is 10 mg. When psilocybin is taken orally, the effects typically become apparent in about twenty minutes⁵⁰⁶ (Shulgin 1980). Rudolf Gelpke (1928– 1972) took between 6 and 20 mg during his self-experiments; with 10 mg, he made his historic “journey to the outer space of the soul”:

Psilocybin

Psilocin

This inebriation was a space flight not into the outer realm, but into the inner person, and for a moment I experienced reality from a position located somewhere beyond the gravity of time. (Gelpke 1962, 395)

With very high dosages, it is common to perceive voices (Beach 1997). This could explain why Indians say that the mushroom talks to them. Toxic dosages are unknown!

Walter Pahnke’s “Good Friday experiment,” in which theology students were administered psilocybin in a church on Good Friday, has become renowned. Pahnke applied the theory of dosage,

set, and setting as part of the test to see whether mystical revelations would occur, which was indeed the case (Pahnke 1972; Pahnke and Richards 1970; cf. Doblin 1991).

Timothy Leary and his colleagues at Harvard experimented with psilocybin on prisoners. Their experiments were aimed at determining whether the psychedelic constituent was suitable for use in therapy with inmates. It was hoped that the drug experience would enable the prisoners to attain insights into their behavior that would then enable them to change themselves on their own. Although these experiments showed great promise, they had to be terminated (Clark 1970; Forcier and Doblin 1994; Riedlinger and Leary 1994).

Both psilocybin and two synthetic derivatives (CZ-74, CY-19) have been used with success in psychedelic and psycholytic therapy (Leuner 1963; Leuner and Baer 1965; Passie 1995, 1996). Psilocybin can release, stimulate, and inspire creativity (Fischer et al. 1972), as an increasing number of studies have shown (Baggott 1997; Spitzer et al. 1996), and “archetypal art therapy” is making use of this effect (Allen 1995).

Today, psilocybin is playing a central role in neurochemical research into brain activity, in which it is being studied with the very elaborate and costly positron-emission tomography (PET) method (Vollenweider 1996).

Jochen Gartz has discovered that fungal enzymes synthesize the “synthetic” psilocin analog CZ-74 (diethyl-4-hydroxytryptamine, 4-OH-DET) from diethyltryptamine when it is added to a ***Psilocybe spp.*** substrate (J. Gartz, pers. comm.). It is possible that the “synthetic” CY-19 (= diethyl-4-phosphoryloxytryptamine) can be produced in the same fashion.

Commercial Forms and Regulations

Both psilocybin and psilocin are classified as Schedule I drugs in the United States (Shulgin 1980). They are internationally regarded as illegal “narcotics.” The analog substances psilocin-(eth) and psilocybin-(eth) are also illegal (Körner 1994, 40*).

Microscopic views of psilocybin and psilocin, the active constituents in mushrooms, after crystallization from methanol.
(Photograph: Albert Hofmann)

Baeocystin

Tryptophan

The structural formulas of the two active mushroom constituents psilocybin and psilocin, shown here in the handwriting of their discoverer, Albert Hofmann.

“The chemical structures of psilocybin and psilocin were new and important in a number of ways. These two mushroom constituents were the first naturally occurring indole compounds with a hydroxyl function in the 4th position of the indole system. Psilocybin is the only known indole alkaloid [apart from its analog baeocystin] in which there is a substituted phosphoryloxy group. The chemical relationship between psilocin and the neurotransmitter serotonin is of particular importance.”

Salvinorin A

Other Names

Divinorin A

Empirical formula: $C_{23}H_{28}C_8$

Substance type: **diterpene** (clerodane)

Salvinorin A is the active constituent in *Salvia divinorum*. Apart from **THC** and the constituents in **essential oils**, it is the only known nonnitrogenous psychoactive plant constituent. Salvinorin is not an alkaloid.

The substance was first described by Ortega et al., who named it salvinorin (1982). The same substance was subsequently described under the name divinorin A (Valdes et al. 1984). Salvinorin A is extracted from fresh plant material. The effective dosage is between 200 and 500 μ .

Salvinorin A can be smoked in a glass pipe; a better technique involves vaporizing the plant and then inhaling the fumes. It can also be taken in solution under the tongue. When the substance is smoked or inhaled, the effects are immediately apparent, and the primary effects last from five to ten minutes. When it is administered sublingually, the effects become manifest after about ninety seconds and reach their peak some ten to fifteen minutes later, after which they gradually diminish (Turner 1996).

The potent and strange psychoactive effects of salvinorin A were probably discovered by Daniel Siebert:

Salvinorin A is an extremely powerful compound for altering consciousness. In fact, it is **the most potent naturally occurring hallucinogen** that has been isolated to date. But before potential experimenters become too interested, it must be clearly stated that the effects are often **extremely** unnerving and that there is a very real risk that persons may physically harm themselves when using it. . . .

I have seen people get up and jump across the room, thereby falling over the furniture, babbling incomprehensible nonsense, and hitting their heads against the wall. Several people tried to leave the house. When the experience was over, they did not remember what had happened. In fact, they actually believed that they remembered entirely different events. To an outside observer, it appears as though these people have an empty expression in their eyes, as though they are not present (and perhaps they really are not). (Siebert 1995, 4)

This description is strongly reminiscent of phenomena that occur with high dosages (overdoses) of nightshades (*Atropa belladonna*, *Brugmansia* spp., *Hyoscyamus niger*, *Datura* spp.) and the tropane alkaloids **atropine** and **scopolamine**. Most subjects have no desire at all to repeat an experiment with salvinorin.

The neurochemistry of salvinorin A is still unresolved. In spite of extensive receptor testing (NovaScreen method), salvinorin A has not been found to bind to any known neurotransmitter receptors, including the receptor that ketamine occupies (David Nichols, pers. comm.). The daring

and extreme experiments of D. M. Turner suggest that salvinorin A does not have any negative cross-tolerance with other psychoactive substances (such as LSD, **N,N-DMT**, ketamine) (Turner 1996).

Commercial Forms and Regulations

None

Scopolamine

Other Names

Hyoscin, (–)-hyoscin, hyoscine, hyoszin, L6(–),7-epoxytropin-tropate, *l*-hyoscine, scopolamin, [7(S)-(1 α ,2 β ,4 β ,5 α ,7 β)]- α -(hydroxymethyl) benzeneacetic acid 9-methyl-3-oxa-9-azatricyclo-[3.3.1.0^{2,4}]non-7-ylester, skopolamin, tropane acid ester of skopolin

Empirical formula: C₁₇H₂₁ON₄

Substance type: **tropane alkaloid**

Scopolamine was first isolated in 1888 by E. Schmidt from the roots of “*Scopolia atropoides*” (= *Scopolia carniolica*). It is very closely related to **atropine** and is a characteristic component of plants from the Nightshade Family (Solanaceae), especially the psychoactive species. For the pharmaceutical industry, the most important sources of scopolamine are the Australian duboisias (*Duboisia* spp.), the dried leaves of which can contain up to 7% alkaloids. Scopolamine is also produced by the recrystallization of hyoscyamine.

For medicinal purposes, scopolamine is administered at dosages of 0.5 to 1 mg, with a total daily maximum dosage of 3 mg. The lowest lethal dosage for humans is about 14 mg (Roth et al. 1994:921*).

Scopolamine is a very potent hallucinogen that Leuner (1981*) classified as a “Class II” hallucinogen because of its simultaneously hallucinogenic and narcotic/consciousness-clouding effects (cf. also Dittrich 1996*).

According to Hunnius, scopolamine is utilized in medicine as a hypnotic agent, especially for cases of “agitated states in the mentally ill, for Parkinson’s and paralysis agitans, and for treating withdrawal of morphine users” (Hunnius 1975, 609*).

In contrast to atropine, which initially stimulates the central nervous system, scopolamine induces predominantly a narcotic paralysis from the beginning, which is why it serves as a “chemical straitjacket” for agitated mental patients. Delirium and hallucinations are not infrequently seen . . . with therapeutic application. . . . Chronic scopolamine poisoning with gradually increasing dosages leads to psychoses with hallucinations. (Fühner 1943, 202 f.*)

In the former East Germany, scopolamine was still being used as a “chemical straightjacket” in the 1980s (Ludwig 1982, 148*; Schwarz 1984). Scopolamine may be combined with **morphine** for the same purpose (Römpp 1950, 264*). A combination of scopolamine hydrobromide and morphine hydrochloride is used as a preoperative anesthesia (cf. **soporific sponge**). Recent tests with mice found that scopolamine hydrobromide causes a marked increase in anxiety as compared to scopolamine methylbromide (Rodgers and Cole 1995).

To treat motion sickness—a use to which scopolamine has long been put (Römpp 1950, 265*)—an adhesive patch was developed that contains 1.5 mg scopolamine and can be adhered behind the ear as needed. The active component is absorbed through the skin into the blood vessels of the ear region and affects the organs of balance in the ear. This property of scopolamine supports the idea that the

constituents found in **witches’ ointments** could be absorbed when the mixtures were rubbed onto the skin.

Scopolamine was a popular inebriant in the Munich jazz scene of the 1950s. Because the dosages used were often so high, many of the concerts had to end early.

Commercial Forms and Regulations

The alkaloid is available as scopolamine hydrobromide and scopolamine hydrochloride. Pharmacies usually carry these substances in the form of small flasks for use in injections. Scopolamine requires a prescription.

Scopoletin

Other Names

Chrysatropasäure, gelseminsäure, scopoletina, scopolétine, 7-hydroxy-6-methoxycumarine, 6-methoxyumbelliferon, skopoletin, 3-methylesculetin

Empirical formula: C₁₀H₁₈O₄

Substance type: **coumarin**

The coumarin-derivative scopoletin was first isolated from the genus *Scopolia* and is named for the genus (Chaubal and Iyer 1977). Scopoletin is found in numerous plants that are utilized for medicinal or psychoactive purposes. It is the characteristic constituent in ***Brunfelsia* spp.** (Mors and Ribeiro 1957).

Scopoletin is known to inhibit plant growth. It may possibly have a certain psychoactive effect on humans, although there is no data at present to support this assertion. Scopoletin is a substance that clearly merits additional research.

Commercial Forms and Regulations

None

Plants Containing Scopoletin

Strychnine

Other Names

Estricnina, stricnina, strychnidin-10-on, strychnin, 2,4*a*,5,5*a*,8,15*a*,15*b*,15*c*-decahydro-4,6-methano-14*H*,16*H*-indolo[3,2,1,*ij*]oxepino-[2,3,4-*de*]-pyrrolo[2,3-*h*]chinolin-14-on

Empirical formula: C₂₁H₂₂N₂O₂

Substance type: **indole alkaloid**, strychnos alkaloid

Strychnine was first isolated in 1818 by Caventou and Pelletier from the Philippine Ignatius bean (*Strychnos ignatii* Berg.; cf. ***Strychnos* spp.**). Strychnine occurs in many *Strychnos* species (Loganiaceae); the primary sources are ***Strychnos nux-vomica*** and *Strychnos ignatii*. Contrary to widespread belief, the hairs of *Lophophora williamsii* do not contain any strychnine!

Strychnine is an analeptic, a substance that at low dosages activates certain parts of the central nervous system and in higher dosages acts as a convulsive poison:

Milligram dosages of strychnine nitrate administered internally or subcutaneously cause an increased sensitivity of the senses (the feeling that vision, hearing, taste, smell are more acute) and faster reflex response. (Fühner 1943, 221*)

Strychnine docks to the glycine receptor. At lower dosages it is clearly psychoactive, in a manner very similar to **yohimbine**. The therapeutic dosage for tonic purposes is listed as 1 to 3 mg; a dosage of 5 mg produces aphrodisiac and psychoactive effects. However, 10 mg can cause convulsions, and dosages above 30 mg can lead to difficulty in breathing and severe anxiety (Neuwinger 1994, 527*). From 100 to 300 mg is normally regarded as a lethal dosage for adults, while dosages as low as 1 to 5 mg can prove fatal to small children (Roth et al. 1994, 935*). Strychnine is an extremely stable molecule and could still be detected in corpses that were exhumed as much as four years after burial (Roth et al. 1994, 935*). **Diazepam** is recommended as an antidote in cases of strychnine poisoning or overdose (Moeschlin 1980). Kavapyrones and kava-kava can also be used as antidotes for strychnine poisoning (cf. ***Piper methysticum***).

Strychnine is also an effective aphrodisiac, but the dosage must be very precise:

The literature contains numerous references to the stimulating effects of strychnine on the sexual apparatus. Many experienced immediate erections. But the extraordinary toxicity of the substance makes it an especially dangerous aphrodisiac. Strychnine has for this reason always played a dangerous role in criminality in this regard as well. (Hirschfeld and Linsert 1930, 210*)

A very effective recipe for a “firm erection” can be prepared with strychnine and other substances (from Gottlieb 1974, 81*):

5 mg **yohimbine** hydrochloride

5 mg methyltestosterone

25 mg pemoline

2 mg strychnine sulfate

Strychnine is said to have been the favorite drug of Adolf Hitler, who also appears to have used cocaine (Schmidbauer and vom Scheidt 1984, 260*):

Moreover, we will never know if and how Hitler's strategy and war leadership might have changed if he had not been making his decisions while in a euphoric trance state induced by high dosages of strychnine. . . . (Irving 1980, 135)

Strychnine has also had an impact on sports because of its prominent role as a doping agent (Schmidbauer and vom Scheidt 1984, 289*).

Strychnine is a popular rat poison and is still used for this purpose today. In the United States, the members of some rather extreme Christian sects drink such rat poisons as an ordeal and an inebriant during their worship services. It is said that the Holy Spirit will protect the true believers from dying from the poison. Surprisingly, these cults have not yet become extinct.

Commercial Forms and Regulations

The substance is available in the form of a base and as strychnine hydrochloride, strychnine nitrate, strychnine phosphate, and strychnine sulfate. All forms of the substance are subject to the regulations concerning dangerous substances. Strychnine is listed in Class 1 of the Swiss Poison List. In principle, however, strychnine is legal.

Strychnine

Poison nuts or crow's eyes (the seeds of *Strychnos nux-vomica*) contain high concentrations of strychnine. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

“The symptoms of strychnine are marked by spontaneous convulsions and states of nervousness in animals.”

THC

Other Names

Δ 9-tetrahydrocannabinol, Δ 9-THC, delta-9-THC, Δ 1-3,4-*trans*-tetrahydrocannabinol, tetrahydro-6,6,9-trimethyl-3-pentyl-6*H*-di-benzo[*b,d*]pyran-1-ol, *trans*-THC

Empirical formula: C₂₁H₃₀O₂

Substance type: cannabinoid, pyrane derivative, pyranol derivative

THC is the main active constituent of the three hemp species *Cannabis indica*, *Cannabis ruderalis*, and *Cannabis sativa*. THC has not yet been found in any other plants. The information suggesting that THC is pyrochemically synthesized when olibanum (the resin of *Boswellia sacra*) is burned is contradictory. Similarly, no trace of THC or its analogs has yet been found in hops (*Humulus lupulus*). THC and its metabolites have been found in Egyptian mummies (Balabanova et al. 1992*).

While *trans*-THC is psychoactive, the isomer *cis*-THC is not (Kempfert 1977):

The effective dosage of THC when smoked is between 2 and 22 mg and when taken orally is between 20 and 90 mg. When smoked under normal conditions, 16 to 19% of the THC is consumed and the rest is pyrolyzed. No lethal dosage is known. However, experiments with animals indicate that the ratio between an effective and a lethal dosage can be estimated to be 4,000 to 40,000. In comparison, this ratio for alcohol is 4 to 10. (Fromberg 1996, 37)

In the blood, THC is transformed into the active metabolite 11-hydroxy- Δ 9-THC. This substance is absorbed by fatty tissues after about thirty minutes and is then released back into the blood, metabolized, and excreted. After only a few days, all of the substance has been excreted by the body. With chronic use, 11-hydroxy-THC accumulates in the fatty tissues and in the liver and can be detected for a longer period of time (urine tests!; cf. Rippchen 1996).

THC receptors have been discovered both in the central nervous system and in the peripheral pathways (Compton 1993; Devane et al. 1989; Matsuda et al. 1990). The THC or cannabinoid receptor in the nervous system has now been studied extensively and is very well understood (Pertwee 1995). Normally, endogenous neuro-transmitters known as anandamides bind to these receptors (Devane et al. 1992; Devane and Axelrod 1994; Kruszka and Gross 1994). Nerve diseases (such as multiple sclerosis) can result if the body does not produce sufficient amounts of anandamides. If anandamide deficiencies are responsible for these diseases, it is possible that they could be successfully treated with THC (Mechoulam et al. 1994).

Anandamide (= arachidonylethanolamide)—the name is derived from the Sanskrit word *ananda*, “bliss”—binds to THC receptors in the brain and is the endogenous THC analog, even though the inner structures of the two are quite different. Recently, anandamide has been discovered in chocolate and cocoa beans (*Theobroma cacao*) as well as in red wine (cf. *Vitis vinifera*) (Grotenhermen 1996).

Since 1971, cannabis products have been tested experimentally as medicines for treating alcoholism, heroin and amphetamine addiction, emotional disturbances, muscle spasms, and glaucoma. In 1990, the microbiologist Gerald Lancs of the University of South Florida discovered

that marijuana kills the herpes virus (AFP announcement on May 16, 1990), providing scientific validation of an old Roman remedy for herpes. The traditional use of hemp products for asthma has also received scientific support: “THC dilates the bronchial passages. Like other medicines, it can be inhaled as an aerosol to treat bronchial asthma and produces equally positive effects” (Maurer 1989, 48).

The medicinal use of THC and its analogs for the treatment of glaucoma has become an established practice. No other substance has been demonstrated to be better tolerated or more effective than THC (Maurer 1989). A Swiss group of researchers was able to show that THC relaxes the muscular cramping associated with central nervous system spasticity (e.g., due to multiple sclerosis or spinal cord injury) (Maurer et al. 1990). The researchers found that THC (at a dosage of 5 mg) produces effects that are similar to those of **codeine** but more effective and that THC is also more easily tolerated. There have also been encouraging attempts to utilize THC in the clinical treatment of spasticity and the associated pain (Hagenbach 1996).

“While cannabis and chocolate do not contain the same substances, they do produce similar effects. Moreover, the body itself also produces the substance in chocolate. These substances were named anandamides, after the Sanskrit word for bliss.”

FRANJO GROTENHERMEN “SCHOKOLADE, HASCHISCH UND ANANDAMIDE” [CHOCOLATE, HASHISH, AND ANANDAMIDE] (1996, 14)

THC is the main active constituent in the resin produced by the hemp plant. (Engraving from Pereira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

The potential applications [of synthetic THC] range from the treatment of epilepsy, chronic pain, multiple sclerosis, and lack of appetite to a reduction in the “addictive pressure” associated with opiate addiction. (Schmidt 1996, 30)

Synthetic THC is better known by the trade name Marinol. A dosage of 20 to 45 mg of Marinol induces a “high” that lasts for only sixty to ninety minutes. Many patients in the United States who take Marinol complain that the expensive medicine is ineffective compared to marijuana when either smoked or eaten (Jack Herer, pers. comm.).

Pharmacological research is now under way to develop synthetic THC analogs that could be marketed as medicines. The goal is to isolate the medically useful properties of THC while removing the psychoactive ones (Evans 1991). One of the products that has been synthesized as a result of this research is the cannabinoid analog HU-210, chemically known as (–)11-OH- Δ^8 -THC-dimethylheptyl. This substance not only is psychoactive but is some one hundred to eight hundred times more potent than natural THC (Ovadia et al. 1995). However, government health departments and pharmaceutical companies are more interested in THC analogs that are devoid of psychoactive effects. Some critics of this research take a different position, arguing that the therapeutic effects of THC are directly related to its psychoactivity.

Commercial Forms and Regulations

In principle, THC is an illegal substance throughout the world (cf. ***Cannabis indica***). However, for the past several years certain prescription drugs containing THC have been available in the United States under the trade names Canasol and Marinol. Physicians may prescribe these for glaucoma and cancer patients. In Europe, these drugs can be obtained only from pharmacies that sell foreign medicines,

and they are extremely expensive. Recently, there have been efforts in several states in the United States as well as in several European nations to make THC and/or *Cannabis* products more readily available to patients suffering from a variety of conditions. There is, however, considerable resistance to such liberalization efforts. In spite of the very long history of use of THC and *Cannabis* in numerous cultures and for a wide variety of purposes (see Räscht 2001*), it remains to be seen whether these substances will ever become widely accepted and legitimately used.

“While a person who smokes cannabis can at most smoke [himself or herself] to sleep and an overdose is not possible, a handful of THC capsules is sufficient to induce unconsciousness in a person for a long time. In addition to this flaw, the occasional indications of psychosis as well as such side effects as sleep disorders that last for weeks, irritability, and diarrhea speak against the use of the synthetic substance. It appears as though the gentle drug has been turned into a bitter pill in the laboratory.”

SEBASTIAN SCHMIDT

“DIE THC-PILLE AUF REZEPT” [THE THC PILL ON PRESCRIPTION] (1996, 31)

The cocoa tree produces anandamide (or a precursor) in its fruits. Anandamide is the substance that binds to the THC or cannabinoid receptors in the human brain. (Engraving from Peireira, *De Beginnselen der Materia Medica en der Therapie*, 1849)

Tropane Alkaloids

Other Names

Tropanalkaloide, tropanes, tropeine

Tropane alkaloids are esters of tropanal combined with various acids. They occur primarily in nightshades (Solanaceae), especially the psycho-active ones. The most important psychoactive tropane alkaloids are **atropine**, **scopolamine**, and hyoscyamine. These substances are “quickly absorbed through the mucous membranes but also through the intact skin” (Roth et al. 1994, 944*). For this reason, plant preparations in the form of ointments with these tropane alkaloids can induce psychoactive effects (cf. ***Datura innoxia***, **witches’ ointments**). Atropine, scopola-mine, and hyoscyamine are found in the genera *Atropa*, *Brugmansia*, *Datura*, *Hyoscyamus*, *Iochroma*, *Juanulloa*, *Mandragora*, *Solandra*, and *Scopolia*.

The psychoactive tropane alkaloid hyoscyamine (cf. ***Hyoscyamus niger***) occurs in the following nightshades in concentrations that appear to make them useful for psychoactive purposes (Festi 1995, 132 f.*): *Anthocercis littorea* Labill. (herbage), *Crenedium spinescens* Haegi (leaves), *Cyphanthera anthocercidea* (F.v. Muell.) Haegi (leaves), *Mandragora caulescens* C.B. Clarke (entire plant; cf. ***Mandragora* spp.**), *Physochlaina praealta* (Decne.) Miers (entire plant), and *Scopolia lurida* Dunal (roots; cf. ***Scopolia carniolica***). As a plant dries, the hyoscyamine it contains is usually transformed into its analog **scopolamine**. The profile of effects of hyoscyamine is essentially the same as that of scopolamine.

Tropanes and **cocaine** are chemically related and can under certain conditions elicit similar pharmacological effects (Sauerwein et al. 1993). The tropane alkaloid 2-tropanone is a metabolic product of cocaine. Tropane alkaloids occur in most if not all *Erythroxylum* species (Al-Said et al. 1989). The bark of *Erythroxylum zambesiaceum* N. Robson has been found to contain various tropanes (Christen et al. 1993). The root bark of *Erythroxylum hypericifolium* Lam., a species indigenous to Mauritius that is used in folk medicine to treat kidney problems, contains large amounts of hygrine as well as other tropanes (e.g., cuscohygrine) (Al-Said et al. 1989). Both hygrine and cuscohygrine are also found in the leaves and bark of the two coca species ***Erythroxylum coca*** and ***Erythroxylum novogranatense*** (Al-Said et al. 1989, 672). The leaves of the Southeast Asian species *Erythroxylum cuneatum* (Wall.) Kurz, which is used in Malaysia as a tonic, were found to contain as their primary alkaloid (\pm)-3 α ,6 β -dibenzoyloxytropane; another major constituent in the leaves is **nicotine**. The main alkaloid in the leaves of another ethnomedicinally useful Southeast Asian species, *Erythroxylum ecarinatum* Burck., is tropacacaine. The root bark of the Australian species *Erythroxylum australe* F.v. Muell. also contain numerous tropanes (meteloidine) (El-Imam et al. 1988).

The tropane alkaloids are typical constituents of almost all members of the Nightshade Family (Solanaceae). (A *Lycianthes* species from South America)

Tropane skeleton

“But how does it happen that people ill with fevers or who are destroying their nervous system with narcotics—in other words, making it more sensitive—‘imagine’ that they see gruesome faces when their consciousness is dulled? Why do mice, after having been injected with hyoscyamine, raise themselves up on their hind legs—something they would normally never do when they see an enemy—and with gestures of utmost terror betray to us that they are perceiving something that is hidden from our senses?”

GUSTAV MEYRINK *SÜDSEE-MASKEN/DAS HAUS DER LETZTEN LATERN 1* [SOUTH SEA MASKS/THE HOUSE OF THE LAST LANTERN 1] (REISSUE 1973)

Tropane alkaloids also appear to be present in the Proteaceae Family, e.g., in the species *Knightia strobolina* (El-Imam et al. 1988:2182). In Australia, several members of the genera *Hakea* and *Banksia* are used to produce **wine**.

The recent discovery of tropane alkaloids (tropine, tropinone, cuscohygrine, hygrine) in field bindweed (*Convolvulus arvensis* L.; cf. ***Convolvulus tricolor***) is very interesting; the species also contains **ergot alkaloids** (Todd et al. 1995). Tropane alkaloids have also been found in the hedge bindweed *Calystegia sepium* (L.) R. Br. [syn. *Convolvulus sepium*] (Goldmann et al. 1990).

Withanolides

Other Names

None

Withanolides are not alkaloids but C₂₈ steroidal lactones. More than one hundred withanolides have been isolated and described to date (Christen 1989). They occur only (or primarily) in members of the Nightshade Family (Solanaceae) (Christen 1989; Evans et al. 1984; Lavie 1986).

The withanolides withaferine A and withanolide E have very interesting biological and pharmacological effects: they are antiinflammatory, stimulate the immune system, and inhibit the formation of tumors (Christen 1989). Despite the fact that many plants with psychoactive properties contain only or primarily withanolides, not a single psychoactive constituent from this group has been isolated or described to date.

The shoo-fly or apple-of-Peru (*Nicandra physalodes*; Solanaceae), a plant from Peru, contains primarily withanolides and produces an effect similar to that of hyoscyamine. This may be the reason behind the French name for the plant: *belladonne de pays*, “belladonna of the countryside.”

The central European hedge bindweed (*Calystegia sepium*) contains psychoactive tropane alkaloids. (Photographed in Schönbrühl, near Bern, Switzerland)

Plants Containing Withanolides

Yohimbine

Other Names

Aphroodin, corymbin, corynin, hydroergotocin, johimbin, quebrachin, quebrachina, yohimbenin, yohimbin, yohimbina, yohimbinum, yohimvetol

Empirical formula: $C_{21}H_{26}N_2O_3$

Substance type: aspidosperma alkaloid, **indole alkaloid**

Yohimbine was first extracted from the bark of ***Pausinystalia yohimba*** and described in the nineteenth century. It is a typical alkaloid in plants from the Apocynaceae Family and is related to the Rauvolfia alkaloids, and it constitutes the primary alkaloid (1%) in *Alstonia angustifolia*. It is also present in some species of ***Rauvolfia***, especially the African species *Rauvolfia macrophylla* Stapf (Timmins and Court 1974).

Yohimbine was once regarded as an MAO inhibitor, a view that is no longer considered accurate. Rather, it is simply an α -adrenergic blocker that consequently stimulates the release of nor-adrenaline at the nerve endings. This makes noradrenaline available in the corpus cavernosum and results in an erection (Roth et al. 1994, 955*; Wren 1988, 292*).

As a sympatholytic agent, [yohimbine] dilates the peripheral blood vessels and reduces blood pressure. The aphrodisiac effect is explained through a vasodilatation of the genital organs and an increased excitability of the reflexes in the sacral medulla. (Roth et al. 1994, 545*)

Yohimbine's aphrodisiac and virility-enhancing effects, and its therapeutic efficaciousness in treating impotence, have been demonstrated in a number of clinical double-blind studies (Buffum 1982; Miller 1968; Sobotka 1969).⁵⁰⁷ Consequently, yohimbine hydrochloride has been approved as a specific medicine for the treatment of impotence (sexual neurasthenia). The recommended dosage is 5 to 10 mg taken three times daily as a short-term treatment over three to four weeks. Higher individual dosages (15 to 25 mg) result in psychoactive effects that are somewhat reminiscent of those of LSD, but with much less emotional content and an emphasis on physical phenomena (sexual desire, erotic enjoyment, and increased sensations of pleasure). Overdoses can be unpleasant but do not appear to be particularly dangerous (cf. Lewin 1992, 750*):

A chemist had taken an almost 1000-fold dosage (1.8 g). He became unconscious for a few hours (during which time a pronounced priapism was observed) but was able to be discharged from the hospital within a day. (Roth et al. 1994, 956*)

Yohimbine

Yohimbine is a characteristic constituent in the bark of many *Alstonia* species, some of which have been traditionally utilized as aphrodisiacs. (*Alstonia macrophylla*, photographed in Hawaii)

Commercial Forms and Regulations

The alkaloid is available as yohimbine hydro-chloride. Yohimbine is a prescription medication.

“Yohimbe acts both as a central nervous-system stimulant and as a mild hallucinogen. . . . The first effects are a lethargic weakness of the limbs and a vague restlessness, similar to the initial effects of LSD. Chills and warm spinal shivers may also be felt, along with slight dizziness and nausea. . . . Then the effects produce a relaxed, somewhat inebriated mental and physical feeling accompanied by slight auditory/visual hallucinations. Spinal ganglia are then affected, causing erection of the sex organs. These effects last from two to four hours.”

RICHARD ALAN MILLER

THE MAGICAL AND RITUAL USE OF APHRODISIACS

(1985, 116–17*)

Botanical Taxonomy of Psychoactive Plants and Fungi

The following list contains all of the plants and fungi that are discussed in this encyclopedia in both the major and the minor monographs. The psychoactive properties of some of the species are uncertain or only purported and may even have been incorrectly described; these species are nevertheless included here for the sake of comprehensiveness (and further research can often bring astonishing discoveries).

This taxonomy follows that found in Dörfelt 1989,* Frohne and Jensen 1992,* Roth et al. 1990,** and Zander 1994.* It is based on the taxonomic order established by the late botanist Richard Evans Schultes of Harvard.

Mushrooms—Fungi

Class Deuteromycetes—conidial fungi

mold fungi

Aspergillus fumigatus

Class Ascomycetes—ascomycota

Order Clavicipitales

Balansiae

Balansia cyperi

Hypocreaceae (= Clavicipitaceae)

Claviceps paspali

Claviceps purpurea

Claviceps spp.

Cordyceps spp.

Class Basidiomycetes

Order Lycoperdales

Lycoperdaceae

Lycoperdon marginatum

Lycoperdon mixtecorum

Scleroderma verrucosum

Vascellum pratense

Order Phallales

Phallaceae

Vanda roxburghii
Vanilla planifolia

Footnotes

- [1](#) Editor's note: DAB6 refers to the sixth edition of a German pharmacopoeia entitled *Deutsches Apotheker Buch*.
- [2](#) Translator's note: Effective July 1, 1992, khat leaves were added to Appendix 2 of the Swiss Federal Drug List, thereby making them illegal to import, possess, or use in Switzerland. Cathinone was already listed in the same appendix as a hallucinogen.
- [3](#) It should be noted, however, that many plants that are characterized as “magical plants” in folklore or literature are not psychoactive (cf. Schöpf 1986; Storl 1996c; Weustenfeld 1995).
- [4](#) “The fear of the psychedelic experience is quite literally the fear of losing control. Dominator types today don't understand that it's not important to maintain control if you are not in control in the first place” (Terence McKenna, in Sheldrake et al. 2001, 50).
- [5](#) E.g., among the Tukano and Desana Indians (Reichel-Dolmatoff 1971).
- [6](#) This is very similar to the Indian concept of *maya*, “the illusion that conceals reality as a result of ignorance” (Zimmer 1973, 31*).
- [7](#) Psilocybin is an analog of serotonin, mescaline of dopamine, LSA of the tryptamine-like endopsychedelics, and scopolamine of acetylcholine (Rätsch 1993c, 42).
- [8](#) It should be noted that Western psychiatry has or still does use the active substances in these four drugs for psychotherapeutic purposes. The discovery of mescaline led to a revolution in European psychiatry (Hermle et al. 1993; La Barre 1960). Psilocybin and its derivatives were used extensively in psycholytic therapy (Leuner 1981). Because of their hypnotic properties, the alkaloids in ololiuqui were tested in experimental psychiatry (Heim et al. 1968; Isbell and Gorodetzky 1966; Osmund 1955). Scopolamine was used as a truth serum and in narcoanalysis, and in psychiatry it is still used as a “chemical straitjacket” (Rätsch 1991b).
- [9](#) Typically, the altered state of consciousness produced by alcohol is viewed medically as being fundamentally different from the state produced by hallucinogens (Winkelman 1992, 186). This notwithstanding, Mexican shamans use both hallucinogens and alcohol to induce a shamanic trance. The effects of alcohol that we are familiar with (ranging from being slightly tipsy to delirium tremens) are thus at least partially conditioned by culture. After all, the ancient descriptions of the Dionysian frenzy (cf. Emboden 1977) are fundamentally different from the descriptions of alcohol intoxication in modern industrialized societies.
- [10](#) The ritual and hygienic use of sweat houses (*temazcal* in Aztec) was widespread in Mexico before the arrival of the Spanish. Today, it has almost vanished (cf. Cresson 1938).
- [11](#) See Jilek (1971) for an extensive study of the contradictions and changes that have taken place in the images of shamans.
- [12](#) *Reise in Süd-Amerika* [Journey in South America] (Mannheim 1854).
- [13](#) In the older ethnographic literature, the key role that psychoactive substances play in shamanism was typically suppressed. Some authors even went so far as to suggest that those shamans who “required” drugs to produce their trance state (which was referred to as toxic ecstasy) were “degenerate” and no longer capable of “true ecstasy.” In the years following Eliade's “classic” publication (1951), the more recent ethnological and cultural anthropological literature on shamanism has essentially corrected this earlier view, for it has now been determined that almost all shamans ingest drugs (cf. Rosenbohm 1991) and that pharmacological techniques for inducing altered states of consciousness are much more important than all the others.
- [14](#) Many psychopharmacological drugs and medicines used in psychiatry exert a palliative effect upon sick people but have no effects upon healthy individuals (cf. V. Faust 1994).
- [15](#) Seeds of *Datura stramonium* are also added to dolo beer (Voltz 1981, 176).
- [16](#) “An external change of the drug is also effected by boiling the tuber in cow urine, a common custom, which apparently protects them against the attacks of insects, which they are otherwise very prone to. In this condition, it largely loses its color and also yields a dark brown solution in water after just a short period of time. For medicinal purposes, this latter form of the drug is completely

useless; it can be used only as a poison for killing wild animals, as is often done in India” (Pabst 1887, 8*).

- [17](#) Pseudoaconitine has the same properties as aconitine and is chemically related to veratrum acid (cf. *Veratrum album*).
- [18](#) This name is also given to, and in fact is primarily used for, *Hyoscyamus niger*.
- [19](#) According to legend, Claudius was poisoned with a mushroom (*Amanita phalloides*) (Deltgen and Kauer 1973; Wasson 1972). But this did not prove powerful enough, so *Aconitum* was used as well.
- [20](#) Botanists have recently questioned whether sweet flag does indeed belong in the Araceae Family (cf. Grayum 1987).
- [21](#) “*Akoron*, some call it *choros aphrodisias* [= dance of Venus’s plant], the Romans *venerea* [= Venus plant], also *Radix nautica* [= ship’s root], the Gauls *peperacium* [= water pepper], has leaves that resemble those of the sword lily but are narrower, and not dissimilar roots, although these are not intertwined with one another and do not grow straight, but grow toward the light at an angle and are interrupted at intervals, whitish, with a pungent taste and not unpleasant scent. The thick and white ones, which have not been eaten and are full of aroma, are superior. Such a one is that which in Colchis and Galatia is called *splenion* [= agent against spleen disorders]” (Dioscorides, *De materia medica* 1.2).
- [22](#) Like the European hazelwort (*Asarum europaeum* L.), *Asarum canadense* L. also contains asarone (the name of which was derived from the genus name).
- [23](#) “In high doses, α - and β -asarone can induce visual hallucinations and LSD-like states of inebriation” (Roth et al. 1994, 92*).
- [24](#) The siphonlike cucurbit vessels used to tap pulque are known as *acacote*. The pulque sack itself (*bota*) is made from an animal skin and a cow horn.
- [25](#) The so-called Brazilian pepper is regarded as a poisonous plant (Morton 1978).
- [26](#) The leaves have been shown to contain the alkaloid *N*-methyl- β phenethylamine (Argueta et al. 1994, 1338*); it may also be present in the root.
- [27](#) The closely related species *Prosopis nigra* (Grisebach) Hieron. contains β carbolines (Ott 1993, 263*).
- [28](#) This variety does not appear to have been used for psychoactive purposes (C. Manuel Torres, pers. comm.).
- [29](#) Some authors regard this name not as a synonym but as a name for a separate species—*Parapiptadenia excelsa* (Griseb.) Burk.—popularly known as *cebil*, *cebil blanco*, *sacha cebil*, or *horcocebil* (Santos Biloni 1990, 18*).
- [30](#) This name may be linguistically related to *curupira*, a term for a mythical protective spirit of the forest (cf. Pavia 1995, 90*).
- [31](#) In Argentina, the folk name *guayacán* is also used to refer to other hardwood trees, e.g., *Caesalpinia paraguariensis* (D. Parodi) Burkart (Santos Biloni 1990, 100*).
- [32](#) In Chile, the name *quebracho* is also used for *Cassia closiana* Phil. (= *Senna candoleana*) (Donoso Zegers and Ramírez García 1994, 38*).
- [33](#) The name *uals ria to* is used in Peru primarily to refer to the claw thorn (*Uncaria tomentosa*); one of its uses is as an **ayahuasca** additive.
- [34](#) In Peru, the white quebracho tree (*Aspidosperma quebracho-blanco*) is also called *willca* (Santos Biloni 1990, 118*).
- [35](#) During excavations in the area of Jujuy (Argentina), C. Manuel Torres found a chilamlake pipe that was some five thousand years old. The pipe still contained clearly identifiable remains of the seeds. Unfortunately, the object was lost when it was sent to Sweden for chemical analysis.
- [36](#) The author believes that the seedpods are those of *Anadenanthera peregrina*; however, in pre-Columbian Peru, it is much more likely that *A. colubrina* was being used.
- [37](#) While the algorrobo (*Prosopis chilensis*) does indeed produce seedpods, neither are these segmented (as are those of *Anadenanthera*), nor do their ends taper to a small, fine point. In Peru, Chile, and Argentina, algorrobo is used as a fermenting

agent for **beer** and **chicha**.

- [38](#) “In addition, the following substitutes were also mentioned: among the Weddas on Ceylon, the bark of the mora tree (*Nephelium longana* Camb.); on the Philippines, the bark of *Psidium guajava* Raddi; in Cochin, China, the poisonous roots of *Derris elliptica* Lour., which are otherwise used as an arrow poison. Finally, Ibn Baithar (thirteenth century) names red sandalwood and coriander as substitutes for areca nut, although he does not specifically refer to their use in betel chewing” (Hartwich 1911, 529*).
- [39](#) Some authors regard this taxon as a separate species (Grey-Wilson 1995, 74, 75*).
- [40](#) This name is also used to refer to the white-blooming Mexican *Argemone platyceras* Link et Otto (Grey-Wilson 1995, 76f.*). Another Mexican member of the poppy family, *Bocconia arborea* Wats., is also called *chicalote* or *chicalote de árbol* (Martínez 1987, 1058*).
- [41](#) Other psychoactive plants, such as *Datura spp.*, are also known by this name.
- [42](#) *Ipomoea tuberosa* L. does not contain any lysergic acid derivatives and also has no known psychoactive effects (Ott 1993, 140*).
- [43](#) The entheogenic effects of this species, which is probably only an African variety or race of *Argyreia nervosa*, have been demonstrated; chemical studies, however, are lacking (Ott 1993*).
- [44](#) *Ariocarpus denegrii* (Fric) W.T. Marsh. is now known as *Obregonia denegrii* Fric (see *Lophophora williamsii*); *Ariocarpus strobiliformis* Werderm. is now *Pelecyphora strobiliformis* (Werderm.) Kreuzgr. (cf. *Pelecyphora aselliformis*).
- [45](#) In Turin [Italy], wormwood wine was made from *Artemisia absinthium* as well as *Artemisia pontica* L. and *Artemisia abrotanum* L. (Hartwich 1911, 772*).
- [46](#) According to Pliny (*Natural History* 25.73), the name is derived from that of a certain Artemisia, the wife of King Mausolus of Caria.
- [47](#) *Artemisia ludoviciana* Nutt. and *Artemisia klotzchiana* Basser are also known as *estafiate* (cf. *Artemisia spp.*).
- [48](#) Chrysartemins also occur in *Chrysanthemum* spp., which are used as additives in tea (*Camellia sinensis*) and **sake** (Romo et al. 1970).
- [49](#) As Elisabeth Blackwell wrote in her *Herbal*, “The berries, which look so lovely, almost always bring either deadly vomiting or a deadly rage, as tragic experiences have confirmed” (Heilmann 1984, 96*).
- [50](#) During the first seven days of the fasting period, an apple could be eaten at midnight on every second day; otherwise, only water could be consumed (Magister Botanicus 1995, 185*).
- [51](#) The Makú Indians use this name (which is applied throughout Amazonia to *Banisteriopsis caapi*) to refer to another vine from the same family: *Tetrapteris methystica*.
- [52](#) *Boswellia serrata* is sometimes alleged to be hallucinogenic (Schultes and Hofmann 1980, 367*).
- [53](#) H 15 (also known as H15-ayurvedica) is a standardized extract of the gum resin of *Boswellia serrata*. One tablet contains 400 mg of the dried lipophilic extract (Etzel 1996, 91).
- [54](#) “Also brought to our attention as a result of repeated observations of addiction [!], we began to consider which constituents could produce these effects. We became aware of the fact that there is a possibility for synthesizing the hashish constituent Δ^9 -tetrahydrocannabinol through the conversion of olivetol (5-pentylresorcin) with verbenol. . . . Verbenol, like phenols and phenol ether, has frequently been described as a component in incenses; in addition, other phenolic structures might be formed in the course of the combustion process, so that we are of the opinion that the formation of a basic tetrahydrocannabinol structure . . . is entirely possible. . . . It is also entirely possible that such inebriating and stimulating substances may be produced during the chewing process or in the digestive tract as a result of enzyme activity, whereby the essential oils are of course also of some importance” (Martinetz et al. 1989, 138).
- [55](#) In folk taxonomy, the name *borrachera* is also used to refer to and classify other plants, e.g., *Iresine celosia* L. and *Iresine herbstii* Hook. f. (cf. *Iresine spp.*, **cimora**), as well as all other species of *Brugmansia*, but also *Ichroma fuchsoides* (Bristol 1969, 184).

- [56](#) In Indonesia, *kecubong* is normally used to refer to ***Datura metel***.
- [57](#) The name *tecomaxochitl* is normally used for ***Solandra* spp.** (cf. Díaz, 1979: 84*).
- [58](#) The name *kiéri* is used usually for ***Solandra* spp.** and less frequently for ***Datura innoxia***.
- [59](#) In South America, many inebriating plants are known as *borrachero* or *borrachera*. Some of these (e.g., ***Brugmansia* spp., *Iochroma fuchsoides***) have psychoactive properties. But the name is also applied to some plants that are not known to exert any psychoactive effects; *Pilocarpus alvaradoi* Pittier (Rutaceae), for example, is known as *borrachero* in Venezuela (Blohm 1962, 45*).
- [60](#) In Spanish, the European snowdrop (*Galanthus nivalis*) is referred to as *campanilla blanca*.
- [61](#) This name is used in South America (and especially in Chile) for ***Datura stramonium***.
- [62](#) In Peru, this name is also applied to other plants that are used as additives to cimora and San Pedro drinks: *Iresine* spp., *Pedilanthus tithymaloides*, and *Hippobroma longiflorum* (see ***Trichocereus pachanoi***).
- [63](#) In Sibundoy (Colombia), the name *guamuco* also refers to *Spigelia pedunculata* H.B.K.
- [64](#) Some Lacandon Mayans see angel's trumpets as relatives (*u báho'*) of the plant they call *k'äni bākel*, the "yellow scented" (***Solandra* spp.**). And indeed, the plants are members of the same family (Solanaceae). The scent of *Solandra* is quite similar to that of *Brugmansia suaveolens*.
- [65](#) On the Putumayo (Colombia), this name is also used to refer to the fever tree (*Stephanopodium peruvianum* Poeppig et Endlicher; Dichapetalaceae) (Schultes 1983a, 262*).
- [66](#) Possibly a synonym for *Brunfelsia pauciflora* var. *calycina* (Benth.) J.A. Schmidt (Roth et al. 1994, 174*).
- [67](#) The common garden plant *Brunfelsia uniflora* (Pohl) D. Don is very easily confused with the very similar *Brunfelsia australis* Benth. (Plowman 1977, 290). The constituents of *Brunfelsia australis* are practically unknown. Little is known about any possible psychoactive effects; reports of any psychoactive use are lacking. The plant is, however, regarded as poisonous.
- [68](#) In South America, the name *borrachera* or *borrachero*, "inebriator," is given to almost all inebriating nightshades (cf. ***Brugmansia*, *Datura*, *Iochroma***).
- [69](#) This name is also given to the tree ***Lucuma salicifolia*** H.B.K., which has psychoactive properties and is known in modern Mexico as *zapote borrachero*.
- [70](#) In the Yucatán, this Mayan name is also used for the closely related species *Calea urticifolia* (Mill.) DC. as well as its subspecies *Calea urticifolia* var. *axillaris* (DC.) Blake (Barrera Marin et al. 1976, 214; Martínez 1987, 1069).
- [71](#) The Melanesian dream fish (*Kyphosus fuseus*) is said to produce oneirogenic effects like those of *Calea zacatechichi* (cf. Ott 1993, 410).
- [72](#) Germacranolides are apparently of chemotaxonomic significance in the genus *Calea* (Ferreira et al. 1980).
- [73](#) "In Tunisia, the medical establishment regards the black tea that is used there 'almost as a dangerous drug' and regards its consumption as 'a widespread toximania' " (Aléijos 1977, 109).
- [74](#) Cobra venom can also be sniffed and is said to induce extreme psychedelic effects (per oral communication from Ossi Urchs). In the Himalayas, it is believed that hemp that grows over a buried cobra will become especially potent as a result of its venom and have extremely strong inebriating effects (Sharma 1972, 208).
- [75](#) According to a different Indian myth, the first hemp plant arose at the spot where a drop of juice pressed from ***Datura metel*** fell upon the earth (Schleiffer 1979, 60*).
- [76](#) Comparable homeopathic agents (relations) include *Belladonna* (deadly nightshade), *Hyoscyamus* (henbane), and *Stramonium* (thorn apple), the "witches' herbs" of old. *Anhalonium lewinii*, the extract of ***Lophophora williamsii***, is a substitute (Boericke 1992*).

- [77](#) The homeopathic essence (Tct. Cannabis, homoeopath.) was once even called Aphrodisiacum (Arends 1935, 15*).
- [78](#) The *Kommentar zum* [Commentary on the] *Betäubungsmittelgesetz* (BtMG 1994) states: “The use of Cannabis plants to manufacture Cannabis cigarettes, to manufacture medicaments and Cannabis tinctures (cough agents, sleeping agents, asthma and migraine agents) is forbidden.”
- [79](#) Various no more precisely identified species of the genus *Canavalia* have been found in archaeological contexts dating to the prehistoric period in Peru and northern Mexico (Dressler 1953, 126*). *Canavalia maritima* is native to Polynesia. It is highly questionable whether the plant truly does have psychoactive effects. The presence of L-betonicine has been demonstrated (Schultes and Hofmann 1995, 37*).
- [80](#) The primary ethnobotanical importance of the genus *Cecropia* in South America is as a source of ash for coca chewing (cf. *Erythroxylum coca*).
- [81](#) It is possible that the plant referred to is *Mimosa pudica*, which is known in Guatemala and Mexico by the same name (*dormilona*, “sleeping plant”) (Ott 1993, 400*). In Mexico, the following plants are also known as *dormilona*: *Mimosa albida* Humb. et Bonpl., *Mimosa pigra* L., *Phyllanthus lathyroides* H.B.K., *Neptunia oleracea* Bour., and *Bellis perennis* L. Interestingly, *Psilocybe aztecorum* is known as *dormilón* (Martínez 1987, 317*).
- [82](#) This plant, which contains ephedrine, is also used in the Brazilian Candomblé cult as a “liturgical” (i.e., sacred) plant (Voeks 1989, 127*).
- [83](#) To date, no biodynamic or psychoactive compounds have been found in the tropical genus *Zornia* (Schultes 1981, 20*; Schultes and Hofmann 1995, 59*).
- [84](#) The Pima of northern Mexico drink a tea made from the leaves of the “snake plant” to treat shivering (Pennington 1973, 223*).
- [85](#) Possibly *Senecio eriophyton* Remy (cf. ***Senecio* spp.**), an aromatic Compositae known in the Atacama Desert as *chachacoma* and used as a medicinal incense (Hofmann et al. 1992, 83*).
- [86](#) In ancient times, the name Scythian was a catchall phrase for nomadic horse-riders who lived on the Black Sea, along the Danube, and in southern Russia and who spoke several Indo-Iranian languages or dialects. Many of the Scythian tribes developed extensive trade relationships with the Pontic Greeks. They were feared as brave and wild warriors and were consequently a respected people (Pavlinkaya 1989).
- [87](#) The “cedar wood” actually comes from a species of juniper (*Juniperus* spp.; cf. ***Juniperus recurva***). The descendants of the Scythians in the Hindu Kush still inhale juniper smoke to induce a shamanic trance (Jettmar 1981, 312).
- [88](#) In Mexico, tree tobacco (*Nicotiana glauca*; see ***Nicotiana* spp.**) is also known by the name *marijuana* (V. Reko 1936, 62*).
- [89](#) “The African aphrodisiac khala-khif consists of normal marijuana mixed with hemp resin; a blue mold is then allowed to develop on the mixture for about one month, after which this potent product is dried and smoked” (Stark 1984, 60*).
- [90](#) In Sonora and Baja California, the somewhat larger and sweeter fruit of the cactus *Cereus thurberi* Engelm., known as *pitahaya dulce*, is used in a very similar manner (Havard 1896, 36*).
- [91](#) In the literature, this family name is often written as *Celestraceae* (e.g., Elmi 1983, 164); according to Zander (1994, 171*), the correct spelling is *Celastraceae* (cf. also Frohne and Jensen 1992, 175*).
- [92](#) The describing author was Pehr Forsskål (Krikorian 1985, 515; Zander 1994, 710*). The correct abbreviation is actually Forssk., but Forsk. has become accepted internationally.
- [93](#) Louis Lewin (1980*) placed khat in the group of the Excitantia, together with camphor (***Cinnamomum camphora***), tea (***Camellia sinensis***), coffee (***Coffea arabica***), and **betel**.
- [94](#) *Catha transvaalensis* has been found to contain sesquiterpenes but no other psychoactive alkaloids (Mathys 1993, 15). To date, no studies of *Catha abbottii* have been carried out (Brenneisen and Mathys 1992, 732).
- [95](#) This name is also given to ***Artemisia mexicana***.

- [96](#) A Caribbean relative, *Cestrum latifolium* Lam., is also known by this name (Wong 1976, 37*).
- [97](#) In the Andes, the closely related species *Cestrum matthewsii* Dun. (which may possibly also produce narcotic or other psychoactive effects) is also known by the name *hediondilla* (Bastien 1987, 116 f.*).
- [98](#) In contrast, camphor is regarded as an anaphrodisiac in Cuba and is used in medicine as such (Morton 1977, 106*).
- [99](#) “A man who accidentally ingested 3.7 g of camphor at one time became dizzy, felt cold in his extremities, and experienced great anxiety, cold sweats, mild delirium, somnolence, and weak pulse, soon thereafter extreme heat, rapid pulse, and red urine” (Roth et al. 1994, 232*).
- [100](#) In China, recent or petrified alga colonies (*Collenia sinensis*) were also thought to be “dragon brains” and used for medicinal purposes (Read 1977, 9*).
- [101](#) The tender fruit flesh of the Seychelles’s coco-de-mer (*Lodoicea maldivica* [J.F. Gmel.] Druce [syn. *Lodoicea seychellarum* Labill]) also has the reputation of being a powerful aphrodisiac. No constituent that might produce such effects has yet been found (Müller-Ebeling and Rätsch 1989, 39 f.*).
- [102](#) In Arabic, **wine** is usually referred to as *khamr*, a word that means “inebriating” (cf. *Vitis vinifera*).
- [103](#) In the underground drug scene, the term *double espresso* is also used to refer to **cocaine** (because of the similar effects).
- [104](#) It is questionable whether the songwriters were actually speaking of coffee and caffeine, for in the music scene, the terms *coffee* and *double espresso* are sometimes used as cover names for cocaine.
- [105](#) This Yoruba name is originally from Africa. Santería followers in South America now also use the name to refer to the coconut (***Cocos nucifera***) (González-Wippler 1981, 97*).
- [106](#) “The orishas are energies that largely represent the different aspects of nature” (Neimark 1996, 23).
- [107](#) The *helxine* has also been interpreted as the field convolvulus (*Convolvulus arvensis* L.).
- [108](#) Synonyms: *Corynanthe macroceras* K. Schum., *Pausinystalia pachyceras* (K. Schum.) De Wild., *Pseudocinchona africana* A. Chev. ex E. Perrot, *Pseudocinchona pachyceras* (K. Schum.) A. Chev.
- [109](#) Meadow saffron is an ancient Colchic magical and witches’ plant that can produce serious toxic effects if used incorrectly (Rätsch 1995a, 190ff.*).
- [110](#) This Mazatec name (Díaz 1979, 84*) is identical to the Zuni name for *Datura* (*a’neglakya*; cf. Schultes and Hofmann 1992, 106*).
- [111](#) The name *kiéri* (or *kiéli*) is usually used for ***Solandra* spp.**, and less often for ***Brugmansia***.
- [112](#) This name is normally used for various species in the genera ***Astragalus*** and ***Oxytropis***.
- [113](#) For more on the meaning European tarot cards have in Mexican *brujería*, see Devine (1982).
- [114](#) *Brujería* can be translated as “sorcery.” In Mexico, the term is used to refer to magical practices that are conducted by *brujas* (“[female] witches”) or *brujos* (“[male] witches/sorcerers”). These typically syncretistic practices combine Indian, Catholic, and esoteric and occult elements (Scheffler 1983*; Sepulveda 1983*).
- [115](#) In Mexican folklore, Empress Carlotta’s insanity was said to have resulted from her having been poisoned with toloache (Havard 1896, 39*).
- [116](#) Interestingly, Jacques-Joseph Moreau de Tours published an article in *Memoirs* in 1841 titled “Traitement des hallucinations par le *Datura stramonium*.”
- [117](#) Throughout the world, this and other *Datura* species have great importance as aphrodisiacs (Kennedy and Rätsch 1985).

- [118](#) This name is also used for *Erythrina fulgens* and *Erythrina indica* (see *Erythrina* spp.).
- [119](#) This name is also given to the nightshades *Cestrum nocturnum* and *Cestrum parqui*. The ground leaves of these *Cestrum* species have the same scent as the crushed leaves of *Datura stramonium*.
- [120](#) This name is applied to a number of psychoactive nightshades: *Atropa belladonna*, *Hyoscyamus niger*, *Scopolia carniolica* (Arends 1935, 268*).
- [121](#) The name *tollkörner* is also given to the seeds of *Anarmita cocculus* (also known as fructus cocculi) (Arends 1935, 268*).
- [122](#) In Iran, the name *kachola* is also used for the poison nut (*Strychnos nuxvomica*) (Hooper 1937, 112*).
- [123](#) The Jíbaro Indians (Ecuador) use *Brugmansia suaveolens* in a similar manner.
- [124](#) Some authors (e.g., Diaz) have identified *atl inan* as the plant *Rumex pulcher*. However, this plant is not known to produce any inebriating effects.
- [125](#) This name is also used to refer to a fructiferous plant (*Ugni candollei* [Barn.] Berg), the berries of which are used to make chicha (Mösbach 1992, 95*).
- [126](#) The non-Aboriginal inhabitants of Australia now refer to all chewing tobacco (*Nicotiana* spp.) as *pituri* (Peterson 1979, 178*).
- [127](#) There are more than 130 species of *Hakea*, many of which the Aborigines use as food, medicines, and the basis for a mildly alcoholic drink (Low 1992b, 184 f.).
- [128](#) This American name is supposedly derived from the saying “In treating patients without much knowledge, you are asking for trouble,” which a Chinese herb dealer said to a student after the student had wrongly recommended the use of the mahuang plant (Lu 1991, 84*).
- [129](#) The closely related species *Erythrina chiapasana* Kruk., which occurs in the highlands of Chiapas, is also known by this name (Martínez 1987, 112*).
- [130](#) In West Africa, the related species *Pericopsis laxiflora* (Benth. ex Bak.) van Meeuwen [syn. *Aromosia laxiflora* (Benth. ex Bak.) Harms, *Ormosia laxiflora* Benth. ex Bak.] is reported to have a “kind of hypnotic or hallucinogenic effect” (Neuwinger 1994, 635*).
- [131](#) The name *Erythroxydon*, which is of Greek derivation, is actually correct. However, in accordance with the now accepted international rules of botanical nomenclature, (most of) the original Greek names have been Latinized, i.e., the ending *-on* has become *-um* (Plowman 1967).
- [132](#) Other species of the genus (*E. areolatum*, *E. tortuosum*) are sources of timber (Anzeneder et al. 1993, 65*).
- [133](#) *Trichocereus* from a California culture was found to contain 0.075% candicine (Shulgin 1995, 26*).
- [134](#) The fresh leaves of this *Tagetes* species are also chewed alone as a cold remedy (Plowman 1980, 254).
- [135](#) The resin consists of 30% protamyrine, 25% protelemic acid, 37.5% protele resin, and oils. In Amazonia, it is often burned in the local churches as an incense (Schultes 1957, 246). It is also the most important **incense** in the Brazilian Santo Daime cult (see **ayahuasca**).
- [136](#) There are some fifteen species of the genus *Cecropia* in Amazonia, many of which have ethnobotanical uses (Berg 1978); cf. **snuffs** and marijuana substitutes (*Cannabis indica*).
- [137](#) *Chamairo* can also be chewed alone; it produces mild euphoriant effects (Plowman 1980, 258).
- [138](#) According to the Taiwano, this additive makes the coca stronger and “better” for certain ritual dances (Schultes 1983a, 258*; Schultes and Raffauf 1990, 170*).
- [139](#) The unripe fruit husks of the closely related *Tachigalia ptychophysca* Spruce ex Benthham are esteemed as an aphrodisiac (Schultes 1978a, 184*).

- [140](#) The addition of this leaf powder is said to prevent and heal the sores that can develop in the mouth as a result of constant coca chewing (Schultes 1977, 117*).
- [141](#) In the Caribbean, the related species *Erythroxylum rotundifolia* Lunan is used as an ingredient in love drinks (McClure and Eshbaugh 1983*).
- [142](#) For the treatment of asthma, the bark of this tree is tossed into the fire and the resulting smoke inhaled (Schultes 1977b, 117*).
- [143](#) This substance is also present in the essential oil of black tea (see *Camellia sinensis*).
- [144](#) While this wild relative of cultivated coca does contain cocaine, the concentrations are significantly lower. The Barasana say that you can eat this coca and that it was “the coca of our fathers” (Schultes and Raffauf 1990, 166*).
- [145](#) According to the Mapuche of southern Chile, a tea made from the leaves of this daisy thistle (also known as *ulhuihuaca*) lowers body temperature and purifies the blood (Houghton and Manby 1985, 100*). The root of the plant, which is also referred to as *facu*, *llaupange*, *pangue*, *nalca*, and *oder*, contains large amounts of tannins (Mösbach 1992, 81*).
- [146](#) These leaves are also chewed “against the cold” (Plowman 1980, 254).
- [147](#) Pedro de Cieza de León, a chronicler from the colonial period, provided a short description of the sexual practices of the last Mochica: “The women practiced sodomy [i.e., anal copulation] with their spouses or other men, even while they were nursing their own children. . . . In spite of the fact that there was no shortage of women, some of whom were beautiful, I was assured that most of these indulged in the abominable vice of anal copulation, about which they were very proud” (cited in von Hagen 1979, 67, 70).
- [148](#) This name is normally used for *Solandra* spp.
- [149](#) Coptisine and sanguinarine are present in most members of the poppy family; however, they do not produce any noticeable psychoactive effects (Brown and Malone 1978, 8*).
- [150](#) In South America, this and similar names (*khoa*, *khoba*) are also used for pennyroyal (*Mentha pulegium*; cf. **kykeon**), which is also used as a ritual incense in traditional Indian ceremonies. In the Atacama Desert, a plant known as *koa*, *Lepidophyllum quadrangulare* (Mey.) Benth. et Hook, also is used as a ritual incense (Munizaga A. and Gunckel 1958, 32*).
- [151](#) The Mapuche also use this name for a plant of similar appearance from the Family Papilionaceae: *Anarthrophyllum andicola* (Gill. ex H. et A.) F. Phil. (Mösbach 1992, 84*). Further studies are needed to determine whether this plant was or is also used as a ritual **incense**. *Lepidophyllum cupressiforme* (Lam.) Cass. also is called *pichi* (Mösbach 1992, 110*).
- [152](#) This same folk name is used in Chile for *Anarthrophyllum andicola* (Gill. ex H. et A.) F. Phil., a common Andean plant that bears a distant resemblance to *Fabiana imbricata* and is also used in folk medicine as a diuretic (Montes and Wilkomirsky 1987, 106*).
- [153](#) *Romero* is actually the Spanish name for rosemary (*Rosmarinus officinalis* L.).
- [154](#) This Quechua word is also used to refer to *Baccharis boliviensis* (Wedd.) Cabr. (Mösbach 1992, 110*).
- [155](#) In Spanish, *tola* is actually used to refer to *Baccharis tola*.
- [156](#) Some of these sesquiterpenes also occur in *Pernettya furens* (cf. **Pernettya** spp.) and *Matricaria recutita* (Brown 1994, 432).
- [157](#) In Mexico, the same name is used to refer to the henna plant *Lawsonia inermis* L. (Lythraceae); in Mexican folk medicine, this plant was also used as a sedative (Díaz 1979, 77*).
- [158](#) This name is also used for *Passiflora* spp.
- [159](#) In Mexico, this name is also used for the plants *Selloa glutinosum* Spreng. and *Baccharis glutinosa* Pers. (Díaz 1979, 76*).
- [160](#) In Mexico, this name is also used for *Helenium mexicanum* H.B.K. and *Ipomoea orizabensis* Leden [syn. *Ipomoea thryanthina* Lindl.] (Díaz 1979, 76*).

- [161](#) This species is rumored to be used for hallucinogenic purposes (Grubber 1991, 61*).
- [162](#) Rosemary is an important ingredient in many aphrodisiac bath additives (Rätsch 1995a, 334*).
- [163](#) “Lavender flowers have sedative effects upon the central nervous system and on the nervous system of the trachea” (Pahlow 1993, 206*).
- [164](#) The genus *Humulus* is composed of three species: *H. lupulus* L., *H. japonicus* Sieb. et Zucc. [syn. *H. scandens* (Lour.) Merr.], and *H. yunnanensis* Hu (Wohlfahrt 1993, 447). *H. japonicus* can be used only for ornamental purposes.
- [165](#) Many of the folk names given to *Hyoscyamus niger* are also used for yellow henbane (Schneider 1974, 2:184*).
- [166](#) The so-called smoke of Delphi has also been attributed to *Catha edulis*, *Datura stramonium*, *Cannabis indica*, and *Laurus nobilis*.
- [167](#) According to J. M. Fericgla, the Spanish *veneno*, “poison,” may have been derived from this name.
- [168](#) This name is also used for *Datura stramonium*.
- [169](#) In her *Herbal*, Elisabeth Blackwell noted, “The entire plant stinks, overpowers the head, and the smell alone betrays its powers to make one stupid” (Heilmann 1984, 124*).
- [170](#) In Romania, a similar ritual using the mandrake (*Mandragora officinarum*) instead of henbane was still being conducted in the twentieth century.
- [171](#) Ernst Schoen, *Nomina popularia plantarum medicinalium*, Zurich, Galenica, 1963, p. 36.
- [172](#) The city that gave its name to the modern, heavily hopped beer known as pilsener acquired its name from henbane, which thus also gave its name to the true or original pilsener beer. In Switzerland, the ancient name *pilsener krut* lives on in the name *Pilsenkraut* (henbane plant).
- [173](#) The “drink of forgetfulness” that Gudrun gave to Sigurd (in the Volsunga Saga) has often been interpreted as a henbane brew.
- [174](#) This family is very closely related to the Celestraceae (cf. *Catha edulis*) (Schultes and Raffauf 1990, 79*).
- [175](#) “The word is said to be derived from *assie*, ‘little leaf,’ and comes from the language of the also extinct Timuna Indians, who adopted it from the Creek who migrated into their territory” (Hartwich 1911, 468*).
- [176](#) Although holly (*Ilex aquifolium*) does not contain any caffeine, it does contain some theobromine (Alikaridis 1987).
- [177](#) In Ecuador, other plants are also known by the name *guayusa*, particularly several members of the Piperaceae Family, as well as *Siparuna eggersii* Hieron. (Monimiaceae) and possibly others as well (Patiño 1968, 315). One member of the genus *Hedyosmum* (Chloranthaceae), the species identification of which is uncertain, not only is known by the name *guayusa* but also is used to produce a stimulating drink (Schultes 1972, 128).
- [178](#) The use of penis bones as aphrodisiacs is a worldwide phenomenon. The Maya of southern Mexico also use coati penis bones to manufacture love drinks. The Chol, who live in the region of Palenque, drink penis bone scrapings in alcohol three times daily (Helfrich 1972, 153*).
- [179](#) Other *Tabebuia* species are used in South America as **ayahuasca** additives. The Caribbean *Tabebuia bahamensis* (Northrop) Britt. is an important ingredient in love drinks (McClure and Eshbaugh 1983*).
- [180](#) Today, in Florida, these snail shells are used primarily as ritual objects by members of the Afro-Cuban Santería cult. The shells of Caribbean snails are exported even as far away as the Himalayas, where they are used ritually as sacred snails.
- [181](#) The Kamsá use the same name to refer to *Cestrum* spp. (Schultes and Raffauf 1991, 37*).
- [182](#) The closely related species *Iochroma lanceolatum* Miers is also known by this name (Bristol 1965, 290*).

- [183](#) In California, the species *Iochroma coccineum* Scheid., *Iochroma lanceolatum* Miers, and *Iochroma tubulosum* Benth. also have been successfully cultivated as ornamentals (Grubber 1991, 40 f.*).
- [184](#) This name is a folk taxonomic indication of the plant's (botanical) relationship to the angel's trumpets (*Brugmansia* spp.), which are known in Latin America as *campana*.
- [185](#) Now regarded as a synonym (Wasson 1971, 340).
- [186](#) It is doubtful whether Reichel-Dolmatoff's botanical identification is correct. If it is, then *Ipomoea violacea* must have already made its way to Colombia in pre-Columbian times, perhaps through trade. The plant in question may be *Ipomoea carnea* Jacq., which is indigenous to South America and is actually more potent. In another article (1978), Reichel-Dolmatoff refers only to a Convolvulaceae.
- [187](#) In Yucatec Mayan, the closely related species *Ipomoea cornicalyx* Moor and *Ipomoea seleri* Millsp. are also known as *tu'xikin* (Barrera M. et al. 1976, 249*; Martínez 1987, 1137*).
- [188](#) Very often, the noninitiated populace regards ritual plants and fungi with psychoactive effects (e.g., fly agaric mushrooms, thorn apple, henbane) as poisonous, or at least very dangerous.
- [189](#) Unfortunately, these authors erroneously illustrated their monograph with a photograph of *Convolvulus tricolor*.
- [190](#) In Japan, this vine is regarded as a “sibling” of the thorn apple (see *Datura metel*).
- [191](#) The pink-blossomed morning glory *Ipomoea sepiaria* Roxb. [syn. *Ipomoea maxima* auct. non. (L. f.) Sweet] is also known in Sanskrit as *lakshmana* and bears the same name in many other Indian languages. It is also regarded as a tonic, aphrodisiac, and rejuvenant (Warrier et al. 1995, 3:237).
- [192](#) The seeds contain alkaloids, including elymoclavine (Asolka et al. 1992, 371; Gröger 1963). This species is found throughout the Amazon basin (Almeida Falcão 1971).
- [193](#) *Juniperus macropoda* Boiss. may possibly be synonymous with *Juniperus excelsa* M. Bieb. (Goodman and Gharfoor 1992, 14*).
- [194](#) In Nepali, the same name is also given to other *Juniperus* species (e.g., *Juniperus communis* L. var. *saxatilis* Pallas [Indian juniper], *Juniperus excelsa* M. Bieb. [Himalayan pencil cedar, *shukpa*], and *Juniperus wallichiana* Hook [*techokpo*]), and to both cultivated and introduced forms and cultivars (e.g., *Juniperus chinensis* L., *J. polycarpa* Koch); it is also used for the conifer *Cryptomeria japonica* (L. f.) D. Don (= *dhupi sala*; cf. Storrs 1988, 88 f.) and the Himalayan cypress *Cupressus torulosa* D. Don, which is also used as a temple incense (Polunin and Stainton 1985, 389).
- [195](#) This consists of α -pinene, sabinene, camphene, cadinene, juniperol, juniperine, junen, and terpineol-4.
- [196](#) This name is also used to refer to the Venezuelan *Justicia caracasana*, which is used as an additive in *chimó* (cf. *Nicotiana tabacum*) (Ott 1993, 410*).
- [197](#) *Tilo* is actually a Spanish term for the linden tree (which is not indigenous to the Americas). Today, Florida is home to numerous Cubans who have preserved their own businesses and relationship structures. They trade in *justicia* leaves and flowers, which are then (as if there were not already enough confusion) sold under the American name *linden flowers with leaves*.
- [198](#) In former times, lactucarium was also obtained from blooming *Lactuca sativa* L., the cultivated garden salad (Schneider 1974, 2:226*).
- [199](#) Even chlorinated *Lactuca sativa* leaves have been smoked as a marijuana substitute (cf. *Cannabis indica*).
- [200](#) Lactucine and lactupicrine also occur in the dandelion (*Taraxacum officinale* Web.) (Frohne and Pfänder 1983, 68*).
- [201](#) This same name is used in Chiloé (southern Chile) to refer to *Desfontainia spinosa*.
- [202](#) Not to be confused with the archaeological culture of Valdivia, Ecuador (Baumann 1981). The Chilean Valdivia lies in the heart of Araucana. This ostensibly European city was founded in 1552 by the conquistador and general Pedro de Valdivia (1505–1553).

- [203](#) The genus *Ledum* is composed of some six species. The closely related Labrador tea bush (*Ledum latifolium* Jacq.) is very similar in appearance to though somewhat larger than wild rosemary; it grows in Greenland, Labrador, and northern North America. The Indians and the Inuit (Eskimos) use its aromatic leaves as a medicinal tea that they drink for asthma and colds and also as incense. The Kwakiutl Indians of the Canadian Pacific coast obtained a narcotic from the Greenland porsch (*Ledum groenlandicum* Oed. [syn. *Ledum latifolium* Ait. non Jacq.]) that they used in shamanic healing. The Inuit used the dried tips of the twigs of *Ledum decumbens* (Ait.) Lodd. (possibly a synonym for *Ledum latifolium*) as a medicinal incense for treating children's ailments (cf. Rätsch 1996).
- [204](#) Many authors continue to believe that the berserkers used fly agaric mushrooms (cf. *Amanita muscaria*) to induce their battle ecstasy. The fly agaric, however, is completely unsuited for this purpose, because its effects tend to be more sedative and opium-like, conducive to dreaming and listening to music.
- [205](#) This name is also used to refer to the very similar *Leonurus japonicus* Houtt. (Karting et al. 1993, 648).
- [206](#) This name is now regarded as an old synonym for the species *Gliricidia sepium* (Jacq.) Steud.
- [207](#) In Quintana Roo (Mexico), the closely related species *Lonchocarpus castilloi* Standl. is also known as *balche* in Mayan (Cioro 1982, 123*).
- [208](#) This Mayan name is also applied to other trees from the Legume Family, including *Gliricidia sepium* (Jacq.) Steud. (Arvigo and Balick 1994, 140).
- [209](#) The genus *Lonchocarpus* H.B.K. consists of some 175 species, most of which are found in the tropics of the New World (Allen and Allen 1981, 395*).
- [210](#) Geoffroy first isolated rotenone from *Lonchocarpus nicou* (Aubl.) DC. [syn. *Robinia nicou*] between 1892 and 1895 and presented it under the name *nicouline* (Allen and Allen 1981, 396*).
- [211](#) The root of this plant is also used as a substitute for the areca nut (*Areca catechu*)
- [212](#) See ***Agave* spp.** for a discussion of the confusion surrounding the term *mescal* (cf. also Schultes 1937b).
- [213](#) The etymology is not entirely certain; the name *peyotl* may be derived from the Aztec *pepeyoni*, “excite,” or *peyona-nic*, “stimulate” (cf. Anderson 1980, 139).
- [214](#) Although *piule* appears to be a corruption of *peyote*, in Mexico the word is used as a catchall term for psychoactive plants that are used by the so-called *piuleros*, or traveling diviners.
- [215](#) One seventeenth-century source (Ortego, *Historia del Nayarit*) provides a description of the peyote dance festival of the Cora (cf. Schultes 1938; Schultes and Hofmann 1987, 134).
- [216](#) Dream catchers are small, flat, woven objects resembling spiderwebs. It is believed that they capture dreams in their webs and can thus be associated with a particular place.
- [217](#) Rhythms of 200 to 220 bpm are regarded as trance-inducing (Goodman 1992*). Modern techno music (cf. **herbal ecstasy**) purposefully uses this range to produce altered and extraordinary states of consciousness (Rätsch 1995d, 316ff.*).
- [218](#) Jonathan Ott has suggested that the Bromeliaceae Family, and perhaps even the genus *Tillandsia*, may contain potent entheogenic species (cf. Ott 1993, 108, 420*; cf. also **shahuán-peco**).
- [219](#) This species is quite variable, with numerous forms, varieties, and subspecies already described (cf. Preston-Mafhan 1995, 44*).
- [220](#) In Mexico, this species is attributed with aphrodisiac powers. To date, no psychoactive effects or constituents have been identified (Schultes and Hofmann 1992, 37*).
- [221](#) This orchid, which occurs from Mexico to Paraguay, possesses a strong rhizome and blooms in late winter (Wiard 1987, 109). It is occasionally available through the international orchid trade (Rysy 1992, 140). The genus *Oncidium* is one of the most species-rich genera in the New World (Stacy 1975).
- [222](#) This old synonym has caused much confusion in the botanical, ethnobotanical, and history of medicine literature (e.g., in Eliade

1982, 215–34).

[223](#) This name is also used for *Atropa belladonna* and *Scopolia carniolica*.

[224](#) The ancient Aztecs are said to have known the mandrake by this name (Cerna 1932, 304*). However, *Mandragora* was not part of the pre-Columbian flora.

[225](#) A play on the Arabic love story “Majnun and Layla.”

[226](#) According to Thompson (1949, 217*), the Assyrian *namtargira* is strikingly similar phonetically to the Greek *mandragora*.

[227](#) The Solanaceae are typically given a great deal of consideration in the modern toxicological literature. Remarkably, mandrake does not appear in most compendiums on poisonous plants. In my opinion, this is due to the fact that its alleged toxicity has been greatly exaggerated. Moreover, the rarity of the plant means that almost no incidence of hospitalized cases of poisoning have occurred. The experientially oriented literature on psychedelics also makes little mention of the plant (it is not mentioned in Hartwich 1911* or in Lewin 1980 [orig. pub. 1929]*!) or speaks of it only in passing. There are no firsthand reports of experiences with the plant. It appears as though the magical aura that has surrounded the root since ancient times has frightened away psychedelic experimenters, many of whom are otherwise so ready to try anything new.

[228](#) The root of the American mandrake (= mayapple) is sold in North American “voodoo drugstores” as *mandrake root*. It is esteemed as a talisman. The root is said to bring luck in love (it makes the bearer of the talisman attractive and lovable in the eyes of the other sex), attract wealth (= money), protect from magical spells and the evil eye, and ward off demons. In general, the root of the American mandrake is attributed with the same properties as the true mandrake.

[229](#) This taxon cannot be identified from the literature.

[230](#) In northern Dalmatia, where chelidonium root is known as *cimitrk*, it is used in love magic in a very similar manner to the true mandrake (Mitrovic 1907, 233).

[231](#) See Hylands and Masour (1982) for information on the chemistry of white bryony.

[232](#) Women accused of being witches, including Joan of Arc, the Virgin of Orleans, were charged with having worn a mandrake on their chest (Schmidbauer 1969, 282).

[233](#) The Biblical *dûdâ’îm* has been construed as *Cucumis dudaim* L., as *Citrus medica* L., and even as the common edible field mushroom (*Agaricus campestris* L.) and as jasmine (*Jasminum spp.*) (Moldenke and Moldenke 1986, 138*). Others have interpreted *dûdâ’îm* as flowerpots, cherries, jujube fruits (*Zizyphus*), blackberries, bananas (*Musa x sapientum*), and melons (*Cucumis aegypticus reticulatus*) (Friedreich 1966, 159 f.). “Luther, who used the translation ‘lilies,’ in particular got onto the wrong track, for these are the plant symbols of chastity, the greatest of all repressive achievements” (Müller-Ebeling n.d., 97).

[234](#) In this city, located by the Red Sea, stood a giant rue tree (*peganon*, presumably *Ruta montana* [Kottek 1994, 130 f.] or *Peganum harmala*). Here too is where the lost cities of Sodom and Gomorrah were said to have been located, and John the Baptist was supposedly beheaded here (cf. Schlosser 1987, 88). The magical root, in other words, was at home in a completely “sinful” land.

[235](#) This luminous plant (*baaras* is derived from the Hebrew *ba’ar*, “to burn”) has been the subject of considerable discussion. To date, botanists know of no plant that gives off light during the night. In moist areas and rain forests, however, it has been observed that rotting roots or tree trunks phosphoresce and glow in an almost otherworldly manner at night. Rahner has proposed the following interpretation of the luminous mandrake, which I find very compelling: “The glow worms in Palestine like to rest upon the beautiful leaf rosettes of the spring mandrake, so that the plant looks like a glowing lamp. When persons looking for the plant approach, the light goes out, to reappear once more on another mandrake. Today, the Arabs in the Holy Land still refer to the mandrake as ‘Sirag el-Kotrub,’ ‘devil’s lamp’ ” (Rahner 1957, 210*).

[236](#) Hematite, or bloodstone, is a common iron oxide mineral. It usually has a black or reddish luster. When hematite is ground or cut, the powder takes on a bloodred color.

[237](#) “In an ancient Egyptian myth of the gods, it is told how the mandrake fruits came from Nubia, from whence they were brought to the temples and royal palaces of Egypt. There they were given to a goddess in a vessel filled with beer. This magic drink made her eyes shiny and caused her to enter into such an inebriated state ‘that after sunrise she could no longer see’ ” (Kreuter 1982, 19*).

[238](#) “Folk belief regarded the mandrake as a chthonic plant, one that was classed with the dark demons. For the place of these spirits is in the West, and so it was believed that a look to the West would banish the spirits of darkness. The Greeks directed their sacrifices

for the dead and curses to the West. . . . One had to protect oneself from the wind [from the West], for otherwise the scent of the still unrisen plants could transmit the evil influence of the plant demon. But the look to the West can also mean that the rhizotome wished to insure himself of the powers of the nocturnal spirits that are thought to be present in the root and for this reason asked with a look for ‘permission’ as it were to remove it without harm” (Rahner 1957, 205*).

- [239](#) Dierbach (1833, 195*) considers the mandragora of Hecate to be the mandragora of Theophrastus and regards it as the deadly nightshade, ***Atropa belladonna***. I am doubtful about this interpretation, as the deadly nightshade is not indigenous to the land of Hecate, whereas the mandrake is.
- [240](#) “In the myths and poetry of the Greeks, we learn about the great witches such as Circe and Medea. But perhaps these were not originally witches, but goddesses or priestesses of deities of a long-lost religion. Their knowledge of herbs, roots, and mushrooms represents primeval experiences whose secrets were guarded and which gave them special powers. They were priestesses in their own culture; subsequent generations made them into dangerous magicians” (Luck 1990, 46*). Similar things can be said about Roman poetry (cf. Luck 1962, 60 f.*).
- [241](#) Emboden (1989) has hypothesized that both ***Nymphaea caerulea*** and mandrake were used for shamanic experiences or practices in dynastic Egypt.
- [242](#) In ancient times, representations of plants were used as illustrations in medicinal, pharmaceutical, and botanical works. Unfortunately, few of these pictures have been preserved; cf. Stückelberge 1994, 79.
- [243](#) According to Schultes and Hofmann (1980: 298*), cuscohygrine and mandragorine are identical. The empirical formula of the alkaloid “mandragorine” is $C_{15}H_{19}NO_2$ (Roth et al. 1994: 485*).
- [244](#) *Translator’s note:* The foehn is a high-pressure weather pattern common in southern Germany.
- [245](#) As late as the early Middle Ages, the story of the male elephant eating mandrake leaves that grow near the Garden of Eden as an aphrodisiac before mating was often found in books about animals (Hansen 1981, 32*).
- [246](#) In spite of this distinction, there is considerable confusion on this topic in the literature. Even today, the voluminous German-language standard reference work on poisonous plants states that *M. officinarum* blooms in the fall and *M. autumnalis* (*autumnalis* means “autumnal”!) in the spring (Roth et al. 1994, 485*).
- [247](#) This plant has not been identified with certainty, although many authors have interpreted it as the common thorn apple (***Datura stramonium***). The plant, which presumably came from India or the Caspian Sea, has been construed as the trance-inducing inebriant used by the Pythia on several occasions (Mehra 1979, 167*). Pliny reported that the “one that makes mad” (*manikon*) produces effects in which “one is led to perceive apparitions and hallucinations” (21.178).
- [248](#) German-language literature continues to use the family name Aizoaceae (Frohne and Jensen 1992, 125*; Zander 1994*). The name Mesembryanthemaceae is preferred in English-language literature (Herre 1971) (cf. ***Sceletium tortuosum***).
- [249](#) This name is also used for *Mimosa nigra*, which contains DMT and was used as a substitute (albeit only rarely) for *Mimosa tenuiflora* to produce jurema drinks (Schultes and Hofmann 1980, 155*).
- [250](#) In South America, this name is also given to the psychedelic cactus ***Trichocereus pachanoi*** as well as to other *Trichocereus* species (***Trichocereus*** spp.).
- [251](#) *Lobelia nicotianaefolia* is also known as wild tobacco (cf. ***Lobelia inflata***).
- [252](#) In the German-speaking regions, the name *strong tobacco* (*starker tobak*) was once also given to hemp (***Cannabis sativa***).
- [253](#) The name Peter is derived from the Latin word *petrus*, “rock.” This implies that the saint was a “sacred stone.”
- [254](#) The same name is used for ***Piper auritum***.
- [255](#) *Sterculia pruriens* contains a cyanogenic substance that is considered toxic (Schultes and Raffauf 1990, 447*).
- [256](#) In the Putumayo region, the dried leaves of the closely related species *Cephalis williamsii* Standley are smoked together with tobacco (Schultes and Raffauf 1990, 379*).

- [257](#) This may be an incorrect botanical identification from the older literature. Kamen-Kaye believes that the leaves of a *Psychotria* species (***Psychotria** spp.*), a genus that is very closely related to and easily confused with the genus *Palicourea*, may have been or are used as an additive containing tryptamines (1971, 47).
- [258](#) An alkaline substance is not necessary to liberate the alkaloid (nicotine) from the plant material (unlike ***Erythroxylum coca*** and ***Areca catechu***). However, laboratory studies have demonstrated that an alkaline additive potentiates the effects of the nicotine (Kamen-Kaye 1971, 41).
- [259](#) The same bark ash is also added to **snuffs** (made from ***Virola** spp.*).
- [260](#) In Colombia, the dried roots and leaves of *Piper interitum* Trelease (cf. ***Piper** spp.*) are used as a substitute for sniffing tobacco (Davis and Yost 1983, 182*; Schultes 1978b, 226f.*).
- [261](#) “This notion corresponds to deliberations as to whether birds had already carried tobacco seeds from the Americas to Polynesia and then to New Guinea [and perhaps Australia] during prehistoric times” (Michel 1981, 260) (cf. also Feinhandler et al. 1979).
- [262](#) The word *cigar* is derived from the Quiché term *siq’ar*, which refers to tobacco that has been rolled without a cover leaf (Richter 1921). Quiché is a Mayan language spoken in the highlands of Guatemala.
- [263](#) In this context, it should be noted that it cannot be assumed that the cigars of the smoking god were made only of tobacco. There is a great deal of ethnographic evidence attesting to the fact that the shamans of the various Mayan peoples smoke other plants (***Brugmansia suaveolens***, ***Datura innoxia***, ***Datura stramonium***, ***Amanita muscaria***) besides tobacco.
- [264](#) The Yucatec Maya believe that burning tobacco will keep snakes at bay (Redfield 1950, 124).
- [265](#) This plant, whose name means “Inca tobacco,” may have been smoked or even used as a **snuff** (Alvear 1971, 22*). It is doubtful, however, that the botanical name is correct.
- [266](#) “Ground to a fine powder and mixed with some **chicha**, this plant can invoke almost the same symptoms as ***Datura stramonium***” (Hargous 1976, 158*).
- [267](#) *Solanum mauritianum*, which is also known as wild tobacco or wild tobacco tree, was not smoked as tobacco. The fruits of this plant are edible. The Aborigines used the soft leaves as toilet paper (Low 1992a, 78*). However, this plant is usually regarded as poisonous (Jacks 1992, 40*).
- [268](#) Ancient Germans also used a nightshade (***Hyoscyamus niger***) for rain magic. Some authors have conjectured that nightshades can induce auditory hallucinations that sound like rain or flowing water. For this reason, such plants were utilized in sympathetic magic.
- [269](#) The *Nymphaia* of Theophrastus should probably also be construed as *Nuphar lutea*.
- [270](#) In the Yucatán, this name is also used for *Centella asiatica* Urban (Barrera M. 1976, 115*). *Naab* is both a name for the water lily and the measure between the thumb and little finger (app. 20 cm).
- [271](#) *Mehen-naab*, “little water lily,” is a name used in the Yucatán for *Hydrocotyle umbellata* L., thereby establishing a folk taxonomic relationship between the plants (Barrera M. et al. 1976, 112*).
- [272](#) There are uncertain reports suggesting that the flowers of *Nymphaea stellata* also have narcotic effects (Emboden 1978, 401).
- [273](#) Höfler 1990, pp. 92f.*; cf. ***Hyoscyamus niger***.
- [274](#) This umbelliferous plant has the same effect on grazing cattle as the bearded darnel (***Lolium temulentum***) (Roth et al. 1994, 210*).
- [275](#) A similar iconographic recipe can be found on an image of Demeter.
- [276](#) According to Langham (1579), children should be given the ground seeds together with hemp (***Cannabis sativa***) and almonds in milk or **beer** (ale).
- [277](#) “The quantities of harmaline in *Passiflora incarnata* are very slight and lie according to the state of knowledge at the time in the range of 50 to 300 mg in 100 g of dried drug. This is far removed from the effective dosage, which was investigated in the 1950s and was said to lie at 10 to 35 mg daily for a sedative effect in humans” (Meier 1995b, 119).

- [278](#) The plant was formerly assigned to the Family Rutaceae.
- [279](#) The German name for American pokeberry (*Phytolacca americana* L.) is *amerikanischer nachtschatten* (“American nightshade”) (Schneider 1974, 2:59*).
- [280](#) This name is also used for black nightshade (*Solanum nigrum*; see ***Solanum* spp.**).
- [281](#) In South America, another herbaceous pepper plant (*Pothomorphe peltata* [L.] Miquel) is also known by this name (Vickers and Plowman 1984, 26*).
- [282](#) This same name is used in the Santo Daime cult to refer to marijuana (***Cannabis sativa***) (cf. **ayahuasca**).
- [283](#) The South American *Ugni molinae* Turcz. [syn. *Myrtus ugni* Mol., *Eugenia ugni* (Mol.) Hook. et Arn.] (Myrtaceae) is known in German as *chilenische guava* (“Chilean guava”) (Zander 1994, 556*; see **chicha**).
- [284](#) The crategolic acid that has been found in the leaves is also found in clove (*Syzygium aromaticum*; cf. **essential oils**) and appears to be at least partially responsible for the analgesic effects (Brieskorn et al. 1975).
- [285](#) Quercetin (= cyanidanol, cyanidenolen 1522, 3,3',4',5,7-pentahydroxyflavone, meletin, sophorin, ericin) is very common in the plant kingdom, especially in the bark of trees. Significant quantities are found in the Douglas fir (*Pseudotsuga menziesii* [Mirb.] Franco), pansies (*Viola tricolor* L.), the false hellebore (*Adonis vernalis* L.), the horse chestnut (*Aesculus hippocastanum* L.), the true chamomile (***Matricaria recutita***), the English hawthorn (*Crataegus laevigata* [Poir.] DC.), hops (***Humulus lupulus***), oaks (*Quercus* spp.), the apple tree (*Malus sylvestris* Mill., *Malus* spp.), catechu resin (cf. ***Acacia* spp.**), ***Fabiana imbricata***, wormwood (***Artemisia absinthium***), and many members of the Family Ericaceae (***Ledum palustre***, ***Vaccinium uliginosum***, *Arctostaphylos* spp.; cf. **kinnikinnick**) (Römpf 1995, 3746*).
- [286](#) Pellagra (maidism) is a disease of malnutrition that results from a one-sided maize diet with deficiencies in niacin and nicotine amide.
- [287](#) “To date, little that is certain is known about the age of the salvia ritual, as corresponding ethnographic or historical evidence is lacking, but Wasson attempted to identify a plant known in ancient Aztec as *pipizintli* or *pepetzintle* with *Salvia divinorum*, basing his arguments on the Spanish chronicles. The monk Agustin de Vetancourt reported on an inebriating drug named *pepetichinque*, the root of which produced effects similar to those of the peyotl cactus [***Lophophora williamsii***] or ololiuqui seeds [***Turbina corymbosa***]. There was a male and a female form of this plant, the *macho* and the *hembra*. In the National Archives in Mexico City, Inquisition files from the years 1696, 1698, and 1706 refer to the plant *pipiltzintzin* and mention its inebriating effects, but the details are too vague to unequivocally recognize this as a species of salvia” (Mayer 1977, 779).
- [288](#) Loliolide is a known ant repellent (Brand 1994, 540).
- [289](#) Many Westerners have reported having experiences while under the influence of ketamine that are strongly reminiscent of shamanic experiences (dismemberment, death and rebirth, cosmic flight, body doubles, relocalization, clairvoyance, et cetera). Many users of *Salvia divinorum* who are also familiar with ketamine have shown a tendency to compare the two agents. To date, however, ketamine is known only as a synthetic substance related to PCP (“angel dust”), although it may soon be found in a natural form. The receptor to which the ketamine molecule binds is known. **Salvinorin A** does not attach to this receptor site.
- [290](#) This species also contains the **β-phenethylamine** hordenine, a characteristic constituent of the cacti (Arndt and Kruger 1970).
- [291](#) In Romania, the same name is given to ***Mandragora officinarum*** (Fühner 1919).
- [292](#) In Lithuania, this name is also used for water hemlock (*Cicuta virosa*) (cf. **witches’ ointments**).
- [293](#) This Nahuatl name is also used to refer to ***Brugmansia arborea*** (Díaz 1979, 84*).
- [294](#) At the time, the authors (Furst and Myerhoff 1966) still assumed that *kiéli* was either ***Datura innoxia*** or ***Datura stramonium***, an interpretation that subsequently was corrected (Furst 1996).
- [295](#) There is also an association between a nightshade species and this shamanic animal in South America: the Waorani of the Ecuadoran Amazon say that *Solanum pectinatum* Dunal in DC. was originally planted by a jaguar (Davis and Yost 1983, 204*).
- [296](#) This name is usually used for *Kalmia latifolia* (cf. **kinnikinnick**).

- [297](#) “Owners of various saloons in the port cities in China have long added a similar red bean, *Sophora tomentosa* L., to alcoholic beverages so that their patrons, typically sailors who would drink themselves into a heavy state of drunkenness after just a few draughts, could be duly robbed while in this condition” (Reko 1938, 138*).
- [298](#) In Colombia, another alkaloid-rich plant from the Family Apocynaceae is also referred to as *sanango*: *Bonaifousia tetrastachya* (H.B.K.) Markgraf (Schultes and Raffauf 1986, 277*).
- [299](#) This mushroom was also used in other magical rites in West Africa but is now a component only of the Bwiti mythology, in which it serves as a symbol for the brain and for “the first man to die” (Samorini 1995, 111). It has been claimed that the powdered mushroom has psychedelic effects and was once used in connection with or as an additive to iboga (Fernandez 1972, 246).
- [300](#) In Gabon, some one thousand to two thousand temples are said to lie along the “streets of the iboga” (Samorini 1993, 6).
- [301](#) The same name is used for *Piper auritum*.
- [302](#) The fresh leaves of this *Tagetes* species are also chewed alone as a cold remedy (Plowman 1980, 254).
- [303](#) The information that Siegel et al. published has not been verified by any other ethnographic research (Stacy Schaefer, pers. comm.).
- [304](#) The name *hutkih* is given to all white-flowering scented vines, e.g., *Ipomoea alba* (cf. *Ipomoea* spp.).
- [305](#) This name is said to have been used for *Theobroma angustifolium* DC. as well (Furst 1995, 121*).
- [306](#) In Veracruz, the cacao flower tree (*Quararibea funebris*) is called *canela* (Martínez 1987, 1199*). *Calliandra anomala* is known as *canelo* in Mexico. For more on canella, *canelo*, et cetera, see **incense**.
- [307](#) “. . . San Pedro is extremely fast growing. Specimens in my greenhouse have gained almost eighteen inches in one year. It is also uncommonly easy to cultivate, and will thrive almost anyplace where the winters are relatively mild” (DeKorne 1994, 86*).
- [308](#) More than one hundred alkaloids have been found in the genus *Lycopodium* (club mosses) (Gerard and MacLean 1986). To date, it is not known whether any of these alkaloids are psychoactive. Six alkaloids have been detected in the Chilean species *Lycopodium magellanicum* (Loyola et al. 1979).
- [309](#) In Amazonia, this name is used for pleasantly scented *Cyperus* spp. (cf. **ayahuasca**).
- [310](#) This name is not used solely for *Trichocereus pasacana*. In northern Chile, the edible fruits of various columnar cacti are also referred to as *pasakana*, including those of *Trichocereus atacamensis*, *Oreocereus hendriksenianus* Backeb., and a *Soehrensia* species (Aldunate et al. 1981, 211, 213, 217*).
- [311](#) In only one sample of a *Trichocereus spachianus* cultivated in Indiana were traces of **mescaline** detected (Shulgin 1995*).
- [312](#) For the name *piule* and its etymology, see *Rhynchosia pyramidalis*.
- [313](#) See *Rhynchosia pyramidalis* for more on the name *piule*.
- [314](#) This name is used in Querétaro (Martínez 1994, 119*); in Oaxaca, it is used for *Salvia divinorum*.
- [315](#) Unfortunately, no pharmacological studies of these effects have been conducted to date (Lowry 1984, 267).
- [316](#) “Small amounts of the Schneeberger Schnupftabak—which contains only a little hellebore—can be consumed without concern. Anyone who snuffs too frequently or too much may occasionally have nosebleeds” (Pahlow 1993, 242*).
- [317](#) “Apart from the profane use, the cauldron, as archaeological and written sources have confirmed, was *the* sacred and ritual vessel of the Celts, comparable to the Christian chalice, which myth elevated from a household to a sacral object. It became a complex symbol, a true focal point of mythology” (Bothroyd 1992, 180). The Celts also used cauldrons to brew **beer** and **mead**.
- [318](#) Both names were also used for *Veratrum eschscholtzii* Gray [syn. *Veratrum eschscholtzianum* (R. et S.) Rydb.].

- [319](#) This name is also given to *Osteophloeum platyspermum* (DC.) Warburg and *Iryanthera macrophylla* (Benth.) Warburg (see *Iryanthera juruensis*), both of which are used as oral hallucinogens (Schultes et al. 1977, 264).
- [320](#) In Amazonia, the following trees are also known by the name *paricá*: *Cassia fastuosa* Willd., *Cedrelinga catenaeformis* Ducke, *Parkia* spp., *Piptadenia* spp., *Pithecolobium* spp., *Schizolobium amazonicum* (Hub.) Ducke, *Schizolobium parahybum* (Vell.) Blake, *Senegalia* spp., and other Leguminosae (Schultes 1954, 257 f.).
- [321](#) This name may suggest a psychoactive use. The association with *Theobroma cacao* is also of interest.
- [322](#) Whether the Mundurukú actually make their parika from a *Virola* or from an *Anadenanthera* is unclear. One early report mentioned a Leguminosae (*Acacia angico*) as the stock plant, the seeds of which are mixed with the juice from the leaves of a moonseed known as *abuta* (“cocculus”; cf. *Anarmita cocculus*) (Schultes 1954, 257).
- [323](#) It has often been claimed that the word *coffee* is derived from the Arabic word for wine, i.e., *khamr* or *gahwa* (cf. *Catha edulis*, *Coffea arabica*, *wine*). *Khamr* essentially means “inebriating.”
- [324](#) The dervishes, who have preserved certain elements of the orgiastic Orphic cult of Dionysos in their tradition, esteemed and “esteem wine (*sharab*) as a means to ecstasy” (Frembgen 1993, 198*).
- [325](#) Henze’s opera (a musical drama in one act by W. H. Auden and Chester Kallman) is a modern adaptation of Euripides’ *The Bacchae*. “An—unfortunately lost—tragedy by the playwright Aischylos was called ‘The Bassarids.’ From what we know, this drama appears to have been a counterpart to ‘The Bacchae’ of Euripides. The name ‘Bassarids’ refers to Dionysos Bassareus, the ‘Dionysos in a fox skin,’ after whose example the Maenads would occasionally wrap themselves in the characteristic red fox furs that their name ‘Bassarids’ refers to” (Giani 1994, 98*). The “Bassariká” of an almost unknown poet named Dionysios provided the model for the “Dionysiaka” of Nonnos (Merkelbach 1988, 50).
- [326](#) Hauff, who wrote a number of famous fairy tales, effusively described the Bremen *ratskeller* as the “seat of bliss.”
- [327](#) This English name is normally given to *Hyoscyamus niger*.
- [328](#) In eastern Australia, the cinnamon wood tree (*Cinnamomum oliveri*) is also called sassafras (Pearson 1992, 62*).
- [329](#) Some authors have suggested that the synonym refers to a different species. *Caesalpinia japonica* Sieb. et Zucc. is said to be another synonym (Bärtels 1993, 206*). Here again we find taxonomic confusion, an unfortunately frequent occurrence.
- [330](#) “And inasmuch as they [the Prussians] did not know of [the Christian] God, it so happened that they worshipped the entire creature-world instead of God, namely: the sun, moon and stars, the thunder, birds, even the four-legged animals, including toads. They also had holy groves, sacred fields, and waters.” (*Chronicon Prussiae*, by Peter Dusberg, 1326; in Gimbutas 1983, 179).
- [331](#) The Leguminosae *Enterolobium cyclocarpum* (Jacq.) Griseb. is listed in the Florentine Codex (Sahagun) under the same name (Díaz 1979, 94*).
- [332](#) This may correspond to the three subspecies: *Hedera helix* L. ssp. *canariensis* (Willd.) Cout. [syn. *H. canariensis* Willd., *H. algeriensis* Hibb.], ssp. *helix*, and ssp. *poetarum* Nym. It could also refer to *Hedera colchica* (K. Koch) K. Koch or *Hedera pastuchovii* Woron. of southwestern Asia.
- [333](#) In Islamic literature, for example, hashish, the “inebriant par excellence for the wandering dervishes,” is often referred to as “wine” (Frembgen 1993, 200*).
- [334](#) Two alkaloids and two lignans have been found in this plant, the pharmacology of which is unknown (D. McKenna 1995, 101*).
- [335](#) The related species *Metteniusa nucifera* (Pittier) Sleumer is also called *canyí* and is also said to be used by the Kogi in ritual contexts. In other areas, it is regarded as a fruit tree (Lozano-C. and Lozano 1988, 26).
- [336](#) This notwithstanding, in the Ayurvedic view *Ocimum sanctum* has the power to affect the mind: “Basil opens the heart and the mind and distributes the energy of love and devotion (*bhakti*). Basil is sacred to *Vishnu* and *Krishna* and strengthens faith, compassion, and clarity. *Tulsi* stalks are worn as garlands and strengthen the energy of attachment. Basil imparts divine protection by purifying the aura and invigorating the immune system. It contains natural mercury that, as the seed of Shiva, imparts the germinative power of pure consciousness” (Lad and Frawley 1987, 156*).

- [337](#) Not to be confused with the grass *Cyperus* spp., which is called *piripiri*.
- [338](#) This name is also used to refer to puffballs (see *Lycoperdon* spp.) and to *Ephedra* spp.
- [339](#) Numerous medicinal plants, e.g., *Valeriana* sp., are known by these names in South America.
- [340](#) The Mataco whom I was able to interview had never heard anything about these plants.
- [341](#) The taxonomy of this genus is rather chaotic. *Voacanga africana* alone is known under the following synonyms: *Voacanga glabra* Schum., *V. schweinfurthii* var. *parvifolia* Schum., *V. magnifolia* Wernham, *V. talbotti* Wern., *V. eketensis* Wern., *V. glaberrima* Wern., and *V. africana* var. *glabra* Schum. (Oliver-Bever 1982, 29).
- [342](#) The botanical genus name *Daphne* L. is not associated in any way with the laurels but rather belongs to the Family Thymelaeaceae.
- [343](#) “We also find the peony in Hecate’s magic garden, which suggests the plant has magical powers” (Baumann 1982, 100*).
- [344](#) In Ecuador, *Gnaphalium dysodes* Spreng. (Compositae) is still known as *ispingo* (Naranjo et al. 1981).
- [345](#) If the ancient sources are correct, a verbena known as *hiera botane*, “sacred plant,” was a magical and psychoactive plant (cf. Ratsch 1995a, 154 ff. *).
- [346](#) Ambrosia consisted of **honey**, water, fruits, olive oil, cheese, and barley. The first letters of the Greek names of these ingredients yield the word *myceta*, the accusative form of *mykes*, “fungus.” Graves sees this as a secret message indicating that the ambrosia of the gods actually consisted of (psychoactive) fungi (Graves 1957**).
- [347](#) “Whether invoked in a natural manner or through special techniques, through hallucinogenic essences, or through inebriating drinks—in Druidism as in shamanism, the dream is always an elementary component of the world” (Markale 1989, 208*).
- [348](#) For Theophrastus, *monocoli*, literally “one-footed,” was a metaphor for plants that have only one stem (Ruck 1981, 181**).
- [349](#) In Sanskrit, the word for mushroom is *chattra*, a word derived from *chad*, “to cover,” which originally meant “parasol” (Samorini 1995, 35).
- [350](#) In 1809, G. H. von Langsdorf suggested referring to the fly agaric of Kamchatka as a distinct variety: *Amanita muscaria* var. *camtschatica*. This name (nom. nud.), however, has never been accepted.
- [351](#) Fly agaric mushrooms still grow in Greece today (Baumann 1982, 140 f.*).
- [352](#) Dionysos was usually worshipped in the form of a phallus. Also called *mykes*, “mushroom,” this phallus was eaten by the frenzied maenads (Danielou 1992*)—an obvious metaphor for the mycomorphosed god as a fly agaric. In general, the fly agaric is regarded as the “penis of god” (Heinrich 1992).
- [353](#) *Hippomanes* (literally, “breast secretion of mares in heat”) was originally the term for a “tough body obtained from the pineal glands (epiphyses) of newborn foals that (because of its melatonin content) was used primarily as an aphrodisiac” (Genaust 1996, 290*). Ruck has argued that *hippomanes* means “horse madness” and was a name for *Datura stramonium* (Ruck 1995, 135*).
- [354](#) The mythical apples of the Hesperides have also been interpreted as mandrake fruits (cf. *Mandragora officinarum*).
- [355](#) In Egypt, mushrooms in general are known as ‘*eisch-al-ghorâb*, “raven’s bread” (Gholam M. and Geerken 1979, 64).
- [356](#) “Certain species of mushrooms grow in ‘witches’ rings’—also known as fairy rings or elf dance sites—small circles in which, it was assumed, the witches—or the fairies—would dance at night. These fairy rings appear when the decaying fruiting bodies from the mushrooms of the previous year fertilize the mycelia that are growing out at the border. The tender, threadlike fibers—which have the same function as a root system—then cause new mushrooms to grow around” (Mercatante 1980, 254 f.*).
- [357](#) Today, one still finds repeated in the literature, where the idea is perpetuated and passed on without reflection, the thesis that the berserkers acquired their enormous power and their legendary courage, the so-called berserker madness or *furor teutonica*, through their use of fly agaric (e.g., Roth et al. 1990, 274**). But the psychoactive effects of the fly agaric more closely resemble those of opium, and the user will seldom experience anything more than a euphoric state with certain synaesthetic visions. The fly agaric only rarely reveals its entheogenic effects (Cosack 1995). The fly agaric is most certainly *not* the drug of the berserkers.

The only psychoactive that is able to produce real aggression, raving madness, and rage is **alcohol**. The berserker madness was also induced by a **beer** to which *Ledum palustre* had been added.

- [358](#) In Yucatec Maya dictionaries from the colonial period, *uay xibalba* is translated as “necromancer” or “conjurer of the dead”; my own knowledge of Mayan, however, suggests that the name may mean “changer of the other world” or “shaman of the parallel world.”
- [359](#) In Japan, the word *kami* is usually used to refer to ancient Shinto deities or sacred objects (Lowell 1894). The word itself appears to be related to the Turko-Tatar word *kam* and the Mongolian word *kami*, both of which mean “shaman” (Coulina 1995, 63**; Eliade 1975, 14**).
- [360](#) The Japanese red kite (*Accipiter gularis*) is usually identified with *tengus*.
- [361](#) This was actually an art song that became popularized among the people. The text was written by August Heinrich Hoffmann von Fallersleben (1798–1874) (Bauer 1992, 46).
- [362](#) “Russian forest workers have reported chewing dried pieces of fly agarics so that they could deal more easily with the physical exertion” (Neukom 1996, 392).
- [363](#) The very poisonous species *Amanita verna* (Fr.) Qué. is known in Japanese as *shiro-tamago-tengu-take*, “white egg *tengu* mushroom” (Imazeki 1973, 47**).
- [364](#) According to Zander (1994, 420*), the grass is originally from North America and became naturalized in the Mediterranean region only after the conquest of the New World! It is not mentioned by a single ancient author (cf. *Arundo donax*, *Phalaris arundinacea*, *Phalaris* spp., *Phragmites australis*).
- [365](#) In India, the closely related grass *Paspalum dilatatum* Poir. may also be infected with *Claviceps paspali* (Aaronson 1988, 346).
- [366](#) *Lolium temulentum* is also known as *tollkorn*.
- [367](#) In 1934, Hindemith composed a symphony entitled *Mathis der Maler*, which also set the temptations to music.
- [368](#) Bradley had already mentioned the “dancing madness” that ergot induced during the Middle Ages in her novel *Darkover Landfall*, which was first published in 1972 (Bradley 1972, 60).
- [369](#) Ergot infesting the Argentinian grass *Spartina alternifolia* (Gramineae) produces primarily α -ergokriptine (Ferraro et al. 1978).
- [370](#) In Japan, *Psilocybe venenata* (Imai) Hongo [syn. *Stropharia venenata*, *Stropharia caerulescens* Imai] (cf. *Psilocybe* spp.) is referred to as *waraitakemodoki*, “false laughing mushroom,” or *shibiretake*, “inebriating mushroom.”
- [371](#) The true tinder fungus is *Fomes fomentarius* (Fr. ex L.) Kichx. (Cetto 1987, 1:377**). “No fire can be made using a birch fungus, as its tissue is too thick. But the birch polypore does contain two interesting substances: polyporic acid C and ugulinic acid. Polyporic acid has antibacterial effects. This species of fungus can be used as an antibiotic, i.e., a medicinal agent. The glacier man was thus carrying with him a kind of first-aid kit” (Barfield et al. 1992, 96).
- [372](#) *Fomes fomentarius* is depicted in the scene of the temptation of Saint Anthony on Matthias Grünewald’s Isenheim Altar (cf. *Claviceps purpurea*). It is a symbol for the transitory nature of life. (Claudia Müller-Ebeling, pers. comm.)
- [373](#) The *ling chih* is usually interpreted as *Ganoderma lucidum* but has occasionally been seen as a fly agaric (*Amanita muscaria*) (Mackenzie 1994, 107).
- [374](#) This species was used in Japan as a tinder fungus (Wasson 1973, 23**).
- [375](#) See *Rhynchosia pyramidalis* for more on this name, its etymology, and its meaning.
- [376](#) In his first three books, Castaneda reported that entheogenic mushrooms were being used as a “little smoke.” This claim has been severely criticized by ethnomycologists. No one would believe him, although many people tried smoking the mushrooms—but without success (cf. Clare 1988**; Siegel 1988*). Gordon Wasson apparently wrote a very critical letter to Castaneda; Castaneda later stated his own position in an interview: “After the publication of *The Teachings of Don Juan*, I received a thoughtful letter from Gordon Wasson, the founder of ethnomycology, who has studied the human use of mushrooms and fungi. . . . And then Dr.

Wasson [*sic*] asked me to clarify certain aspects of Don Juan's use of psychotropic mushrooms. I happily sent him several pages of my field notes that were relevant to his area of interest, after which we met two more times. From that point on, he spoke of me as an 'honest and serious young man' or in a similar manner." (From "Carlos Castaneda: Portrait eines Zauberers—1994," in *Energy* 6/94: 4–7, 14–18)

- [377](#) Mixe soothsayers also use other entheogens besides the mushrooms: *ma"zhun paHk* (*Turbina corymbosa*/*Ipomoea violacea*), *ama'y mushtak* (*Datura stramonium*), *po:b piH* (*Brugmansia* x *candida*), and *piH* (*Tagetes erecta*; see *Tagetes* spp.) (Lipp 1990, 151 f.).
- [378](#) Like the Mazatec, the Mixe use the species *Psilocybe caerulescens*, *Psilocybe cordispora*, *Psilocybe hoogshagenii*, and *Psilocybe yungensis* (cf. *Psilocybe* spp.).
- [379](#) In modern Mexico, the word *copal* is used to refer to all aromatic incenses. The true copal is obtained from a tropical deciduous tree (*Protium copal* [Schl. et Cham.] Engl. [Burseraceae]; cf. *Bursera bipinnata*).
- [380](#) From an interview in Maurizio Venturini and Claudio Vannini, *Zur Geschichte der Halluzinogenforschung: Schwerpunkt Schweiz (Teil I: 1938–1965)*, licentiate thesis at the Philosophischen Fakultät I of the Universität Zürich, 1995, page 101.
- [381](#) In northern India, the meadow champignon (*Agaricus campestris* L.) is still known as *mokshai*, "the liberator" (Morgan 1995, 149**).
- [382](#) Since ancient times, the deer truffle (*Elaphomyces*) has been esteemed as an aphrodisiac and magical agent (Brøndegaard 1975).
- [383](#) The opossum (*Didelphis marsupialis*) will eat fly agaric mushrooms (*Amanita muscaria*), but it learns to recognize their inebriating qualities and then avoids the mushroom (Ott 1993, 335*).
- [384](#) In Mexico, this name is also used to refer to *Ephedra* spp. as well as the fern *Pellaea cordata* J. Sm. (see *Polypodium* spp.) (Díaz 1979, 93*).
- [385](#) The literature occasionally claims that *Lycoperdon mixtecorum* and *L. marginatum* contain tryptamine derivatives (Benjamin 1995, 326**).
- [386](#) Under certain circumstances, this puffball can be mistaken for very young specimens of *Amanita muscaria*.
- [387](#) In the psychiatric literature, the effects produced by mushrooms that contain psilocybin are often also characterized as "mushroom madness" (McDonald 1980).
- [388](#) "Samandarin is a convulsive poison; it affects the central nervous system but also has hypertensive and local anesthetic effects. Externally, it is extremely irritating to the mucous membranes" (Altmann 1980, 130*).
- [389](#) Amazonian Indians claim that the fruits of this tree produce an unusual effect. They are eaten by certain birds (*Nothocrax urumutum* Spix), which are in turn hunted and eaten by the Indians. When their dogs eat the bones of these birds, they immediately exhibit severe toxic symptoms (Schultes 1960).
- [390](#) Older texts claim that *Prestonia* contains *N,N*-DMT; this information is unfortunately incorrect. The common name *yagé* probably refers solely to the fact that the plant is used as an ayahuasca admixture (Schultes and Raffauf 1960).
- [391](#) In the Afro-Brazilian Candomblé cult, the aromatic roots of *dandá da costa* (*Cyperus rotundus*) are chewed in order to give one the power to influence other people and to acquire personal power (Voeks 1989, 122, 123*).
- [392](#) The Shipibo-Conibo call *Petiveria alliacea* L., a member of the Family Phytolaccaceae (cf. *Phytolacca acinosa*), *vuén mucura* or *mucura sacha*. They claim that it has "hallucinogenic properties" and esteem it as a "master teacher of the healing arts" (Gebhart-Sayer 1987, 336).
- [393](#) In West Africa, this plant is used in combination with *Combretum micranthum* to treat fever (Assi and Guinko 1991, 122*).
- [394](#) Several South American *Croton* species contain morphinelike alkaloids (see **morphine**) (Bennett 1992, 490; Schultes and Raffauf 1990*).
- [395](#) In the Ecuadoran Amazon, a black "paint" is prepared from *ko-pi*, the fruits of the nightshade *Cyphomandra hartwegii* (Mier)

Sendtner ex Walper. This preparation is used to paint on pottery the geometric patterns that represent the visual hallucinations of ayahuasca (Schultes and Raffauf 1991, 37*).

- [396](#) In Nepal, the Himalayan species *Hypericum choisianum* Choisy [syn. *Hypericum cernuum* Roxb.] is one of the plants sacred to Kali (the wife of Shiva; cf. ***Cannabis indica***). Its veneration as a plant of the gods suggests that it may have some kind of psychoactivity.
- [397](#) Tetrahydro- β -carbolines are common in this family, although often only in trace amounts (Drost-Karbowska et al. 1978, 289).
- [398](#) In Yemen, the shoots of this plant are used as an antispasmodic agent (Fleurentin and Pelt 1982, 92 f.*).
- [399](#) Many *Desmodium* species have ethnomedicinal and folk medicinal significance (e.g., Akendengué 1992:169*); to date, no psychoactive use among traditional peoples has been observed.
- [400](#) The leaves of this plant are used in African folk medicine to treat asthma (N’Gouemo et al. 1996).
- [401](#) *Xuchit* is the Mayan version of the Aztec *xochitl*, “flower” (Helfrich 1972, 145*).
- [402](#) The name *nicte* is used both for the vulva and for *Plumeria* (Helfrich 1972, 145*).
- [403](#) Although it is uncertain whether the bog myrtle (*Myrica gale* L.; Myricaceae) induces psychoactive effects, it is possible; the fruits contain substances (chalcones, flavonoids) with preservative properties (Mathiesen et al. 1995). The **essential oil** has exhibited sedative properties in animal studies (Simpson et al. 1996, 127).
- [404](#) Unfortunately, no further details about this species are known. There is considerable evidence for the existence of psychoactive beetles, e.g., *Phromnia marginella* Oliv. This insect from the Family Fulgoridae occurs in Uttar Pradesh (India). It is purportedly used in the Garwhal district for its alleged psychoactive effects (Reichel-Dolmatoff 1975, 200, n. 248*).
- [405](#) This wild relative of the cultivated betel palm is indigenous to the mountain forests of New Guinea (Seyfarth 1981, 562).
- [406](#) The use of cocaine as an additive to betel quids has been previously described for the region from Iran to Pakistan (Krenger 1942c, 2929).
- [407](#) This extract of the Rubiaceae is sometimes sold under the name *catechu* or *pale catechu*.
- [408](#) The use of heroin is a new invention that appears to be found primarily in Taiwan (Chu 1995, 183).
- [409](#) The use of amphetamines as an (illegal) betel additive is common in Taiwan (Chu 1995, 183).
- [410](#) What these “permitted spices” are is unclear. I presume that the ingredients that are not permitted are datura seeds, crow’s eyes (***Strychnos nux-vomica***), opium, hashish (***Cannabis indica***), and possibly arsenic and ***Aconitum***—all ingredients found in Tantric inebriating mixtures. Such ingredients, however, are sometimes available under the counter: Prince Pan, a betel shop in Delhi, sells special betel quids with such rare and illegal ingredients as gold leaf, opium, and even **cocaine**!
- [411](#) Interestingly, the World Health Organization classifies betel as a nonaddictive drug (cf. ***Areca catechu***). In contrast, the literature frequently uses such terms as *habit*, *addiction*, and *betel nut psychoses* (cf. Seyfarth 1981, 565).
- [412](#) Some *Gaultheria* species are reputed to be psychoactive (Schultes and Hofmann 1995, 43*). Wintergreen (*Gaultheria procumbens* L.), however, is drunk only as a tea substitute (called Salvador tea or mountain tea) and does not have any psychoactive effects. It contains only methylsalicylate (Frohne and Pfänder 1983, 106*).
- [413](#) The chicha prepared from these is usually known as *tecu* (Mösbach 1992, 91*).
- [414](#) This name is also used for ***Desfontainia spinosa***.
- [415](#) This plant, originally from the Caribbean region, was taken to Sri Lanka, where it is now feared as a deadly horse poison (Macmillan 1991, 430*).
- [416](#) “Lampe describes especially the eye injuries caused by the [milk] latex. The seeds or latex induce long-lasting vomiting and diarrhea, leading to electrolyte imbalances” (Roth et al. 1994, 547*).

- [417](#) Even wheat **beer** (*weizenbier*) has been administered as an enema (Degenhard 1985, 333).
- [418](#) In traditional Chinese medicine, it is said that oyster shells (from *Crassostrea gigas* Thunb., *Ostrea rivularis* Gould, *Ostrea talienwhanensis* Crosse) “stabilize and calm the mind: used for pounding heart accompanied by anxiety, restlessness, and insomnia” (Bensky and Gamble 1986, 571*).
- [419](#) Despite the linguistic connection between **soma** and *haoma*, there is no evidence supporting the assumption that the two terms refer to the same plant, much less the same preparation.
- [420](#) “In his divine zeal, the prophet [Zarathustra] characterized the inebriating beverage (*hauma*), which was drunk during meals, as ‘urine’ (Yasna 48, 10)” (Merkelbach 1984, 11). It is possible that a urine rich in active constituents was actually consumed (cf. *Amanita muscaria*).
- [421](#) It has been suggested that “the pre-Zoroastrian Iranian religion was ruled by communities of ecstatic warriors who cultivated shamanic ecstasies and journeyed in the realms beyond. Inebriated by *haoma*, these warriors would enter into a dangerous state of murderous frenzy (*aeshma*). Zarathustra’s reforms were directed against these male, shamanic brotherhoods of warriors” (Couliano 1995, 136*).
- [422](#) It is here that the Spanish bullfight has its origins.
- [423](#) The following description of the first sacrifice of a bull is found in the Persian book on the “creation” (*Bundahishin*): “The good god Ohrmazd (the later form of Ahura Mazda) created the bull, ‘white and brilliant like the moon’ (1, 49), but later the evil one (Ahriman) slipped into the world, and Ohrmazd saw in advance that he would slaughter the bull. And so he gave the bull hemp to eat, thereby inducing in the animal a hashish sedation, ‘so that the injustice of its killing and the affliction of its pain would be lessened’ (chapter 4). From the bull were all the small animals then created, as well as 55 kinds of grain and 12 kinds of healing plants. The bull’s semen was borne to the moon, where it was filtered; it contains the seeds of all life. The soul of the bull will nourish all earthly creatures and be recreated as a beneficial animal in the material life” (Merkelbach 1984, 12). “The death of a cosmic primordial being . . . , which is sacrificed and cut into pieces and, in dying, brings forth the universe out of itself” (Gina 1994, 11*), is an archetypal image and is, in fact, the most primordial experience of life. It is only by killing our food that we are able to preserve our lives!
- [424](#) A recent double-blind study found that regular administration of ginkgo extracts led to substantial and significant improvements in memory performance in people affected by senile dementia of the Alzheimer’s type (Hofferberth 1994).
- [425](#) A pharmacognostic study conducted at the Pharmaceutical Institute in Bern (Switzerland) was unable to identify this component as a raw drug obtained from *Myristica* spp. (Leitner 1995, 6).
- [426](#) This terpene is also present in many other plants, e.g., bog rosemary (*Andromeda polifolia* L.), mountain laurel (*Kalmia latifolia* L.), prickly heath (*Pernettya mucronata* [L. f.] Gaudich ex Spreng.), and the Siberian alpine rhododendron (*Rhododendron chrysanthum* Pall.) (Roth et al. 1994, 758*). It is conceivable that bees also visit these plants.
- [427](#) Arsenic not only is one of the most famous poisons of criminal history but also is a tonic and inebriant (cf. Lewin 1980 [orig. pub. 1929], 417 ff.*).
- [428](#) The resin known as benzoin is derived from two plant sources. The Siamese benzoin tree grows in Thailand and Malaysia, while in Indonesia the source is *Styrax benzoin* Dryander (Sumatran benzoin tree, benzoin storax tree) [syn. *Laurus benzoin* Houtt., *Benzoin officinale* Hayne, *Lithocarpus benzoin* Blume].
- [429](#) The popular and historical literature often confuses the rare and very valuable lignum aloe with *Aloe vera*.
- [430](#) This incense is said to hold witches (*nahuallis*) at bay. The ascending smoke is said to be deadly (for them) (Knab 1995, 156*).
- [431](#) “Sorcerers burned coriander seeds to dispel evil spirits and to induce hallucinations. The narcotic effect has been confirmed by modern science—as long as large quantities of coriander are consumed. Perhaps it is because of this narcotic effect that the seeds are still used to make gin” (Drury 1989, 55).
- [432](#) The modern, worldwide esoteric movement, especially in the United States (California) and Europe, has developed numerous recipes for a variety of types of incense. These have become known chiefly through esoteric publications (e.g., Caland 1992, Lee 1993, Rose 1979, Vinci 1980, Wollner 1995).

- [433](#) This species has a reputation for being hallucinogenic (Schultes and Farnsworth 1982, 189*; Schultes and Hofmann 1980, 367*).
- [434](#) This species occurs in two varieties: *Drimys winteri* var. *winteri* and *D. winteri* var. *chilensis* (DC) A. Gray. Some botanists assign it to its own family: Winteraceae (Mösbach 1992, 78*). **[1389]**
- [435](#) From personal communication with Amelie Schenk (September 1996).
- [436](#) It is very unlikely that the plant being referred to is khat (*Catha edulis*), as this does not grow in England.
- [437](#) This may be one of the sumac species that were introduced from North America to Europe, such as fragrant sumac (*Rhus aromatica* Ait. [syn. *Rhus canadensis* Marsh. non Mill.]), staghorn sumac (*Rhus typhina* L.), and poison sumac (*Toxicodendron quercifolium* [Michx.] Greene [syn. *Rhus toxicodendron* L., *Toxicodendron radicans* (L.) O. Kuntze]). Poison sumac has severe toxic effects, including dizziness, stupor, and states of excitation, and may indeed be experienced as psychoactive (cf. Roth et al. 1994, 704 f.*).
- [438](#) *Lobelia nicotianaefolia* is also known as wild tobacco (cf. *Lobelia inflata*).
- [439](#) Settlers drank a tea made from the leaves of this strawberry as a nerve tonic (Foster and Duke 1990, 38).
- [440](#) This substance has a cannabinoid-like structure (Kindscher 1992, 226*).
- [441](#) The use of hemp as an ingredient in smoking blends is a recent development.
- [442](#) The leaves were formerly smoked by themselves as a tobacco substitute (Foster and Duke 1990, 44).
- [443](#) The Cherokee used the root of this plant when they suffered from “bad memory.” The leaves were also smoked alone (Foster and Duke 1990, 180).
- [444](#) In California, this species also has ritual significance as an **incense**. The leaves were also chewed (Hartwich 1911, 33*).
- [445](#) An herbarium specimen bears the note: “The plant has toxic-narcotic properties” (von Reis and Lipp 1982, 228*).
- [446](#) Apparently, Demeter had to refuse the sacred sacrament of the wild Dionysos and provided a **beer** recipe in its place (cf. Ruck 1982*).
- [447](#) Unfortunately, the next lines (22 to 26 of them) have been lost. They may have contained further instructions for the drink and may have been destroyed intentionally.
- [448](#) The grain-mother Demeter was well versed in the world of plants and said of herself: “For I know the powerful great herbs that are gathered and the talisman plant that wards off possession” (*Homeric Hymn to Demeter*, line 229 ff.; in Wasson et al. 1998, 75).
- [449](#) The Telesterion was quite unsuited for use as a theater (Eyer 1993).
- [450](#) The name *polei* was once used to refer to various plants, including species from the genus *Nepeta* (cf. *Nepeta cataria*) (Fuchs 1545, 245*). *Polion* (= polium) has also been construed as golden germander (*Teucrium polium* L.) (Baumann 1982, 114*).
- [451](#) The symptoms described here suggest the effects of nightshade plants.
- [452](#) There are six species of *Datura* in Australia, of which only one is native. All the others were introduced either inadvertently or purposely as medicinal and decorative plants. Both the native thorn apple (*Datura leichhardtii* F. Muell.; cf. *Datura* ssp.) and the imported species (*Datura stramonium* L., *Datura stramonium* ssp. *ferox*) were (are?) used as pituri or pituri substitutes (Dowling and McKenzie 1993, 126 ff.*).
- [453](#) There are more than seven hundred species of *Eucalyptus* in Australia. Eucalyptus gum (crystallized resin), which is exuded from the bark when the wood is injured, can be obtained from almost all of them. The Aborigines use the gum (= *mijilypa*, *munuun*, *arrkiypira*, *wokalba*, *jior*) of numerous species primarily for medicinal purposes (Barr 1990, 122–25*; Macpherson 1939).
- [454](#) I have discussed this problem extensively with Jonathan Ott, Rob Montgomery, and Manuel Torres, who share the views given here.

- [455](#) South American **snuffs** made from *Anadenanthera peregrina* act in a similar manner. The self-experimentation by and reports of C. Manuel Torres indicate that pure *Anadenanthera* powder has almost no effects, while the full DMT effects immediately become apparent when the powder is mixed with ash (C. M. Torres, pers. comm.).
- [456](#) This species is originally from the West Indies (Zander 1994, 312*).
- [457](#) The chrysanthemum flower is a symbol of long life. A “liquor of longevity” is prepared by adding the flowers (flos chrysanthemi), mixed with *Polygonum multiflorum* Thunb., *Lycium chinense* Mill., and red dates (*Zizyphus jujuba* Mill.), to sake or rice schnapps. Chrysanthemum flowers contain flavone derivatives, sesquiterpenoids, amino acids, borneol, camphor (cf. *Cinnamomum camphora*), chrysanthellone, and other substances (Paulus and Ding 1987, 183 f.*).
- [458](#) Nevertheless, some experimenters have repeatedly reported experiencing mild psychoactive effects from smoking *Psilocybe* mushrooms.
- [459](#) The medicinal use of sneezing powder is also found in South America, where the powdered bark of *Myrica stornatatoria* (nom. nud.!) is snuffed to clear the mind and to treat headaches (Schultes 1980, 92*).
- [460](#) Thorns from *Trichocereus atacamensis*, which are more than 20 cm long, were used to clean the tubes and prevent them from becoming clogged (cf. *Trichocereus* spp.).
- [461](#) 2-CB (4-bromo-2,5-dimethoxyphenethylamine), which produces effects somewhere between those of **mescaline** and MDMA, was discovered by Alexander Shulgin (cf. Shulgin and Shulgin 1991, 503 ff.).
- [462](#) Whether this variety was indeed used traditionally to prepare snuffs is questionable (C. Manuel Torres, pers. comm.).
- [463](#) A note on an herbarium specimen collected by J. A. Steyermark in Brazil in 1970 includes the remark: “The bark of the tree is used here by the Guaica Indians [= Waika/Yanomamö] as an ingredient in *yopo*” (von Reis and Lipp 1982, 126*).
- [464](#) This species, which has been described for Argentina, is synonymous with *Anadenanthera colubrina*. Its seeds and pods contain DMT and other tryptamines (Holmstedt and Lindgren 1967, 362).
- [465](#) It is very likely that this Argentinean species is synonymous with a variety of *Anadenanthera colubrina*.
- [466](#) It is rather unlikely that a snuff made from *Banisteriopsis* would have psychopharmacological effects.
- [467](#) The Peruvian mestizo *ayahuasqueros* use the species *Trichilia tocacheana*, a tree known as *lupana*, to make **ayahuasca**. They fill ayahuasca, mixed with tobacco juice, into a hollow in the trunk of the tree and allow it to be enriched by the toxic resin that is exuded (Schultes and Raffauf 1990, 435*).
- [468](#) The shamans of the Barasana and Makuna used the powdered leaves as a ritual snuff for divination. However, there are no reports demonstrating that this powder exerts any psychoactive effects (Schultes 1980).
- [469](#) 5-OH-DMT = **bufotenine**.
- [470](#) The urine of people inebriated on psilocybin mushrooms (cf. *Psilocybe* spp.) can also be used as an entheogen. Twenty-five percent of orally ingested psilocybin ends up in the urine one to two hours after the mushrooms are eaten (J. Ott, pers. comm.).
- [471](#) To date, this plant has been found to contain triterpenes and sapogenins with no known psychoactive effects (Kulshreshtha and Rastogi 1973). However, the leaves are the primary ingredient of Brahmi Rasayan, an Ayurvedic nerve tonic that does exert an effect upon the central nervous system (Shukia et al. 1987).
- [472](#) In Tibet, dried rhubarb leaves were mixed with tobacco (*Nicotiana tabacum*) or smoked as a tobacco substitute (Hartwich 1911, 108*).
- [473](#) This plant is from Africa. Its latex is used as a fish poison (Tyler 1966, 284*). Other species contain triterpenes (Domínguez et al. 1974).
- [474](#) The aromatic bush *Vitex negundo* L. (Verbenaceae) contains large amounts of flavonoids with antiandrogenous effects (Bhargava 1989) as well as an essential oil whose primary constituents are sabinene, terpinene-4-ol, β -caryophyllene, globulol, and bis[1,1-dimethyl]-methylphenol. In Ayurvedic medicine, the plant is used as a remedy for feverish and rheumatic complaints (Mallavarapu

et al. 1994).

- [475](#) This plant, which is also known as *kumburu-wel*, is used in Southeast Asian folk medicine to treat toothaches and parasitic worms (Macmillan 1991, 423*).
- [476](#) The Bodos and Kacharis (tribal peoples of Assam, India) regard this plant as sacred and make offerings to it. The flowers are strung together to make garlands for offerings (Boissya et al. 1981, 221*). The tribal peoples of Bastar (India) believe that *Dendrophthoe falcata* (L. f.) Etting (Loranthaceae), which grows parasitically on *Calotropis gigantea*, is able to increase “brain power” (intelligence) (Jain 1965, 245*). In Southeast Asia, where *Calotropis gigantea* is known as *wara*, its roots are used as a tonic (Macmillan 1991, 423*).
- [477](#) Known as *guduchi*, this Himalayan plant was referred to in the Sanskrit literature as *amrita*, “nectar of immortality.” *Amrita* is also translated as “life-giving drink.”
- [478](#) The roots contain desmodium alkaloids and possibly *N,N*-DMT and other tryptamines (Ghosal and Bhattacharya 1972).
- [479](#) In Persian, *tary ak* means both “poison” and “antidote” and is also a name for opium. The opium-eating Turks were known as *theriakis*.
- [480](#) *Nigromantie* is a neologism from the Middle Ages that can be traced back to Isidor (ca. 530–636), the archbishop of Seville. It is derived from the word *necromancy* (“divination of the dead” or “divination by the dead”—i.e., conjuring the dead).
- [481](#) From Heinrich Marzell, *Wörterbuch der deutschen Pflanzennamen* [Dictionary of German Plant Names], 5 vols. (Leipzig, 1943–1979); Hanns Bächtold-Stäubli, ed., *Handwörterbuch des deutschen Aberglaubens* [Hand Dictionary of German Superstitions], 10 vols. (Berlin, 1927–1942).
- [482](#) The “iron plant” of antiquity was known as *hiera botane*, “sacred plant,” and was presumably not identical to *Verbena officinalis*, because the ancient literature (Pliny 25.105 f.) ascribed it with powerful magical and mind-altering properties (cf. Rätsch 1995, 154–57*). The iron plant is also known by the folk names *druidenkraut* (“druid plant”), *merkurbhutkraut* (“Mercury’s blood plant”), and *sagenkraut* (“plant of legend”). *Verbena officinalis* has no psychoactive properties of any kind.
- [483](#) “In the sixteenth century, scholars such as Cardano or Della Porta formulated a different view: animal transformations, flying, and manifestations of the devil were the effects of malnutrition or the use of hallucinogenic substances such as found in plant decoctions or in ointments. These explanations have not yet lost any of their fascinating effects. Yet in and of itself, no form of deprivation, no substance, and no ecstatic technique, is able to provoke the repeated appearance of such complex experiences. In the face of this biological determinism, it is emphatically important to remember that the key to this codified repetition can only be a cultural one. Naturally, the intentional ingestion of psychotropic or hallucinogenic substances, even when they do not explain the ecstasy of the followers of the nocturnal goddess, the werewolves, etc., nevertheless places them in a dimension that is not exclusively mythical. Would it be possible to prove the existence of such ritual frameworks?” (Ginzburg 1990, 296 f.)
- [484](#) It is likely that Bacon wrote most, if not all, of the plays attributed to William Shakespeare. This is the reason Shakespeare’s pharmacological details concerning poisons and medicinal plants are so correct (cf. Tabor 1970*).
- [485](#) Although the yew tree is regarded almost everywhere as very poisonous, it also finds use in ethnomedicine. In India, a beverage called *jya* is cooked from a few pieces of the bark and some salt and ghee (clarified butter). It is said to bestow mental power and vitality (Shah and Joshi 1971, 419*).
- [486](#) In the literature, one occasionally encounters the claim that hemlock is psychoactive in and of itself. Since both *Conium maculatum* and *Cicuta virosa* are among the most well studied of all medicinal and poisonous plants, it can be presumed that any purported psychoactivity would not have escaped the pharmacologists of the past three thousand years. Both hemlocks contain highly toxic alkaloids, furanocoumarins, and bioactive polyacetylenes (Teuscher 1992; Wittstock et al. 1992; Wittstock et al. 1995).
- [487](#) Zombies and “voodoo people” number among the figures that Westerners often hallucinate while under the influence of a psychoactive substance, e.g., *Datura* (Siegel 1981, 325*).
- [488](#) In West Africa, a drug known as *ibok usiak owo* is obtained from the closely related species *Albizia zygia*. It was used in ordeals and as a truth serum (Davis 1983b, 144). The first part of the drug’s name is reminiscent of that of iboga (see *Tabernanthe iboga*).
- [489](#) Seabrook noted that the food the zombies eat cannot contain salt of any kind; otherwise, the effects of the zombification will be counteracted (1931, 103, 105).

- [490](#) The sorcerers, who are able to transform themselves into wolves or other animals, are called *loups garous* in Haiti, and they are greatly feared by the people (Simpson 1942). It is possible that these sorcerers use a preparation made with cathedral bells (*Kalanchoe pinnata* [Lam.] Pers.; Crassulaceae), which is known locally as *loup garou*.
- [491](#) Laughing gas (nitrous oxide, nitrous monoxide, N₂O) was first produced in 1776 by Joseph Priestley (1733–1804), the theologian and chemist who discovered oxygen. By 1799, Humphrey Davy was suggesting that laughing gas could be used as an anesthesia, although its first successful application for this purpose did not occur until 1844. Today, laughing gas is back in fashion, for it is inhaled at techno-parties and raves (cf. **herbal ecstasy**). Despite the fact that the substance has been known for a long time, its mechanism of activity has not yet been clarified (see *Laughing Gas*, ed. Michael Sheldin and Davis Wallechinski [Berkeley, Calif: Ronin Publishing, 1992]).
- [492](#) Despite its name, *Gymnocactus mandragora* (Berger) Backeb. [syn. *Neolloydia mandragora* (Berger) Anderson] should not be confused with the mandrake (***Mandragora officinarum***).
- [493](#) A study of secretions of the Vietnamese *Bufo melanostictus* Schneider found only four sterols (Verpoorte et al. 1979).
- [494](#) In Africa, *Combretum mucronatum* (Schum. et Thonn.) is used as an anthelmintic (Ayensu 1978, 90*).
- [495](#) The seeds of the Australian tree *kurrajong* (*Brachychiton diversifolius* R. Br.) contain 1.8% caffeine. The seeds are traditionally roasted, brewed, and drunk as a stimulant (Bock 1994).
- [496](#) This opera, the libretto of which was written by Hugo von Hoffmannsthal, includes a character named Mandryka. Could the author have been making an allusion to ***Mandragora***?
- [497](#) Kavapyrones have a similar anesthetic effect to cocaine and its derivatives procaine and lidocaine (cf. ***Piper methysticum***).
- [498](#) In addition to codeine, many cough syrups also contain **ephedrine**, camphor (***Cinnamomum camphora***), **essential oils**, and sometimes even extracts of ***Atropa belladonna*** and ***Aconitum napellus***. They are thus somewhat reminiscent of **witches' ointments, soporific sponges, and theriac**.
- [499](#) The derivative hydroxynorcytisine is also present in the fruit pods of the golden chain tree (Hayman and Gray 1989).
- [500](#) It has been discovered that people who suffer from sleep disorders can do without diazepam, and that a combination of hops (***Humulus lupulus***) and valerian (***Valeriana officinalis***) can be used as a substitute (Flesch 1996).
- [501](#) 2-methyl-3-buten-2-ol, found in the essential oil of hops (***Humulus lupulus***), has strong sedative properties.
- [502](#) In West Africa, ***Tabernanthe iboga*** is supposedly preferred over yohimbe (***Pausinystalia yohimba***) as an aphrodisiac (Prins 1988, 6).
- [503](#) The Subfamily Plumerioideae (Apocynaceae) is rich in indole alkaloids (Omino and Kokwaro 1993, 174*).
- [504](#) This cactus has a very high mescaline content of 0.9% (Schultes and Farnsworth 1982, 159*).
- [505](#) Although the prickly pear doubtlessly originated in Mexico, it was introduced to Europe and North Africa at an early date (Dressler 1953, 140*).
- [506](#) Because psilocybin mushrooms are sometimes difficult to digest, more time (up to one and a half hours) may pass before the effects become manifest.
- [507](#) These results have occasionally been called into question: “Nevertheless, in animal studies the author was able to demonstrate an increase in frequency of copulation and in blood flow through the penis after premedication with yohimbine” (Weyers 1982, 64).

About the Author

Christian Rätsch, Ph.D., is a world-renowned anthropologist and ethnopharmacologist who specializes in the shamanic uses of plants. He is the author of *Marijuana Medicine* and coauthor of *Plants of the Gods*, *Shamanism and Tantra in the Himalayas*, *Witchcraft Medicine*, and *The Encyclopedia of Psychoactive Plants*. He lives in Hamburg, Germany, and lectures around the world.

About Inner Traditions • Bear & Company

Founded in 1975, Inner Traditions is a leading publisher of books on indigenous cultures, perennial philosophy, visionary art, spiritual traditions of the East and West, sexuality, holistic health and healing, self-development, as well as recordings of ethnic music and accompaniments for meditation.

In July 2000, Bear & Company joined with Inner Traditions and moved from Santa Fe, New Mexico, where it was founded in 1980, to Rochester, Vermont. Together Inner Traditions • Bear & Company have eleven imprints: Inner Traditions, Bear & Company, Healing Arts Press, Destiny Books, Park Street Press, Bindu Books, Bear Cub Books, Destiny Recordings, Destiny Audio Editions, Inner Traditions en Español, and Inner Traditions India.

For more information or to browse through our more than one thousand titles in print, visit www.InnerTraditions.com.

General Bibliography

This bibliography lists only works of an introductory or general nature. Specialized literature and monographs are listed under the specific plants, products, and active components. See also the general literature on psychoactive fungi on pages 689–693.

Those sources that are marked in the monographs with a single * may be found in this bibliography. Those marked with a double ** can be found in the general literature on psychoactive fungi.

“The mysterious and essential center of a culture is its books. If we do not have a living culture before us, then we can still experience it through its books. Books are the soul of a culture.”

TERENCE McKENNA
(1995)

Periodicals

The following journals, magazines, yearbooks, and series contain numerous articles about

psychoactive plants.

Altrove. Has been published since 1993 and is the yearbook of the Italian Society for the Study of the States of Consciousness (= SISSC).

Anthropology of Consciousness. Has been published since 1989 by the Society for the Anthropology of Consciousness, a section of the American Anthropological Association. However, most of the contributions focus on the anthropology of consciousness, with only an occasional article on psychoactive substances.

Botanical Museum Leaflets, Harvard University. This journal was published between 1932 and 1986; it contains numerous important articles on the ethnopharmacology of psychoactive plants and fungi.

Curare—Zeitschrift für Ethnomedizin. This interdisciplinary journal is the organ of the German Society Arbeitsgemeinschaft Ethnomedizin e.V.; it frequently contains articles on psychoactive plants, shamanism, traditional healers; reports on congresses; book reviews; et cetera.

Economic Botany. Published by the New York Botanical Garden, this journal is probably the most important ethnobotanical periodical.

Eleusis—A Quarterly Bulletin of the Italian Society for the Study of the States of Consciousness. This additional organ of the Italian Society for the Study of the States of Consciousness (= SISSC) has been published since April 1995. The bulletin is published in two languages (Italian and English). Address: SISSC, c/o Museo Civico di Rovereto, Largo S. Catarina 43, I-38068 Rovereto (TN), Italy.

Entheogene. This journal, which is edited by Jim DeKorne and Bert Marco Schuldes, has been published in Germany since the fall of 1994. The full title is *Entheogene: Forum für entheogene Forschungen, Verfahren und Erfahrungen* [Entheogens: A forum for entheogenic studies, techniques, and experiences]. In this journal, the themes from Jim DeKorne's book *Psychedelic Shamanism* (Port Townsend, Wash.: Loompanics Unlimited, 1994) are continued and discussed in greater depth. The publication is an adaptation of the *Entheogen Newsletter*, published in the United States by Jim DeKorne. Address: B. M. Schuldes, Hauptstr. 70, D-99759 Rehungen, Germany.

Grow! Marijuana Magazin. The first issue of this quarterly journal appeared in the summer of 1995.

HanfBlatt. This monthly journal has been published in northern Germany since 1994.

Hanf! Das zeitkritische Journal. This bimonthly journal has been published since April/May 1995.

Hemplife Magazine. This bimonthly magazine has been published since December 1998. It is produced in Holland.

Integration—Zeitschrift für geistbewegende Pflanzen und Kultur. Published at irregular intervals since 1991, this journal consists almost exclusively of articles about psychoactive substances.

Jahrbuch des Europäischen Collegiums für Bewußtseinsstudien / Yearbook of the European College for the Study of Consciousness. Edited by Michael Schlichting and Hanscarl Leuner, this series has been published since 1992; almost all of the articles deal with psychoactive substances.

Jahrbuch für Ethnomedizin und Bewußtseinsforschung / Yearbook for Ethnomedicine and the Study of Consciousness. Edited by Christian Rätsch and John R. Baker, this series was published from 1992 until 1998; almost all of the articles deal with ethnobotany and psychoactive substances.

Jahrbuch für Transkulturelle Medizin und Psychotherapie / Yearbook of Cross-Cultural Medicine and Psychotherapy. Edited by Walter Andritzky, this series has been published since 1990; all of the volumes have contained articles on psychoactive substances.

- Journal of Ethnobiology*. Published since 1980, this journal occasionally contains articles on psychoactive substances.
- Journal of Ethnopharmacology*. Published by Elsevier since 1978, the first volumes contained almost exclusively ethnopharmacological articles about psychoactive plants. It has now become more of a clearinghouse for pharmacognostic and purely pharmacological works by authors from Third World countries.
- Journal of Psychedelic Drugs*. Vol. 1–12, 1967–1980; renamed *Journal of Psychoactive Drugs* as of vol. 13 in 1981.
- Journal of the International Hemp Association*. This scientific journal has been published in Amsterdam since 1994 (two issues per year).
- Lloydia/Journal of Natural Products*. This journal, which focuses on the chemistry of naturally occurring substances, was named for the Lloyd brothers. It contains numerous articles on the chemistry of psychoactive plants and fungi.
- MAPS Bulletin*. Published by the Multidisciplinary Association for Psychedelic Studies, this bulletin contains primarily reports on current research projects, conferences, and publications. The emphasis is on MDMA, psilocybin, DMT, medicinal cannabis, and therapy.
- Mreža Drog*. From Slovenia, this journal (ISSN 1318–2609) is devoted primarily to the classic psychedelics and entheogens. Many of the articles it contains are translations of German, Italian, or English literature. Published since 1994; the editors are Bojan Dekleva (editor in chief) and Ivan Valeňcič (associate editor).
- Pan*. A “psychoactive network” has been producing a quarterly publication in the Netherlands since May 1995 titled *PAN FORUM* (ISSN 1382–4538). All of the articles are in Dutch.
- Phytochemistry*. Published by Pergamon Press since 1962; contains numerous reports on chemical studies of psychoactive plants.
- Psychedelic Monographs and Essays*. Published since 1985 by Thomas Lytle. Numerous volumes have appeared to date. Lytle published the best articles in book form in 1994.
- Psychedelic Review*. Published from 1964 until 1972. Weil et al. published the best articles as a book (*The Psychedelic Reader*) in 1973.
- Shaman's Drum*. Published in the United States; contains articles discussing all aspects of shamanism, including many that deal with the shamanic use of psychoactive substances.
- Takiwasi*. Has appeared at irregular intervals since 1991; contains only articles about psychoactive substances and altered states of consciousness. Many of the articles are translations of previously published material.

From the Translator

This is an extraordinarily detailed and complex book, and translating it into English has posed many challenges. Thanks to the people that have been involved in the preparation and production of this edition, these challenges have all been met. It gives me great pleasure to acknowledge the people that have played a part.

I would like to thank the entire staff at Inner Traditions for their professionalism and expertise. Jon Graham (acquisitions editor) got the project off the ground. Nancy Ringer (copy editor) repeatedly amazed me with her sharp eyes and uncanny ability to point out that the spelling of a term on page 854 deviated from its spelling on page 532. The quality and accuracy of the finished text is a direct reflection of her attention to detail. Doris Troy (proofreader) was indispensable in pointing out and helping to clarify ambiguities and inconsistencies in the text. Priscilla Baker (typesetter) is responsible for the wonderful look of the book. Special thanks go to the two people that I worked with the closest. Laura Schlivek (project editor) provided much expert guidance and good-humored support. She kept the leash loose and still managed to keep things under control. Jeanie Levitan (managing editor) has hovered over this project like an angel. From the beginning, her flexibility, can-do attitude, and unusual working hours have made my side of things much easier.

Annabel Lee and Cornelia Ballent provided excellent translations of parts of the manuscript, and I cannot thank them enough for their assistance. Without their help, I'd still be somewhere in the jungle.

Finally, a word of thanks to Big George and Fatima. Their acceptance of my irregular schedule and support for this project have made things the easiest where I needed it the most: at home with the pack. You guys are the best!

John R. Baker
